Several people have noticed that the cover of the UK edition of my book is being widely emulated, see here and here.

The folks at Axes and Alleys have a review of my book in their latest issue. It seems that the members of the Royal Tractor Repair and Maintenance Society of Outer Mongolia found the book quite confusing. I guess this is only fair, since I've always found them quite confusing…

In case anyone is worried about the supply of unadulterated hype about string/M-theory drying up, there's a new book out by John Gribbin which I took a look at yesterday in the bookstore.

Since the KITP does such a great job of providing a video record of the activities there, informal talks at the string theory phenomenology program have provided a fascinating public record of the way in which well-known string theorists are struggling with the all-too-obvious collapse of any reasonable hopes for getting predictions out of string theory. Last week there was an informal discussion with Michael Douglas of the String Vacuum Project, which was quite fascinating to listen to. I had trouble hearing what David Gross had to say, which was a shame, maybe someone with better ears who listens to this can report what they hear. Douglas encountered objections from the audience when he claimed that if one could get virtually any low energy physics out of one string vacuum or another, there was not any point to the whole project, with someone making the now standard claim that this situation is no worse than that of QFT.

   November 13, 2006

   John Gribbin's expertise in scientific predictions was first confirmed when at Nature in 1974, he came up with the money-spinning 'Jupiter Effect', which bears an uncanny similarity in some respects to biblical prophecy, alas without the confirmed predictions.

   His book with Plagemann, 'The Jupiter Effect' (1977 edition paperback), stated: 'in 1982, when the Moon is in the seventh house, and Jupiter aligns with Mars and with the other seven planets of the solar system, Los Angeles will be destroyed.'

   Obviously, Dr Gribbin merely omitted to mention that this prophecy was fulfilled in an alternative parallel universe of the cosmic landscape of string theory.

   See http://www.gi.alaska.edu/ScienceForum/ASF5/526.html

   November 13, 2006

   Hi Peter,

   Thanks for mentioning the Honeywell-Initiative. Coincidentally, I came across their site today, but didn't realize it's new (I just assumed I had never seen it before.) I found it a bit disappointing though, both in design as in content, but then I guess they'll stock up their database.

   […]a global education initiative designed to connect students across the globe with Nobel Prize winners in Chemistry and Physics… […] The Honeywell – Nobel Initiative establishes a forum for students worldwide to learn directly from Nobel Laureates in Chemistry and Physics

   Does somebody know if their concept of 'global' and 'worldwide' goes beyond those who have an high-speed internet access?

   Thanks also for the link to my blog, I hope you don't mind the joke.

   Best,

   B.

   Funny, I thought that was when peace would guide the planets and love would steer the stars. I guess that prediction got superseded.

4. **anonymous**
November 14, 2006

it is highly surprising that the "now standard claim that this situation is no worse than that of QFT" is standard. If the situation is no better than in QFT, what is the purpose of studying strings?

5. **Thomas Larsson**
November 14, 2006

with someone making the now standard claim that this situation is no worse than that of QFT.

I think I finally understand what is wrong with this statement. It is true that there is an infinite landscape of QFTs, but it is the simplest ones that are realized in nature. Already free theories give a qualitatively correct picture of photons and phonons, and the simplest interacting theories are also realized in nature. phi^4 theory (Ising model) is the generic critical point and phi^6 theory (tricritical Ising) is the generic tricritical point, and among gauge theories, nature has selected the ones with the smallest gauge groups.

You can in principle realize models deep inside the QFT landscape in nature. E.g., phi^300 theory would be the generic 150-critical point, which can be realized experimentally by fine-tuning 150 parameters, and the 150th RSOS model exhibits such behaviour. But although such complicated models exist in theory, they don't exist in reality.

In contrast, the simplest string theories are deeply unphysical: neither 26 flat dimensions and tachyons, nor 10 flat dimensions, unbroken SUSY and 496 gauge bosons are compatible with observation. There might be complicated models in the ST landscape which agree with experiments (or rather, have not yet been ruled out), but the big difference compared to QFT is that the simple string theories are wrong.

6. **spacepig**
November 14, 2006

Anonymous and TL:

It is implicit that by going to string theory one has solved also the problem of quantum gravity. And, the people making this claim, all have in mind that (as with QFT) one should look for some new "stringy" phenomenon that determines which class of vacua is correct. Having observed this phenomenon, string theory fits the data (including gravity), QFT does not, and one used experiment instead of magical divination to find the correct description of nature.

Many people try to get you to falsely see the issue as: "strings have a landscape, therefore we'll never derive the correct vacuum without unforeseen breakthroughs." That is not the issue. We never derived the correct vacuum in QFT either, we found it by experiment.

The only obvious tuning that is required is for the CC. And that is NOT just a feature of string theory, it is a feature of ANY theory we currently have for the CC. So to say it is analogous to requiring a highly tuned phi to the 150th QFT is just wrong. Strings do not add any tuning that isn't there in all approaches we have to the current data. And it solves problems that other approaches don't.

The whole landscape discussion in this sense has been deeply misleading. A feature (that one can make more realistic models) has been turned into a bug (how do we ever derive which of the much better models we now have is correct??). Of course that has been done on purpose, both by Peter and Lee (who dislike string theory),and by those string theorists whose dreams of changing science into an exercise in mathematics ("derive the world from thought alone!") has been seemingly stymied.

7. **woit**
November 14, 2006

pig,

You're engaging in pure sophistry, not science. A scientific theory is supposed to predict the result of an experiment. String theory doesn't do this, and the nature of the landscape is the main reason why.

Here and at Clifford's blog you spend your time anonymously attacking not only me, but those string theorists (Dine, Taylor, Douglas) who are actually trying to do science and get a real prediction out of string theory. They're not dreaming of "changing science into an exercise in mathematics", they're trying to do what scientists are supposed to do, come up with a prediction of what an experiment will see so the theory can be tested. What they're finding is more and more evidence that this is impossible.

8. **John Baez**
November 14, 2006

Peter writes:

> A scientific theory is supposed to predict the result of an experiment. String theory doesn't do this, and the nature of the landscape is the main reason why.

I think it's wiser to take spacepig at his word. He says the problem of determining the correct vacuum in string theory is comparable to the problem of finding the right Lagrangian in quantum field theory: we should give up on "deriving" it; it should be determined by experiment. That's a consistent position, though a strong retreat from the long-held hope that string theory would relieve us of this need.

If we take this position, we should ask whether it's *possible* to find a string theory vacuum that matches existing experiments.

As far as I can tell, the vacua most people like to study don't work: they are manifestly supersymmetric, so they predict that for each boson (e.g. the photon) there should be a fermion (e.g. the "photino") of the same mass, and vice versa. None of these "superpartners" have been seen. So, for string theory to have a chance to match existing experiment, people need to find vacua that aren't supersymmetric.

One approach is to come up with a theory of "spontaneous supersymmetry breaking" which could save the vacua that people like from being irrelevant to physics – but as far as I can tell, this is very hard, so not much progress is happening in this direction.

It seems the hard-core theorists mainly leave this crucial problem to "phenomenologists", who solve it by throw in *ad hoc* "soft supersymmetry breaking terms" into the field theories that can be derived from string theory vacua. To get theories similar to the Standard Model, this requires choosing over 100 new numbers. I don't like all those free parameters. And what I like less is that nobody knows where these "soft supersymmetry breaking terms" should come from. As far as I can tell, they're just stuck in by hand, out of desperation at being unable to solve the supersymmetry breaking problem in a principled manner.

In short: if string theory now demands that we choose a vacuum to match existing experiments, it would be really nice if someone could *find* a vacuum that match existing experiments!

Until then, Michael Douglas' claim that string theory is "no worse" than ordinary quantum field theory seems overoptimistic. Yes, we can get gravity, but no, we can't get matter that matches what we observe – not without extra *ad hoc* assumptions that nobody is able to derive from string theory.

Saying we can get "virtually any low energy physics out of one string vacuum or another" also seems overoptimistic. We can get lots of different choices of low energy physics, but none of them match *our universe* – until one throws in extra "soft supersymmetry breaking terms" by hand.

This at least is my impression. If progress has been made on this since I last checked, I'd love to hear about it.

9. **Bert Schroer**
November 14, 2006

The view of spacepig about QFT is a caricature seen through stringy eyes. It has nothing to do with what QFT really is. It starts with his metaphoric inflationary use of the terminology "vacua".
In QFT you have a dichotomy of algebraic structure and states. A theory is given by the spacetime-indexed net of observable algebras and its "states of physical interests" can be classified and hence belong all to the same theory. If there is a spacetime symmetry group acting on the algebraic net one can define a distinguished invariant state, the vacuum state, if there is no global symmetry (as in the generic QFT in CST situation) there is no distinguished reference state at all (in particular no vacuum). The total state space of the theory is a direct sum of "superselection sectors" (no coherent superposition between sectors) and the vacuum (if present at all) only belongs to one sector.
In a reasonable way of counting there is only a finite number of perturbative renormalizable theories and renormalizability in the standard sense does not go beyond spin 1. There are quadrilinear couplings between scalar fields and Yukawa as well as gauge couplings up to spin 1, i.e. 3 types of couplings. The only remaining feature which one can play around with are multiplicities (different SU(n) or O(n) symmetry groups) but nobody with a rest of physical reasoning left would compare this to the different physical principles which underly the different string vacuua. QFT (even outside that perturbative setting) is bound together by testable physical principles (e.g. dispersion relations for scattering amplitudes); what bind string vacua together is metaphoric garbage.
In order to save QFT from such a metaphoric sellout by ST, I posted a paper in todays hep-th.

10. **woit**
November 14, 2006

John,

As Thomas pointed out, and I've argued repeatedly, the difference between the string vacuum case and the QFT case is that the simplest of a beautiful class of QFTs (gauge theories) works incredibly well and makes a huge number of confirmed non-trivial predictions, while the simplest string vacua are ruled out, and one has to go to ever more complex constructions, just in order to match some of the crudest features of the standard model.

The problem with supersymmetry breaking terms is that you don't even know what they are, just that they have to be big enough to avoid conflict with experiment. People seem to have string vacua that do have large enough amounts of supersymmetry breaking. It's true that the state of current technology is that no one can do accurate calculations of most things in these vacua, but as far as I know there is no known reason that these things can't give the SM at low energy. And if one vacuum gives the SM, all indications are that there will be essentially an infinity of others, ruining the hope of making any predictions.

One could argue that one should pursue these studies as a way of potentially falsifying string theory. If one could understand all string vacua and see that none agreed with the SM at low energies, that would be something. Unfortunately, understanding in that detail "all string vacua" looks hopeless, and no one has seen any kind of argument that would allow a general conclusion that some aspect of the SM can not be matched by a sufficiently complicated construction.

11. **spacepig**
November 14, 2006

John;

Thanks, you got my point exactly. I do not mean to be attacking anyone in a personal sense, I really think the quest to "derive" predictions from string theory would be rather like the quest to "derive" the correct Lagrangian for nature. (It is a bit different, in that the different Lagrangians are a superselection issue while in string theory the vacua are part of one theory, but this is irrelevant given the cosmological issues involved in probing one vacuum from another).

It is not true any longer that string theorists study only supersymmetric vacua. Much of the fuss about the KKLT paper was that they proposed ways to break supersymmetry while nominally retaining computational control (and keeping the scale of breaking quite low, perhaps low enough to explain the hierarchy). This has been expanded upon in many works which explain how to break supersymmetry, in an apparently controlled way, in the framework of string theory. By now there is a huge literature on this, and most of the landscape papers that Peter and others deride, are actually working steadily to improve the technology for supersymmetry breaking in string theory. The most recent burst of activity in this regard has been tying the Intriliator-Seiberg-Shih models to string constructions, but there are many other approaches too.

12. **Anon**
November 14, 2006

Bert,

What do you make of QFT's like pure N=2 supersymmetric SU(2) Yang-Mills, which have continuous families of inequivalent choices of vacuum state (superselection sectors with inequivalent physics)?

13. **Bert Schroer**
November 14, 2006

John, it is simply not true that hard-core theorists do not look at the question at spontaneous SUSY breaking. The result is that it cannot be spontaneously broken in the sense as e.g. the Lorentz symmetry is broken in a thermal medium. They found such under such circumstances it "collapses" (i.e. there is no averaging which can save the symmetry in a highly mixed state, see my hep-th paper for more details and references).
Again I emphasize that QFT models are bound together by common model-independent testable (and tested!!) common principles. This is a hell of a difference to the "vacuum problem of ST".

14. **spacepig**
November 14, 2006

John:

I don't know what Bert is talking about, but standard references which
discuss the issue of supersymmetry breaking include reviews like:

Poppitz and Trivedi, hep-th/9803107
Shadmi and Shirman, hep-th/9907225

The subject developed after Edward Witten described the possibility of dynamical breaking of supersymmetry in the early 1980s, in the very famous paper Nucl Phys B 188 p. 513.

As I said a significant recent effort has been devoted to making such models in string theory in conjunction with other moderately realistic features, and it seems pretty clear that one can do this, by now.

15. **Bert Schroer**
November 14, 2006

The word "spontaneous breaking"has a very precise conceptual and mathematical meaning. Its consequence is that by forming mixed avaerage states one still can recover symmetry (albeit in an artificial mixed state which violates cluster properties). Such an averaging does not exist for supersymmetry (the only known exception).

16. **spacepig**
November 14, 2006

Well, Bert, the references I gave are for the standard usage. These theories are thought (by e.g. the thousands of people who work on string theory and also go to SUSY 200X conferences each year) to be theories whose Hamiltonians are supersymmetric, but which do admit admit a supersymmetric ground state. Or in some cases (those with metastable susy breaking vacua), theories which possess both supersymmetric ground states and long lived metastable quasi-ground states.

It is quite possible you have some "rigorous" meaning in mind, which I do not know about, but which is also not thought by the many phenomenologists who work on the MSSM, to be all that relevant. I suspect when they discover SUSY and some structure of soft terms at LHC, no one will care much about the axiomatic QFT existence of the definition of breaking which you are worried about.

17. **spacepig**
November 14, 2006

erratum:

I am sorry, I meant "…but which do not admit a supersymmetric ground state." Somehow I typed admit twice.

18. **Bert Schroer**
November 14, 2006

There is nothing "axiomatic" about a clear conceptual distinction between spontaneous symmetry breaking and no symmetry (=broken symmetry), you should not try to push common sense into some axiomatic or high-brow corner.

19. **spacepig**
November 14, 2006

The standard usage of "spontaneously broken" that I know of, states that a theory exhibits spontaneous breaking if the hamiltonian exhibits a symmetry that is broken by the ground state.

That is the sense in which I was using the term.

If you were using it in a different or more precise sense, the theories I mention may not exhibit spontaneous breaking by your definition. They do by the definition I gave.

This is important: it means that in the theories I mentioned, the divergence structure is not sensitive to very high energies for certain processes. E.g. corrections to the vacuum energy, are cut off at the scale of supersymmetry breaking. So in principle it is finite and calculable.

20. **Bert Schroer**
November 14, 2006

This is not quite the correct definition. The diffeomorphism group of the circle e.g. does not leave the conformal vacuum invariant (only the Moebius subgroup has this property) but this group is by no means broken in chiral theories.
Your definition does not cover the breaking in thermal states. The problem there is that the ground state Hamiltonian is not the same as the one which leaves the thermal average state invariant (one cannot argue here with quantization boxed and Gibbs states because they break the supersymmetry in an explicit manner).
Coming back to the statement of John, there is no mathematical theorem that supersymmetry can never be spontaneously broken in vacuum state (presumably you want it in such a way that the Poincare-group is conserved) but that special "collapse" aspect in a heat bath (where any other symmetry is at most spontaneously broken) makes the whole issue of spontaneous SUSY breaking extremely suspicious. Fermions and Bosons are separated by the strongest superselection rule in this world: the univalence superselection rule. My physical explanation for the thermal collapse phenomenon: you only get SUSY by an extremely fine tuning of coupling strength and such a fine tuning is extremely unstable (more unstable than the fine-tuning problems which SUSY is supposed to solve).

21. **spacepig**
November 14, 2006

OK. Well, supersymmetry can be spontaneously broken by my definition; that is the definition the phenomenologists who work on the MSSM and its extensions use; and theories with that kind of breaking of SUSY lead to the successful prediction of unification of couplings, good dark matter candidates, and a solution of the hierarchy problem. The recent landscape constructions incorporate more or less this kind of supersymmetry breaking into string theory, quite successfully. (Though by no means producing a fully realistic model of the world — who knows if that is possible).

I have no knowledge of, or intelligent comment to make, about your definition.

22. **Bert Schroer**
November 14, 2006

No, the situation remains undecided. Whatever our definitions are, we don't spontaneously break a symmetry rather the question is whether nature permits such phases (symmetric and phases with order parameters).
I think that your picture of breaking "by hand" is caused by a too formal reading of the Schwinger-Higgs mechanism which is not a symmetry-breaking (even though people use this misleading terminology). Local gauge transformations have nothing to do with symmetry and hence cannot be broken. There is a hell of conceptual distinction between the Goldstone spontaneous broken phase and the Schwinger-Higgs description of interacting massive vectormesons even though formally (in the

Lagrangian approach) they look very similar.

23. **spacepig**
November 14, 2006

At this point, I can only make the sociological comment: the rest of the field
has already moved on, so in practice, the issue is decided. Spontaneously broken susy plays a central role in many papers that appear each day on the arXiv. I think this is well justified, but other readers will have to judge for themselves.

Just as the field has moved on (correctly or not), I will too. I have nothing else to say about this subject.

24. **Bert Schroer**
November 14, 2006

o.k. I know that there is a difference between science and sociology and the only thing what happened in this long discussion (which is now finished) is that you confirmed this.

25. **Peter Woit**
November 14, 2006

As far as I can tell, this discussion of the formal status of supersymmetry breaking is irrelevant. Partly because you don't actually have a real underlying theory that does what you want to discuss (no non-perturbative version of string theory), partly because even if it does what you want (break supersymmetry), you end up with all sorts of different classes of models. The simplest of these models that doesn't violate what you already know (the MSSM) has 105 extra parameters in it, and no known reason these cannot have arbitrary values.

Using the word "success" in this context is a bit absurd. The bottom line is that you can't even tell us if the LHC will see anything at all. If it does happen to see exactly the superpartners, you can extract predictions about some of their behavior, but if these predictions don't work out, all you've done is falsified the simplest model, and you have an infinite array of other models you can use to match the data. In that case you're not testing a theory or predicting anything, just parametrizing observations in a complicated way.

26. **Bert Schroer**
November 14, 2006

Fine, so there is after all a scientific conclusion.
Spontaneous supersymmetry-breaking is conceptually extremely suspicious and phenomenologically (in the form of superstrings) totally futile.

27. **JC**
November 14, 2006

Years ago I first bought into the SUSY thing largely from the standard arguments in favor of it, such as dealing with the hierarchy problem, unification of coupling constants, etc … When I came to the realization it would take around 100 free parameters to incorporate SUSY into the Standard Model, that's when I was turned off from SUSY initially. (Before that time, I thought the Standard Model had too many free parameters).

When string theory became popular, I initially thought it could find an easy way to reduce the number of free parameters in the MSSM. But so far that has not happened yet in a convincing manner. At times I wonder why some theorists are tolerant of the idea of zillions of free parameters. Do any string theorists today believe in the idea that string phenomenology can completely determine the free parameters of the Standard Model?

28. **Anon**
November 14, 2006

Finite temperature breaks supersymmetry, just as it break Lorentz invariance (there's a preferred reference frame, in which you are at rest, with respect to the thermal bath).

This is not what people are talking about, when they talk about the spontaneous breaking of supersymmetry (at zero temperature). As spacepig points out, there are plenty of theories, in which the Hamiltonian (or Lagrangian) is supersymmetric, but there is no supersymmetric ground state. Instead, there's a massless Goldstone fermion, which transforms inhomogeneously under supersymmetry, etc…

The real setting, for phenomenology, is one in which one is looking at supergravity, rather than global supersymmetry. The massless Goldstino is eaten by the gravitino, in an analog of the Higgs mechanism.

Bert Schroer will complain that this statement is not solidly grounded in quantum field theory. He is correct. Supergravity (or any kind of quantum gravity theory) is not a QFT, as he understands the term. And, to really define supergravity, it needs to be embedded in some UV-complete theory (like string theory) that he would consider completely beyond the pale.

But I think he misunderstands even the case of globally supersymmetric QFTs, in which supersymmetry is spontaneously broken.

29. **spacepig**
November 14, 2006

Hello:

Wow, the opinions here, about SUSY and its breaking, are totally nonstandard. Anyone trying to "learn" about physics from blogs, beware!
Mr. Schroer has lightly dismissed the work of thousands of papers over a period of 20 or more years, finding theories that exhibit spontaneous and dynamical (spontaneous, nonperturbative) SUSY breaking.

JC: The MSSM does have approximately 125 parameters. However relatively trivial symmetries, which are also required by data (things like R-parity, needed to avoid proton decay), cut down the number. There are a few well motivated scenarios with just a handful of parameters.

It is however a problem of some interest, usually now called the LHC inverse problem, to try and figure out which version of the MSSM with soft breaking parameters is the correct one, given some hypothetical LHC data that confirms SUSY. It is not an easy problem, and indeed because of the large number of parameters, one might have to wait for ILC or some other machine to really nail down the model.

Most string theorists do not believe the use of the theory will be to determine these (kinds of) parameters. It will be useful for phenomenology if and when some stringy signature, like cosmic strings or moduli, shows up in experiments. This is something peter continually refuses to acknowledge, but is a far more likely scenario for contact,

than classifying string vacua and then finding the right one by brute force. It has been useful for more conceptual issues (like singularity resolution and black hole entropy), solving gauge theories, motivating new classes of models, etc. already. In fact it would be hard to gauge the strength of its impact on these subjects over the past 20 years, it has been enormous.
And, from the viewpoint of many established, contributing theorists in
many top departments, it has been very positive.

30. **Bert Schroer**
November 14, 2006

In my case it was not lightly; it would be much simpler for me if I permit myself to use what Feynman called "excuses".

31. **Peter Woit**
November 14, 2006

pig,

I agree that the most likely scenario for making contact between string theory and phenomenology would be if astronomers find a cosmic string, study its properties, and find that it has the properties elementary strings of cosmic size are suppose to have distinguishing them from cosmic strings coming from a Higgs field.

But there is not the slightest evidence for this, and there is no reason to expect it other than pure wishful thinking. It also would be strong evidence for string theory if, when LHC collisions begin, an angel appears out of the interaction region with gold tablets explaining that the multiverse exists and is governed by the laws of string theory. I just don't see any reason to expect this to happen, but you're welcome to put your hopes in it. Just doesn't seem like science to me.

32. **spacepig**
November 14, 2006

The cosmic string scenario seems more likely than the one with angels,
to me. As do scenarios with 5th forces (which is why several groups are doing experiments to detect them). Or scenarios with low string scale (which is why Lisa Randall wrote a popular book that recently won her the Lilienfeld prize, about string-inspired scenarios which solve the hierarchy problem).

Particle physics has always progressed by "model building," not by epiphanies which predict the structure of the whole theory. You can make fun of this and say "there is no guarantee any interesting model will be selected by the data," and you're right. But there was no such guarantee for the past 100 years, and yet, we did fine. The problem for the last 25 has been the lack of experiments that push the energy frontier, the SSC cancellation didn't help, and with LHC that will finally be corrected. I expect the bottom up approach will continue to succeed, with no need for angels, and interesting phenomena will continue to turn up.

33. **Peter Woit**
November 14, 2006

If we see a 5th force it will be quite interesting, but far from evidence for string theory.

I certainly hope and expect that interesting phenomena will turn up at the LHC or elsewhere, I just see no reason at all to expect that they will have anything to do with a 10/11d string/M-theory with something very complicated done to the 6/7 extra dimensions.

Particle physics has not progressed due to model-building itself, it has progressed due to people coming up with models that actually have to do with the real world, based on finding testable, compelling models that both explain things already seen, and predict things not yet seen, which are then confirmed.

That Lisa Randall's popular book has received a prize is absolutely irrelevant to the question of the validity of the models she discusses. You seem very concerned with sociological rather than scientific evidence for models. If someone decides to award a prize to my book, will that prove that string theory has failed as an idea about unification?

34. **spacepig**
November 14, 2006

Peter, you fail to acknowledge that in fact string theory has been an inspiring source of models that have to do with the real world, have testable and compelling features, and predict things not yet seen. None of these models have yet been confirmed. If one is, it will not be proof of string theory. But to pretend string theory has not had this role, is really strange.

35. **Peter Woit**
November 14, 2006

pig,

String theory has inspired all sorts of things over the last 35 years, some of them very important, some of them worthless. One thing it has definitely inspired is some great mathematics. I don't happen to be a big fan of the kind of phenomenological models I think you have in mind; they appear to me to be complicated, and don't actually seem to really explain anything that we observe. Maybe I'm wrong and the LHC will provide experimental evidence for them, we'll see. If so, that would be a positive thing to attribute to string theory research. It wouldn't mean though that the world is 10/11 dimensional, or that string theory ideas about unification have anything to do with reality.

36. **JC**
November 14, 2006

spacepig,

How would you feel if the LHC and all other near-term future colliders (ie. built and running before 2100), only found the standard model Higgs particle and nothing else?

37. **anon.**
November 15, 2006

"… the opinions here, about SUSY and its breaking, are totally nonstandard. Anyone trying to "learn" about physics from blogs, beware!" – Spacepig (comment number 19,194)

Spacepig, you mean to write, surely, "… Anyone trying to 'learn' about orthodox string theory which we claim is physics, from blogs, beware!"

"String theory has inspired all sorts of things over the last 35 years, some of them very important, some of them worthless. One thing it has definitely inspired is some great mathematics." – Peter Woit (second to last comment).

Can you actually substantiate this claim, please? Please give a great equation from string, and show how to solve it. Kaku in a New Scientist essay a year or two ago wrote that he cried when he first saw the elegant simplicity and predictive power of Dirac's equation. Is there anything like that in the stringy Calabi-Yau's? I thought that the whole point is that the failure of string theory is a mathematical failure to actually solve the extradimensional equations because they're so inelegant? Surely there is nothing useful in equations which can have so many solutions?

38. **Bert Schroer**
November 15, 2006

Anon,
this is an issue on which I agree with you; perhaps one can bring it more to the point by the following remarks.
It is not mathematical physics which is helpful for unifying mathematics but rather "physical" mathematics i.e. metaphoric ideas about particle physics which are produced most abundandly in the present crisis of particle physics. This is pretty evident in the way physics ideas enter the Langlands program. It is not the world (say the SM) as it is in nature, but rather the way Atiyah, Seiberg and Witten… want it to jump over their e-m duality stick which is useful for mathematics. The reason why this is successful is that mathematicians need once in a while (especially for unification of their field) to get away from the rigor and activate their free-floating imagination; metaphorical ideas from particle physics are the ideal catalyzer for this.
What is fruitful for mathematics is a dead end for particle physics.

November 15, 2006

spacepig,

you abandon the hope of predicting the vacuum. You abandon the hope of making statistical predictions. You suggest that what theorists did so far is enough. I agree that some scenarios would smell more stringy than others and that finding just the SM at LHC would smell anthropic. But selecting a QFT means selecting a QFT and does not mean proofing that string theory is the theory of quantum gravity.

If you wish to abandon the scientific method, we can close now the issue about string theory with the following pool:

a) it is 26th-century physics that fell by chance into the 21th century;

b) it is 21th-century archeology;

c) it is a fart in 11d space-time.

If instead you want to follow the scientific method, you must provide testable predictions. In my opinion, if this cannot be done, string theory has to dissolve as in c).

November 15, 2006

Now that I have a copy of Freeman Dyson's book "The Scientist as Rebel", I see in it some passages that, like its cover, remind me of Peter's description of superstring theory.

Dyson said:
"… At the beginning of the seventeenth century, the birth of modern science had been proclaimed by … Bacon in England and … Descartes in France.
…
According to Bacon, scientists should experiment … and collect facts … until the accumulation of facts would make clear the way nature behaves.
…
According to Descartes, scientists should deduce the laws of nature by pure reason … Cartesian vortices were supposed to fill space … pushing celestial objects along their orbits.
…
At the time when Newton made his discoveries, the learned men of England were mostly doing science in the empirical styple of Bacon, but … believed in the Cartesian theory of vortices because it was the only theory available.
…
In 1667 Newton … resumed his solitary existence in Cambridge. … He spoke to nobody about his alchemical studies, and to almost nobody about his discoveries in physics.
For him, alchemy and physics and theology were parts of a single enterprise, three aspects of a single search for knowledge that God had placed within his grasp. Since he was not free to talk about his theology, he saw no reason why he should talk about his alchemy or his physics.
He might never have talked about his physics, if his friend Halley had not come to Cambridge in 1684 begging him to publish what he knew. Then, once he had started writing … he did not stop until he had finished the three volumes of the Principia. …
In the first two volumes …[of] the Principia …[Newton]… built a grand edifice of mathematics … and then in the third volume he … demonstrat[ed] with an abundance of observational facts that nature danced to his tune.
As soon as the Principia was published and widely circulated,
the Cartesian vortices were dead. …".

If Halley had not convinced Newton to publish the Principia, what would have been the course of science ?
Would others (using Hooke gravity, Leibnitz calculus, etc) have produced a Principia,
or
would Hooke gravity have remained as empirical physics and Leibnitz calculus have remained as mathematics reasoning, with the Newtonian synthesis never occurring ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – I guess I should say explicitly that the similarity that I see is that:
Baconian accumulation of facts = Standard Model plus gravity
and
Cartesian vortices = superstring theory
and
"the only theory available" = "the only game in town"
and
maybe a Newtonian synthesis (a model using new or unconventional math techniques that enables calculation of particle masses, force strengths, etc) might be necessary to unify Baconian standard model plus gravity physicists with Cartesian beautiful-math physicists.

PPS – As Dyson's essay also said:
"… Newton himself was at heart a Cartesian …".
That is borne out by the fact that Newton lived his life in accord with an Ovid quotation on Descartes's tombstone:
"Bene qui latuit, bene vixit."
Sadly,
there exist today pressures against unconventional physics similar to the pressures against unconventional theology in Newton's time, and it may be that even today some feel that they have a better life by hiding their true feelings.

I've been trying to look at books that might have something to say about strings and say to myself, "What would Peter think?" to evaluate it. I'm not very far into it, but I was actually thinking that Gribbin's book, though undoubtedly pro-strings, was more skeptical than I'd thought it would be.

I stop and say good by to all who engaged me in interesting discussions. It is not only the spam-filter which irritated me but I find this whole enterprise unworthy, regimented to rules which never were spelled out, and at the end and plainly ridiculous.

More On Geometric Langlands (a Grand Unified Theory of Math?)

November 14, 2006
Categories: Langlands

After mentioning in the last posting that Witten is giving talks in Berkeley and Cambridge this week, I found out about various recent developments in Geometric Langlands, some of which Witten presumably will be talking about.

Edward Frenkel has put a draft version of his new book Langlands Correspondence for Loop Groups on his web-site. In the introduction he describes the Langlands Program as "a kind of Grand Unified Theory of Mathematics", initially linking number theory and representation theory, now expanding into relations with geometry and quantum field theory. The book is nearly 400 pages long, and to be published by Cambridge University Press. Frenkel also notes that recent developments in geometric Langlands have focused on extending the story from the case of flat connections on a Riemann surface to connections with ramification (i.e. certain point singularities are allowed). He has a new paper out on the arXiv about this, entitled Ramifications of the geometric Langlands program, and he writes that:

in a forthcoming paper the geometric Langlands correspondence with tame ramification is studied from the point of view of dimensional reduction of four-dimensional supersymmetric Yang-Mills theory.

The title of the forthcoming Gukov-Witten paper is supposedly "Gauge theory, ramification, and the geometric Langlands program."

Presumably people attending Witten's talks in Berkeley and Cambridge will get to hear about this new story for the ramified case. For the rest of us, on his web-site David Ben-Zvi has notes from talks this summer by Witten at Luminy where he describes some of this. Ben-Zvi also has an announcement of a series of lectures on geometric Langlands that he'll be giving at Oxford next April. The summary of the lectures says that he'll "describe upcoming work of Gukov and Witten which brings together geometric Langlands and link homology theory." Link homology theory is also known as Khovanov homology, and I wrote about this two years ago here, advertising Atiyah's speculation that there may be a 4d TQFT story going on, something I always have found very intriguing. Ben-Zvi has recently lectured on Khovanov homology at Austin, and began his lecture by saying that this material relates "themes in 21st century representation theory" to 4d TQFT. He goes on to cover some of the ideas about 4d TQFT and "categorification" that I was very impressed by when I heard about them from a talk by Igor Frenkel a few months ago (described here).

At first I thought Ed Frenkel's claim that geometric Langlands was going to give a Grand Unified Theory of mathematics was completely over the top, but seeing how some of these very different and fascinating relations between new kinds of mathematics and quantum field theory seem to be coming together, I'm more and more willing to believe that investigating them will come to dominate mathematical physics in the coming years.

Update: Slides from Witten's Berkeley lectures are here. And many thanks to David Ben-Zvi for the informative comments!

Comments

1. **A.J.**
   November 14, 2006

   Hi Peter,

   Witten has only delivered one lecture so far, and it was devoted to reviewing background material: mostly S-duality and a few words about topological twisting, all of which can be found in the Kapustin-Witten paper.

2. **Peter Woit**
   November 14, 2006

   Thanks A.J.!
   It would be great if you could keep us informed about the rest of the lectures…

   November 14, 2006

   It sounds like they are doing interesting math, but leaving physics to the LQG crowd.

4. **atrings**
   November 14, 2006

   I agree with SFB for the "interesting math ",but not for the"LQG crowd".

5. **Richard**
   November 14, 2006

   "At first I thought Ed Frenkel's claim that geometric Langlands was going to give a Grand Unified Theory of mathematics was completely over the top, but seeing how some of these very different and fascinating relations between new kinds of mathematics and quantum field theory seem to be coming together, I'm more and more willing to believe that investigating them will come to dominate mathematical physics in the coming years."

   Perhaps a domination of mathematical physics, but the claim of a grand unification of mathematics is in fact way over the top unless you believe that mathematics is nothing but mathematical physics. It probably all depends on your own personal values, biases, points of view, and even whom you believe owns mathematics. Recall Lubos' wild claim that someday mathematics will be completely subsumed by string theory?

6. **onymous**
   November 14, 2006

   I expect many of the people who have been working on geometric Langlands for years would be kind of shocked to be called mathematical physicists, Richard. Do they all instantly become mathematical physicists just because Witten got interested in what they're doing?

7. **Richard**
   November 14, 2006

   Onymous – I don't believe I said that.

8. **onymous**
November 14, 2006

Apologies, I misread Peter's original statement — didn't notice that he specifically singled out mathematical physics — and so misinterpreted your "…unless you believe that mathematics is nothing but mathematical physics" as an implication that geometric Langlands is mathematical physics. Never mind.

9. **David Ben-Zvi**
November 15, 2006

Hi and thanks for the references! (all notes on my page should be taken with many grains of salt..)
I should point out that the preprint by Gukov and Witten doesn't actually talk at all about link homology, so my talk description was perhaps premature, but a connection between
geometric Langlands and some kind of link homology is to be expected following their ideas (cf Gukov's Strings talk).
Cautis and Kamnitzer also have very interesting work in progress on such a relation.

After all, geometric Langlands is a very general categorification
program in representation theory, so one would expect it to
relate to the kinds of categorifications that give rise to Khovanov homology. There just aren't too many fundamental structures associated with a semisimple Lie group, and they all connect..

Of course it's a joke to speak of geometric Langlands as
a grand unified theory… but the Langlands duality is certainly
among the broadest themes in math, a kind of nonabelian
generalization of the Fourier transform, and it's extremely exciting
that we can view it in the geometric setting as electric-magnetic duality in four dimensional gauge theories!

10. **relativist**
November 15, 2006

David Ben-Zvi says

"it's extremely exciting that we can view it in the geometric setting as electric-magnetic duality in four dimensional gauge theories!"

Can you expand on that? Sounds very interesting.

11. **urs**
November 15, 2006

> it's extremely exciting that we can view it in the geometric setting as electric-magnetic duality in four dimensional gauge theories!

Can you expand on that? Sounds very interesting.

This is the insight of the Kapustin-Witten paper.

You can find a summary here.

12. **urs**
November 15, 2006

> a kind of nonabelian generalization of the Fourier transform

Is it a nonabelian generalization, or isn't it rather a categorification of the Fourier transform?

It seemed to me that much of Langlands can be nicely understood as taking place in categorified linear algebra. I have made remarks on how the Hecke operator looks like a 2-linear map for instance here.

13. **urs**
November 15, 2006

> It would be great if you could keep us informed about the rest of the lectures…

If anyone feels like reporting on interesting lectures online, we have a guest account for that over on the n-Café.

For instance we had David Roberts guest-reporting from a lecture by Brian Wang here, similar to the many guest reports we had # at the string coffee table.

14. **David Ben-Zvi**
November 15, 2006

Urs:

"Is it a nonabelian generalization, or isn't it rather a categorification of the Fourier transform?"

well it's both.. the main difficulty is the nonabelian nature
rather than the categorification, and that is where Langlands tells
us what to do (in the geometric or classical, noncategorified setting).
Categorifications of the Fourier transform have been
used for almost 30 years I think (starting with the Fourier-Deligne
transform, see eg Laumon's first ICM), and the geometric Langlands
program suggests that one can extend this to nonabelian settings
(G-bundles on curves).

By the way maybe this is an excuse to air one of my pet
peeves, the use of the term "Fourier-Mukai"
to refer to any functor between derived categories given

by an integral kernel.. I would be surprised if an analyst
referred to any map on function spaces given by
integration against a kernel (or any matrix) as a Fourier transform, and the same should hold in the categorified setting — in some
precise sense (due to Toen and which I'm badly paraphrasing)
all functors between derived categories are given by integral kernels!
"Honest" Fourier-Mukai transforms should have additional
structure and properties (for example taking convolution
to tensor product). Similarly not any duality is a T-duality!

15. **urs**
November 15, 2006

> well it's both.. […] Categorifications of the Fourier transform have been used […] and the geometric Langlands program suggests that one can extend this to nonabelian settings […]

Great, thanks! That's what I was hoping some expert would say. Probably I just talked to the wrong experts so far!

Because each time I'd ask a question along the lines

"isn't an eigenbrane just a categorified eigenvector in some 2-vector space"

the answer I'd get would be something like

"no, 2-vector space only appear after we categorify Langlands itself, like Kapranov discussed."

http://golem.ph.utexas.edu/category/2006/10/quantization_and_cohomology_we_1.html#c005444

16. **Peter Orland**
November 15, 2006

I don't know much category theory, but I thought that the
non-Abelian generalization of the Fourier transform is the character expansion (or Plancherel transform in the non-compact case) for functions on non-Abelian groups. Aside from a character formula, that is the simplest generalization.

Obviously, I am missing the point and something deeper is meant. Can anyone explain this to a dumb theoretical physicist?

17. **Peter Orland**
November 15, 2006

I just wanted to add that the sort of examples I mentioned don't help much with non-Abelian duality in classical or quantum field theory. To perform a duality transformation, a zero-curvature condition is Fourier transformed and the parameter integrated over is the dual field. This only really works in the Abelian case. There are non-Abelian generalizations of duality done this way, but they are rather messy, and not obviously useful.

18. **A.J.**
November 16, 2006

Well, Witten finished his lectures, but ran out of time to say much of anything about ramification. There's just too much information to be covered in (somewhat less than) 3 hours. Most of what he said is pretty well covered in David Ben-Zvi's notes, and in Urs's posts on the subject, or in the Kapustin-Witten paper for that matter.

We did get scans of his notes, so perhaps those will be available online one of these days.

19. **urs**
November 16, 2006

> Can anyone explain this to a dumb theoretical physicist?

One way to get an intuition for what is going on with these Hecke operators and similar transformations is to consider the drastically oversimplified baby toy example situation where the underlying spaces are in fact just – finite sets.

A vector bundle over a finite set is then just an array of finitely many vector spaces.

Think of that as a vector whose entries are vector spaces. Such a beast is known as a (Kapranov-Voevodsky) 2-vector.

The categorification involved here is that which takes the monoid of complex numbers and replaces it by the monoidal category of complex vector spaces.

So we can imagine doing linear algebra with these vectors whose entries are vector spaces by replacing sums of complex numbers by direct sums of vector spaces and products of complex numbers by tensor products of vector spaces.

In particular, let X any Y be two finite sets and consider a vector bundle L over X x Y .

By the above, this is now like a |X| x |Y| matrix with entries being vector spaces. Using the above dictionary, we can define the categorified matrix product of L with a 2-vector over Y, simply by using the ordinary prescription for matrix multiplication but replacing sums of numbers by direct sums of vector spaces and products of numbers by tensor products of vector spaces.

One can convince onself, that this categorified action of a 2-matrix on a 2-vector can equivalently be reformulated in a more arrow-theoretic way as follows:

We have projections p1 and p2 from X x Y to X and to Y, respectively. This makes X x Y into a span

http://golem.ph.utexas.edu/category/2006/10/klein_2geometry_vi.html#c005232

Given a 2-vector V -> X over X, we may pull it back along p1 to X x Y, tensor the result componentwise with L and push the result of that back along p2.

This operation produces precisely the naive categorified matrix product that I mentioned above.

But the nice thing is that this pullback-tensor-pushforward along a "correspondence" like X x Y generalizes to vastly more interesting situations.

There is an entire zoo of well-known operations of this kind. The Fourier-Moukai transformation is one example. The Hecke transformation that appears in geometric Langlans is another.

In the above sense, all of these operations can be understodd as linear maps on 2-vector spaces.

A description of what I just said, including some helpful diagrams and links to further material can be found here:

Fourier-Mukai, T-Duality and other linear 2-Maps.

20. **urs**
November 16, 2006

Concerning the abelian vs. nonabelian categorified Fourier transform:

there is something called the "classical limit" of geometric Langlands, as decribed for instance here:

Pantev on Langlands, II

The Hecke operation in geometric Langlands is a generalization of the categorified Fourier transformation: is a "2-linear map" in the sense of my comment above

http://www.math.columbia.edu/~woit/wordpress/?p=492#comment-19258

such that it coincides with the Fourier-Moukai transformation in this "classical limit".

In other words, the Hecke operation is a deformation of the Fourier-Moukai transformation.

21. **Bert Schroer**
November 16, 2006

I never understood what is the relation of elliptic cohomology (not that I don't know what it presents mathematically since I have followed the area with an ever increasing distance since the days of the Atiyah-Singer index theorem) with particle physics except that Witten has generated a certain enthusiasmus with some particle physicists. Since I have learned to make a distiction between physics and what (some) physicists are doing and since this blog (as Peter's book) is primarily about the present state of particle physics I think it is a legitimate question to ask about its relation to particle physics. If this is not permitted then this will be my last contribution to this blog.

22. **Anon**
November 16, 2006

To Peter Orland:

You are correct about the Plancheral theorem. But that tells you that if you know the irreducible representations, and their dimensions/characters, you know how to decompose functions. It doesnt tell you what the characters are.

In the first instance Langlands is a parameterization of irreducible reps, and a determination of their character; roughly they are in bijection with conjugacy classes in another group.

The categorification nonsense is an elaboration of this, to say *all* information you can extract comes from this dual group.

23. **Peter Orland**
November 16, 2006

Urs and Anon,

Thanks for the responses. I understand that a character formula of some sort is need to make Plancheral meaningful. What I worry about is that even with such a character formula, there isn't enough for non-Abelian electromagnetic duality. In fact, I am skeptical a USEFUL duality for pure Yang-Mills theorists exists.

To carry out a duality transformation, the Bianchi identity needs to be imposed by integrating over a new field (in 3+1 dimensions, this field is a one-form). Then we would like to integrate out the orginal gauge field to obtain a action in this new field. Doing this in practice is tough. There are tricks for doing it with certain character formulas, but the dual theory is a mess, since the dual fields are discretely valued (o.k. on the lattice, but without a good continuum interpretation).

Are these new techniques are somehow better? If so, it would be very interesting.

24. **urs**
November 16, 2006

> In the first instance Langlands is a parameterization of irreducible reps, and a determination of their character; roughly they are in bijection with conjugacy classes in another group.

That's the original "algebraic" Langlands thing.

> The categorification nonsense is an elaboration of this, to say *all*

I think the categorification nonsense comes in when you pass from the original to the *geometric* Langlands correspondence.

In the original Langlands setup, the Hecke operator is an ordinary linear map, acting on a space of modular forms.

In the geometric version of the theory, it becomes the Hecke operator that acts on derived coherent sheaves on some moduli space. And that guy is no longer an ordinary linear map. But it is a categorified linear map, if you like (and also if you don't like it).

In particular, in a special limit it is nothing but a certain categorification of the Fourier transformation.

25. **urs**
November 16, 2006

> I never understood what is the relation of elliptic cohomology […] with particle physics

Elliptic cohomology is not about particle physics. It is about string physics.

Elliptic cohomology is to strings like particles are to K-cohomology [#](#).

But what is the direct relation of elliptic cohomology to geometric Langlands, that made you bring this up here?

26. **Bert Schroer**
November 16, 2006

Interesting, so after all elliptic cohomology isn't about particle physics it is rather about ST. That's precisely what I expected.

27. **Bert Schroer**
November 16, 2006

Urs
Interesting, so after all elliptic cohomology isn't about particle physics it is rather about ST. That's precisely what I expected. I guess I got into the Langland's column by accident, but without this accident I probably would not have received such a precise answer.

28. **urs**
November 16, 2006

> Interesting, so after all elliptic cohomology isn't about particle physics it is rather about ST.

Yes, check out the table at the beginning of the introduction of [those notes](#).

Generalized cohomology theories are labelled by something called their "chromatic filtration".

The idea is that a cohomology theory of chromatic level p comes from the physics of "p-particles" – otherwise known as (p-1)-branes.

K-cohomology has filtration 1. It corresponds to 1-particles (0-branes). Ordinary points, that is.

Elliptic cohomology has filtration 2. It corresponds to 2-particles, otherwise known as 1-branes or strings.

Ordinary (singular) cohomology has filtration level 0. There is a precise sense in which it corresponds to 0-particles (or (-1) branes).

I expect this table is open ended. But I have never seen anything about cohomology theories of chromatic filtration larger than 2.

29. **urs**
November 16, 2006

> I am skeptical a USEFUL duality for pure Yang-Mills theorists exists.

It is a famous conjecture that 4-dimensional Yang-Mills theory has a duality called *S-duality*.

Yang-Mills theories (in a given dimension, for a fixed number of supercharges) are parameterized by a complex number

tau ,

the coupling constant, and a Lie group

G,

the gauge group.

For N=4 supersymmetric Yang-Mills, there is conjectured to be an isomorphism between Yang-Mills theory for

(tau,G)

and that for

(-1/tau , G^L) .

-1/tau is, roughly, the inverted coupling constant (therefore: "weak-strong coupling duality") and G^L is the Lie group that is Langlands dual to G.

See the first few paragraphs of [this](#), for instance.

That this is indeed an isomorphism of field theories is not a theorem, but it is supported by enough evidence that makes everybody assume it is indeed true. This is the *S-duality conjecture*.

Since the Langlands dual group appears in this conjecture, it has long been speculated that there is indeed a relation between S-duality and the Langlands program. But until recently nobody could really substantiate this.

The achievement of the Kapustin-Witten work is to show that for the special case that the 4-dimensional Yang-Mills theory is suitably compactified down to two dimensions, the S-dualiy conjecture for Yang-Mills theory is essentially equivalent to the geometric Langlands conjecture.

All the ingredients of geometric Langlands, like those moduli spaces of bundles and the derived coherent sheaves on them, can be understood in terms of field configurations and boundary conditions of compactified N=4 super Yang-Mills theory.

Notice that this amounts to further support for the S-duality conjecture, because it increases the number of people that truest the S-duality conjecture by those mathematicians that trust the geometric Langland conjecture.

But it might also be noteworthy that this suggests that the geometric Langlands duality is only a tiny aspect of a much bigger story – since it is (apparently) just the special case of S-duality applied to a very specific compactification of Yang-Mills theory only.

30. **Peter Orland**
November 16, 2006

Urs,

Yes, I know about the S-duality conjecture (I would much more interested in a similar conjecture about pure Yang-Mills than N=2 or N=4 Yang-Mills. Theories with adjoint matter are very different from those we know about in nature).

Though a conjecture is nice, to really prove it operator equivalences are needed. The procedure I discussed before, character expansions of the Bianchi identity, etc., is the first step to find such equivalences. In Abelian theories, this is how Kramers-Wannier duality works. There are some non-Abelian constructions due to Sharachandra and Anishetty, they haven't proved useful yet.

31. **A.J.**
November 17, 2006

Urs,

Their's a mild caveat to be added to your statement that

> All the ingredients of geometric Langlands, like those moduli spaces of bundles and the derived coherent sheaves on them, can be understood in terms of field configurations and boundary conditions of compactified N=4 super Yang-Mills theory.

The geometric Langlands correspondence is stated in terms of D-modules on the moduli stack of not-necessarily stable G-bundles. Kapustin & Witten's work doesn't quite give full information about the moduli stack, but only its semi-stable locus. As I far as I can tell, the relation between N=4 SYM and the Langlands correspondence for D-modules on the full stack hasn't been completely spelled out.

32. **ks**
November 17, 2006

Question to Urs. First of all thanks a lot for all your explanations. You work on cool stuff anyway (though it is a little over my head at this time). Do I understand your research program correctly when I assume that You try to link the standard model and ST in purely algebraic terms by means of higher category theory? Hence when changing the algebraic setting they do not look much different but are connected through certain higher morphisms?

33. **Bert Schroer**
November 17, 2006

Peter Orland
Conceptual realism demands to separate Kramers-Wannier duality (and its structural extension the order-disorder issue) from speculative ideas. The o-d duality is a local quantum physical phenomenon which has no known analog in higher dimensions. Whereas o-d is a phenomenon which has a solid operator algebraic intrinsic understanding (if you want I can provide you with recent literature) there is nothing like this for the S conjecture.
By now Wikipedia has more material on wild conjectures than about genuine results. There is the danger that we may be fooled to our own simulacrums and metaphors in particular that conjectures solidify because they comes from somebody with a high status in the community or because they have been hanging around for a long time so that several generations have stepped on them.

34. **urs**
November 17, 2006

> wild conjectures

S-duality is certainly a conjecture, but hardly a wild conjecture.

I mean, that's the point: S-duality is apparently as wild as geometric Langlands.

35. **urs**
November 17, 2006

> Kapustin & Witten's work doesn't quite give full information about the moduli stack, but only its semi-stable locus.

Right, thanks. There are probably a couple of such technicalities. I am not working on this stuff, so it's hard to keep them all in mind.

So what about that "classical limit" in which, apparently, geometric Langlands is only proven so far. Does compactified SYM exactly coincide with the geometric Langlands data in that limit?

36. **David**
November 17, 2006

A couple of comments: Kapustin-Witten's theory does (as far as I
understand) cover the full stack of bundles, not just the semistable locus. The sigma-model/mirror symmetry description
fails outside the semistable locus, but they emphasize
in the paper that the gauge theory sees the entire stack
of bundles — I think the problem is us geometers
have only been able in the past really to process
the classical aspects of the theory (solns of the equations of motion
etc) but quantum gauge theory is a lot smarter than we
are (speaking for myself at least). As far as I know they
can't completely say what S-duality predicts off the semistable locus, but the important point is it does actually apply there.

The classical limit of Langlands is only proven
generically, missing the hardest locus — it's a beautiful
result and one of the best in the subject, but saying classical
geometric Langlands is understood is on the same

level as saying you understand (noncompact) Lie groups
when you understand their diagonalizable elements —
the hardest part involved unipotents..

Also I'm not sure I would think of Hecke operators as Fourier transforms – the Hecke operators are the symmetries of moduli
of bundles (and sheaves on them), while the Fourier-Mukai
type transforms relate G and G^ the dual group.

One sense (of many) in which geometric Langlands is a nonabelian
categorified generalization of the Fourier transform is that while Plancherel helps you decompose spaces of functions on a group,
geometric Langlands type results help you decompose the
CATEGORY of all representations of a group —
since these categories are not semisimple
there's a big difference between listing irreducibles and their characters and actually describing the structure of general
representations. (Geometric Langlands ideas
can be used to study for example the category
of Harish-Chandra modules for a real semisimple Lie group).

37. **Peter Orland**
November 17, 2006

Bert,

I cannot understand your explanation especially well. In my attempt to translate your statement into simple language, I conclude you mean more conjectures than solid statements dominate our field. I don't need to be reminded of this, since I have
seen it all over the literature for the last decade or so.

I was asking if the experts on Langlands believe a useful concrete electric-magnetic duality transformation can be constructed from non-Abelian Fourier transforms (character expansions). I suspect the answer is no, since no one gave me a simple "yes".

38. **John Gonsowski**
November 17, 2006

I'm probably mixing algebraic number theory with analytic number theory but is there a relationship between elliptic cohomology and elliptic Mobius transformations?

39. **urs**
November 17, 2006

> Also I'm not sure I would think of Hecke operators as Fourier transforms – the Hecke operators are the symmetries of moduli
> of bundles

Oh, sorry, I misspoke if I said that. The Langlands correspondence is analogous to the Fourier transform, exchanging skyscraper sheaves (analogous to delta-functions) with Hecke-eigensheaves (analogous to plane waves). So, in this analogy, the Hecke operator is like a categorified derivative.

40. **Bert Schroer**
November 17, 2006

I am afraid the sad truth is the answer is "no". It is better to live in quantum reality than to become complacent with a Disney version of it.
I was not trying to explain anything in technical terms but only pointing to the obvious observation that Kramers-Wannier on a microscopic level (achieved by Leo Kadanoff) was quantum from the beginning whereas the Seiberg Witten duality is from a physical Disney dreamland which precisely of this is so useful to a large part of mathematics. The kind of mathematics for which it had no use is the operator-algebraic mathematical setting of QT which dates back to von Neumann and has been enriched by the locality principle in AQFT. By the way the manner Kadanoff has extracted (noncommutative) operator commutation relations for the (what we nowadays call) the Ising primary fields from the Euclidean lattice setting (via a partially guessed properties of the transfer matrix formalism) had my deep admiration; the Leitmotiv of all my work with Swieca in the early 70s was related to adapt ate Kadanoff's order/disorder ideas to the continuous setting of QFT; in many cases we even succeeded to read this back into a continuous functional integrals setting by using an Aharonov-Bohm analog language. Later, when I was working with Rehren on an algebraic approach to chiral conformal QFT I remembered those Kadanoff ideas and we found a completely explicit operator version of an "exchange algebra" for the conformal Ising field theory from which it was possible to compute its n-point Wightman functions. A historical review can be found in
http://br.arxiv.org/abs/hep-th/0504206
but thinking about this now, I should have written much more about Leo Kadanoff's contributions; he really deserved a Nobel prize together with Wilson.
In those days we also convinced ourselves that this order-disorder idea has no electric-magnetic counterpart in the full QFT setting.

41. **Peter Orland**
November 17, 2006

Bert,

I also worked extensively on duality. Like you, I concluded that
there is no simple operator equivalence between a non-Abelian
gauge theory and its dual. But there are intriguing exceptions
of systems with non-Abelian systems which do have duality
transformations and disorder operators. In my Ph.D. thesis I found lattice systems with permutation-group S_{N} symmetry which have nontrivial duals. But I will spare people here from a list of more publications on the subject.

Regards,
Peter (O.)

42. **Thomas Larsson**
November 18, 2006

Conceptual realism demands to separate Kramers-Wannier duality (and its structural extension the order-disorder issue) from speculative ideas. The o-d duality is a local quantum physical phenomenon which has no known analog in higher dimensions.

???

The 3D Ising model on a cubic lattice is Kramers-Wannier dual to Ising gauge theory on the same lattice. Why is this not o-d duality in higher dimensions?

43. **urs**
November 18, 2006

> I concluded that there is no simple operator equivalence between a non-Abelian gauge theory and its dual.

Is this saying that you consider the S-duality conjecture to be in fact false?

If so, I'd be interested in the details of the assumptions that go into this.

I recall that Bert Schroer was (similarly ?) claiming that the AdS/CFT duality conjecture (in the sense of Maldacena) is false, and that the correct duality statement was along the lines of Rehren's work.

In that case I got the impression that two rather different concepts were being compared, and that in fact Rehren's work had little relation to the setup considered by Maldacena et al. Compare for instance Jacques Distler's account.

The crucial difference in this case is that Rehren's work was based on a fixed and precise axiom set, while Maldacena's work uses notions of quantum field theory that have not been axiomatized yet.

For people like Bert Schroer this is reason enough to completely reject all QFT that does not fit into the AQFT axioms. For other people, in contrast, the restrictive applicability of the AQFT axioms is reason enough to reject those.

To some extent it is a matter of taste concerning which role of rigour you find useful in physics research. I can easily tolerate both these standpoints. But I would like to know in each case which one is assumed by which participant.

44. **woit**
November 18, 2006

Urs,

You keep ignoring the fact that Peter Orland is asking about pure YM theory, not N=4 SYM. There's a beautiful story about duality in non-supersymmetric abelian gauge theories, and many people (including Peter) have tried hard to generalize this to the non-abelian case. I gather that he's trying to understand whether geometric Langlands gives any insight into that problem, and as far as I can tell, the answer is just no.

45. **Peter Orland**
November 18, 2006

Urs,

Sorry that I am giving long-winded answers to your questions. I am
mainly interested in advancing methods in asymptotically-free field theories and in constructions which could eventually facilitate calculations. I try to learn other stuff, because I can't predict what I may need to know in the future. But I am more interested in theoretical, rather than mathematical physics (as people abuse use the term nowadays, to study mathematical techniques, rather than to prove theorems).

I believe (after some years of trying to show the contrary) there is no USEFUL version of Kramers-Wannier duality which is true for PURE non-Abelian gauge theories. There are non-Abelian dualities for some special \$S_N\$-invariant systems, which I mentioned above (there is also non-Abelian Bosonization in two dimensions).

The general problem for duality in non-Abelian theories is constructing dual fields with local commutation or anti-commutation relations. Supersymmetric or other theories with adoint matter have some sort of charge-monopole duality – but such theories are effectively Abelian. These theories are interesting in their own right, but to my way of thinking, they are not as important as Yang-Mills theories coupled only to fundamental (not adjoint) Fermion color charges, or pure Yang-Mills theories.

There are other notions of duality in QCD. The 't Hooft loop is the disorder operator. Unfortunately, there is probably no useful local dual-field-theory formulation for which it is the order parameter.

46. **urs**
November 19, 2006

> You keep ignoring the fact that Peter Orland is asking about pure YM theory, not N=4 SYM.

In as far as I am ignoring anything, it is not on purpose. I'd be glad to be enlightened.

Maybe I found Peter Orland's statement

> I concluded that there is no simple operator equivalence between a non-Abelian gauge theory and its dual.
>
> #

seemed to refer to arbitrary gauge theories.

> I gather that he's trying to understand whether geometric Langlands gives any insight into that problem, and as far as I can tell, the answer is just no.

Hm, maybe here is the source of the misunderstanding. Kapustin-Witten show that geometric Langlands does give insight into the type of duality present in N=4 SYM. So in far as this is different to other types of duality, geometric Langlands apparently does not apply to these.

> Supersymmetric or other theories with adoint matter have some sort of charge-monopole duality – but such theories are effectively Abelian.

Could you expand on what you mean by "effectively abelian" here? Thanks!

47. **Peter Orland**
November 19, 2006

Urs,

By "effectively Abelian", I mean that that the magnetic-monopole charge is well-defined and quantized. In QCD or pure Yang-Mills, there is no precise definition of magnetic-monopole charge.

In the Georgi-Glashow model (an the related deformation of N=2 supersymmetric gauge theory) a Higgs field breaks the gauge group down to the Cartan subgroup. Thus there are Abelian monopoles, with quantized charge, etc. These theories have a confined phase for sufficiently small monopole mass, which goes back to Polyakov's observations in the 70's. Duality for such theories is not so different from those of Abelian Wilson lattice gauge theories. They are, however, quite different from QCD.

Now there is an old result made by many people (Fradkin, Shenker, Rabinovici and others) that there is little difference between a Higgs field in a gauge theory and a scalar field in that gauge theory without a Higgs potential. The basic point is that the operator creating a massive vector Boson in the Higgs theory looks just like the operator creating a "meson" built from scalars in the confined phase. From this point of view, any theory with scalar matter is not so different from a Higgs theory. In particular, it is possible to define magnetic charge, no matter what the scalar potential happens to be. So in such theories charge-monopole duality is a sensible concept.

The reason why the possibility of duality for Yang-Mills theories is interesting is because it could yield insight into the confinement phase. Some sort of magnetic condensation occurs, producing confinement and a mass gap, as simulations show, but we want to know why.

48. **anonymous**
November 19, 2006

Off-topic mathematical physics fun: Andre LeClair is claiming there's a physical system, which, on physical grounds, suggests the Riemann hypothesis is true. Are there any experts around to comment on whether it's plausible?

Esquire On The State of Particle Theory

November 15, 2006
Categories: Uncategorized

You know things are getting strange when Esquire magazine starts running an article on the current state of particle theory. As you might expect, their take on this is rather odd. It centers around Nima Arkani-Hamed and begins with:

For a hundred years, physicists have been scraping away at the strange and complicated phenomena obscuring the true face of our universe. Finally, a few brillant young thinkers may be on the verge of getting the first real glimpse.

which is pretty much complete nonsense, totally ignoring the huge success of the standard model in favor of the latest extremely speculative models promoted by some people.

The Esquire writer talked to several theorists, including Lee Smolin and Laurent Freidel at Perimeter, where he describes young postdocs as hanging out at a local hipster bar, with one of their number describing string theorists as "the post 9/11 theocons", afraid of anything new: "The string theorists just masturbate to their same ideas." The postdocs do note that at Perimeter string theorists and non-string theorists get along fine. Freidel, a faculty member at Perimeter, is described as not having slept for two weeks straight when he was working on a solution of QCD, with his wife asking a colleague "Can you do something? He's going insane."

After describing Perimeter, the article then moves on to Witten and Maldacena at the Institute in Princeton. Witten's comments about the current state of things go as follows:

Well, you can't have your best year every year… I've lived through two periods, the mid-eighties and mid-nineties, where for about six or seven years, roughly, there were a lot of really interesting results that were also relatively easy. And I've also lived through several periods by now where you have to work a little harder to get something interesting.

Witten goes on to say that he is putting his hopes in the LHC and the idea that it is likely to tell us something about the nature of electroweak symmetry breaking.

There's some attempt to describe Maldacena and his AdS/CFT conjecture, which is characterized as "a mind fuck, but not crazy." The article then moves back to Arkani-Hamed at Harvard, with "For crazy, you have to go about 250 miles north." His view of the current controversy over string theory is said to be "forget the antistring polemicists! They're just reactionaries! This could be the greatest discovery of our time!", and he heavily promotes the anthropic landscape and the idea that the LHC will provide evidence for it. He says:

The mantra of string theory ten years ago was that the theory was smarter than you… Well, exactly that–just follow the theory where it leads you and it leads to this precipice. And now we have to decide what to do. So now a number of people are deciding to jump… And I think that those of us that decided to take the plunge are staring at the true nature of the beast for the first time.

Personally, I think if a scientific theory with no experimental evidence for it takes you to the edge of a precipice and tells you to jump, the sensible thing to do is to say "No Thanks!", back away, and go find another theory. But that's just me.

The latest New Scientist also has something about the string theory controversy, an article by Michio Kaku entitled Will we ever have a theory of everything?, part of a series of articles on "The Big Questions". Kaku describes the controversy dramatically:

It's all-out war. The hostilities have begun. With guns blazing, daily salvos are being fired by both sides. Welcome to the conflict raging within the rarefied world of theoretical physics, where a civil war has erupted over string theory and a theory of everything.

While I disagree with the far too rosy picture he paints of the prospects for string theory, Kaku takes a very sensible attitude towards the whole thing:

So who's right? Actually, both have a legitimate point of view. But far from signalling a collapse in physics, this debate is actually rather healthy. It's a sign of the vitality of theoretical physics that people are so passionate about the outcome. Science flourishes with controversy.

and ends, reasonably enough with:

One day, some bright, enterprising physicist, perhaps inspired by this article, will complete the theory, open the doorway, and use the power of pure thought to determine if string theory is a theory of everything, anything, or nothing.

New Scientist also asked various well-known physicists what they thought might happen in physics in the next 50 years. Weinberg says that he hopes for a final theory of particle physics, with discovery of superpartners a first step. Tegmark also hopes for a final theory, one which will have us living in just one of many "parallel universes". 't Hooft hopes for a deterministic model that would unify quantum mechanics and gravity, Randall for a new understanding of space and time, Carroll for a theory of the big bang, Wilczek for a new golden age of particle physics catalyzed by the LHC, Kolb for the discovery of gravitational waves and Vilenkin for the discovery of a cosmic string. The most popular question on many these people's minds is that of whether or not we live in a multiverse (Tegmark, Rees, Krauss mention this). Among mathematicians, Marcus du Sautoy suggests we'll have a proof of the Riemann hypothesis, Timothy Gowers favors P=NP.

Among all these and other scientists, I think the most plausible prediction comes from my graduate school roommate, Nathan Myhrvold, who thinks a revolution will come from materials science, with the development of new "metamaterials", substances with new, intricate synthetic structures.

Update: Somehow I hadn't noticed that New Scientist also had a prediction from Witten:

String theory will continue to be an extremely fertile source of new ideas. It will still be viewed as the interesting candidate for quantum gravity, and may even be more or less understood by 2056.

Interesting that he thinks that 50 years from now the situation will be much the same, with string theory still just a "candidate" for quantum gravity, and he doesn't predict that we will have string-based unification of particle physics and gravity.

Comments

1. **Aaron Bergman**
   November 15, 2006

   "One of PI's initial faculty hires, Smolin, fifty-one, began his career in string theory before becoming fed up with the lack of progress and turning instead to loop quantum gravity, an alternate possible unified theory."

2. **Troublemaker**

November 16, 2006

and use the power of pure thought to determine if string theory is a theory of everything, anything, or nothing.

Mmmm, Aristotle-icious! I prefer the power of comparing empirical results to theoretical predictions, but sure, pure thought is fun, too.

3. **Chris Oakley**
   November 16, 2006

   This is my favourite bit of the *Esquire* article:

   > A different, even more extreme explanation for the symmetry breakdown is known as supersymmetry, which theorizes a set of counterparts to our known subatomic particles that are embedded in the architecture of space-time. Besides explaining electroweak interactions, the discovery of supersymmetric particles, with cool names such as squarks, sleptons, and selectrons, would be a huge boon to string theorists, whose model of the universe depends upon them.

   … so now I know something I was previously unaware of, i.e. that supersymmetry explains something.

4. **a**
   November 16, 2006

   Actually, the precipice or feature or bug has little to do with smart string theory: all models with extra dimensions have multiple vacua and/or moduli.

   By the way, the most interesting observation about "is the weak scale anthropic?" was made in hep-ph/9707380 (1997: when it was not a fashionable string theory topic!), but this really brillant work is mostly ignored by popular journals.

5. **Mary**
   November 16, 2006

   Another pop-culture mention of the string theory controversy: this Zippy the Pinhead comic strip.

   (Zippy is a weird, surrealist sort of strip, and doesn't usually make even this much sense…)

6. **Pot Smoking Hippie**
   November 16, 2006

   "Personally, I think if a scientific theory with no experimental evidence for it takes you to the edge of a precipice and tells you to jump, the sensible thing to do is to say "No Thanks!", back away, and go find another theory. But that's just me."

   So, has your theory actually taken you anywhere besides another precipice? Does it offer any more experimental evidence than any other theory? Perhaps the string theorists are rappelling instead of free falling. Maybe the loop people could try rappelling with chains made of their loops? It's just a wild thought.

7. **Bert Schroer**
   November 16, 2006

   Pot Smoking Hippie,
   How many joints are necessary to write a blog like yours?

8. **Who**
   November 16, 2006

   Hippie, I watch post-string QG research and have seen no indication that those you call "loop people" have come to any metaphorical precipice. Progress appears steady along several lines of investigation. Preliminary contacts with matter and with classical gravity have been made (see recent papers by Rovelli et al and Freidel et al). Lately some problems with the ground state appear to have been gotten around (see Randono's papers of this past week for some recent results).

   So you seem to be generalizing needlessly—-just because somebody like Nima might see string research at a precipice which he believes the adventurous are jumping off and meeting "the beast", does not mean that non-string QG is in a similar situation. I think, instead, it is beginning to unearth more fundamental degrees of freedom from which space time and matter emerge at large scale.

9. **Alejandro Rivero**
   November 16, 2006

   this one is from 1994:
   space to let

10. **Garbage**
    November 16, 2006

    "Weinberg says that he hopes for a final theory of particle physics, with discovery of superpartners a first step. Tegmark also hopes for a final theory, one which will have us living in just one of many parallel universes. t Hooft hopes for a deterministic model that would unify quantum
    mechanics and gravity, Randall for a new understanding of space and time, Carroll for a theory of the big bang, Wilczek for a new golden age of particle physics catalyzed by the LHC, Kolb for the discovery of gravitational waves and Vilenkin for the discovery of a cosmic string."

    There is a high chance any of this will happen. I mean:

    1) No SUSY

    2) One Universe

    3) QM is not ultimately deterministic

    4) I assume Lisa awaits XD, so here I'd so no more than 4 (and please no "four more"! 😉)

    5) I'm guessing a better theory of big bang is to understand the initial singularity, keep waiting…

6) LHC will single out just the Higgs.

7) LISA will never launch, but perhaps/hopefully LIGO II will see something.

8) Cosmic strings would be fun watching, in purple and red ;). Even if we find such objects, how do we know they come from M-theory? magic?

And then what?

There is a high chance we'll just see the Higgs and then new physics will have to come in indirect ways, that is still very interesting. I would support ILC anyhow, there is a lot of stuff to do/check, but not a completly mind f*ck I'm afraid…:)

Like Witten says, just a "little harder" 🙂

In the mean time, keep on gnitabrutsam…

11. **Bee**
November 16, 2006

well, I can report the local hipster bar isn't so hip anymore. besides this, I like the sentence:

Taking up residence here is a bit like joining the priesthood. You're segregated from the rest of the world, and your job is to get into God's head and figure out how the big damn machine works.

So, that's then a priesthood that hangs out in the local hipster bar.

Sneakers and jeans rule

That makes a priesthood in sneakers and jeans that hangs out in the local hipster bar. I should add, I learned that Canadians call their sneakers 'runners'. But better:

It's like exploring a forest[…] as if it were a fort, planning a means of attack […] as if the search for a unified theory were the world's biggest game of sudoku.

And let's combine that with what The New Yorker wrote:

a sort of Menshevik cell of physicists in Canada

Okay, so we have a Menshevik cell of priests in runners and jeans that – when it doesn't hang out in the local hipster bar – plans attacks on forests and plays sodoku.

Also completely priceless: our universe is *[…] a giant DVD floating among an infinite number of other DVDs* and gravity is *like a bottle of whiskey that has been passed around the galaxy a few too many times.*

Now I'll go back into God's head. Deus vobiscum.

'There's some attempt to describe Maldacena and his AdS/CFT conjecture, which is characterized as "a mind f***, but not crazy."'

Please asterisk-out the major parts of poor language, or your site will probably be put on a parental hot list by search engines (as unsuitable for teenage kids who need to know this physics controversy).

13. **Tommaso Dorigo**
November 16, 2006

Well said, garbage.

I already placed a bet which covers your points 1, 4, and 6, 1000 US$ says they hold.

I am willing to bet 25,000 US$ on point 2, one and only one universe. I will make the check payable in another universe, of choice of the winner, however. No, seriously, I cannot bet more than a year of salary, but I would be happy to lose that one bet too. Any takers ?

Cheers,
T.

14. **Gil Kalai**
November 16, 2006

When brilliant and hilarious Scott Aaronson came to town last month he was much more enthusiastic to tell us about the recent physics controversies, the new books about string theory, and the related blog excitements, than discussing quantum computer's skepticism. Scott surely got us interested!

What might happend for physics in the next 50 years? Good question! And what the future be for string theory? Below are six alternatives:

This (light) piece is inspired by the (deep and serious) classic paper by Russell Impaglliazzo on the five possible universes regarding computation and cryptography. (Russel's paper is also one of Scott's favorite papers.)

Apart from the illustrative details (which are meant to be amusing) I regard each of the six alternatives below as realistic. The second alternative can be regarded as the current default cautiously-optimistic main-stream approach of the scientific community which, perhaps, make it the most plausible.

Six Alternatives For String Theory's Future

1. UTOPIA

String theory continues to progress and converges in a few decades to become a solid part of our scientific understanding with plenty of empirical direct and indirect confirmations and many applications to all other areas of physics. Some of the landmarks after the "Maldacena conjectures" (1997) were the "Johnson Postulate" (2009), the "Motl Ansatz" (2014), the "Diestel Paradigm" (2017) followed by the powerful "E-F-W Calculus" (2022). String theory becomes the "language of physics" perhaps

even “the language of nature”. Every graduate student
in physics is able to make string theory computations, and this is what most physicists do. String theory represents a sound mathematical theory, in fact, mathematics is now considered just as “the special case of string theory for Plank constant 0”. A few exciting problems remain.

Peter Woit’s book “TRUE!” tops the NYT best sellers lists for 24 weeks.(In his book Woit advises caution concerning applications of string theory to the area of finance.)

2. TRIUMPH and ISOLATION

String theory continues to progress and converges in a few decades to a solid part of our scientific understanding with convincing empirical direct and indirect confirmations but with little applications and relevance to other areas of physics. Computations with string theory are extremely hard. (Computations based on the E-F-W calculus are computationally infeasible even on the newly built “quantum computers”.) Mathematical foundations of string theory as of earlier high-energy physics remain shaky.

Peter Woit’s book “NOT WRONG!” hits the market,

3. PERPETUUM MOBILE

String theory continues to progress but it does not converge. String theory thus remains a “useful divergent theory” whatever this means. More and more exciting connections to mathematics are found. More and more conceptual revolutions in the theory itself are taking place. (The latest is the “13th superstring revolution”.) String theory leads to a whole new way to look at physics and, even more, it is a scientific experience not seen before. The best most brilliant minds are attracted to this theory as before.

The 17th edition of Woit’s “Not even wrong” appears.

4. DECAY

String theory continues to progress but the progress is slower, the attractiveness of the theory seems smaller. String theory indeed looks more promising than ever but while the success looks around the corner, string theory is not sufficiently promising to attract the best people. Interest in physics is shifted to other directions.

5. GLORIOUS FAILURE

A brilliant string theorist from Vanderbilt University discovers a potential feature of supersymmetric string theory which contradicts basic physics insights. Massive computations in the “String Vacuum Project ” confirm her discovery. After several years of extensive research (with beautiful new connections to mathematics found) it is now commonly accepted that string theory was falsified and is no longer an option for a theory of everything. No alternative is seen at sight. 20 prominent string theorists declare string theory as part of “mathematical physics”, rather than a viable physics theory, and within 72 hours, 18 of them get lucrative offers from top mathematics departments.

Woit’s biography of Ed Witten “WRONG!!”, is the basis for a successful Hollywood movie featuring Will Smith as Witten in the main role.

6. ALTERNATIVA

The alternative theory was discovered by cheer coincidence and like string theory itself is based on a technical rather than conceptual idea. The starting step was by an elderly mathematician from Bristol University seeking for mathematical explanation for QEC suggests to replace the term(1/137)^k with (1/137)^k (1-z)^(k(k-1)) where z is a constant smaller than and very close to one. Strangely, this has led to some consistent theory and this technical variation made quantum gravity easier. The next step came when a researcher from the University of Tehran (inspired, in parts, by some rather general suggestions of P. Woit, and the mathematical notion of “noise sensitivity”,) relates dark matter and dark energy with representations of unbounded weights and dimensions. Such representations are prominent in the new theory. (This new type of mass/energy is called “the mess”.) The theory is then developed and brought to completion by a New-Jersey based physicists N. Seiberg and E. Witten.

An extremely surprising feature of the new alternative theory is that the universe is 3+1 dimensional.

The translation of the new addition of Woit’s “Not Even Wrong” to Czech has just appeared.

(My subjective probabilities for the future of string theory, Utopia – 10%, Triumph and isolation – 40%, perpetuum mobile – 10% decay – 20% failure – 15% alternative found – 15%. Of course, some combination or an entirely different scenarios that I missed are also possible.)

15. **Jonathan Vos Post**
November 16, 2006

Esquire has commented on Physics and Mathematics before. But in a fairly superficial way.

Examples:

[The Physics of Immortality: Modern Cosmology, God and the Resurrection of the Dead (Paperback)
by Frank J. Tipler]
“A doozy of a book… it’s 2001: A Space Odyssey meets The Divine Comedy.” –Esquire.

From Wikipedia, the free encyclopedia
Jump to: navigation, search

Cartoon physics is a joking reference to the fact that animation allows regular laws of physics to be ignored in humorous ways or dramatic effects. For example, when a cartoon character runs off a cliff, gravity has no effect until the character notices and mugs an appropriate reaction.[1] Students of animation may hear of the “commandment” “Animation follows the laws of physics – unless it is funnier otherwise,” which is attributed to Art Babbitt.

The phrase also reflects the fact that many of the most famous American animated films, particularly those from Warner Brothers and MGM studios, unconsciously developed a relatively consistent set of such “laws” that have become regularly applied in comic animation.

The idea that cartoons behave differently, but not randomly, than the real world is virtually as old as animation. Walt Disney, for example, spoke of the plausible impossible (see The Plausible Impossible, 1956), deliberately mispronouncing the second word so it rhymed with the first.

Specific reference to cartoon physics extends back at least to June of 1980, when an article "O'Donnell's Laws of Cartoon Motion"[2] appeared in Esquire magazine.
[2] O'Donnell's Laws of Cartoon Motion", Esquire, 6/80, reprinted in IEEE Institute, 10/94; V.18 #7 p.12.

Philip Rosedale: Building a world entire
By Tom Colligan
December 2006, Volume 146, Issue 6

"What's that great line at the beginning of Metropolis? 'Every epoch dreams its successor'?" says Philip Rosedale, sitting at his cluttered desk in downtown San Francis co, at the center of a large white room filled with white desks identical to his own. "I think people have dreamed correctly, that the dream of something like Second Life has always been true. I've just always felt as if this was coming, and I just wanted to see it. I was just bored without it…."

A Physics Lesson: The Meniscus : Esquire : Jun 01, 2006. A Physics Lesson: The Meniscus. By Barry Sonnenfeld. topic: Science …

Angry Physics: Can You Guess Which Sexy Woman Has a crush on Einstein?
Presenting the "other" side of academic physics, where people backstab and … but I came across this teaser in Esquire about the sexiest woman of 2006. …

Nice to be noticed by Esquire. But does that mean that we should dress better and hang out at the right watering holes to keep getting noticed? Kind of like citing Einstein as a fasion expert on hairstyles, who also plays the violin, and does something f***ing crazy with unified field theory in Princeton, and hangs out with noted food minimalist Kurt Godel.

16. **Who**
November 16, 2006

Gil, I believe the scenario 4 "Decay" to which you attach subjective probability 10 percent has already occurred. The rate of publication has declined since 2002 and quality measured by objective standards has plummeted. Recent published papers are no longer innovative enough to garner much citation. Judging by new research, the signs are that independent and ingenious young people are getting out of stringy research, or not entering in the first place.

What you say seems to apply to the present: "string theory is not sufficiently promising to attract the best people. Interest in physics is shifted to other directions."

Perhaps Scott can give you some hints as to where those other directions might be.

November 16, 2006

Nima Arkani-Hamed…"Well, exactly that–just follow the theory where it leads you and it leads to this precipice. And now we have to decide what to do. So now a number of people are deciding to jump… And I think that those of us that decided to take the plunge are staring at the true nature of the beast for the first time. "

Wow, his glee and excitement are palpable; it's like hearing the excited thoughts of a lemming as it takes the plunge into icy artic waters

18. **Aaron Bergman**
November 16, 2006

Lemmings don't actually do that, for whatever it's worth.

19. **amused**
November 17, 2006

"Last year, when Freidel discovered a possible rigorous mathematical solution for the strong force—which acts as the glue between protons, neutrons, and nuclei, and which to that point had been studied only by approximation—he didn't sleep for two weeks straight."

Can we expect a rigorous analytic proof of the mass gap in the coming future then?
The low-key, understated way that LQG'ers describe their work makes such a refreshing contrast with the giddy hype of string theorists.

20. **anon**
November 17, 2006

Bergman…"Lemmings don't actually do that, for whatever it's worth."

Thanks for the reference. Disney's pogrom of Mickey Mouse's family. Looks like they do jump, with the kind help of humans.

21. **a**
November 17, 2006

Tommaso, do you accept "just the SM at LHC" as evidence for an anthropic multiverse? Notice that it is not a joke, it could be the hot issue in 2014. I cannot accept your bet because this outcome might have a negative impact on your 2014 salary.

22. **Thomas Larsson**
November 17, 2006

The alternative theory was discovered by cheer coincidence and like string theory itself is based on a technical rather than conceptual idea.

Gil, there seems to be one possibility that you don't consider. That an alternative theory based on a conceptual rather than technical idea is discovered, not by coincidence but by following the idea's internal logic. The theory predicts four spacetime dimensions and m_p/m_e = 1836.

23. **Bee**
November 17, 2006

Hi Gil,

A 7th alternative:

Sorting out

String theorists will thoroughly focus their efforts towards a successful description of nature, dropping all their nice but irrelevant distractions that are maybe interesting maths but not physics. They will very possible go back to the very basics, and try looking for sideways they might have missed. Very likely, they will discover similarities to other approaches towards quantum gravity. Hopefully, they will be open to them, and everything will converge towards the same direction.

Best,

B. (always the optimist)

———————

The girl went through the back door into the garden, and called out, "You tame pigeons, you turtledoves, and all you birds beneath the sky, come and help me to gather:

The good ones go into the pot,
The bad ones go into your crop."

Two white pigeons came in through the kitchen window, and then the turtledoves, and finally all the birds beneath the sky came whirring and swarming in, and lit around the ashes. The pigeons nodded their heads and began to pick, pick, pick, pick. And the others also began to pick, pick, pick, pick. They gathered all the good grains into the bowl. Hardly one hour had passed before they were finished, and they all flew out again.

24. **Who**
November 17, 2006

Good point Thomas Larsson. It's a possible scenario.

> Gil, there seems to be one possibility that you don't consider. That an alternative theory based on a conceptual rather than technical idea is discovered, not by coincidence but by following the idea's internal logic. The theory predicts four spacetime dimensions and m_p/m_e = 1836.

A sizable fraction of the crowd here seems momentarily reduced to sarcasm or to heckling Bert. The basic cause, I think, is simple: non-string QG, it currently happens, is where the interesting results are being obtained.

Let's have a challenge: can anyone think of a 2006 string paper as consequential as the pair Andy Randono just posted generalizing the Kodama state?

25. **woit**
November 17, 2006

Bert and others,

Stop posting comments that contain personal attacks on people and little else. If one person does this, it's bad enough, but then everyone else wants to join in the fun and the comment section degenerates into hostile noise. I just deleted a half dozen such comments, please stop posting them.

26. **Who**

27. **plank**
November 17, 2006

I can't believe no one found this yet!
—————
(My subjective probabilities for the future of string theory, Utopia – 10%, Triumph and isolation – 40%, perpetuum mobile – 10% decay – 20% failure – 15% alternative found – 15%. Of course, some combination or an entirely different scenarios that I missed are also possible.)
—————-
Well, (10 + 40 + 10 + 20 + 15 + 15)% = 110% > 100%

This can't be a good sign.
People seam to be ignoring basic fundamental consitency checks here. Where else?

28. **plank**
November 17, 2006

consitency checks => consistency checks

People seam => People seem

(I too make mistakes, although these are only "formal", sorry)
🙂

29. **Anon**
November 17, 2006

"Let's have a challenge: can anyone think of a 2006 string paper as consequential as the pair Andy Randono just posted generalizing the Kodama state?"

Kapustin and Witten
Frenkel, Losev and Nekrasov
Hofman and Maldacena
Intriligator, Seiberg and Shih
Arkani-Hamed, Motl, Nicolis and Vafa
Herzog, Karch , P. Kovtun, Kozcaz and Yaffe

to pick 6 random papers.

Peter might object that some of these papers aren't sufficiently "stringy" to count. But all of them use, in an essential way, ideas and techniques developed in a stringy context. And, for the purposes of "bean counting," all of them have author lists who Peter would consider to be "string theorists."

30. **A String Theorist**
November 17, 2006

"Let's have a challenge: can anyone think of a 2006 string paper as consequential as the pair Andy Randono just posted generalizing the Kodama state?"

Ummm, how about hep-th/0511286, in which Witten's open string field theory was finally solved analytically, or hep-th/0610251, in which planar N=4 Yang-Mills was finally solved analytically…

[OK, I generalized "2006" to "within the past year".]

31. **woit**
November 17, 2006

who/A String Theorist,

Please take this kind of partisan LQG/string theory argumentation elsewhere.

32. **MoveOn**
November 18, 2006

Plank => Planck

33. **Chris Oakley**
November 18, 2006

MoveOn,

You don't know that that is a mis-spelling. In England we say that someone is "as thick as two short planks" when they are not bright.

34. **plank**
November 18, 2006

"(I too make mistakes, although these are only "formal", sorry)"

Plank => Planck

— — –

That is deliberate. I have explained this but Woit censored it. Maybe he will censor this post too, I am yet to understand the criteria.

Nice to see people are concentrating on really important things (spelling) vs real mistakes where probabilities are greater than 1 and no need for normalization is hinted.

I for one would like the author to update the "probabilities" with the "correct" values, preferably summing less than 1 to accommodate some kind of other option such as the one (quite relevant I might add) brought up by Larsson.

Again, on my censored post I wrote that if these "probabilities" have been discussed without people making the most basic consistency checks, just imagine what probably happens on more esoteric math/QFT that is sometimes discussed here.

But then again, maybe I am "as thick as two short planks"
🙂

P.S: I would like to know where I can find the criteria used for deleting posts or is it just discretionary.

— — — — —

Criteria is simple, if your post help to sold more copies of Not Even Wrong then is archived, otherwise it is deleted.

36. **woit**
November 18, 2006

Plank and I-don't-know-who,

I spent much of yesterday on planes, and at various airports was kept busy using my laptop to log in to my blog software and delete large numbers of comments people were submitting that were mainly devoted to insulting someone or other. I don't remember Plank's, but presumably it was part of one of several such threads that I deleted wholesale.

Whether I delete comments depends on lots of factors, including what mood I'm in. But if you submit a comment anonymously that's not about the original posting and that is insulting to anyone, there's a good chance it will be deleted.

I of course strongly encourage people to post comments that will sell lots of copies of Not Even Wrong and make me filthy rich, but if my policy was to delete comments that don't do this, the comment sections here would be extremely short….

37. **Tommaso Dorigo**
November 20, 2006

Dear a (nonymous? gnostic? pologetic? posteriori? bominable? to name just a few),

the future can't be so bad as to both provide no further clues on fundamental physics at the LHC experiments AND set the stage for yet another abominable string of useless years of pondering on the sex of angels…

Cheers,
T.

38. **plank**
November 20, 2006

"the future can't be so bad as to both provide no further clues on fundamental physics at the LHC experiments "

——-

Care for a justification as to why the future can't be so bad?

Seems to me you are trying to end a faith based initiative with a belief. That's ironic to say the least.

But I'd love to hear WHY the future can't be so bad. I sure hope it won't, but hope in something doesn't guarantee it happening.

39. **Arun**

Question – isn't the strong CP issue and whatever the cure is, say axions – also a unconfirmed part of the Standard Model?

40. **Peter Orland**
November 20, 2006

Arun Says:

November 20th, 2006 at 11:24 am
Question – isn't the strong CP issue and whatever the cure is, say axions – also a unconfirmed part of the Standard Model?

Yes it is. The axion is the only simple-minded solution to the strong
CP problem.

There was an intriguing alternative suggestion that the CP violating term (which is F*F) is a non-renormalizable operator if QCD is treated non-perturbatively (perturbatively, it is marginal and perfectly okay). If that were true, such a term would disappear at
low energies. Since we can't do a non-perturbative renormalization of the theory with this term, it isn't clear whether this idea still has merit.

41. **Tommaso Dorigo**
November 20, 2006

I would also like to make a general remark here. If a theory predicts the M_p/M_e ratio it does not mean it is The Theory, no more than if I come up with an a posteriori explanation of a set of funny events in my data the explanation has to be correct.

Don't let's forget. PREdictions have to PREcede observation, else a theory is just a good try. Do we need more tries ?

So please come up with values for the neutrino mixing angles, Bs->mumu decays, and other pieces of future reachable measurements, and not non-existing stuff that we will not see. But fast, they are about to get measured.

T.

42. **Jonathan Vos Post**
November 20, 2006

I partly agree and partly disagree with Tomasso. There is still considerable scientific value in a theory which RETRODICTS.

Retrodiction is making conclusions about previously gathered data, once theoretical advances in the specific field of research have happened.

An example of this was the explanation of the already-observed perihelion shift of the orbit of the planet Mercury. Newton's theories of the laws of motion, which in a deeper sense retrodicted Kepler, were unable to explain the phenomenon. Einstein's theory of general relativity was successful in the retrodiction.

Give me a retrodiction of M_p/M_e ratio, neutrino mixing angles, Higgs mass, or the fine structure constant, and I'll certainly pay attention. In some sciences, we have huge data sets, computational problems, and retrodiction is the main stream. Climate analysis, continental drift, there are many such examples.

43. **Tommaso Dorigo**
November 21, 2006

Ok Jonathan,

I have to agree with what you wrote above. My point was roughly that retrodiction by itself is not enough. You also need predictions that can be falsified.

Cheers,
T.

44. **J.F. Moore**
November 21, 2006

I've detected quite a tone of moderation in Kaku's recent interviews. You may recall this summer that he came out fervently (in the NYT?) bashing the Steorn free energy loonies. Easy target, but Kaku in the past has talked so much about wooly-headed nonsense that I was surprised to see him amongst those throwing stones. The cynical part of me thinks he's just mining new markets of less credulous people to sell his backlog of books; but maybe, just maybe he is cluing in to the winds of history and appropriately tacking?

As for Esquire, well, one might as well ask a theorist how to tie a Windsor knot or for the name of their tailor.

45. **Hitchhiker to the Galaxy**
November 23, 2006

I'm reading NEW (Not Even Wrong), a brave book. Has Prof Sokal ever been involved in string theory? He should write "Fashionable Nonsense II." If strong theoriests have not been able to decide on what M of M-theory should stand for, what about Mirage-theory?

46. **Who**
November 23, 2006

Malarky

http://www.worldwidewords.org/qa/qa-mal1.htm

47. **Jonathan Vos Post**
November 24, 2006

With that clarification, I agree with Tomasso.

Given earlier estimates by various writers here on the possible outcome of the String Theory debate, might there not be revisions in the light of Tomasso? That is, (1) by what trajectories with what likelihood will String Theory or M-Theory give apparently good retrodiction; and then ; (2) by what trajectories with what likelihood will String Theory or M-Theory give a prediction as such; and finally (3) by what trajectories with what likelihood will String Theory or M-Theory give a prediction which is tested and found at least approximnately right?

An example, admittedly not Physics at all, gives a good example of how an author who insists that she's doing science, produces controversy with a brilliant book of retrodiction. Only weakly can there be falsifiable prediction following: if traces of the lost colonists are found inland, if letters or other documents germane to the case are uncovered, for instance.

http://www.jhu.edu/%7Ejhumag/1101web/roanoke.html

Rethinking Roanoke

Seeking to solve the mystery of the "Lost Colony" at Roanoke, anthropologist Lee Miller, MA '87 (pictured at left) looks beyond the conventional culprits to spin a tale of sabotage and intrigue.

By Dale Keiger

— Jonathan

Postscript: what would really put this on the map, and boost Woit to bestsellerdom, would be a murder mystery involving String- and anti-string theorists. If some of the people blogging here met face-to-face and one thing led to another. Motive + means + opportunity = murder. Ladies and gentleman, one of us here in this room is the murderer. [the light go out] [gunfire]

Langlands on Langlands

November 21, 2006
Categories: Langlands

In a forthcoming issue of the AMS Bulletin, there will be a long review by Robert Langlands of the book p-adic Automorphic Forms on Shimura Varieties by Haruzo Hida. The book itself is on a very technical subject, but the review includes long sections by Langlands that are much more generally about the current state of the so-called "Langlands Program". While this inspired the "Geometric Langlands Program" that I've written about here recently, it's a quite different subject, one that is very much central to research in number theory. Basically it deals with number fields (extensions of the field of rational numbers), and the function fields of geometric Langlands involve very different issues.

At the same time as making available his review, Langlands also made available commented copies of his correspondence with various experts in the subject about a draft of the review that he had sent them. Much of the review itself is likely to only be accessible to experts, and this is even more true of the correspondence. Casselman comments:

I also have the impression that you have edited this review for the pleasure of experts, and that therefore the cutting-room floor is filled with the sort of stuff The Naive Reader might appreciate.

The response to this from Langlands is:

I had in mind explaining more, but the editing was not a matter of choice but of necessity. I did not understand enough to say more.

I suspect few people will be able to follow the discussion here, but it gives a good idea of what is going on in an active but very difficult area of mathematics.

Both of these documents are from a fantastic resource, a web-site set up by Bill Casselman which contains pretty much the complete works of Langlands on-line. If you want to know more about the Langlands program and where it comes from, there's lots of material worth reading on the site. One of the more readable sources for a beginner is the 1989 Gibbs symposium lecture on Representation theory- its rise and its role in number theory.

For a lower form of entertainment, there's another book review, of Leonard Mlodinow's *Euclid's Window*, which appeared in the AMS Notices. The review is pretty much completely over the top, beginning with the sentence:

This is a shallow book on deep matters, about which the author knows next to nothing.

Update: I should also have mentioned that last month there was a small conference at the IAS on The L-group at 40, in honor Langlands' 70th birthday.

Comments

1. **Peter Orland**
   November 21, 2006

   Since I haven't read Lenny Mlodinow's book, I don't know
   if the review is a fair one. Apropos of nothing, I took classes
   with Lenny at Berkeley before he turned into a writer for "Star
   Trek" and author of pop-science books. The review reminds
   me of the proverbial referee report, "This paper fills a
   much needed gap in the literature." (attributed, no doubt
   falsely, to Paul Halmos).

   But at any rate, I was impressed by Langland's breadth of
   knowledge of the classics of mathematics and of the history of
   science in general.

2. **Scott Aaronson**
   November 21, 2006

   I haven't read Mlodinow's book either, but I feel certain that if I disliked it, it wouldn't be for the reasons given by Langlands. Lewd and tawdry jokes? Cartoon caricatures of complicated historical narratives? A relentlessly late-20th-century perspective? Sounds pretty good to me…

3. **luny**
   November 21, 2006

   On a somewhat unrelated note, check out the closing talk of the Quark Matter conference,
   http://www.sinap.ac.cn/qm2006/ppt/Nov.20/Plenary-15/Larry-McLerran-QM061.ppt
   slide 19 onwards.
   The slides do not convey the extremely caustic sarcasm the speaker presented them.
   Considering the extremely political nature of this conference, this is interesting.

4. **fh**
   November 22, 2006

   "Sounds pretty good to me…"

   You are joking, right?

5. **Gumbi**
   November 22, 2006

   Langlands ironically characterizes his own review as "the pedantry of… one priggish mathematician" and I have to say that is pretty accurate. I have seldom seen a more blatant or arrogant display of a reviewer showing off his superior knowledge and mastery of every aspect of the subject covered by a book.

   I suggest that Langlands put a tiny part of his amazing mind to the study of what economists call "comparative advantage". He will learn that even if he is better than everyone at everything, there is still a role for the lesser minds of the world to make their own efforts, poor though they might be compared to what the great Langlands would have done if he had condescended to devote time to such matters.

6. **Kea**
November 22, 2006

When I met him, I thought Langlands was very nice.

7. **Scott Aaronson**
November 23, 2006

You are joking, right?

Yes, but I also had a serious point. When we talk about the history of science (or anything else), I *don't* agree that we're forbidden from generalizing, making moral judgments, telling stories with heroes and villains, cracking jokes, or asking questions that wouldn't have seemed pertinent at the time but do seem so now.

So for example, anyone who's not a total philistine "knows" that Bertrand Russell's *History of Western Philosophy* and E. T. Bell's *Men of Mathematics* are worthless as intellectual history: "biased," "simplistic," "reductive," "romanticized," and so on. In other words, the trouble with these books is that they're not dry as dust.

Wherever Russell and Bell get their facts wrong, one can and should take them to task for it. But beyond that, they're every bit as entitled to their romantic visions of history as their critics are to their own.

8. **Mark Hillery**
November 23, 2006

When Robert Langlands's review of Leonard Mlodinow's book came out, the two opinions I heard most frequently expressed, which coincided with my own, were that a review that is this over the top says more about the reviewer than the book, and that the AMS Notices should never have published it. Since I have known Leonard for 30 years and enjoyed his books, I wrote to the then editor, Harold Boas (who, weirdly enough, went to high school with Leonard Mlodinow – six degrees of separation anyone?), criticizing the decision to publish the review. Much to my surprise, I received a rather lengthy response. The main thing I remember about it is that I was accused of making an ad hominem attack on Robert Langlands. Why? I had suggested that in order to see what people who want to write popular accounts of mathematics and physics are up against, it might do Prof. Langlands some good to take a little time off from the Institute for Advanced Study and teach a precalculus course at a large state university. It's a tough audience out there and capturing and keeping their interest is not easy.

Writing about science, and especially mathematics, for a popular audience is a very different task than doing research in mathematics or writing scholarly accounts of it. Doing it well takes hard work and a great deal of writing skill. I have read several books by very good scientists, meant for a popular audience, that were quite dull, because the writing was flat. Those of us who work in science benefit from the efforts of those who work to make the public interested in our subject.

9. **fh**
November 23, 2006

"But beyond that, they're every bit as entitled to their romantic visions of history as their critics are to their own."

Whatever became of "Everyone is entitled to their own opinion, but not their own facts."?

Now we all are entitled to have our own mythologies, but just basic scholary and intellectual ethics/honesty forbid the kind of trivializing and falsifying of history for the purpose of entertaining.

Russel no doubt was very aware of the perspectives of the respective times he writes about. This does not mean that we can not or should not analyze them through a modern perspective, but to actually provide anything with any sort of valuable insight one needs to understand first. Their internal consistency and perspectives (as far as possible).

Something which by all appearances the author failed spectacularly at.

Russel uses western philosophy as a canvas to communicate certain insights and structures in philosophy. That is, the book tells us (to some degree at least) about Russell's philosophy not about the historical philosophies. Therein lies (one of) it's value(s).

Also there is a difference between "biased," "simplistic," "reductive," "romanticized," and "flat out wrong," "ahistorical," "without any understanding of the matter" etc… In so far as Langlands review is accurate the author also committed errors in terms of scholary precision that are unforgivable.

Then just as Russels use of a mythizised but essentially insightfull analysis of history is remarkable and praiseworthy, this use of an essentially wrong mangled and disfigured history for the sake of cheap entertaining is abhorrable.

10. **lostsoul Ph. D.**
November 23, 2006

The Langlands assessment of Euclid's Window is renowned as an example of OTT and sarcastic review – it must be (in)famous because even I have heard of it. It owes its celebrity to its acerbic style (which other AMS reviewers have cultivated in the past), and not to whatever it may convey about the book in question (which I have not read, but have heard people speak quite highly of). How different is it from some of the ordure heaped on Peter's book of late? Professional competence and, still less, genius do not guarantee civility and self awareness; just because a fellow is an ass-hole, it doesn't mean he's wrong. But, then again, it doesn't mean he's right either. The perils of popularisation, I suppose.

11. **Jonathan Vos Post**
November 23, 2006

Mlodinow wrote a PhD dissertation on how QM would work in a universe with an infinite number of spatial dimensions. This dazzled Gell-Mann, who had him appointed to a major faculty position at Caltech. Then the story gets interesting.

Mlodinow has had successful teleplay writing during and after his tenured Physics professorship at Caltech, a marvelous biographical book (Feynman's Rainbow), and collaboration with Steven Hawking, that will yield a new movie next year. Might there not be a sour grapes effect here? I admire Langlands' math very much, so far as I understand it. But this reminds me of Carl Sagan being blackballed from the National Academy of Sciences by those jealous of his popular success in books, TV, and film.

12. **L group**
November 23, 2006

It's great that AMS published the review. It will have no impact on the popularity of the book, as the readership of the Notices can form their own opinions and are a drop in the ocean compared to the mass market. More exacting viewpoints, such as Langlands' or that of Weil in earlier times, are much less visible, and it is good that they are represented from time to time.

13. **JC**
November 24, 2006

Jonathan Vos Post,

Was Mlodinow a postdoc or tenured faculty at Caltech? From reading his book, I got the impression he was only a postdoc. What was amusing were Feynman's anti-string tirades, he wrote about.

14. **Peter Woit**
November 24, 2006

The talk mentioned by "luny" seems to be stirring up trouble, see

http://asymptotia.com/2006/11/23/nuclear-guy-goes-nuclear/

and

http://backreaction.blogspot.com/2006/11/more-on-adscft-and-rhic.html

where there's the usual Lubos attack on anyone who points out that string theory is being over hyped.

Mark,

I also think the Langlands review of the Mlodinow book has more to say about Langlands than about the book, and I think the AMS Notices should not have published it.

Reading the many reviews of my book has provided a new perspective on book reviews, and why they often have little to do with reality. While many reviewers misunderstood what I had to say in the book, I can't complain, since on the whole, their misunderstandings led them more often to write positive things than negative things. The one time I tried to contact a publication about whether they were willing to correct something completely factually untrue that a reviewer had written (KC Cole in the LA Times) was an eye-opening experience. The people there made clear to me that their policy (and presumably the policy of many places) is that:

1. While in the rest of the newspaper they care about factual accuracy, reviews are opinion pieces and thus they have no problem with factually inaccurate statements appearing in them.

2. The only standard for these reviews is whether the reviewer has some sort of argument, no matter how irrational and crazy, for what they wrote.

15. **D R Lunsford**
November 24, 2006

Langlands says about his thesis

Examining again, after forty years, the verification of the basic estimates of the second part, I found a large number of misprints, so that it would have been difficult if not impossible to follow my arguments line by line. I have tried in the present version to correct the misprints, but cannot be certain to have fully succeeded.

The thesis remains, to my regret, my only active encounter with partial differential equations, a subject to which I had always hoped to return but in a different vein.

That is remarkable in a way. I wonder what he meant?

-drl

16. **D R Lunsford**
November 24, 2006

Mlodinow was apparently a writer on the Picard version of Star Trek. I think that is the harshest review I've ever seen, of anything! Well no, Ebert's 0-star movie reviews are a lot like this..

I can't say a word about Langlands as a mathematician but he is certainly an entertaining writer. The review leaves one with an uneasy feeling for some reason, as if culture itself, and not just mathematical culture, were in decline, and he is lamenting the passing of it.

-drl

17. **Jonathan Vos Post**
November 24, 2006

JC:

From the Preface to "Feynman's Rainbow: A Search for Beauty in Physics and in Life" [Warner Books, May 2003):

"… this book is about my time just after graduation in 1981, when I was on the faculty of the Calfornia Institute of Technology…."

"I had been given my fellowship…. Did I really fit in here, with two Nobel prize winners down the hall…."

"This book tells the story of my first year on the Caltech faculty"

I admit to the ambiguity: does he mean that "faculty" includes "postdocs"?

I don't think that Caltech had adjuncts, but they also had Instructors, such as my friend Dr. Thomas McDonough. Instructores teach classes, so I suppose are faculty, but not tenure track.

I'd ask Mlodinow directly, but he is sufficiently busy that he answered an email of mine when I invited to speak on a track of an international conference where I chaired 3 sessions, but explained why he had to decline the attractive offer due to how busy he was.

Good question. I'm still not sure.

Do you agree with the possibility of my Carl Sgan / sour grapes analogy? Amusingly, Brian Green had a bit part in the science fiction film “Frequency” and now seems to have been an executive consultant or the like on the big-budget feature “Dej Vu.”

Here we go again with Esquire Physics, or People Magazine Physics.

18. **Heavy Ion Guy**
November 25, 2006

Dear all,

At quark matter this year Larry did make some strong statements about string theory. This was a response to one paragraph in Brian-Greenes Op-Ed piece in the New York Times.

The full paragraph which makes reference to the heavy ion work is here “And in a recent, particularly intriguing development, data now emerging from the Relativistic Heavy Ion Collider at the Brookhaven National Laboratory appear to be more accurately described using string theory methods than with more traditional approaches. ”

This statement in the public press should be called for what it is — a wild exaggeration of the state of the theory in the heavy ion community. Larry’s main point was that if such claims are to be made in the public press they should be held to the same standards of scientific scrutiny as the “more traditional approaches”. Larry was correct to sharply criticize this remark.

That being said, a number of people (who normally think about heavy ion collisions) have recently been calculating transport coefficients with AdS which they really wanted to know in QCD. These transport coefficients have been inferred from hydro and kinetic models of the heavy ion reaction and generally are smaller than what would be expected from a weakly coupled plasma. It is important to emphasize that each of hydro/kinetic models have a number assumptions that can certainly be challenged. Nevertheless to reproduce these small transport coefficients with perturbation theory consistently requires an extrapolation outside the domain of validity into the strong couplign regime. The AdS/CFT provides a useful foil to extrapolations based on perturburation theory into this regime. Many aspects of the strongly coupled N=4 plasma are markedly different from the qualitative features of perturbation theory. It would be nice to determine a relatively clean observable which would probe these qualitative differences. I think that AdS/CFT is a phenomenological long shot, but it is good (and relatively easy) fun.

19. **JC**
November 25, 2006

Jonathan Vos Post,

The Sagan/sour grapes analogy sounds a bit like what happens in many fields and/or niches. “Serious” folks who find success in the popular media/culture, are seen as “sell outs”.

Do you think it is related to how people like to “compare” themselves to others? Many “serious” people see popular culture as something “low brow”.

20. **Juan R.**
November 25, 2006

> This statement in the public press should be called for what it is — a wild exaggeration of the state of the theory in the heavy ion community. Larry’s main point was that if such claims are to be made in the public press they should be held to the same standards of scientific scrutiny as the “more traditional approaches”. Larry was correct to sharply criticize this remark.

Ok, but would be remarked that calls for holding to the same standards of scientific scrutiny in public press are not new. They are part of well-known scientific ethics guidelines in other communities.

About stringers reactions, Clifford is right when states that there is nothing wrong with being publicly excited by the possibility, though.

In the same vein, there is nothing wrong being publicly excited by the possibility string theory leave us nowhere in main goals.

Still, Clifford fail to understand that Greene was critized not because claimed possibilities but because claimed more accuracy becoming from the string part when even there is not qualitative agreement with experimental data.

About Motl comments, i would cite

> But physics is not just about the fundamental Lagrangians as some of the idealized theorists could think. It is about the understanding of all possible phenomena and about predicting of the outcomes of experiments in a wide variety of physical situations.

That is just the reason because string theory is in trouble.

Unfortunately, Motl presents the same class of disturbed reasoning about string theory that Greene. For instance Motl writes

> The most far-reaching new technique in the research of strongly coupled gauge theories is undoubtedly the AdS/CFT correspondence.

Just a few words after you discover that by most far-reaching technique means that many people have very good reasons to expect that this tool will be the most efficient one to understand questions about the strong force. But nobody proved this, just again, like in last 40 years, we receive good hopes from stringers.

November 27, 2006

I somewhat agree with Prof. Langlands’ criticism of Leonard Mlodinow’s “Euclid’s Window”. Unquestionably, Mlodinow is considerably sloppy at conveying “this math/physics pathway towards strings” to the lay public. He’s especially bad at explaining this connection between Non-Euclidean geometry and Einstein’s geodesics of spacetime.

Needless to say though, I’m still rather in shock to discover that Mlodinow holds a PhD in physics. Yet I’m in ever greater shock to find out that he has a specialized degree in perturbation theory, no less! I'd surmise, however, the poor-quality of Mlodinow's work is perhaps more of a reflection of his sub-optimal skills as a pop-physics writer, and less of an intrinsic indicator of his physics know-how.

Just think about it for a moment though, being a writer for "Star Trek" films, Mlodinow isn't required to compose meaty, substantive material; he simply needs to create a script with lots of golly-gee-whiz wizardry.

23. **foo**
November 27, 2006

Why is the review of Mlodinows book by Langlands over the top? Is it factually wrong?

If a book is as badly written as Mlodinows book seems to be, then a slamming is appropriate, I'd say.

24. **Bob**

Nice discussion – very enlightening.

Media and Other News

November 25, 2006
Categories: Uncategorized

There's filming going on outside my office window today, right at the entrance to the Columbia Mathematics building. The film is Brief Interviews With Hideous Men, with a screenplay based on the David Foster Wallace book of the same name.

On the way in here I stopped at a bookstore and took a look at the new Thomas Pynchon novel *Against the Day*. Over at Cosmic Variance, Mark Trodden and Sean Carroll are Pynchon fans and have postings about this. I was quite fond of *Vineland* and enjoyed some of Pynchon's earlier books, but he lost me with *Mason and Dixon*, and this new one doesn't look promising. From flipping through it, one important topic seems to be quaternions and their relation to 4d space-time geometry, and a group of characters are called the Quaternioneers. I almost bought the book, thinking that it was my duty as a chronicler of the nexus of math, physics and popular culture to read the thing. But when I picked it up, its sheer heft caused an immediate feeling of discouragement, so I put it back down and will wait for reports from others.

There's a new movie out this week called Deja Vu, and evidently string theory play a significant role in its time-travel/multiverse based plot. My colleague Brian Greene was scientific consultant on the film, and the Cosmic Log MSNBC blog has a story about this, noting that he's also involved in another time-travel movie project (Mimzy), and appeared in yet a third (Frequency). The MSNBC story does explain that time-travel is not a big topic of current physics research, but describes physicists as "intrigued by the trippy concepts spawned by string theory – indicating that the universe could follow any of 10^{500} possible courses, and that our course seems to be going down just the right path to allow for the development of stars, galaxies and life" (the story does note that some people have a problem with this and gives "Not Even Wrong" a mention). While I gave up on the idea of spending $35 on the Pynchon book and devoting endless hours to reading its more than 1100 pages, spending $10 and devoting a couple hours to watching a cheesy movie seems like a much more viable way of fulfilling my blogger duties, so I think I'll be doing that this evening.

Continuing on the science fiction theme, next year's Les Houches summer school will be on the topic String Theory and the Real World.

In further media news, last week I talked with someone from the CBC radio program The Current, and supposedly they were going to use some of this in a program on the controversy over string theory that aired yesterday. Also someone tells me that this past week's issue of Der Spiegel has an article on this.

Finally, for some non-media science fact, the week before last there was a workshop in Paris on High Energy Physics in the LHC Era. There were quite a few interesting talks, including one by Albert de Roeck on post LHC accelerator possiblities (mainly the SLHC, a luminosity upgrade of the LHC), by Alessandro Strumia on astrophysical neutrino experiments, and by Fabio Zwirner on supersymmetry (see page 18 of his slides for a good reason not to believe in supersymmetry). The summary talk was given by Luciano Maiani, who argued that the next machine after the LHC should be a larger proton-proton machine, on the SSC size scale, to be built in the US (since it wouldn't even fit at CERN), with an electron-positron collider to be built at CERN.

Update: For a more general discussion of the question of whether new physics that solves the naturalness problem will be visible at the LHC, see a recent posting by Tommaso Dorigo, who is reporting on a conference going on in Bologna, especially the talk by Andrea Romanino.

Update: The movie is completely generic, including no strings, but just a standard-issue wormhole.

Comments

   November 25, 2006

   Someone in the New Yorker seems to agree with you on Pynchon's latest opus:

   http://www.newyorker.com/critics/books/articles/061127crbo_books

2. **Jud**
   November 25, 2006

   Re the New Yorker review, "Pynchon writes for Pynchon," "Pynchon writes that way just to show he can," and "Pynchon is too damned obscure" are common complaints among Pynchon non-fans, famously including the Pulitzer jury that reviewed Gravity's Rainbow. Lots of these accusations of egotism and playing with readers seem to stem from Pynchon's use of humor. When the heck did we start requiring our artists to be so solemn? Joyce's "Ulysses" has pages and pages of extended humorous vamps; what got him into trouble wasn't the humor, it was closing the book with 50 pages of a woman giving herself an orgasm. So 80 years ago, sex was the sin; now, apparently, it's laughter.

3. **M**
   November 26, 2006

   It is exciting that, while this epoch of endless speculations is coming to an end, we have no best guess for what LHC will see. Discovering if supersymmetry anticipated LHC results by 20 years, or if we lost 20 years on a wrong speculation will be a sensible issue, like discovering that strings predict things univocally up to a 10^500 ambiguity.

   Concerning colliders, a reasonable point of view is that now we don't know if we will need to do precision physics with a 500 GeV ILC or explore higher energies with a SSC-like collider. So it would be reasonable to keep the second option open, by working on the needed magnetic technologies, and by finding a better name for it.

   Moving all US resources to the first option will put the US in first position, if the physics case for a linear collider will turn out to be correct. If not, it will be difficult to switch to the SSC-like option. The possibly wrong physics case for ILC has been already presented to the congress by somebody who got a recent Pinocchio award: are we sure it is a good strategy?

4. **r hofmann**
   November 26, 2006

   My personal feeling about the ILC is that there will be a lot of very clean new-physics signals to be seen at such a machine nothing to do with supersymmetry. I believe that hadron colliders at higher energies will be more or less redundant judging from the lessons learned with the linear collider and LHC.

5. **K.**
   November 26, 2006

   It is very remarkable that the MSSM adds 100-odd parameters to the SM, yet it seems to need a 1% level tuning in order to evade LEP bounds. In principle it should be able to fit about 30 elephants wagging their tails, if one believes Fermi 🙂

As first light nears, the LHC saga is building up more and more suspense. Who says particle physics is not thrilling?

6. **Tommaso Dorigo**
   November 26, 2006

   Indeed, it is thrilling.
   And, that were not enough, there's more. One of the most thrilling things is that many of the people working in the experiments (Atlas and CMS) do not seem to realize, as close as 1.5 years from serious data taking, how complex are things at a hadron machine.

   At the workshop I attended in Bologna Anna Maria Zanetti gave a very nice talk on the experience in CDF with the start of Run II and the first problems with data taking. I knew all of the stuff, so I could lay back and enjoy the terrified look in the face of many at the sight of what a lost proton beam can do to your apparatus, what fraction of the silicon sensors were burned by beam incidents as the first few nanonarbs of data were being collected, and the ugly effects resonance (not a particle, but the nasty effect of elastic forces at work) can do to sensitive parts of your electronics – exemplified by wirebonds broken in scores in the silicon readout as data taking causing lorentz forces passed through the resonant frequency of the bonds.

   I think it will really be exciting…

   T.

7. **King Ray**
   November 27, 2006

   On the topic of science fiction, I don't know if many people know that Harlan Ellison and Sidney Coleman are childhood friends. I was at an LSC lecture given by Ellison back in the 80's at MIT in Kresge Auditorium and Harlan introduced Sidney as a close friend and had him stand up in the audience.

8. **D R Lunsford**
   November 27, 2006

   Science fiction was much more entertaining when science fact had its act together.

   -drl

9. **King Ray**
   November 28, 2006

   Has anyone seen this?

   http://www.physorg.com/news83924839.html

   Cosmologists expose flaws in anthropic reasoning

   Many scientists never liked it anyway, and now Glenn Starkman from Oxford/Case Western and Roberto Trotta from Oxford show that too many details—and too many unknowns—mean that anthropic reasoning gives inconsistent values of the cosmological constant, some that are far from current estimates. In their recent paper, "Why Anthropic Reasoning Cannot Predict Lambda" (Physical Review Letters), Starkman and Trotta find that different ways of defining the probability of observers in different universes leads to vastly different predictions of the cosmological constant.

   "The significance of our work is to offer a concrete example of how anthropic methods of reasoning can be used to reach conclusions contradictory to those usually arrived at," Starkman told PhysOrg.com. "This suggests to us that anthropic explanations of fundamental questions should be treated very cautiously."

   …

10. **Thomas Love**
    November 28, 2006

    If "anthropic methods of reasoning can be used to reach conclusions contradictory to those usually arrived at" perhaps it is not anthropic methods of reasoning which are wrong. Perhaps the usual modes of reasoning are wrong. Not that I believe in "anthropic methods of reasoning ".

11. **Chris W.**
    November 28, 2006

    TL,

    I think the point that Starkman and Trotta are trying to make is that anthropic reasoning provides way too much room for fudging, to the point where it can't be relied upon to yield coherent conclusions. That is, it can yield one set of conclusions that contradict another set of conclusions previously arrived at by anthropic reasoning.

12. **Chris W.**
    November 28, 2006

    More on the media front: A story for NPR by Robert Krulwich on manufacturing universes in the lab, with Brian Greene and Andre Linde featured prominently:

    "Just imagine if it's true and there's even a small chance it really could work," [Linde] said. "In this perspective, each of us can become a god."

13. **Chris Oakley**
    November 29, 2006

    Re: the Universe Machine, I was not clear on how much customisation is possible. Presumably you can adjust basic things like the total mass, amount of dark matter and Hubble constant, but what about the finer adjustments? Could you, for example, create a universe where the majority of what theoretical particle physicists say to reporters is not total bullsh*t? *That* would be a challenge.

14. **Ari Heikkinen**
    December 1, 2006

So, the movie has to be cheesy because Brian Greene was their consultant on science? I'm sure Greene, even though he's a string theorist, is competent enough to be a credible consultant for a film.

Just pointing this out, because you keep pointing out that people should read your book first before commenting it, so wouldn't it be only fair to first watch the film and comment it afterwards?

15. **Peter Woit**
December 1, 2006

Ari,
You're completely making things up I never wrote. I didn't characterize the movie as cheesy because Brian was a consultant, I characterized it as cheesy because I think pretty much all big-budget thrillers with time-travel themes are cheesy. I had seen the trailer for the movie, read reviews and other articles about it, and all the evidence was that that this would be a cheesy movie. I often like to see cheesy movies, so happily paid my money expecting to see a cheesy movie, and was not disappointed.

16. **anonymous**
December 1, 2006

"I often like to see cheesy movies,"

(Ahem, perhaps you shouldn't be so frank, or some bits of what you say in jest will be quoted out of context by your enemies to make you sound cheesy.)

17. **Chris W.**
December 3, 2006

More on the media front: In the December 1 Science Journal (*Wall Street Journal*) Sharon Begley focuses on anthropic reasoning, with special attention to recent criticisms and research that bears on its alleged effectiveness in answering substantive questions about things like the value of lambda.

In particular she discusses work published in August (in Physical Review D) by Graham Kribs, A Universe Without Weak Interactions (hep-ph/0604027, 4 April 2006).

(Kribs is also a co-author of another interesting paper posted last April, on an alternate derivation of some important AdS/CFT predictions — hep-th/0602110.)

18. **Benni**
December 5, 2006

Job Openings:

2 String theory professorships available in munich:

http://www.asc.physik.lmu.de/MATH/job_openings.shtml

We expect to fill one W1 Junior professorship position (Junior research group) within the Excellency Cluster "Origin and Structure of the Universe" on Extra Dimensions, Strings and Branes (see here for more information). The announcement will appear soon.

We expect to fill one W2 Associate Professorship position as well as one W1 Junior professorship position within Elite Master Study Programme "Theoretical and Mathematical Physics" (see here for more information). The announcements will appear soon.

There aren't many string theory professorships available in europe, and especially in munich, theres lots going on on high energy theory:

especially here:
http://www.theorie.physik.uni-muenchen.de/asc/

here
http://www.mppmu.mpg.de/english/index.html

and here:
http://www.universe-cluster.de/

I think these are worthy positions to take.

Benni

Two Reviews

November 29, 2006
Categories: Not Even Wrong: The Book

Two reviews by physicists of my book and Lee Smolin's have recently appeared.

The first is by David Lindley in the Wilson Quarterly. Lindley has written some excellent popular books about physics, including one about quantum mechanics entitled Where Does The Weirdness Go?, and he has a new one about the history of the uncertainty principle that I look forward to reading. He is also the author of The End of Physics: The Myth of a Unified Theory, which appeared back in 1993, and was the first popular book I know of that explained that the project of finding a unified theory of particle physics had started to run into trouble and was not making progress. In some ways Lindley's book was a precursor to John Horgan's later The End of Science, and Horgan acknowledges Lindley's influence. Lindley notes that I say a bit about his book in mine, saying I misstate one of his arguments. He has to be right about this, so I'm rather curious to know what I got wrong (an internet search shows that he has been pretty successful at keeping his e-mail address non Google-accessible, so I haven't yet contacted him to ask him about this). His description of the books is reasonably accurate and straight-forward, and he ends with the following observation:

As for string theory, it's likely to unravel only when its practitioners begin to get bored with their lack of progress. Like the old Soviet Union, it will have to collapse from within. The publication of these two books is a hopeful sign that theoretical physics may have entered its Gorbachev era.

December's Physics Today has a review of the same two books by Kannan Jagannathan, under the title Scrutinizing string theorists and their future. One unusual aspect of the review is the peculiar description of the reviewer, unlike any I've ever seen before in Physics Today:

Kannan Jagannathan is a professor of physics at Amherst College in Amherst, Massachusetts. Though his background is in high-energy theory, he has no strong stake or expertise in string theory.

It's an indication of the highly partisan nature of the controversy these books have stirred up that Physics Today seems to have found it necessary to include this sort of unusual disclaimer. It appears true that Jagannathan is no partisan, but his disclaimer of expertise on the subject covered by the books is associated with a rather superficial take on the arguments these books are making. His only attempt to evaluate whether there is anything to the claims Smolin and I make about the problematic behavior of some string theorists is to have read Lisa Randall's recent popular book Warped Passages, and found that she doesn't seem to share our concerns.

While avoiding saying anything about the substance of my arguments, Jagannathan does take exception to the style of some of them, suggesting I should use more "temperate rhetoric", and avoid "anecdotes and private communications." Perhaps he's right that tactically it would have been better for me to write a more impersonal book, bending over backwards to appear to not be expressing personal opinions. For better or worse, I chose to do something quite different; to write a very personal book, expressing precisely what I think, and describing experiences that have led me over the years to these opinions.

Comments

1. **Alejandro Rivero**
   November 29, 2006

   The comparision with the Soviet Union is interesting. Acording Lenin, or more properly according a reported talk of Lenin with one of the leaders of Spanish anarchist union CNT, the system was foreseen to allow "about 50 years" (this was 1927 or so), after which it would fall, expectedly towards anarcho-socialism. This bit or the prediction was a sort of failure, but except on this detail Lenin mechanism worked as a clockwork: not having internal renovation of leaderships, the system burnt out itself.
   Now, the hope with physics, or with string theory, is that science self-implemented destruction mechanisms, rooting a theory without experimental input, will work.

2. **Thomas Love**
   November 29, 2006

   Lindley's new book: "Uncertainty: Einstein, Heisenberg, Bohr, and the Struggle for the Soul of Science" sounds like an interesting read, but I'll bet he doesn't mention that the uncertainty principle is classical physics, coming from any wave phenomenon. It is in the classical theory of light and the classical theory of acoustics.

3. **D R Lunsford**
   November 30, 2006

   Peter – you were entirely correct to write in the style you did – it reminds me of Klein's highly personal and very instructive style and humanizes the whole thing. It's an excellent book regardless of your point of view because the arguments are logical and the facts are clear.

   -drl

4. **Tony Smith**
   November 30, 2006

   An Amazon UK synopsis of Lindley's 1993 book "The End of Physics: The Myth of a Unified Theory" says in part:
   "… the particle physicists …[in]… their attempts to reach … for a unifying theory … and unable to subject their findings and theories to experimental scrutiny … have moved into a world governed by mathematical and highly speculative theorizing,
   none of which can be empirically verified.
   David Lindsey argues that a theory of everything derived from particle physics will be full of untested – and untestable – assumptions.
   And if physicists yield to such speculation, the field will retreat from the high ground of science, becoming instead a modern mythology.
   This would surely be the end of physics as it is known today. …".

   Since superstrings were dominant in high-energy physics theory in 1993, it is obvious that Lindley was referring to superstring theory as the "… modern mythology … the end of physics …"
   Now. over a decade later, Lindley says that superstring theory
   "… [i]s likely to unravel only when its practitioners begin to get bored with their lack of progress …"
   which indicates to me that Lindley disagrees with the hopeful view of Alejandro Rivero that
   "… science self-implemented destruction mechanisms, rooting a theory without experimental input, will work …".

   Further, given such things as the videotaped reactions at KITP to Johnson's first talk, the blogs of Lubos Motl and Clifford Johnson, etc, it seems to me that it is very unlikely that superstring "practitioners" will "get bored with their lack of progress" at any time in the foreseeable future,
   so

it seems to me that Lindley's view is that if you want to do high-energy theoretical physics in the forseeable future, your options are either:
do superstring theory or;
work in a relatively small niche field (tolerated as long as it stays in its place as a small niche) like LQG or;
somehow make a living outside the established physics community, record your work for posterity as best you can, and hope that, if it is correct, somebody 100 years or so from now might stumble across it.

In short,
superstringers own the City Hall of high energy theory, and you can't fight City Hall.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

5. **A**
November 30, 2006

Surely past years look like a Breznevian stagnation era. Since 1960 a failure seemed likely but not unavoidable, so a whole apparatus of people who got power thanks to communism, togheter with a few strong believers, could force everybody to keep going for 30 more years in doing something that almost nobody believed.

And the end can take different forms.

Susskind could be a Gorbachev, who destroyed communism in an attempt of changing it. Maybe Motl dreams to be a Kim, who still keeps pure communism in North Korea. More likely, the end could be something constructive like in China.

6. **Thomas Larsson**
November 30, 2006

according a reported talk of Lenin with one of the leaders of Spanish anarchist union CNT, the system was foreseen to allow "about 50 years" (this was 1927 or so)

Nitpick: Lenin died in 1924.

7. **Alejandro Rivero**
November 30, 2006

Nitpicked. You forced me to check notes. Effectively, Angel Pestaña was sent to Moscu in 1920, while Nin was sent in 1921 (1922?). I think the note I remember was a comment from Buenacasa on the report of Pestaña back in Spain. Victor Serge explains he was with Pestaña when they first meet Lenin, but he does not mention this remark about the temporality of the dictatorship.

8. **D R Lunsford**
November 30, 2006

Tony – the entire thesis of the Lindley book is absurd, because we have working example from 1865 – Maxwell's unification of electricity and magnetism. This introduced a new scaling constant called – let me think – oh yes, the speed of light.

-drl

9. **King Ray**
November 30, 2006

I don't think string theory will die until the funding is cut. I knew a guy in grad school who got several postdocs doing string theory who told me he didn't even believe in it but he was getting all these great jobs doing it. I think it is wrong to work on something in science you don't even believe in just to make money and get a job. Science is supposed to be a higher calling.

10. **L group**
November 30, 2006

Experimental input, although the ultimate source of the theory, is itself overhyped in the discussions of string theory and theory in general. If ultimately the only output of string theory is a more efficient formalism for QFT with no additional physical predictions, that is itself a major contribution. Such an existing or expected contribution may or may not justify the current levels of interest in string theory, but neither does harping on the lack of current relation to experiments.

11. **Carl Brannen**
December 1, 2006

On the topic of what will destroy string theory, a very interesting 800+ page book is Collins' on gravity waves. I would never have picked up a book on physics by a "sociologist", except that I took two graduate physics classes from Joe Weber who is the subject of a good bit of the book.

The main subject of the book is how it is that communities of physicists reach agreement on subjects that are debated. The author's well supported contention is that debate does not always change minds and that in the worst case debates both sides are supported by well respected physicists. Since 99.99% of what we know, we know not by direct experience but instead because we trust the judgement of others (for example, I've never measured the mass of an electron), the physics community has no way to decide the issue (think Einstein versus QM).

Eventually, truth is decided when one side or the other gets an advantage at minting graduate students, and the other side dies off. My guess is that the advantage comes about partly by numbers, and partly by way of attractiveness of the calculational techniques, but the author does not discuss this. After one side or the other wins, history is then rewritten so as to make the side that died off look like idiots and old fogies. And a new generation is taught that science is 100% correct.

One can argue that physics has done well with this technique of fighting over the truth — most physicists believe that the foundations of physics are solid. But from a sociological point of view, even if string theory is wrong, we can expect its proponents to go to their graves unrepentant, and to dominate theory until they retire.

12. **Peter Orland**
December 1, 2006

To Carl Brannen:

There are examples of scientific controversies which were resolved by
data and not by sociological forces (such as one side dying off). I don't find Kuhn's thesis especially convincing.

People are naturally reluctant to abandon their theories and ideas for notions suggested by others. Thus science tends to stay a conservative enterprise, in which only the best thought out ideas eventually predominate. This may sound overly idealistic, but it's often true.

As an example, consider Harlow Shaply who refused to believe that spiral nebulae were galaxies external to our own. In spite of his heated arguments with Hubble and others, he eventually changed his mind (and wrote a popular book entitled "Galaxies"). The point is that Shaply didn't have to die for the galaxy concept to win acceptance. There are other examples (Hoyle and the steady-state vs big-bang universe is one).

Anyway, people really can be persuaded by evidence. observational or otherwise, if only to save their own reputations (or in some cases, to get a post-doc).

13. **Johny**
December 1, 2006

Peter Orland: let me add one more example to your list. Schroedinger refused for a long time to accept Einstein's photon idea. He was convinced by Bohr that there was no other way to interpret the photoelectric effect. According to an account by Heisenberg, the discussions were long and difficult. So much so that Schrodinger fell ill, but still Bohr sat by his bed and went on discussing the issue. In the end, Schrodinger didn't die and accepted the particle nature of light.

14. **Tony Smith**
December 1, 2006

King Ray said that he ".. . do[esn]'t think string theory will die until the funding is cut. …"
and
that he "… knew a guy in grad school who got several postdocs doing string theory who told me he didn't even believe in it but he was getting all these great jobs doing it …".

As King ray went on to say, "… it is wrong to work on something in science you don't even believe in just to make money and get a job …".

In light of King Ray's comment, it seems to me that the most accurate USSR analogy for present-day superstring theory is Lysenkoism, which:
got dominant government funding;
viciously attacked competing approaches; and
had worker/supporters who knew about the flaws in Lysenkoism but supported it anyway in order to continue getting funds and jobs, and to preserve positions of prestige and political/funding power.

From a wikipedia entry at http://en.wikipedia.org/wiki/Lysenkoism on Lysenkoism:
"… mass-media presented him [Lysenko] as a genius who had developed a new, revolutionary technique.
… Lysenko … was … supported by the … propaganda machine, which overstated his successes and omitted mention of his failures.
Instead of making controlled experiments, Lysenko relied upon questionnaires …".

To me, that sounds a lot like the present-day superstring cult of personalities, every one relying on praise from each other, similar to Lysenko's "questionnaires" whose replies consited mostly of sycophantic praise.

PS –

15. **Tony Smith**
December 1, 2006

Sorry about the omitted PS –
I was going to remark about how long Lysenkoism lasted and how difficult it was to bring down, but I found writing it to be too depressing if it is an indicator of how long the superstring cult is to last and how difficult it is to bring down, so I stopped writing after "PS -".

Tony Smith

16. **Graduate**
December 1, 2006

I also though of Lysenkoism as a possible analogy to what is going on with string theory. I didn't find it satisfying.

1. For one thing, Lysenko was viewed as providing metaphorical evidence for the validity of certain national policies (As Lysenko sought to vernalize wheat, the soviet people where thought to be vernalized by the harsh policies of the Soviet Union, becoming stronger and hardier with more harsh treatment; or so the theory went). There is no such unholy alliance between string theory and politics.

2. Another important distinction is that Lysenko ignored the results of actual experiments. In string theory, there are no experiements for the theorists to ignore.

I have one question however. I have been wondering about the way theoretical physicists argue mathematics. I understand the mathematical way of proving statements. But I've been confused by the way physicists argue in mathematical sketches. How does one decide which of the debaters has 'won' ? It seems to me entirely possible to string together plausible conjectures and get several contradictory statements. And that indeed seems to happen often. I would appreciate some insight into this aspect of theoretical physics culture.

17. **Peter Woit**
December 1, 2006

TheGraduate,

Physicists characterize all sorts of different things as a "proof at physicist's level of rigor". These range from cases where one has overwhelming evidence from numerical calculations that something is true and cases where something is true for sufficiently well-behaved functions (and the exact characterization of "well-behaved" has not been sorted out), to cases where the evidence is very fragmentary and far from convincing. Traditionally physicists haven't worried too much about whether they really have a sold argument for a conjecture, since it has often been the most efficient tactic to just assume things will work, and go ahead and calculate under that assumption. If the calculations lead to inconsistencies or disagreement with experiment, that's the time to go back and check assumptions.

One big problem with string theory is that the lack of any experimental tests means that all you have to go on is the lack of inconsistency, and given the way the theory is built on a lot of unproved conjectures, this can get problematic.

18. **Tony Smith**
December 1, 2006

Graduate said
"… Lysenko ignored the results of actual experiments.
In string theory, there are no experiements for the theorists to ignore. …".

Actually (in my opinion) there are substantial experimental results that show absence of supersymmetry,
and
those results (in my opinion) have been effectively ignored by superstringers choosing successively heavier scales of supersymmetry breaking as successive experimental results failed to see supersymmetry.

The superstringers (in my opinion) are acting in a way that Feynman considered unscientific in the book Feynman Lectures on Gravitation" (Addison-Wesley 1995) at pages 22 and 23, where Feynman said:

"… a famous professor … asked "… how are you sure that the photon has no rest mass? …
I [Feynman] answered … "… I would be glad to discuss the possibility that the mass is not of a certain definite size. The condition is that after I give you arguments against such mass, it should be against the rules to change the mass."
The professor then chose a mass of 10^(-6) of the electron mass.
My [Feynman's] answer …[was given]…
Then he [the professor] wanted to know what I would have said if he had said 10^(-12) electron masses …
[again, Feynman's answer was given]…
After this, the professor wanted to change the mass again, and make it 10^(-18) electron masses …
[again, Feynman's answer was given]…".

Feynman went on to say
"… We do not want to do similar things in attempting to construct a theory …
we should be prepared to put forth definite theories … and be prepared to reject them if they are inadequate. ".

I think that superstringers have been in violation of Feynman's standards for some time,
and
that superstringers are, and have been for some time, effectively ignoring experimental results indicating that superstring-type supersymmetry does not exist.

It also seems relevant that now, with indirect evidence indicating that even the LHC will not see superstring-type supersymmetry, superstringers such as Lubos Motl are attempting to move the goalposts yet again, exemplified by Lubos Motl saying on his blog, about superstring theory, such things as:

"… we are confident that an answer to these questions exists in the non-supersymmetric case and it will be unique just like it was in the supersymmetric cases. …".

Contrast that statement
with Lubos Motl's past view of supersymmetry as a fundamental part of superstring theory, exemplified by his rejection (in 2004) of a non-supersymmetric string theory model by saying "… "String theory" is a shorthand for "superstring theory" …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

19. **King Ray**
December 2, 2006

Tony, very interesting analogy. I hadn't heard of Lysenko before, but he definitely reminds me of some people I have known.

I'm sure there are many people working on string theory that don't really believe in it; the one person I mention was just the one honest enough to admit it.

I think string theory is just a mutual admiration society; if you agree with everything they say you are a super genius, otherwise you are stupid and a crackpot. I don't think many of them are actually that bright, and none of them have any aesthetic sense or physical intuition such as Einstein had. They are clearly not independent thinkers like Einstein either, but conformists.

20. **Thomas Larsson**
December 2, 2006

In string theory, there are no experiements for the theorists to ignore.

String theory predicts supersymmetry – not seen.

String theory predicts 496 gauge bosons – 12 seen.

String theory predicts extra dimensions – not seen.

String theory predicts a large and negative cosmological constant – the cc is small and positive.

String theory predicts proton decay – not seen.

Aether theory predicts aether wind – not seen.

But then again, Lorentz and Poincare didn't count negative experiments any more than Gross and Witten.

21. **TheGraduate**
December 2, 2006

"Between 1934 and 1940, under Lysenko's admonitions and with Stalin's blessings, many geneticists were executed (including Agol, Levit, and Nadson) or sent to labor camps. The famous Soviet geneticist Nikolai Vavilov, was arrested in 1940 and died in prison in 1943."

This is a quote from Wikipedia.

Look, there is really no comparing Lysenkoism and string theorists. There are lots of historical examples of legitimate scientists who used their academic power to exclude people who disagreed with them. One of these incidents would be a more appropriate comparison.

22. **Peter Woit**
December 2, 2006

TheGraduate is right. Please stop with the highly exaggerated attacks on string theory and string theorists. These are off-topic, not enlightening, and kind of repetitive.

23. **Ludmilla**
December 2, 2006

>String theory predicts supersymmetry – not seen.

The jury is still out on susy, extra dimensions, the Higgs boson, etc. At least until 2008-2010.

Actually, it's not so clear to me that string theory really *predicts* susy. One of the most disappointing features of string theory (or, should I say, of string theorists) is that no clear-cut predictions are made. That's why some say it's *not even wrong*.

In my opinion, string theory is here to stay. Most likely not as a TOE, but as a math-phys framework. Personally, I don't believe in TOEs, stringy or otherwise, I think it's just a silly idea.

24. **anonymous**
December 3, 2006

Maybe the behavior of string theorists is more predictable than string theory: here are my testable clear-cut predictions (or maybe just my worries) about their official reaction to some possible future LHC results:

if LHC sees supersymmetry, eureka we have up to N=8 of them.

if LHC sees extra dimensions, eureka we have 6 or 7 of them.

if LHC sees technicolor, eureka we have AdS/CFT.

If LHC sees dark matter, eureka we have discrete gauge symmetries.

if LHC sees nothing new, eureka eureka we have the anthropic landscape.

Sorry for this non politically-correct comment, but I believe it's true. Hopefully the next few years before LHC will allow to improve the physics and/or the sociology of string theory.

25. **Thomas Larsson**
December 3, 2006

The jury is still out on susy, extra dimensions, the Higgs boson, etc. At least until 2008-2010.

Sure. Every experiment that does not see evidence for susy or extra-dimensions is irrelevant, such as muon g-2, B_s oscillations, permanent electric dipole moment, no deviations from Newton's law, etc.

H. A. Lorentz did not give up on aether theory that easily neither. For years he discovered increasingly complicated, Rube-Goldbergesque constructions, instead of accepting the obvious conclusion of the Michelson-Morley experiment. He never went as far as making anthropic arguments, though (a large aether wind might be incompatible with human life).

Of course, he had his reasons. Aether theory was the only game in town – it follows from Newtonian mechanics and the Galilei group, which had passed every test for 200 years. And he certainly did not care about some crackpot patent clerk, who was ignored by everybody until Max Planck made him his assistent in 1910.

26. **dan**
December 3, 2006

Dear Thomas Larsson,

"String theory predicts a large and negative cosmological constant – the cc is small and positive."

Hasn't this been successfully addressed by the KKLT paper, which shows that string theory can account for a small positive cosmological constant?

27. **Ludmilla**
December 3, 2006

> Sure. Every experiment that does not see evidence for susy or extra-dimensions is irrelevant, such as muon g-2, B_s oscillations, permanent electric dipole moment, no deviations from Newton's law, etc.

No, every experiment that does not see susy, extra dimensions, technicolor, preons, strings, whatever, is not irrelevant. It just puts tighter bounds on each of those possibilities. At some point those bounds can completely exclude one of the possibilities, or at least make it phenomenologically irrelevant.

As far as I know, all known models of new physics are currently pushed into a rather uncomfortably tight region of their respective parameter spaces by experimental data. But

we are not there yet. Ruling out susy (in its
phenomenologically significant variants) will take LHC data.

If you want to know my personal opinion, the MSSM and extra
dimensions will not be seen at the LHC. But then, opinion
is not fact. Also, that point of view does not solve any
problems and, in fact, makes them worse. Without susy, how
do you solve, for example, the LEP paradox and the dark
matter problem? I don't have an answer, do you?

28. **D R Lunsford**
December 3, 2006

TL – that was hysterical. I can see that paper,

"Aether-Wind und Lebensmöglichkeit"

Poor Lorentz, he really was very brilliant. Relativity was so much simpler than what he was doing.

-drl

29. **Chris Oakley**
December 3, 2006

> TL – that was hysterical. I can see that paper,
>
> "Aether-Wind und Lebensmöglichkeit"

I cannot. I doubt that, even in his darkest dreams, he would have contemplated anything so ludicrous, and if he had, he would have being a laughing stock. Now some prominent physicists try to make a laughing stock of those who do *not* believe in the Anthropic Principle, which I suppose only shows how far we have fallen.

30. **anonymous**
December 3, 2006

http://www.kuro5hin.org/story/2006/10/31/161746/39

"String Theory and the Crackpot Index

"…Certainly, Dr. Greene has been been working for a long time (10) on a paradigm shift (10), towards which Einstein struggled on his deathbed (30). For his effort, his theory has no equations (10) and no tests (50). With the starting credit, that much makes 105 points.

"Is Dr. Greene a crackpot? No. But is this how physics should be presented to the public?"

Wonder why Woit doesn't discuss this stuff?

31. **Peter Woit**
December 3, 2006

anonymous,

I saw the story you mention, but the main answer to why I didn't think it was worth discussing is embedded in what you quoted. I think there's a lot wrong with string theory and how it is pursued, but Brian Greene is not a crackpot, and neither are most string theorists.

I disagree with Brian about a scientific issue, the prospects for string-based unification, and, as a result, also don't think the kind of public promotion of this idea he has engaged in is wise. But he's a perfectly reasonable person, willing to admit that string theory may be wrong, just trying to promote and pursue ideas he believes in. I've known him for a long time, work in the same department, and talk to him regularly. I think both of us see our disagreements as scientific ones and want to avoid personalizing them. If you want to engage in Brian-bashing, do it elsewhere.

32. **Thomas Larsson**
December 4, 2006

Hasn't this been successfully addressed by the KKLT paper, which shows that string theory can account for a small positive cosmological constant?

With 10^500 parameters one can fit 2*10^499 tail-wriggling elephants. Or the value of the cosmological constant.

33. **Thomas Larsson**
December 4, 2006

*No, every experiment that does not see susy, extra
dimensions, technicolor, preons, strings, whatever, is not
irrelevant.*

Ludmila, I was responding to Graduate's claim that "In string theory, there are no experiements for the theorists to ignore." So evidently he, as many other string theorists, thinks that none of these experiments is relevant.

34. **Ari Heikkinen**
December 4, 2006

Speaking of books..

I'm soon ordering some books from amazon and just out of curiosity, was thinking of buying a book about string theory and another that points out problems with it.

I'd basicly prefer something with actual equations for backing up any claims instead of merely philosophy (I already have Greene's book about string theory, but it was, although excellent read, a bit too basic without any equations whatsoever), so while I'm leaning towards that Zwiebach's "first course" book on strings (based on searching on amazon), which one should I pick for a rebuttal for it, Lee's or Peter's? What's the difference? Wouldn't want to end up buying another book with just claims and nothing to back them up, be it critics or advocates.

35. **Steve Myers**
December 4, 2006

I hope this isn't entirely off topic, but I've been thinking about popular books and articles on science. How good are they? When I read one on something I know well I find they are too thin or skip the "hard" stuff that you need to understand to even know what's going on. There is a good book by Longair on physics but would you classify it as popular? Scientific American, for example, is often too thin and can give a wrong impression of a field.

When I think about explaining my own rather simple work in a popular way I find that I have to explain FFT and signal processing, etc. What bothers me that even a Dirac prize winner can make a mistake about entropy and the arrow of time, what kind of mistakes are in stuff that I'm not familiar with — like Biochemistry?

This is a serious questions: can one even write a good popular book on a subject — like theoretical particle physics without simplifying too much. I've discussed this with my computer scientist son who says he knows of nothing in his field. I know of & enjoy as light reading books by Gamow, Pagels, Einstein, Feynman, etc., but to even have a vague idea of what's going on in a field I don't know of any better or easier way than reading the technical stuff and working on a problem.

36. **Peter Woit**
December 4, 2006

dan,

The problem with KKLT is that it "accounts for" a small CC by using a very complicated Rube Goldberg setup (Susskind's description), and if you believe this works, you can "account for" just about anything, your theory is unpredictive, and you're not doing science. Thomas inaccurately characterizes KKLT as have 10^500 parameters, which is not right, it's 10^500 solutions, but this doesn't change the problem.

Ari,

My book has some more technical material than Smolin's, but it is still written without using equations, and it was not possible in this format to explain in technical detail many things. I also included quite a few suggestions for more technical further reading. One problem with Zwiebach's book is that it only covers a small part of the string theory story, not taking you very far at all into the issue of how to connect string theory to real physics.

Steve,

I think there's a wide variety of "popular" books out there. Quite a few oversimplify and don't even try and give a legitimate explanation of what is going on. But some do an excellent job of giving an accurate picture of a field, even if a true understanding of the subject requires spending a lot more time and working out some basics techical details for oneself. To my taste, the best books I've seen often take a historical point of view, showing how a scientific subject evolved to the point it is now. Knowing the history of a subject is often a good place to start when trying to learn the basics.

37. **King Ray**
December 4, 2006

I really enjoyed Abraham Pais' Subtle is The Lord, a biography of Einstein with equations along the way to his discovery of GR.

http://www.amazon.com/Subtle-Lord-Science-Albert-Einstein/dp/0192806726/sr=8-4/qid=1165253958/ref=sr_1_4/002-0203434-5813668?ie=UTF8&s=books

38. **John Gonsowski**
December 4, 2006

A lot of things that string theorists talk about exist outside the context of string theory. Brian Greene might talk about ten spacetime dimensions for string theory but John Baez can talk about them outside string theory. Greene might talk about exceptional algebras for string theory but Baez can talk about them outside string theory. Green might talk about string theory worldsheets but Urs Schreiber says there's a deep connection between a worldsheet and Feynman paths (Feynman was not a string theorist). Even the supersymmetry of superstrings exists outside string theory (and there are other types of supersymmetry too). The one nice thing about the anthropic landscape is that it has quite a few critics who are string theorists. Given the politics of physics, sometimes I think it might be easier just to pursuade string theorists to work on different things under the string theory umbrella than to get them to downsize their empire.

39. **Who**
December 4, 2006

I met a PhD student of Steve Giddings just in the past month—he was up from Santa Barbara to hear some talks. He mentioned what his thesis research was about: it wasn't string theory though it was somewhat LIKE string theory—IIRC it didnt need extra dimensions, maybe it lived in 4D like normal people. This is, of course, vague gossip—but I remember getting a
sense of drift, of a program morphing into something else. It wasnt quite cool
anymore to be doing core string, so you emphasized the distance.

40. **Ludmilla**
December 4, 2006

> Ludmila, I was responding to Graduate's claim

Thomas, you quoted from *my* message, so I thought
reasonable to assume you were responding to me. I still
think so.

> *The jury is still out on susy, extra dimensions, the Higgs boson, etc. At least until 2008-2010.*
>
> Sure. Every experiment that does not see evidence for susy or extra-dimensions is irrelevant, such as muon g-2, B_s oscillations, permanent electric dipole moment, no deviations

41. **King Ray**
December 4, 2006

Giddings is Witten's student, isn't he?

I agree that we should explore 4D theories more fully. Higher dimensional theories have never been successful, going back to KK. I think by going to higher dimensions people are taking the easy way out. There should be a theory entropy statistic that is a measure of how complicated a theory is, and very complicated theories should be avoided.

42. **Thomas Larsson**
December 5, 2006

Ludmila, your first post was a response to my statement "String theory predicts supersymmetry – not seen." Evidently you found this objectionable.

String theory predictions have always been wrong in the past. Why should the LHC change this good old tradition?

43. **Ludmilla**
December 5, 2006

String theory predictions have always been wrong in the past. Why should the LHC change this good old tradition?

🙂 That's a good joke. But the same thing could be said of you and every other guy around. So, why should the LHC confirm any of *your* predictions, this one in particular?

44. **Thomas Larsson**
December 5, 2006

Why susy or extra-dimensions are unlikely to be seen at the LHC? Perhaps because other experiments put quite tight constraints on any deviation from the SM – unitarity triangles etc. Susy already requires fine-tuning at the percent level.

45. **Tony Smith**
December 5, 2006

Thomas Larsson said "String theory predictions have always been wrong in the past. ".
Ludmilla replied "… the same thing could be said of you and every other guy around. …".

No.
Some models do make predictions that have NOT always been wrong.
Some aspects of my personal example can be found in the abstract at http://arXiv.org/abs/physics/0207095 and in that paper.
My further work along those lines has been blacklisted by the Cornell arXiv,
but can be found on my web site.

I am not saying that my model is the only model that makes some correct predictions, only that it is one example and that the one example is all that is needed to refute Ludmilla's allegation that predictions of "every other guy" have "always been wrong".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

46. **Ludmilla**
December 6, 2006

one example is all that is needed to refute Ludmilla's allegation

Tony: "every other guy" means roughly "one out of every two". I have always considered you as part of that privileged predictive half.

47. **Tony Smith**
December 7, 2006

Ludmilla, my apologies for misunderstanding what you meant by "every other guy"
(half of the population,
as opposed to all of the population except Thomas Larsson)
and thanks for considering me to be part of the "predictive half".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – My misunderstanding may have been an example of a linguistic version of the ambiguous image phenomenon illustrated by the images at
http://www.questacon.edu.au/html/tg_p8a.htm
The way the human brain works with respect to such things is interesting, but probably off-topic for discussion here.

Lots of Links

December 5, 2006
Categories: Uncategorized

Various things that I've run across recently that seem worth mentioning:

The proceedings of the big yearly lattice gauge theory conference that was mentioned here, Lattice 2006, are now available here.

The New York Times today in its Science Times section has a very interesting article by Dennis Overbye entitled China Pursues Major Role in Particle Physics. It tells some of the history of particle physics in China, describes the BEPC accelerator in Beijing which has just had a luminosity upgrade, and discusses the role China may play in future accelerator projects, especially the ILC. A US physicist who sometimes works at BEPC, Frederick Harris, is quoted as saying "The rate China is growing, this is something they could contemplate hosting in 10 years." Perhaps the future of high-energy frontier accelerator projects really will be in China.

There's also an associated article about the spring 1989 physics conference in Beijing that overlapped with the Tiananmen Square massacre, with David Gross quoted as saying "Until the shooting began, the visit was delightful." He and Vafa describe the bloody van that was supposed to be their transport, after it had been used to pick up wounded students, two of whom died.

Physics World has an article about physicists willing to make bets, called Physicists who fancy a flutter, featuring Tommaso Dorigo's recent $1000 bet with Gordon Watts and Jacques Distler over what the LHC will see.

New Scientist has a feature article Physics Goes Hollywood, about Costas Efthimiou and a course he is teaching at the University of Central Florida. The idea of the course is to have students watch movies, often ones with a sci-fi theme, then use real physics to critique the accuracy of scenes in the movies. Costas is a particle theorist who has worked on conformal field theories, and was a visitor here at Columbia for a while, from what I remember. He has several papers about teachng physics using films, most recently this one.

The Cao-Zhu paper giving the details of the proof of the Poincare conjecture that originally appeared in the Asian Journal of Mathematics has now been posted in revised form on the the arXiv. The revised version includes an apology to Kleiner and Lott for not acknowledging the use of their work in the original version.

Geometric Langlands is definitely the hot topic of the moment, I just learned about two more conferences about this that will take place soon. One is a Gottingen Winterschule, on January 4-7, the second is a program on Langlands Duality and Physics, to be held at the Schrodinger Institute in Vienna from January 9-20.

A couple weeks ago in Hamburg there was a conference on Kahler Geometry and Mathematical Physics, held to celebrate the 100th birthday of Erich Kahler.

Princeton will be hosting a conference next year entitled Geometry and the Imagination in honor of Bill Thurston's 60th birthday.

Dmitry Vaintrob, son of mathematician Arkady Vaintrob, has won a $100,000 scholarship from the Siemens foundation based on a research project in string topology. For more discussion of this, and what it means for string theory, see here.

Update: Two more.

Giorgios Choudalakis took a poll back in August of grad-students, postdocs and professors associated with Fermilab, asking them what they expected the LHC to find. Here are the results. More about this at Fermilab Today.

A commenter points out that this week's Zippy the Pinhead deals with one character's doubts about string theory. Over the last few years, the comic has often dealt with string theory, to see this try typing "string" into this search page.

Comments

1. **Tony Smith**
   December 5, 2006

   Since the New York Times requires registration, I read an article on the freeinternetpress.com web site that said in part:
   "… China Pursues Major Role In Particle Physics 2006-12-05 … Dennis Overbye ..
   The proposed I.L.C. would shoot electrons and positrons at each other with 500 billion electron volts of energy through a tunnel 20 miles long. An approximate price tag will be announced when the international collider planning team meets in Beijing this February.
   … the jockeying for where to put the machine has already begun. The host country for the collider would have the advantage of being the center of 21st-century physics, but would have to bear a larger share of the cost.
   Last spring, a report from the National Academy of Sciences urged the United States to do what it takes to get it built here rather than in Europe or Asia, or face the prospect of relinquishing traditional leadership in physics.
   … Frederick A. Harris, a professor of physics at the University of Hawaii, who works often at the Beijing collider … said, "The rate China is growing, this is something they could contemplate hosting in 10 years."
   … Given the explosive growth of China's economy and the vow of the country's leaders to emphasize science and technology, it is natural to wonder whether some future particles will have Chinese names the way many of the bright stars in the sky have Arabic names. …".

   It is interesting that the USA lobby to get the ILC located in the USA has been proposing a site at Fermilab in Illinois, rather than a site on the Pacific Rim such as California.
   Since the USA lobby's choice of Illinois was based heavily on the political influence of Illinois Republican Dennis Hastert as Speaker of the House
   and
   since the November 2006 elections changed the 2007 Speaker of the House from Illinois Republican Hastert to California Democrat Pelosi,
   it will be interesting to see whether the USA lobby will change its focus to a California site, or even whether the new political situation will weaken the USA lobby so that the eventual site for the ILC will be in Asia, such as Japan or China.

   As Peter said, "… Perhaps the future of high-energy frontier accelerator projects really will be in China. …".

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

2. **SSC**
   December 6, 2006

I am not so sure that we will need a linear collider with center-of-mass energy equal to 500 GeV, not much above the old LEP. Maybe LHC will tell that it is enough for studying spetroscopy of supersymmetric particles. Or maybe not: LHC could instead suggest that we need to explore higher energies. While the US probably have psychological problems with a SSC-like project, China might like the idea of a SinoSuperCollider.

3. **Mary**
December 6, 2006

Since the readers of this blog are possibly the only people in the entire world who will think these comics are funny, I can't resist leaving another link: Zippy the pinhead is doing string theory again.

I have no affiliation with Zippy, just an appreciation for the deeply surreal…

4. **Chris Oakley**
December 6, 2006

Re: Zippy: I don't think that twins should get involved like that – or maybe the inbreeding of its advocates is the key to the success of String Theory – ?

5. **Garbage**
December 6, 2006

I dont understand, how can "the SM Higgs" and "no new Physics" be separated options?
Unless "no NP" means *nothing at all*, not even the Higgs, and that would be more than New!!! 🙂
I mean, somehow the EW Theory has to be unitarized, so *something* HAS to happen, or is *nothing* a logical option? Could the theory break unitarity, at a scale lower than the Planck scale so no QG effect (forget XD) and still make sense, without *anything* ELSE happening?

I'd like to know what was in the minds of those 9%…

6. **J**
December 6, 2006

I'm not sure whether China would play an important role in future particle accelerator programs, but I am thinking that China will definetely be part of it.

7. **Thomas Larsson**
December 7, 2006

*I mean, somehow the EW Theory has to be unitarized, so *something* HAS to happen, or is *nothing* a logical option?*

Was no aether wind a logical option for H. A. Lorentz?

AFAIU, no Higgs at the LHC would disprove QFT. Now **that** would be interesting, but perhaps not very likely. But then again, what is most unlikely, no Higgs at the LHC or no single top production at the Tevatron?

8. **Garbarge**
December 7, 2006

"AFAIU, no Higgs at the LHC would disprove QFT."

which means that *some NP* has to appear to make up a consistent theory. I am talking about the scenario where NOTHING is found.

"Was no aether wind a logical option for H. A. Lorentz?"

Jap, and that's how Relativity was born, new physics at the time 😉

December 7, 2006

Who,

The “axion” result looks highly unbelievable. I find it very hard to believe that if such a particle with that mass existed it wouldn’t have been seen before. Maybe someone more expert can give a more informed opinion about this.

12. **Matti Pitkanen**
December 7, 2006

It is not long time when an axion candidate from optical rotation experiments see posting of Lubos. The mass of this axion was in millieV range so that there is a difference of 12 orders of magnitude as compared to this axion. This makes me wonder why the term “neutral pseudoscalar particle” is not used instead of “axion”: is the reason political?

These two are not the only candidate for neutral pseudoscalars. I add here my comment to the blog of Lubos. The first evidence for pion/axion-like particles created in heavy-nucleus collisions near Coulomb threshold in MeV range came for more than 20 years ago. I developed a TGD based model for their strange production characteristics for more than 15 years ago.

TGD explanation was based on what I called leptohadron physics with quarks replaced by color octet excitations of electrons allowed by TGD view about color. The production mechanism was creation of leptopions in strong non-orthogonal E and B with action given by E.B. Coupling to photons is dictated by partically conserved axial current hypothesis and identical with the coupling of pion/axion. The mass of the lowest leptopion state is very nearly to 2 times electron masses. Also heavier excitations on Regge trajectory are predicted: actually entire spectroscopy of leptomesons and leptobaryons.

Exotic quarks with MeV mass scale and corresponding to Mersenne prime M_127=2^k-1, k=127, characterizing electron, play a key role in TGD based model of nuclei as string like structure with threads connecting nucleons having quark and antiquark at their ends. The model explains tetraneutron and predicts a new exotic states of nuclei.

Quite generally, TGD predicts entire hierarchy of p-adically scaled up variants of standard model physics with mass scales coming as powers of half octaves. p=about 2^k. k prime or power of prime, are favored. Hence pionlike states should exist at various length scales and serve as a signature of various scaled variants of QCD like physics.

*Mass scale 8 MeV (compare with 7 MeV) would correspond to k= 11^2, and thus power of prime.
*Mass scale of 16 MeV (compare with 19 MeV) to p=about 119=7*17.

Below a list of references about early evidence for pionlike states which people for some reason probably related to shortcomings of ancient theories(want to call axions.

December 8, 2006

“Was no aether wind a logical option for H. A. Lorentz?”
Jap, and that’s how Relativity was born, new physics at the time

This is not correct. The proponents of aether theory discovered much of the math of SR, e.g. Lorentz transformations and Poincare algebra. But abandoning aether theory, i.e. saying that Newton’s mechanics is wrong, was a step that they could not take. It took Einstein to do that.

Noone denies that QFT has passed every test for 60 years. But Newton passed every test for 200 years, and was nevertheless superseded by something better. 4D QFT has its problems (incompatible with gravity, renormalization mathematically dubious), and if not even a Higgs shows up at the LHC, it will have problems with unitarity as well. If so, a modification of QFT which preserves unitarity seems necessary.

I don’t seriously think this will happen. But saying that the LHC must see at least a Higgs to save unitarity is similar to saying that Michelson-Morley must see an aether wind to save Newtonian mechanics.

14. **Lux**
December 9, 2006

If no higgs particle were observed, then the higgs sector of the SM would be wrong. It would mean that the mechanism of SSB is different in nature from the simplest possibility implemented in the SM. There are many Higgsless models around, the LHC could tell us if any of them would be right in that case.

But it is the “Higgsless SM” that has problems with unitarity, not QFT. QCD is a QFT, and it’s perfectly unitary whether there’s a HIggs in nature or not.

15. **anonymous**
December 10, 2006

Lux, the trouble is any “Higgsless” model necessarily requires a new particle at or below 800 GeV-ish, which the LHC should be able to find. But 10% of the people in the poll said “no new physics”, which seems logically inconsistent — do those 10% of people really expect violations of unitarity? More likely they meant “only an SM Higgs” and didn’t notice the other option?

16. **Lux**

December 10, 2006

"Nothing at all" is clearly not an option. If anything, without a Higgs electroweak boson physics is going to get quite interesting.

17. **Bob**
January 5, 2007

Efthimiou is a well respected professor at UCF and an all-around good guy.

Polchinski Review at American Scientist and Cosmic Variance

December 7, 2006
Categories: Not Even Wrong: The Book

This month's American Scientist has a review entitled All Strung Out? of *The Trouble With Physics* and *Not Even Wrong* by prominent string theorist Joe Polchinski, and he has posted a slightly edited version of the review with some explanatory footnotes at Cosmic Variance. I assume there will be a lot of discussion of it over there, perhaps with Polchinski participating, so, even though I wanted to write some sort of response here, I'll leave comments off and encourage people to discuss this over at CV.

First of all I should say that I was quite pleased to see Polchinski's review. While I disagree with much of it, it's a serious and reasonable response to the two books, the kind of response I was hoping that they would get, opening the possibility of a fruitful discussion. Unless I've missed something, the only review by a string theorist to appear in a publication so far has been Susskind's almost purely ad hominem one in the Times Higher Education Supplement. There also are two other (not published in conventional media) reviews by string theorists that I know of, a serious one by Aaron Bergman, and a nutty one by Lubos Motl that Princeton University Press paid him to write for some mysterious reason. I've heard that several publications have had a hard time finding a string theorist willing to write a review of the books, which I guess is not too surprising. It's not obviously a rewarding task to involve oneself in a controversy that has become highly contentious, and where some of the main points at issue involve very real and serious problems with the research program one has chosen to pursue.

Much of Polchinski's review refers specifically to Smolin's arguments; some of it deals with the endless debate over "background independence", and the "emergent" nature of space-time in string theory vs. loop quantum gravity. I'll leave that argument to others.

Polchinski notes that I make an important point out of the lack of a non-perturbative formulation of string theory and criticizes this, referring to the existence of non-perturbative definitions based on dualities in certain special backgrounds. The most well-known example of this is AdS/CFT, where it appears that one can simply define string theory in terms of the dual QFT. This gives a string theory with the wrong number of large space-time dimensions (5), and with all sorts of unphysical properties (e.g. exact supersymmetry). If it really works, you've got a precisely well-defined string theory, but one that has a low-energy limit completely different than the standard model in 4d that we want. This kind of string theory is well-worth investigating since it may be a useful tool in better understanding QCD, but it just does not and can not give the standard model. The claim of my book is not that string theories are not interesting or sometimes useful, just that they have failed in the main use for which they are being sold, as a unified theory of particle physics and gravity.

The lack of any progress towards this goal of a unified theory over the past 32 years (counting from the first proposal to use strings to do unification back in 1974) has led string theorists to come up with various dubious historical analogies to justify claiming that 32 years is not an unusual amount of time to investigate a theory and see if it is going to work. In this case Polchinski argues that it took about 50 years to get from the first formulation of QED to a potentially rigorous non-perturbative version of the theory (using lattice gauge theory). The problem with this analogy is of course that in QED non-perturbative effects are pretty much irrelevant, with perturbation theory describing precisely the physics you want to describe and can measure, whereas with string theory the perturbative theory doesn't connect to the real world. When QED was first written down as a perturbative theory, the first-order terms agreed precisely with experimental results, and if anything like this were true of string theory, we wouldn't be having this discussion. For the one theory where non-perturbative effects are important, QCD, the time lag between when people figured out what the right theory was, and when its non-perturbative formulation was written down, was just a few months (Wilson was lecturing on lattice gauge theory in the summer of 1973, having taken up the problem earlier in the year after the discovery of asymptotic freedom).

Polchinski agrees that the key problem for string theory is its inability to come up with predictions about physics at observable energies. He attributes this simply to the fact that the Planck energy is so large, but I think this is misleading. The source of the problem is not really difficulties in extrapolating from the Planck scale down to low energy, but in not even knowing what the theory at the Planck scale is supposed to be (back to that problem about non-perturbative string theory…).

Weinberg's anthropic argument for the size of the cosmological constant is described by Polchinski as a possible "prediction" of string theory, and he recommends Susskind's book as a good description of the latest views of string theorists. I've been far too rude to Polchinski in the past in expressing my views about this "anthropic landscape" philosophy, so I won't go on about it here. He neglects to mention in his review that many of his most prominent colleagues in the string theory community are probably closer in their views on this subject to mine and Smolin's than to his, and that our books are the only ones I know of that explain the extremely serious problems with the landscape philosophy.

Recently string theorists have taken to pointing to attempts to use AdS/CFT to say something about heavy-ion physics as a major success of string theory, and Polchinski also does this. I'm no expert on this subject, but those who are like Larry McLerran have recently been extremely publicly critical of claims like the one here that "Physicists have found that some of the properties of this plasma are better modeled (via duality) as a tiny black hole in a space with extra dimensions than as the predicted clump of elementary particles in the usual four dimensions of spacetime." My impression is that many experts in this subject would take strong exception to the "better" in Polchinski's claim.

Finally, about the "sociological" issues, Polchinski disagrees about their importance, believing they are less important than scientific judgments, but I'm pleased to see that he does to some extent acknowledge that there's a serious question being raised that deserves discussion in the theoretical physics community: "This convergence on an unproven idea is remarkable. Again, it is worth taking a step back and reflecting on whether the net result is the best way to move science forward, and in particular whether young scientists are sufficiently encouraged to think about the big questions of science in new ways. These are important issues — and not simple ones."

Again, my thanks to him for his serious and highly reasonable response to the two books.

Comments

1. **Michael Bacon**
   December 7, 2006

   I thought he treated you better than Lee. Apart from literary comments, and a couple of other hits, his focus on "predictions" was correct, but a conclusion that they are impossible seems a little over the top. Some of this other comments were fair, others were not. How's your book doing anyway?

2. **LDM**
   December 7, 2006

   Just because it is not ad hominem does not mean it is a good review…and it is not…in the sense that a layperson reading it would get an incorrect view of the challenges faced by string theorists.
   Polchinski makes little effort to be accurate and his bias is clear. For example, he incorrectly minimizes the lack of convergence (also mentioned by Penrose, incidentally) of the pertubative expansion. He mentions black holes as an application of string theory, when in fact these black holes are not ones we observe, and scarcely qualifies as an application as is normally understood by the meaning of the word.
   I must say after reading this review, I unfortunately lost a certain amount of respect for Polchinski.

3. **r hofmann**

December 8, 2006

From my own experience with him I agree with the statement that Polchinski is a fair-enough person and surely one of the fastest thinkers available today (not necessarily implying an important role in furthering our understanding of fundamental physics). Since he likes to point out that there are nonperturbative formulations of superstring theory I think it would be reasonable to mention the resolution of the vacuum instability of perturbative bosonic string theory in the presence of D-branes (Sen's work) which to my mind takes away a major motivation to introduce supersymmetry on the world sheet (just like the absence of a naive Higgs sector in the SM may forbid mention of a so-called gauge hierarchy problem).
As far as ADS/QCD as an 'explanation' for certain strong-interaction effects in heavy-ion collisions is concerned I am convinced that these claims are completely unfounded and dangerous because misleading.

4. **MoveOn**
December 8, 2006

"…which to my mind takes away a major motivation to introduce supersymmetry on the world sheet…"

Are you sure you know what you talk about? Susy on the world-sheet is needed to describe fermions, even in a theory that is not supersymmetric in space-time.

"As far as ADS/QCD as an 'explanation' for certain strong-interaction effects in heavy-ion collisions is concerned I am convinced that these claims are completely unfounded and dangerous because misleading."

Is this conviction based on a similar deep understanding of the matters you attempt to judge here?

5. **r hofmann**
December 8, 2006

MoveOn, I believe I know exactly what I am talking about! I was talking about the vacuum instability of a purely bosonic string theory which seems to be cured in the presence of D branes. My personal feeling about fermions is that they are emerging phenomena in certain field theories (YM to be precise) and thus even as a concept should not enter into something soooooo fundamental as a string theory (be it supersymmetric or not in spacetime). I appreciate constructive remarks for one thing. On the other hand, I have developed a certain immunity against put-down attempts of hot-shot string educators.

6. **wolfgang**
December 8, 2006

Peter,

I am just curious; How many copies of your book have been sold until now?

7. **MoveOn**
December 8, 2006

R Hofmann: " My personal feeling about fermions is that they are emerging phenomena in certain field theories"….

Well, if you can provide a model in which the fermions we observe, quarks and leptons that is, emerge from a YM theory, then surely many would appreciate it I do know that via the spin-from-isospin mechanism, fermionic excitations can occur in monopole backgrounds, do you mean something like that? But that hasn't to my knowledge lead to anywhere. And in fact there had been ideas around a while ago where the superstring spectrum arises as some kind of solitons from the bosonic string. Also that AFAIK didn't lead to anywhere.

For the time being, such speculations are much more far fetched than speculations about ordinary supersymmetric field and string theories. Same applies to your apparent disbelief in the HIggs mechanism (I think it was you who expressed that?). The moment you or someone else comes up with any remotely working "alternative" model, that would be great and hundreds would follow right away. But criticising string and/or susy field theories in a generic manner, in the sense "I don't like any of that" for ideological or whatever personal feelings without having anything concrete in hands, is too cheap. Just saying "fermions should be emergent" is in my humble opinion not enough to constitute "constructive criticism".

But constructve criticism is something I haven't seen in this debate anyway. And that's no surprise.

8. **Peter Woit**
December 8, 2006

Not sure what happened here, thought I had turned off comments…

Still, I encourage people to discuss the Polchinski review over at CV. And stop the off-topic and un-enlightening sneering and hostility.

As for how the book is selling, I have only a vague idea, based on the Amazon rankings. As far as I can tell it's doing better than the average book in this area, but is far from a best seller. In other words, somewhat better than Susskind's, nowhere near Brian Greene's. I'm quite happy that the book seems to be doing better than I expected, but, no, it's not going to make me rich. Publishers report sales to authors I guess quarterly, with reports taking quite a long time to be prepared. So, at this point the only sales report I have is from the end of June in the UK, soon after the book went on sale.

9. **r hofmann**
December 8, 2006

MoveOn, ok let's behave … Although Peter doesn't like people being too explicit about their own brain childs at this location I sketch you hereby what I believe a lepton is. SU(2) Yang-Mills theory has a confining phase whose ground state is a condensate of paired, massless magnetic center-vortex loops. Excitations above this ground state are unpaired or twisted center-vortex loops, each selfintersection point constituting a Z2 charge of mass Lambda (the YM scale). If you want to read more about this I refer you to our papers. Peter, please don't see this as an advertisement, its just answering MoveOn's question. In the absence of any experimental evidence of susy but in the presence of anomalies in z pinch experiments, PVLAS, and CMB low multipoles I don't quite see why you believe that admittedly speculative proposals of the kind sketched above are wilder than the MSSM for example.

10. **michael**
December 8, 2006

Dear Ralf,

What you say about the bosonic string is not quite correct. Sen's work has to do with open string tachyons, the closed string tachyon instability remains.

Michael

11. **M**
December 8, 2006

The practical reason why studying non-perturbative phenomena is important is that simple perturbative string models are not realistic. The fact that we now know the extreme non-perturbative limit and that it turned out to be dual to some other perturbative string (i.e. something unrealistic again) means no progress on the above crucial issue.

12. **huh?**
December 8, 2006

Actually, in many models of physics that explain the electroweak scale,
nonperturbative effects are thought to explain the ratio M_W/M_P which is
tiny. This is true in models where susy explains the higgs mass, for instance.
That has driven a lot of interest in studying nonperturbative phenomena.
It is simply not true that people study them only when perturbation theory
"seems to give the wrong answer"; often, as in the case of susy mentioned
above, one carefully looks for circumstances where an effect is
nonperturbative, in order to explain a small ratio in nature. Many such
dimensionless small ratios exist in our standard models.

13. **Michael Bacon**
December 8, 2006

Somewhat better than Susskind's, nowhere near Brian Greene's sounds like just the right spot.

14. **M**
December 8, 2006

huh?, I mean that string models in the weakly-coupled limit predict many non-existing massless moduli (e.g. dilaton gravity instead of gravity): a careful engineering work allows to (meta)stabilize all moduli, but this resulted in the infamous landscape. Years ago the hope was that non-perturbative effects could qualitatively improve the situation. However the present understanding of non-perturbative effects via strong/weak dualities means that in the opposite strong coupling limit one gets the same physics as in the weak coupling limit, and so again the same problems.

15. **Yatima**
December 9, 2006

Well, "The Trouble with Physics" is in the list of "Best Books of 2006" in this week's "Economist". Here's the list for the heading "Science and Technology":

The Revenge of Gaia: Earth's Climate Crisi and the Fate of Humanity. By James Lovelock.
The God Delusion. By Richard Dawkins.
The Omnivore's Dilemma: A Natural History of Four Meals.
The Trouble With Physics: The Rise of String Theory, the Fall of Science, and What Comes Next. By Lee Smolin.

Not an uncontroversial book selection, I would say.

16. **Damysus**
December 9, 2006

The edge.org in its last enquiry asked its correspondents to write a few lines about what they believe, but cannot prove. I believe, but cannot prove, that Ad/CFT with a dual QFT string definition will be found to be correct, but will need a redefinition of dimensions (4+1) and the realisation of a very heavy Higgs. Polchinski may be seeing a rather dim light at the end of a stringy tunnel…

Yet More Links

December 12, 2006
Categories: Uncategorized

The January Notices of the AMS is out. Two quite interesting articles, one of which is an interview with my colleague Joan Birman. She just recently officially retired, but, at the age of 79 is still very active in research and a major presence in the department, an example to us all. The second is an article by Anatoly Vershik about the Clay Millenium Prizes. Vershik argues that these million dollar prizes are not good for mathematics, and that the story of the proof of the Poincare conjecture shows why. Top mathematicians who think they have a chance of solving one of the Clay problems are going to work on them whether or not the prize exists (the money certainly didn't motivate Perelman). The prizes give the public a deformed view of what is important about mathematics and encourage unseemly squabbling about how "credit" for a solution will be assigned. Vershik writes:

In my opinion, all this clamor and fuss show that this method of promoting mathematics is warped and unacceptable, it does not popularize mathematics as a science, on the contrary, it only bewilders the public and leads to unhealthy interest.

There's an excellent article about James Clerk Maxwell in the December Physics World. It's the 175th anniversary of Maxwell's birth this year. He lived only to age 48, dying in 1879. The author of the article speculates that "Had he not died so young, Maxwell would almost certainly have developed special relativity a decade or more before Einstein."

For an update on the US federal budget situation for science, see this AAAS web-page. As far as I can tell, the situation is that (as often happens) the Congress has not yet passed FY2007 appropriations for most of the government, including the DOE and NSF, even though we're now more than a couple months into the fiscal year. As a result, these agencies are operating under a continuing resolution, without access to the increased funds that were supposed to flow because of the "American Competitiveness Initiative". The new Congress will have to deal with this after it convenes in January, and news reports I heard today said that Congressional leaders were considering not producing new appropriations bills but running the government on a continuing resolution for the rest of FY2007. Unclear to me what this means for science funding, but it doesn't sound good. Over the next few years, if the new Democratic Congress makes a serious effort to bring the US federal budget deficit under control, science funding may be under pressure.

At the Scientific American blog, J R Minkel has a story called Comic Books Looove String Theory, about developments in the Ex Machina comic, which is about "a retired semi-super hero turned Mayor of New York City who can control machines with his mind." In issue 10 a lunatic starts ranting

It's not about the branes, it's about the bulk. You were supposed to tell people… Witten is close, but we're closer.

Minkel doesn't mention the recent string theory themes in Zippy the Pinhead.

Witten's new paper with Gukov mentioned here is now available. It is about 160 pages long and generalizes the earlier Kapustin-Witten paper to the ramified case. This involves constructing "surface operators" in the 4d gauge theory, operators attached to surfaces in much the same way 't Hooft operators are attached to curves. Unfortunately it doesn't discuss connections to Khovanov homology that Gukov described in his Strings 2006 talk "Surface Operators in Gauge Theory and Categorification" (I'd provide a link, but the Strings 2006 site seems to be down). The authors also note that Frenkel and Gaitsgory have a "unified approach" to this ramified case, but that "Unfortunately, we make contact here neither with the use of conformal field theory nor with this unified statement. We hope, of course, to eventually understand more." So, there's lots more to do…

If you want to get an idea of what it costs to run a theoretical physics center, check out the report of the Michigan Center for Theoretical Physics. The interim director of the MCTP is Gordon Kane, and they will be hosting a symposium next month to celebrate his 70th birthday.

Over at Cosmic Variance, there's a discussion of the new Martin Scorsese film String Kings, which features "a scene showing work on an extension of the New Jersey turnpike, involving string henchmen (disguised with hard hats and overalls) a large cement truck and Peter Woit." I guess this doesn't seem like such a great plot idea to me for some reason. Personally I've been thinking that the whole recent controversy over string theory would make a great comic novel. The thing to do is to somehow get David Lodge interested…

Update: The Strings 2006 site is back up, and the Gukov talk mentioned is here.

Update: More about the FY 2007 science budget situation from Science and from FYI.

Comments

1. **a**
   December 12, 2006

   "Had he not died so young, Maxwell would almost certainly have developed special relativity a decade or more before Einstein."

   That article states:

   "A velocity appeared in his theory also, but with a different numerical value that had no obvious physical meaning. Maxwell plugged Weber's force ratio into his equations and discovered to his utter astonishment that the velocity exactly equalled the speed of light, which was then known experimentally to an accuracy of 1%. With excitement manifest in italics, he wrote, "We can scarcely avoid the inference that light consists in the transverse undulations of the same medium which is the cause of electric and magnetic phenomena."

   This isn't true, (1) the ONLY numerical value by dimensional analysis using the electric and magnetic constants is was 300,000 km/s, (2) Maxwell did not predict c.

   Dr Alan F. Chalmers' article, 'Maxwell and the Displacement Current' (Physics Education, vol. 10, 1975, pp. 45-9). Chalmers states that Orwell's novel 1984 helps to illustrate how the tale was fabricated:

   '… history was constantly rewritten in such a way that it invariably appeared consistent with the reigning ideology.'

   Maxwell tried to fix his original calculation deliberately in order to obtain the anticipated value for the speed of light, proven by Part 3 of his paper, 'On Physical Lines of Force' (January 1862), as Chalmers explains:

   'Maxwell's derivation contains an error, due to a faulty application of elasticity theory. If this error is corrected, we find that Maxwell's model in fact yields a velocity of propagation in the electromagnetic medium which is a factor of [root 2] smaller than the velocity of light.'

   It took three years for Maxwell to finally force-fit his 'displacement current' theory to take the form which allows it to give the already-known speed of light without the 41% error. Chalmers noted: 'the change was not explicitly acknowledged by Maxwell.'

Weber, not Maxwell, was the first to notice that, by dimensional analysis (which Maxwell popularised), 1/(square root of product of magnetic force permeability and electric force permittivity) = light speed.

The whole story is an insult to any physicist of integrity. Fairy tales distorted from historical facts don't have a place in physics.

Maxwell never wrote the Maxwell equations in vector calculus. He had 20 differential equations and never summarized 4 or 5 key equations, which were written by Heaviside. Hence the doubtfulness of the popular claim made http://www.mathpages.com/home/kmath103/kmath103.htm that Maxwell considered the need for a divergentless field using vector calculus and was led to his discovery in the same way Einstein invented general relativity:

'Just as the inclusion of the "displacement current" in Ampere's formula was the key to a Maxwell's self-consistent field theory of electrodynamics, so the inclusion of the "trace stress-energy" in the expression for the Ricci tensor was the key to Einstein's self-consistent field theory of gravitation. In both cases, the extra term was added in order to give a divergenceless field.'

The most important thing Maxwell did do, which he isn't given credit for, is predicting the electron in the 3rd ed of his Treatise on Electricity and Magnetism. (J.J. Thomson, editor of Maxwell's Treatise, is given credit for discovering the electron when he just measured the charge to mass ratio.)

The claim that Maxwell would have discovered relativity is utter nonsense. There is nothing in Maxwell's work that even discusses these issues, and with good reason – there were too many other basic problems to work on (and not just in electromagnetism) and no experimental evidence at all for the relativity of simultaneity. And just because Maxwell discovered that light is an electromagnetic phenomenon, this in no way "points forward to Einstein and relativity". If anything, it points forward to Lorentz. But even that is a stretch. What it does it to point into the mirror – at Maxwell himself, who needs no context other than the one he provided himself.

December 12, 2006

I have to say that I don't really understand Vershik's argument. The prize had nothing at all to do with stimulating mathematics research in the short term, which he essentially admits in various points in the article; thus, explaining that Perleman didn't do what he did because of the prize is totally irrelevant.

What the prize did do was to generate a ton of media attention for topology and Poincare. Vershik also addresses this and manages to conclude that it's a bad thing, mostly by inexplicably trying to blame the prize for the bad behavior of various mathematicians. Um, I guess that's possible, but I don't really see it.

Here's something I *did* see, though: in the weeks surrounding the Poincare/Perleman media explosion, I had probably more than a dozen long conversations about topology and the conjecture with non-mathematicians in social situations — and I was never the one who brought it up. Sounds like the prize generated press coverage which, in turn, generated a lot of discussions about math. Which sounds like a success to me…

4. **Peter Woit**
December 12, 2006

Hi Daniel,

I have mixed feelings about it, posted about Vershik because I thought it was an interesting and not often expressed point of view. The main thing about the Clay prize that bothers me is the way it depends on picking a person to give the $1 million to, or even worse, trying to decide how to split it among several people. Great mathematical results almost always involve the efforts of more than one person, with no sane way of assigning percentages to each person's contributions.

If I had my druthers, the way it would work would be for the $1 million prize to be awarded at the point the Clay committee agrees that the problem has been solved (or maybe wait a couple years), but that the money should not go to the people who solved it (who, after all, are likely to be rewarded by the university star system with amounts adding up to over $1 million). Instead, the comittee would give the money to some organization or organizations that could use it. In the case of Poincare, giving the money to the support of Russian mathematics research might be appropriate.

5. **Chris W.**
December 12, 2006

Almost any media phenomenon that attracts the attention of millions of people will end up leaving one with reasons to be ambivalent about its effects.

That's inevitable in a democratic mass culture, with enormous diversity in the exposure of the audience to mathematics, not to mention the diversity of individual temperaments and talents. In the case of the Clay Millenium Prizes it seems quite reasonable that the balance might lean to the negative where the culture of mathematics is concerned, for reasons like those Peter mentioned, while leaning in the positive direction where the general public's awareness and interest in mathematics is concerned.

Whenever I reflect on the experiences that first excited my interest in the sciences and mathematics, my positive appreciation for them is also mixed with a certain rueful appreciation for their vulgarity or superficiality, as seen in retrospect. It's enough that one eventually attains that level of understanding and is willing to talk about how one arrived at it. From this point of view there is little point in deploring the original experiences and the ignorance and credulity that might have accompanied them. I'm therefore inclined to agree with Daniel's apparently positive assessment, but then again I'm not a professional mathematician.

That said, it is just as well that misgivings are publicly expressed, because that can also contribute to public understanding of the practice of mathematics and the motivations for doing it. Any thoughtful person with a genuine interest in the subject can learn from the diverse viewpoints expressed in the discussion of the Millenium Prizes.

6. **Turkey Royale**
December 13, 2006

Vershik, who is a serious mathematician, articulates a viewpoint not often enough heard in The US (and western Europe?), namely that one studies mathematics or physics or whatever for the love of the thing and the interest in knowing and aesthetic reasons, and that the best mathematics/physics/etc. comes out of research so motivated rather than out of programmatic, externally directed, or `practically' motived research.

Vershik expresses himself with care and with nuance; he is not dogmatic and it was my impression that he takes seriously the motivations advanced by the Clay Institute for its prizes. He certainly does give credit to the motivation of stimulating youths with an interest in math, and he does not disparage the need for educating the general public about math (judging from his extensive professional involvements, he is well aware of the complexities of funding mathematics research). As an aside he seems to want to put on record an authoritative debunking of some of the claims made about Perelman, while still respecting Perelman's privacy (that is not providing correct information, simply pointing out the incorrect); whether he succeeded, I don't know, since I don't know the true state of affairs vis-a-vis Perelman.

Vershik does not agree with Paris Hilton than any publicity is good, whereas many mathematicians in `the West' do. One might crudely summarize his critique as – perhaps amateur pornography is not the best way to promote oneself.

Vershik operates with an implicit distinction between `unhealthy interest' and healthy interest in mathematics. He also worries that placing a priori value on the solution of certain problems accords unnecessarily importance to those problems, and perhaps makes the study of non-anointed problems, or themes, more difficult. By the way, he clearly does not view mathematics as the business of solving problems already clearly posed; I suspect for Vershik the activity of researchers like Gromov or Thurston (who in some sense are anything but problem solvers) is more congenial than was the activity of Erdos, although he respects also Erdos.

His is not a simplistic `mathematics for mathematics sake', although I may have made it sound that way. On the other hand, it seems to me he is implicitly critquing the programmatic, business part of scientific research in particular in the US.

7. **plank**
December 13, 2006

“Maxwell never wrote the Maxwell equations in vector calculus. He had 20 differential equations and never summarized 4 or 5 key equations, which were written by Heaviside.”

— — — —

actually I think he did manage to summarize the equations using a quaternionic formalism. It’s been quite a while since I’ve read this so I could be wrong.

8. **David Corfield**
December 13, 2006

On page 29 of this I expressed similar sentiments to Vershik’s. If the prizes have any effect on mathematicians, it won’t be towards the greater openness to which we aspire at the n-category café.

9. **D R Lunsford**
December 13, 2006

plank – That is right – that’s what really annoyed me about the relativity statement – it ignored Heaviside, Gibbs, Lorentz, Hertz, Roentgen, and on and on, all the people who discovered the phenomena and developed the theory before Einstein came along and put it all right.

For the record, Maxwell had his own phrases for div grad and curl (*con*vergence, slope, and *twirl*) and did in fact apply quaternions to his theory, sometime in the early 1870s before his book was published. I don’t recall if it is in the book but I think it is at least mentioned.

However he did not have grad – i d/dt, which you need to really do his theory with quaternions. Had he had that, THEN he would have been one step away from the Lorentz transformation.

-drl

10. **Peter Shor**
December 13, 2006

Of course, a novel about the string theory controversy (if it’s not one of those postmodern novels) requires some kind of ending. Here are some possibilities.
(1) The string theorists are unexpectedly vindicated by LHC. (Many string theorists clearly are hoping for this ending, even though it seems rather unlikely.)
(2) The hero has a mental breakdown, quits theoretical physics, and writes a semi-autobiographical best-selling novel. (Also unlikely.)
(3) Finer examination of the cosmic microwave background reveals a message from God, in which He reveals the true workings of the universe. None of the competing theories come even close to the right answer. (I’m not betting on this outcome either.)

11. **Chris W.**
December 13, 2006

At risk of beating a dying horse, I’ll ask yet again what “vindication” of string theory by results from the LHC is supposed to mean, in light of the string theory Landscape, which seems capable of “vindication” by just about any result one pleases.

Is this not the case? If so, why not? My assumption is that the current efforts to statistically survey the structure of the Landscape represent fairly desperate and ever more unpromising attempts to answer these questions. Without such answers the above-mentioned hopes of many string theorists would seem to be simple delusions, regardless of what the LHC reveals.

(All this reminds me of undergraduate attempts to prove some mathematical assertion in the wee hours of the morning, which end pathetically in “establishing” some tautology.)

12. **Jonathan Vos Post**
December 14, 2006

Is there really a Physics equivalent of this?

By definition, a [first order] Celebrity is someone who is famous for being famous. Paris Hilton is a second order Celebrity: someone who is famous for being unjustifiably a first order Celebrity. More and more, morning major network “news” programs feature interviews with second order Celebrities who have appeared on some “reality TV” show on the same network as the “news” program.

Although there have been Physicists who became first order celebrities, although treated as second order, such as Einstein, Sagan, and Hawking, I am not aware of any true second order Celebrity Physicists, aside from TV personality engineers masquerading as scientists, such as Bill Nye Science Guy, and the debate raging about String Theory. Am I wrong?

13. **Arun**
December 14, 2006

Maxwell’s treatise on electricity and magnetism is viewable on books.google.com

14. **Lame**
December 15, 2006

Peter:

We are begging, BEGGING you to give us an actual technical argument here; why do you ALWAYS rely on authority when any physics issue comes up? Much easier playing pretend physicist on your blog huh? Sure impresses all your fans, particularly convenient that it requires NO INTELLECTUAL EFFORT OR SKILL on your part! Nice deal.

You remind me of those annoying undergraduates who talk a big game but don't actually KNOW anything. How about backing up your words with some content for once? Can you do that without running away to Mommy/Daddy/d'Hoker and Phong to bail you out when the discussion requires actual knowledge? Tell us what is wrong with AMS with an argument other than "people who know tell me there is something wrong with AMS".

Lousy science journalists will fall for your act Peter, but you don't fool a single decent theorist.

15. **Jonathan**
December 15, 2006

The files from the strings 2006 talks still seem to be online and at least here in China I can access them.
http://strings06.itp.ac.cn/?id=agenda_arr

If you really can't see them from the US then e-mail me and I can speak to those in charge of the site.

J

16. **Peter Woit**
December 15, 2006

Jonathan,

Thanks! The site seems to have just been temporarily down. I'll add the link to the Gukov paper.

Lame,

Thanks for the hilarious parody of the behavior of Jacques, Clifford, Lubos and various of their anonymous allies over at Asymptotia. Very, very funny!

17. **D R Lunsford**
December 15, 2006

Arun – that is very nice – I see he does mention quaternions in passing but does not attempt a systematic development (articles 618 and 619 in ch IX). That is good because none was possible. It does make one wonder if he had considered adjoining d/dt to grad.

-r

18. **Ari Heikkinen**
December 15, 2006

"Vershik argues that these million dollar prizes are not good for mathematics"

I couldn't disagree more. I mean, if there's a million dollar prize, it'll make the brightest minds pursue those ideas worth the prize.

I think the most useful problems to the human kind should have prizes worth even more.

Surely, even Peter, as a mathematician, would gladly work on something worth a million dollars prize, if that's something he'd have a good intuition to work on.

19. **Ari Heikkinen**
December 15, 2006

And my only hope is that Peter Woit and Brian Greene can go have beers and disagree with respect.. 😉

If they can't, then science isn't probably worth any funding from the government's perspective..

20. **Peter Woit**
December 15, 2006

Ari,

I'm not so sure the million dollars makes much difference on whether people work on these famous, high-profile mathematics problems. If I thought I had a good idea about how to solve one of them, I'd work on it, even if it didn't have the million dollars attached. Unfortunately I don't have any promising ideas about any of those problems, so it's not an issue….

And don't worry, I and Brian have never had a problem disagreeing respectfully, and this is true of just about all the string theorists I know. The weird unprofessional behavior of a small number of them in response to scientific disagreements has very much surprised me in recent years.

21. **nontrad**
December 15, 2006

I've posted here several times, because I hang out here quite a bit; because I appreciate whatever it is that I appreciate about it…

But, for whatever reason, it seems appropriate at this juncture to say that as far as I am concerned NEW is well worth the effort and not *just* because I have similar dispositions to concerns in, for a complete lack of anything better to call it, the philosophy/economics/policies of today's physics but because I find this blog to consistently be a collection of excellent / affordable / cogent pieces of writing about topics I find fascinating. It's damn good blogging… is what I'm saying!

But, I think it speaks volumes that unnecessarily aggressive posts repeatedly appear here. Not that authors shouldn't think twice about their statements: This is the internet afterall and we all speak freely here. Instead, the record speaks for itself.

22. **Neville**

December 15, 2006

In my experience, much of the general population views mathematics as a dead subject, which reached its zenith with the discovery of long division. Many scientists and engineers of my acquaintance seem to think mathematical discovery was finished in the 19th century. The Clay Millenium Prizes publicize mathematics as a living subject. Perhaps some youngsters will find inspiration in the notion that mathematical mysteries abound.

23. **mathjunkie**
December 16, 2006

The author of the article speculates that "Had he not died so young, Maxwell would almost certainly have developed special relativity a decade or more before Einstein."

What is the basis of saying that?

24. **Steven H. Cullinane**
December 17, 2006

The January AMS Notices now has online a letter from Birman on the Yau-vs.-New-Yorker controversy.

25. **I Care**
December 18, 2006

The entire academic community needs to police itself (field by field) to ensure that the same (more or less) review process be applied to every paper submitted to a particular journal, regardless of how influential/famous/well-established its author(s) or editor(s) may be. That may sound a bit idealistic, but if one is not, one shouldn't be working in the ivory tower anyway. Academic politics is oxymoronic to me, if the area one studies is indeed objective and rigourous.

26. **Peter Orland**
December 20, 2006

I Care:

If large communities of people police themselves, they will
soon become victims of police brutality. Academic freedom
has drawbacks; nastiness, unfairness, etc. But policing academic
communities (even self-policing) will have ten times as much
of these drawbacks. If you think academic politics is bad, imagine
how it would be with acedemic aristocracy.

27. **Moeen**
December 23, 2006

Peter,

I'm not sure how you come to your conclusion. What's wrong with setting ethical standards in academic communities and making sure there are consequences for people that violate those standards regardless of their fame or influence? I don't see how this would create an "academic aristocracy", this is about ethics, not politics, and with few people outside academic communities with an interest in policing them, self-policing seems like a pretty good idea.

28. **Peter Orland**
December 24, 2006

Moeen,

There are such ethics. There are consequences. I know
pesonally of cases where famous people have had their
papers rejected because they did not meet certain standards (unfortunately, I can't tell you who who). There is peer
review. Sure, the system isn't perfect. But yes, it IS about
politics.

In free academic communities, just as in free societies,
people often get away with unethical behavior. This problem
won't be cured by imposing more control. A "self-policed" academia is inevitably going to be policed by some selves
and not by other selves.

What people who advocate more control on any
society overlook; in a more rigorously-policed society, just
as in a self-policed state, MORE people get away with WORSE unethical behavior. Rigorously-policed societies have more corruption, not less.

29. **Moeen**
December 26, 2006

Peter,

I'm not sure what you had in mind by self-policing, but all I was aiming for was merely setting higher ethical standards for the entire community. It won't help if only some parts of the community impose higher standards an others don't, there has to be a consensus.

It is because the mathematics community failed to uphold better standards for themselves that, as Joan Birman said, "the entire profession has received a very public and very bad mark." If academic communities fail to do so in the future, the loss is their own.

I don't think the analogy to police-states is a good one since the only examples of such governments I'm aware of are usually responsible for various human rights violations. Regardless, I was not trying to promote the academic equivalent of a police-state, as that would have just been silly.

30. **Maroc**
December 27, 2006

Of course, a novel about the string theory controversy (if it's not one of those postmodern novels) requires some kind of ending. Here are some possibilities.

(1) The string theorists are unexpectedly vindicated by LHC. (Many string theorists clearly are hoping for this ending, even though it seems rather unlikely.)
(2) The hero has a mental breakdown, quits theoretical physics, and writes a semi-autobiographical best-selling novel. (Also unlikely.)
(3) Finer examination of the cosmic microwave background reveals a message from God, in which He reveals the true workings of the universe. None of the competing theories come even close to the right answer. (I'm not betting on this outcome either.)

31. **Peter Orland**
December 27, 2006

Moeen,

How can the community impose (your word, not mine) higher standards without leading to abuse of authority? My point is that the current system is flawed, but it does work. As long as journal editors, referees and reviewers are human, there will be mistakes and abuses. Do you really think this can be resolved by some new system of authority?

The consequence of imposing good science is bad science, just as the consequence of imposing good art is bad art.

32. **Moeen**
January 1, 2007

Peter,

I still do not see how if the community as a whole decides to set higher standards for everyone, then that would lead to an abuse of authority. All this means is that no matter how much influence you have, you're still subject to the same rules as everyone else. Sure the system works, but that doesn't mean it can't be better. There doesn't have to be a new system of authority just an improved one.

The analogy to art doesn't work because what makes "good" art different from "bad" art can be pretty subjective, whereas in science, and certainly math, there's a very clear difference: good science is accurate, bad science isn't.

In any case, as far the events that Birman was referring to, Yau violated the normal peer review process by pushing the Cao-Zhu paper into the AJM journal by bypassing the editors, and no one called him on it. As a result, they seemed to be implying that they were okay with this kind of behavior, damaging the integrity of the profession. Seems like Yau is the one responsible for an abuse of power here, not anyone else.

33. **Peter Orland**
January 1, 2007

Moeen,

I don't think we are going to agree on this, so this is my last effort against more stringent control of science, though I am happy to hear your response.

How is this the system of authority going to be improved? I don't see how to do it reasonably. The final authority is the scientific community. As long as the main goal of people in that community is the truth, that is the best authority. Changing the power structure will make things worse, not better.

I still think my anology with art is a pretty good analogy. Consider how poor the general quality of science, as well as art has been under totalitarian regimes (they both fare somewhat better under authoritarian regimes, but not well).

It seems to me that the system worked very well on the Poincare-conjecture affair. The Cao-Zhu paper was published, as you say, but the reaction of the math community is clear. This is a simple matter of democracy in action.

34. **Jeff Holtz**
February 1, 2007

Peter,

I agree. The math community has responded quite effectively to the manner in which the Cao/Zhu article was published. But, I don't think it has responded very effectively to the downright plagiarism of Lemma 7.1.2 .

This document clearly shows that it was not just a accidental side step, but deliberate copying from Kleiner and Lott. I'd be interest to hear opinions on why there has been such a tempered response.
See this file:
http://www.cds.caltech.edu/%7Enair/pdfs/CaoZhu_plagiarism.pdf

02138

December 16, 2006
Categories: Uncategorized

There's a new magazine aimed at Harvard alums, named 02138 (after the local zip-code), and its second issue has just appeared. Personally I've never quite understood the phenomenon of people who retain a lifelong fascination with the fact that they attended Harvard, but it seems that there are a lot of them, and the magazine is partly aimed at them or at anyone with an interest in the place or its alumni. The university already has an alumni magazine that it sponsors, but 02138 appears to intend to provide something edgier and not so much along the lines of promotional material.

This latest issue contains an article about the string controversy, written by John Sedgwick and with a focus on the Harvard angle, including me, fellow Harvard grad Brian Greene, and current Harvard faculty member Lubos Motl. The piece is called Unstrung Heroes, and for the full thing I guess you'll have to subscribe to the magazine. I fear that Sedgwick has done an excellent job of accurately putting together the most outrageous statements that he could find on this topic, including some things I told him when he came down to New York a couple months ago. He also got some interesting quotes from quite a few physicists about the current state of string theory. These included Glashow, who "said he considers a big book like Woit's long overdue, because *string theory has gone exactly as we imagined*. If anything, he adds, *it's even worse than it was*." Weinberg is quoted as saying:

The critics are right. We have no single prediction of string theory that is verified by observation. Even worse, we don't know how to use string theory to make predictions. Even worse than that, we don't really know what string theory is.

Cumrun Vafa "calls string theory *the major leagues* in the field of quantum gravity. As for other theoretical pursuits, he derides them as *little efforts here and there*." Barton Zwiebach promotes string theory as possibly being able to "see the origin of the universe, and the very meaning of how space and time are born and what they are." Michael Peskin claims that we might discover a universe that existed before time as we know it began, while noting "But there is a big debate as to whether this idea makes any sense."

Sedgwick tells the story of Lubos Motl's reference to me as the "black crackpot", and Lee Smolin as the "blue crackpot" (because of the colors of the covers of our books), and his discussion of the desirability of my death. Lubos has evidently been told he's not supposed to say things like that anymore, and responded to a request for an interview with "I don't enjoy elementary human rights right now." There's a quote which I think originated as a comment on my blog to the effect that Lubos has done for the image of string theory "what the movie *Deliverance* did for canoeing holidays."

Perhaps the most outrageous quote is an accurate one from me characterizing some of my experiences criticizing string theory from a position outside the field's standard rigid hierarchy as being analogous to what happens when one messes with the dominance hierarchy of a chimpanzee troupe. This leads to a lot of strange behavior, flinging of shit, showing of behinds, and all sorts of bizarre behavior. In order to avoid offending people I wasn't referring to, I should explain that I had in mind specifically some of my experiences when first starting this blog, see in particular the comment section of this posting.

It's a bit embarassing that I'm made out to in some degree be the hero of this piece, the oppressed underdog that the author tries to set up in contrast to overlord Brian Greene. Sedgwick sees the story of how string theory dominates an academic field despite very limited achievements as quite analogous to the phenomenon he had personal experience with of how "theory" came to dominate the humanities in academia. I think there is something to the analogy, with both kinds of "theorists" starting out as an insurgent minority needing a certain amount of fanaticism to survive and expand their influence. Both groups revel in the complexity and obscurity of their work, convinced that those who disagree with them are stuck in the past or just too dumb to appreciate the great achievements of the difficult ideas involved in the two kinds of "theory".

Chris W. has pointed me to a site that brings together the two sorts of "theory". It's called Scriblerus Press, is run by Sean Miller, who has a blog and is working on a PhD thesis in English on the topic of "the cultural currency of string theory." Scriblerus is sponsoring and now looking for contributions to an anthology of short creative works that deal with string theory in one way or another.

Comments

1. **Alejandro Rivero**
   December 16, 2006

   one messes with the dominance hierarchy of a chimpanzee troupe.

   Er, you have a curious instinct to put the finger on bogus science, if you are referring to "Chimpanzee Politics", of Frans de Waal. In the revised edition, he explains (in the small letter) that the chimpanzee causing all the history was received in the Zoo as a donation of "Disney on Ice" or a similar circus show.

2. **luke**
   December 16, 2006

   Peter can you get permission to post the article on this website?

3. **Kris Krogh**
   December 16, 2006

   For my money, Weinberg is among the most honest traders in the "marketplace of ideas." His advocacy of string theory has troubled me more than anyone else's. So this turn is a relief — maybe there's a place for normal scientific standards in theoretical physics.

4. **D R Lunsford**
   December 17, 2006

   I should point out that I have been making this analogy of humanities to physics since the 80s, and that they both lurk in the dark shadow cast by postmodernism.

   -drl

5. **Anonymous**
   December 17, 2006

   Both groups revel in the complexity and obscurity of their work, convinced that those who disagree with them are stuck in the past or just too dumb to appreciate the great achievements of the difficult ideas involved in the two kinds of "theory".

   Isn't the situation broadly similar in cosmology, with Big Bang's dark matter, dark energy etc.?

6. **Big Crimson**
December 17, 2006

“Personally I’ve never quite understood the phenomenon of people who retain a lifelong fascination with the fact that they attended Harvard, but it seems that there are a lot of them, and the magazine is partly aimed at them or at anyone with an interest in the place or its alumni.”

The university teaches this habit as part of its famous core curriculum, now under revision. The mental habit of self-adulation provides an important basis for the mental habit of donating money to wealthy institutions.

7. **Troublemaker**
December 17, 2006

Isn’t the situation broadly similar in cosmology, with Big Bang’s dark matter, dark energy etc.?

Experimental cosmology is a field that…well, exists. Experimental string theory doesn’t.

8. **Michael**
December 17, 2006

Dear Peter:

I just read one of your earlier posts (post=3 actually) giving some idea of your academic background; it’s nice to know that while you have the requisite background to provide thoughtful and meaningful commentary on current theoretical physics (trends) and related areas, you don’t engage in the usual ramblings and shouting that sometimes characterize other commentators. (I always felt the mark of genuine scholarship was objectiveness, sound reasoning and clarity of thought… something not particularly paid much attention to in the current sub-culture of particle physics a la string theory.)

Well, anyhow, the reason for writing was to ask you the following:

1) You seem to view Representation theory an integral part of mathematical investigations of current particle physics. Exactly how, I wonder? [I am new to hep-th.]

2) You further view Atiyah’s works as fundamental to QFT-related studies. Can you explain how? [Only an outline would do.]

3) I am reading “The Road to Reality”; there, Roger Penrose advocates twistor theory; why, for example, do you not share the same level / degree of excitement as Roger Penrose regarding his program? I would have thought that you, among a handful of individuals who take objectiveness in research rather seriously, would want to assist Sir Roger in his investigations as much as possible.

4) [Optional] Can you send me an e-copy of Coleman’s QFT notes (if you have one)?

Thanks.
Michael

9. **CapitalistImperialistPig**
December 17, 2006

Peter,

Thanks. You just saved me $65. (I read the linked comments from Mark Srednicki.)

10. **Jonathan Vos Post**
December 17, 2006

I suspect that 02138 is “edgier” (not in the Feynman diagram sense, which would have some magazines “loopier”) to appeal to younger alumni. My father got his degree at Harvard, cum laude, and maintained a lifelong love for his alma mater, including dining almost daily at the Harvard Club in New York, buying me Harvard neckties, rooting in “The Game” (Harvard-Yale football), and snailmailing me articles cut from the harvard alumni magazine. However, my father was 82 when he died, and the mainstream of magazine publishing appears to have shifted considerably. I’d hypothesize that 02138 has “edgier” graphics (further along the spectrum towards “Wired”) and a slant towards controverial human interest stories.

Now, should Caltech change its almni magazine’s name from “Engineering and Science” to “91125”?

11. **D R Lunsford**
December 17, 2006

CIP – Peter won that argument flat-out, and with dignity rather than arrogance.

-drl

12. **CapitalistImperialistPig**
December 17, 2006

D R – absolutely.

Bending over backwards to be fair to Mark, he’s probably not the first person to go off half-cocked. The deliberate obtuseness on the SU(2) question was a bit much though.

13. **Tony Smith**
December 17, 2006

Michael asked Peter “… [Optional] Can you send me an e-copy of Coleman’s QFT notes (if you have one)? …”.

Coleman’s QFT notes were published in a 1999 Cambridge University Press book entitled
“Quantum Field Theory for Mathematicians”
by Robin Ticciati, who, as the preface states, “… had audited Sidney Coleman’s outstanding Harvard lectures and had taken very good notes. Equally fortunate, I [Robin Ticciati] had Robert Brandenberger’s official solutions to all the homework sets. … “.

Tony Smith

December 17, 2006

Michael,

Your questions are good ones, but to answer them in detail would take more time than I have now, and get into topics far afield from the posting. I'll try and say a bit though, in reverse order…

Lots of physicists, like me, probably have a yellowing set of notes from Coleman's course around, and many people have taught courses from these. The Harvard web-site for the course (this semester taught by Lubos Motl, who seems to be following Coleman's notes) has a copy of such notes, see:

http://my.harvard.edu/icb/icb.do?course=fas-phys253a&pageid=tk.page.phys253a.dir.96baa9f5f565ad359215beb46d7685a9

About twistors: I've always been very interested in the geometry of twistors, and long ago even wrote a paper about what they might have to do with the standard model, one that I now think of as very naive. I think the fundamental problem with twistors is that, while they provide a different and more interesting set of variables to use in thinking about space-time geometry, no one really knows how to relate these to particle physics, or how to use them in a quantum field theory of space-time. This is a very deep problem, I'll bet that someday it will be an important part of future progress, but no one has been able to solve it yet.

About Atiyah. Atiyah's work on index theory and K-theory is one of the great advances of mathematics in the last half of the last century. It brings together geometry, algebra and analysis in a fascinating way, with the Dirac operator playing a crucial role. If you believe like me that the deepest ideas about mathematics are related to physics, this looks like a promising place to be searching for new ideas about physics. Atiyah himself did some things related to QFT (work on anomalies), and a lot on the geometry of gauge theories. He retired a while back and has not been as active as he was during the 70s and 80s. His student Graeme Segal has been someone thinking deeply about QFT and CFTs more recently.

I highly recommend reading Segal's notes on the subject that you can find on the web. Trying to understand the full implications of this kind of mathematics for QFT is still very much a work in progress, with many interesting things known, but we're far from a clear picture about this.

In general, Atiyah is also a master expositor, so his papers are well worth reading. But as for his actual work on QFT, it's fragmentary. One of the most impressive things he did was to come up with the idea of a topological QFT, convince himself that there had to be a TQFT for Donaldson theory, and for what are now known as Gromov-Witten invariants, and then badger Witten about this until Witten actually figured out that such theories really exist and how to define them.

Representation theory is a huge subject, and it's a great unifying idea in mathematics. Some beautiful 1+1 d QFTs can be understood in terms of the representation theory of loop groups and the group of diffeomorphisms of the circle. These groups are infinite dimensional and their representation theory was not well-understood until people started thinking about the relation to QFT. My belief is that higher dimensional QFTs may have a close relation to the representation theory of higher dimensional gauge and diffeomorphism groups, but very little is known about this subject. We seem to still be missing some crucial ideas. One idea that I've thought a lot about is that of using equivariant K-theory, a subject that was developed by Atiyah and Segal, and brings together representation theory and K-theory.

December 17, 2006

Thanks for the post. I can't say I'm going to run out and subscribe 02138, but my interest is definitely peaked and I will check out the article next time I'm at the Coop. I got a good laugh from your blog, and have been clicking on links going deeper and deeper down the rabbit hole into the battle of string theory land. How I love the chimp throwing shit analogy. And even better is the quote, "I don't enjoy elementary human rights right now." HA! This is such great fodder . . . very bloggeriffic.

16. **woit**
December 17, 2006

CIP,

Srednicki was the one at the George Johnson KITP talk to raise his hand when Johnson said something like "no one thinks Smolin is a crackpot", generating much merriment from various chimps in attendance. From a quick look, his QFT book appears to be detailed, competent, but not in any way original or particularly insightful. Distler's behavior in that comment section, and many other later similar exchanges, is just bizarre.

One thing that has struck me is how it seems to be people like Srednicki, Motl and Distler, who are nowhere near the top of the string theory hierarchy (Srednicki is not even a string theorist), who get most frantic at the very idea that someone who they see as an outsider or lower than them on the hierarchy challenging in any way those at the top. They seem to be the ones with the most emotionally invested in the maintenance of hierarchy. I'm not sure what this means.

17. **gunpowder&noodles**
December 17, 2006

The fact that all three have given up research might also be relevant.

18. **D R Lunsford**
December 17, 2006

Pter – these people were always around. The Internets and the Googles give them a voice.

-drl

19. **D R Lunsford**
December 17, 2006

Peter – yes twistors are fascinating, but hopeless for the current model of matter with its insistence on point particles. The idea is very simple – make a line geometry for spacetime rather than space – but with that, the point particle becomes a derived object, and so there is no hope of twistors having an intrinsic meaning for the usual model of matter. A new model of matter might have a better expression in terms of line geometry. What twistors really point to is a new model of matter.

-drl

20. **Peter Orland**
December 17, 2006

Just a quick comment to Gunpowder and Noodles:

Better not to write people off as having given up research, unless you are sure. I'm not sure it hurts anyone, but it poisons the dialogue (yes, I know that other people have already pumped it full of toxin). I wouldn't seriously write "hey, that Gunpowder and Noodles sure doesn't explode pasta like in the olden days".

Anyway, I expect you get my point.

I think Mark wrote a few papers recently.

21. **woit**
December 17, 2006

I agree with Peter Orland. Enough with the less than accurate hostile comments.

22. **Michael**
December 18, 2006

Peter:

As regarding the [Optional] question, thanks! I'll look through them; just wish they had been type-written though.

Ahem… might you have his "Erice Lectures" in e-format as well? :-(=)

23. **Michael**
December 18, 2006

Sorry, wanted to make [grin] symbol.

24. **MathPhys**
December 18, 2006

"They seem to be the ones with the most emotionally invested in the maintenance of hierarchy. I'm not sure what this means."

I think it's their way of being "more royal than the king".

25. **MathPhys**
December 18, 2006

Coleman's Erice lectures are copyrighted.

26. **Michael**
December 18, 2006

MathPhys:

I just asked if he [Peter] had them in e-format?

27. **Michael**
December 18, 2006

And by the way, sometimes authors make their works available free of cost, e.g. Connes' NG or Warren Siegel's 'String Field Theory'.

28. **anonymous**
December 18, 2006

it's a pity that the Coleman lectures are too old to be freely available on arXiv; maybe you can find the following file:

Coleman S. Aspects of symmetry (CUP, 1985)(L)(T)(207s).djvu

29. **Peter Woit**
December 18, 2006

I don't have a copy of Coleman's Erice lectures in electronic format, and if I did, I wouldn't be making it publicly available, since this can't legally be done without the publisher's permission, and I see no reason they would give it. This web-site is hosted on university equipment, and I'm sure the university does not want me opening them up to possible legal problems by violating a publisher's copyright.

In any case, I think having articles all available on-line is great, but for books and monographs I hate trying to read such things online and would much rather have a real book in hand. It's also a shame that students are getting the idea that anything that is not available on-line is not worth looking at. They should get used to using whatever libraries they have access to (I realize there are some people for whom this is a problem). Especially if you can get yourself to a research physics or math library, they have an immense number of very valuable books there which you're not going to find on-line, and looking into these is time well-spent.

30. **anonymous**
December 18, 2006

bringing dozens of physics textbooks in a laptop is so useful that many physicists would buy good pdf copies of books that they already have. For the moment it cannot be done legally, but it is reasonable to expect that authors and/or publishers will realize that this pre-internet system is unconvenient for everybody.

31. **Roy Lisker**
December 18, 2006

In regards to the Harvard Magazine "02138". Residences of Cambridge recognize that Harvard snobbery extends even to its Zip Code. Proles who live at an 023139 Zip Code address are definitely looked down on.

32. **MathPhys**
December 18, 2006

" —- for books and monographs I hate trying to read such things online and would much rather have a real book in hand."

Peter, you're so —- behind the times 🙂

Here is something I recently found (which is not entirely, entirely off topic)

" —— Grothendieck is now convinced that the Devil is working to falsify the speed of light. Schneps ascribes his concerns with the speed of light to his anxiety about the methodological compromises physicists make. He talks constantly, however, about the Devil, semi-metaphorically, sitting behind good people and nudging them in the direction of compromise, of the fudge, of the move towards corruption."

33. **a.n. onymous**
December 18, 2006

when they make a book-like (tablet type laptop) PDF reader to replace books, then electronic books will take off more. Something as cheap as a book, no heavier or bulkier than a book, and whose batteries will last long enough to actually read a whole book…

34. **MathPhys**
December 18, 2006

But can you take it to bed?

35. **Tony Smith**
December 18, 2006

Roy Lisker said about "Harvard snobbery" and the Harvard Zip Code 02138:
"… Proles who live at an 023139 Zip Code address are definitely looked down on. …".

Poor MIT.
Its address at web.mit.edu is given as
"… 77 massachusetts avenue cambridge, ma 02139-4307 …".
I guess engineers are too close to the real world
to fit in with the "Warped Passages" among the "Hidden Dimensions" of Harvard Intelligentsia.
Oh, wait !!
Harvard is planning to move its SuperStringers to Allston, which is 02134 !!!
(see http://www.allston.harvard.edu/)
The indignity must be intolerable.
Maybe they can get their own magazine as a consolation prize.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – However, at least MIT can hold its head up about its area code, 617.

36. **LDM**
December 18, 2006

Regarding electronic books…Sometimes when one purchases the print version from Amazon, there is an option to upgrade to an e version…which allows you to highlight, underline, and add notes…as you would a print version.

The fact that 02138 is reporting the controversy on string theory as it is leads me to believe that the mass media, thanks to NEW and TTWP, has pretty much figured out that they were originally oversold on strings…
Now…when a salesperson oversells a product, he eventually loses credibility,and eventually sales. I would expect that any granting agencies that have been funding string related research adopt a similar tightening of the purse strings.

37. **Peter Orland**
December 18, 2006

LDM,

Don't bet on it happening soon. Funding doesn't work
that way. Panels and reviewers make the final decision
as to who gets funded – and these are mercurial. People
at the top have to get heavy-handed before there is change.

It is unfortunate (for who?, we might ask) that funding
agencies have been tough on non-string particle theory
(other that hard-core number crunching or phenomology).
I have to add that I think it would be just as unfortunate
for agencies to get tough on someone just because he or
she happens to do string theory. There is some really
interesting string stuff out there, in my humble opinion,
though almost all of it fits in the AdS/CFT (NOT AdS/QCD)
category.

But I reiterate, don't hold your breath. Hell didn't freeze over
in a day, as somebody famous said.

38. **J.F. Moore**
December 19, 2006

Regarding the theory/postmodern parallels with string theory, is there a physics analog to Finnegan's Wake? Specifically, an indecipherable monograph which appeared to be (or perhaps was) written by a madman but was later adopted and heralded as a masterpiece, and around which this dominant movement coalesced? Just curious.

39. **D R Lunsford**
December 19, 2006

JF – I would say the bad times started with Bourbaki and their mouthpiece, Dieudonne. Weyl, like Klein before him, strove mightly – and unsuccessfully – to stem the tide of formalism. (See his book 'The Continuum".) I think now the works of Bourbaki are thought of highly among academic mathematizers (for reasons that are unfathomable to a poor physicist like me). Without the triumph of formalism, string theory, inflation etc. would be inconceivable.

-drl

-drl

40. **JC**
December 19, 2006

D R Lunsford,

It's amusing coming across some old K-6 math textbooks from the 1960's which covered the "New Math" program of that era. "New Math" attempted to cover things like modular arithmetic (ie. clock math), set theory, groups, relations + functions, limits, base-n arithmetic (where n is a base other than 10), etc … to kids from kindergarten to grade 6 or 7. (Nowhere was there anything like multiplication times tables). The guys who came up with "New Math" must have caught the Bourbaki "virus".

41. **anonymous**
December 19, 2006

MathPhys, your objection ("But can you take it to bed?") was an important one a few years ago. With current laptop technology, and up to copyright problems, you can even take it to the toilet.

42. **Michael**
December 19, 2006

anonymous:

Hypothetically speaking… [kinda' like O. J.'s 'hypothetical' new book soon to be not out ;-)]

maybe I kinda' did search for the file, but maybe I couldn't find any freely available copy. Just maybe where can I find a FREE copy… in a hypothetical sense?

43. **Peter Woit**
December 19, 2006

About Bourbaki,

They definitely did very much influence the "New Math" and you certainly can blame them for inflicting things like Venn diagrams and injective mappings on grade-school kids. But the problems with string theory are not at all their fault, or in general, not the fault of mathematicians at all. Just take a look at the great majority of string theory papers these days. Many of them don't involve mathematics more sophisticated than what we teach our first and second year undergrads, and the calculations are often very informal, based on very unclear definitions, the complete antithesis of the Bourbaki philosophy, much more like what Bourbaki was reacting against.

It's also not true at all that the works of Bourbaki are now thought highly of among research mathematicians. Their heyday was in the fifties and sixties; by the late seventies and eighties, this kind of formalism was not so popular. My impression is that now most mathematicians don't ever look at most of the Bourbaki volumes except every so often as a reference for some specific definition or result, and no one thinks they're a good place to try and learn something from. The volumes on Lie algebras and groups, which were mostly written by Borel, are probably the ones that people think most highly of and still use. Even the people most interested in formalism are not interested in Bourbaki, instead they care about Grothendieck's work and use categories, a point of view that Bourbaki never adopted (and this is one reason that the Bourbaki project ground to a halt).

44. **JC**
December 19, 2006

Hopefully I'm not the only one who actually liked Bourbaki's "theory of sets" book. 😉

45. **J.F. Moore**
December 19, 2006

Peter,

Thanks for illuminating the topic. I was a bit confused by drl's prior response. In addition to what you say, my impression of Bourbaki is that what they wrote wasn't wrong, or nonsensical, or 'not even wrong', in the sense that the "two theories" you refer to in this post just might be, but it just turned out not ultimately to be possible to wrap it all up, which was the initial point. I am not well read at all on 'pure' mathematics, though, so I could be totally off on that. Maybe if I had been in grammar school in the 60s …

Anyway, I was probably asking about something that just doesn't exist (a Rosetta Stone of postmodern physics), which is probably a good thing.

46. **Peter Woit**
December 19, 2006

J.F. Moore,

I don't know of any Rosetta Stone of postmodern physics, no analog of Finnegan's Wake for string theory. Pretty much ALL string theory papers were being ignored by most theorists before 1984.

Bourbaki accomplished a lot of what it initially set out to do during the 30s, which was to provide the details of a logically rigorous framework for certain kinds of mathematics that people were working on. They did this for analysis and algebra, but not for geometry (they couldn't even agree on exactly how to define a manifold, from what I remember). The problem is that mathematics evolves, and as it does, ideas about what's the right foundational material change. Grothendieck's new ideas about the foundations of algebraic geometry changed the way mathematicians look at the subject, and made some of Bourbaki not wrong, just incomplete and less interesting. I suspect a project like Bourbaki needs to be reinvented and redone from the ground up every few generations.

47. **D R Lunsford**
December 19, 2006

Peter – what I know of Bourbaki comes from a mathematician friend who was forced to endure it at Columbia and MIT. He had a satori about it and completely retaught himself math from a non-formalist point of view, so he had both an insider's and an outsider's perspective. I myself could never tolerate excessive formalism so it never entered my consciousness directly. His awakening moment came when he realized that after proving some complex existence theorems for PDEs in his thesis, he discovered in his new career as an applied mathematician that he couldn't easily do a simple surface integral 🙂 This fact struck me like a thunderbolt. Excessive formalism had led to a situation where a brilliant person could not tackle a simple problem. I do see parallels with this and the rise of unreasonable physics ideas. There is some input that must come from the intuition about what makes physical sense. This intuition can't be taught, and without it, what is one going to say? The answer is to hide behind formalist axiomatizing – the string hypothesis is really a formalist conception that is not stimulated by physical necessity or experimental evidence. The postmodernist will say – it doesn't matter what you say, only the social context in which it is said. This is very much at the bottom of what Smolin describes when he talks about the milieu of string theorists.

-drl

48. **Peter Woit**
December 19, 2006

drl,

Abstract formalisms are just one kind of tool, and they can be used well or misused. It's certainly true that some people learn formalism without understanding what it's useful for, and just get wrapped up in it. Mathematics suffered through a lot of that in the 50s-70s, and some people still suffer from this. But most really good mathematicians know when to use abstract formalism and when not, when this is an appropriate tool and when it isn't. These days, you'll often hear mathematicians refer to certain formalisms as "abstract nonsense", as in "at this point in the proof, such and such can be shown by abstract nonsense". This terminology comes from an appropriate skepticism about overvaluing abstract formalism.

It's also true that what research mathematicians are often trying to do is to come up with new tools. People spend a lot of time playing with new abstract formalisms trying to understand what you can do with them (a good example would be the n-categories you see people investigating these days). It's not that someone like John Baez doesn't know how to do much more concrete things, it's that the more concrete ideas have been around a long time, and it's pretty well understood what you can and can't do with them. If you want to find something new, you have to try out different things, including new abstract ideas.

49. **PatrickNewYork**
December 19, 2006

Can Witten do hard integrals? Could he ever do hard integrals and solve tough blood and guts PDEs by hand? How would he do on the putnam exam?

I'm not trying to put Witten down. I am just trying to get a handle on how he thinks about math and physics. Does Witten just divine the closed form solution to tough integrals and PDEs without doing all the hard algebra tricks.

I read some where that when Witten was a grad student, he solved Quantum Field Theory course problems with a few few lines of deep conceptual reasoning rather than grinding out a calculation over several pages. If this is true, maybe someone should teach all theoretical students to solve QFT course problems this way.

Same question about Graothendieck. CAn/did he do hard integrals and Putnam type problems with ease.

50. **Peter Woit**
December 19, 2006

I don't know much about Witten's skills at doing integrals, but I'd guess that he can do them as well as most theorists, while there are some people out there much more skilled at this than him. His talents definitely lie in finding elegant conceptual solutions to problems, rather than in finding brute force computational solutions or being a master of computational tricks. Unfortunately I think this is something that is hard or impossible to teach.

51. **Neville**
December 19, 2006

I have fond memories of Bourbaki's Commutative Algebra. Some don't. I seem to remember some comment of Grothendieck to the effect that EGA started where Bourbaki's Commutative Algebra left off.

An Iranian interviewer asked Alain Connes about his very brief participation in Bourbaki meetings. He said:

"Another reason to leave was that they had a life style which was unpleasant. People would leave without saying good bye, being rude was the main feature of the founders they seemed to cherish. I found it very irritating. Clearly the founders did great things.."

This is the same interview in which Connes told the famous anecdote about a physicist not thinking for himself:

"I went to Chicago in 1996, and gave a talk in the physics department. A well known physicist was there and he left the room before the talk was over. I didn't meet this physicist for two years and then, two years later, I gave the same talk in the Dirac Forum in Rutherford laboratory near Oxford. This time the same physicist was attending, looking very open and convinced and when he gave his talk later he mentioned my talk quite positively. This was quite amazing because it was the same talk and I had not forgotten his
previous reaction. So on the way back to Oxford, I was sitting next to him in the bus, and asked him openly how can it be that you attended the same talk in Chicago and you left before the end and now you really liked it. The guy was not a beginner and was in his forties, his answer was "Witten was seen reading your book in the library in Princeton"!"

Speaking of Alain Connes, he told me something to the effect that the most trivial paper he ever wrote involved string theory. Because of the string theory connection, it's also his most highly cited paper.

Any inaccuracy in the statement above is purely due to my own feeble memory. However I'm pretty sure I'm recalling the gist of his remark correctly. The phrase "most trivial" sticks in my mind.

52. **yagwara**
December 19, 2006

It has been fashionable for the past 20-30 years to bash Bourbaki – an attitude promulgated particularly by Russian mathematicians. But it is difficult for a mathematician trained today to appreciate how *confused* mathematics was at the time. Each subfield had its own language, unspoken assumptions, and rules of thumb. Simple things like the definition of a vector space, or even the definition of a function, while they certainly existed in the research literature, were not common currency.

The whole picture of mathematical objects as *sets with structure*, which we can scarcely imagine thinking without, was the creation of Bourbaki. One can argue that we need to move past it, but at the time, that foundation desperately needed to be laid.

It is worth noting that Weil, one of Bourbaki's prime architects, had a particularly historical and organic vision of mathematics, and was appalled that today's mathematicians have not grown up reading Euler, Gauss, and Riemann.

53. **Tony Smith**
December 19, 2006

Peter said "… Bourbaki['s]… heyday was in the fifties and sixties …".
yagwara said "… it is difficult for a mathematician trained today to appreciate how confused mathematics was at the time. Each subfield had its own language, unspoken assumptions, and rules of thumb. Simple things like the definition of a vector space, or even the definition of a function, while they certainly existed in the research literature, were not common currency.
The whole picture of mathematical objects as sets with structure, which we can scarcely imagine thinking without, was the creation of Bourbaki. One can argue that we need to move past it, but at the time, that foundation desperately needed to be laid. …".

Having studied math in the early 1960s, and having found Bourbaki to be a useful anchor in my studies, I agree with the comment of yagwara.
It should be noted that the exercises in Bourbaki provided some useful concrete realizations of the abstract main body of each volume.
It should also be noted that the Bourbaki Seminars published much interesting work that did not all find its way into the formal Bourbaki series of books.

Peter said, further: "… Bourbaki['s]… volumes on Lie algebras and groups, which were mostly written by Borel, are probably the ones that people think most highly of and still use …".
I also agree with that statement.
I would add that, almost in the spirit of the Lie Groups and Algebras volumes of Bourbaki, and the exercises,
a later pseudonymous group of French mathematicians, Arthur L. Besse, wrote such useful books as Einstein Manifolds (Springer-Verlag 1987).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

54. **Richard**
December 19, 2006

Peter – "I suspect a project like Bourbaki needs to be reinvented and redone from the ground up every few generations."

I agree, although this becomes more difficult as mathematics becomes ever larger in scope. On the other hand, as time passes and we continue uncovering unexpected connections between different areas of mathematics, the need and desire for updated and more sophisticated formal frameworks will become great. It should be interesting.

55. **Neville**
December 19, 2006

I agree completely with yagwara's statement "… it is difficult for a mathematician trained today to appreciate how confused mathematics was at the time."

Looking at old mathematics books and papers, I sometimes felt lost in a forest of words, trying to find the actual statement of a theorem, never mind the proof.

56. **Neville**
December 20, 2006

I seem to recall reading the Deligne started reading Bourbaki when he was 14 years old. Didn't seem to do him any harm.

57. **geometer**
December 20, 2006

Does the term *abstract nonsense* really "comes from an appropriate skepticism about overvaluing abstract formalism", as Peter Woit suggested? I am not so sure. Certainly, this expression has been in use for a while, e.g I saw it in Lang's *Algebra* written in early 60s. Was anyone skeptical back then?

I never really read any Bourbaki's book, even though I own quite a few of them, but I suspect many math textbooks that I did read were greatly influenced by Bourbaki, and it sounds like a good history project to trace those influences. (Maybe this has been done?)

I personally dislike math research written in Bourbaki's style (which may be okay for "dead math"). Unfortunately, this is how many (especially French) mathematicians still write: theorem-proof-theorem-proof. This style of writing has been the greatest of Bourbaki's influences, I think. Rather I prefer the authors who motivate everything, and explain what they want to accomplish even when they cannot do it. I think, brevity is not always a virtue, and all too often people hide behind brevity when they do not want to admit they do not understand something.

58. **Alejandro Rivero**
December 20, 2006

Bourbaki's group theory is still widely used for practical purposes, at least I have seem high-calibre mathematicians to walk the library while checking against Bourbaki.

It should be mentioned that not only Bourbaki come to the "new mathematics" textbooks. Also the Groethendiek method to get a group out of a semigroup is the preferred way to define integer numbers and then rational numbers in the "new math" textbooks. Actually I liked it, and it is useful when one comes to K-theory. The only think I do not like about the new mathematics is the algebraic aproach to the proof of Pythagoras theorem.

By the way, if I recall correctly, Groethendiek's father and Weil's sister fought in the same war. Probably they never met, because Simone was sent home after some months, she was assigned to a anarchist patrol (in the aragonese border?) and she accidentally put the foot inside the boiling pot they were using to cook the food. On the other hand, both Groethendiek and Weil are famous because of their anti-war postures.

59. **Walt**
December 20, 2006

A pet peeve of mine: The Grothendieck method to get a group out of a semigroup is not by Grothendieck at all, but discovered years before. (The basic idea goes back to Dedekind, but the specific construction of group from a semigroup was pointed out by someone — I forget who — well before Grothendieck.)

60. **mclaren**
December 20, 2006

You have to wonder if the drift into vacuous untestable abstractions in both literary and string theory forms part of a larger breakdown by Western culture into an essentially medieval mindset.

We find untestable wallows in idle speculation not just in literary crticisim and string theory, but also in music (the mania for set theory, aleatoric composition, and other psuedoscientific conjurations which reduce the role of the composer to nothing and consistently contradict the available data from psychoacoustics experiments), in the arts ("conceptual" art in which, no matter how negative or contemptuous the reaction from thepublic, the artist always claims "That's the entire point of the piece") politics (phoney think tanks set up to deny global warming, teaching creationism rather than evoution, claims that "We found the WMDs in Iraq") religion (rapture frenzy), economics (rational choice theory which confidently predicts that MLK's voting rights drive of the early 1960s could not have happened), finance (the disastrous reign of Merton & Scholes at Long Term Capital Management) and almost everywhere else you look in modern Western society.

Over the past 20 years, our brightest minds seem to have drifted into self-delusion, arguing about vacuous terminology with no verifiable connection to observed reality. We've seen it just about everywhere in Western culture over the past 20 years, from politics to theoretical physics. It's a form of dementia which induces people to ignore measurable reality and disappear into word games and mathematical calisthenics with no objectively verifiable connection to anything we can observe.

New Dark Ages?

Whatever is going on, it's disturbing. When simple straightforward statements like "Science has to involve experimentally testable hypotheses" become the focus of fierce controversky by some of the most respected minds in physics, we're in big trouble.

61. **Jeremy**
December 20, 2006

Y'know, we had considered interviewing Brian Greene and Mr. Motl for our piece on Not Even Wrong, but we felt the book stood on its own (and I really didn't want to interview Lubos). I understand the need to create controversy, but it's stupid. It's already there. Why make more?

62. **D R Lunsford**
December 20, 2006

mclaren – ah men. see what you lost.

beyond postmodernism is narcissism, and for that, no answer.

-drl

63. **LDM**
December 21, 2006

"Science has to involve experimentally testable hypotheses" become the focus of fierce controversky by some of the most respected minds in physics, we're in big trouble.

There is no controversy…
Can you imagine something similar in Biology, Chemistry, Medicine, etc adopting a similar view. I cannot. Anybody who thinks an eventually testable hypothesis is not needed has stopped doing science — by definition. Period. And anybody who advocates such a view has just become a non-respected mind in physics.

64. **Aaron Bergman**
December 21, 2006

Anybody who thinks an eventually testable hypothesis is not needed has stopped doing science — by definition. Period. And anybody who advocates such a view has just become a non-respected mind in physics.

Good thing nobody thinks that, then.

65. **Alejandro Rivero**
December 21, 2006

Walt, indeed I had always suspected of Dedekind (and his methods to define numbers). But I was actually very surprised in the graduate courses in K-theory when they finally explained us about these virtual bundles, then the teacher menaces us with "The Groethendiek Construction", and next day he comes with a argument we knew from the elementary school 😀

66. **ME**
December 21, 2006

"Can you imagine something similar in Biology, Chemistry, Medicine, etc adopting a similar view. I cannot."

— — — — —

I can imagine, it's happening.

* Take for instance all the people in those fields who say clinical trials regarding the efficiency of ADD medication is not needed (or that they exist when they don't).

* the thousands of people "diagnosed" as manic-depressive (oh! sorry, "bipolar") on the basis they have a brain chemical imbalance that never gets measured. Similar things (worse) for the physiological reasons behind schizophrenia.

* I could find others

The current situation in HEP is bad, but not nearly as bad in some of the fields you mention…

At least in HEP most people agree there is a problem and (I think) are trying genuinely to address it. Other fields usually don't even see the problem.

Why do you think most scientific frauds happen in the so called "life sciences". I know, most research happens in those fields, but I "think" that even after normalizing in some meaningful way, it would still be quite higher than in Physics.

Bottom line: things are rough in Physics but they haven't even reached that point on the other fields you mention and thats not a good thing.

67. **woit**
December 21, 2006

Aaron is correct, in that few if any string theorists believe it is all right if string theory doesn't eventually produce a testable hypothesis. They're not saying that, and it isn't fair to say that they are.

But what many of them are saying is much the same thing, and almost as dangerous. The way I read Susskind and many other string theorists, they are claiming that string theory remains the most promising approach to a unified theory and deserves to continue to dominate research in this field, even though they believe it inherently leads to an exponentially large number of different kinds of physics, and there is no plausible known way to use it to legitimately predict anything. While they are not claiming it is fine for the the theory not to predict anything, they are saying that it is an acceptable situation to have a theory which now can only be used to make "anthropic" predictions (and they claim the CC "prediction" as such a success). While not having any ideas about how to ever get real predictions out of the theory, they acknowledge the importance of ultimately doing so, making dubious historical analogies like "well, it took more than 2000 years to get predictions out of the theory that there are atoms". In practice I don't see much difference between saying it is all right that your theory doesn't predict anything, and saying that you hope that some day it will, with these hopes not appearing to be much more than wishful thinking.

68. **a**
December 21, 2006

actually, the analogy with ancient greeks seems a good one. For some time it was nice to debate theories about atoms, water, fire, etc, etc, etc. At some point greeks realized that the net result of all these speculations was empty words and get bored. Real progress started 2000 years later, when it was possible to experimentally explore atoms.

Quantum gravity seems in a similar situation. String theory shows that quantum gravity does not need to imply a predictive theory of everything able of predicting something at low energy, and that does not need to imply new detectable effects (such as violations of Lorentz invariance from spacetime foam). If today we have no way of experimenting quantum gravity, people will continue trying fascinating speculations until they will get bored by the lack of real progress.

69. **John Gonsowski**
December 21, 2006

In the beginning, string theory was supposed to have a GUT and GUTs do make predictions. I still think a GUT is the best way to get predictions out of string theory. Course anything other than a minimal GUT would worry me cause the GUT could be tweeked to fit the data maybe. One can have a minimal GUT even in a SUSY model, right? One could maybe have a correct GUT and an incorrect overall string theory but the correct GUT would be quite wonderful just by itself.

70. **Peter Orland**
December 21, 2006

John,

The main purpose GUTs have served was to promote the construction of huge neutrino detectors. This was timely, but there are reasons not to take this kind of unification too seriously.

There were two theoretical "successes" of GUTs. One was the prediction that the sum of electric charges in each generation of quarks and leptons is zero. The other was that there seems to be a common unification scale for the U(1) and SU(2) of the Schwinger-Glashow-Ward-Weinberg-Salam model and the SU(3) of QCD.

The first "success" is a fake – it is necessary to insure that anomalies (quantum breaking of gauge invariance) are absent. It turns out that the sum of electric charges in each generation has to be zero anyway, to eliminate anomalies from the standard model. So GUTs buy nothing here.

The second "success" just tells you that there is probably some sort of unification at 10^{16}eV. This is a huge scale, not as lofty as the Planck scale, but still way up there. And it is by no means clear that the wherever the theories unify, the unification is a GUT.

I think even Georgi and Glashow are skeptical about GUTs these days, though I wouldn't want to put words in their mouths.

71. **James Graber**
December 22, 2006

John, Peter O., Peter W. and anyone else:
About GUTs: Long ago, people used to talk about SO(10), SU(4)xSU(4), and flipped SU(5)xU(1), after SU(5) was ruled out. Now you almost never hear about them. Does anyone care any more? Could LHC produce any results which would significantly favor or disfavor these GUTs? Or is only proton decay relevant?

By the way, there was a Harvard magazine called "Cambridge 38″ way back in 1958. This old chestnut never dies.

Best,
Jim Graber

72. **Peter Orland**
December 22, 2006

James,

The main problem is that the unification scale is very high.
I don't know if the LHC will have any bearing. There are,
however, new generations of astrophysical neutrino
detectors which might (Ice Cube for example). The details
of neutrino mixing does tell us something about what
happens at scales of the order of the unification mass.

A neutrino experimentalist or phenomenologist would know
more about all this than I do.

73. **mclaren**
December 24, 2006

Dr. Woit astutely remarked:

"While they are not claiming it is fine for the theory not to predict
anything, they are saying that it is an acceptable situation to have
a theory which now can only be used to make `anthropic' predictions
(and they claim the CC `prediction' as such a success)."

Several questions:

Q: What is the difference between a HEP theory which predicts anything
you could possibly observe, and a HEP theory which predicts nothing?

Q: What is the difference between an elegant scientific theory with
so many adulterations and encrustations and baroque modifications, like
current string theory which has now turned into M-theory, that it becomes ugly and intractable…and an outright kludge that's ugly and intractable to start with, like the Ptolemaic epicyclic system?

Q: What is the difference between saying "it took 2000 years to
experimentally verify the existence of atoms, so it could conceivably
take that long to experimentally verify string theory" and "it took
2000 years to experimentally verify the existence of atoms, so it
could conceivably take that long to experimentally verify [feng shui /
ufology / orgone energy / (ad nauseum)]"?

Q: What is the difference between a theory like the phlogiston
theory of heat, which was pursued for several hundred years
without success, and string theory if we pursue it for another
50 or 100 years without producing any experimentally falsifiable
predictions?

Q: If people like Motl claim that it's okay to continue to
pursue string theory for decades or perhaps generations
before getting testable numbers out of it, what's the time
limit? How long is long enough? 50 years? 70 years? 100
years? 200 years? Longer?

Q: How can the statements "String theory is currently the dominant
theory in HEP" and "there are no viable scientific alternatives
to current string theory in HEP" be falsified, given that
current HEP grad students find themselves forced either to work
in string theory to get tenure, or find another profession?

Bonus question: Isn't this like saying to a young Russian
economist circa 1970 "Marxist-Leninist dialectical materialist
theory is (and must be) the one correct theory of economics,
for there is at present no other viable theory of economics in
the Union of the Soviet Socialist Republics"?

On a more serious note…

The big question remains whether string theory can produce any slight but experimentally observable departures from the Standard Model at energies much lower than those required to reach the Planck scale. If so, we have a real shot at observing something that might confirm or disconfirm string theory. No possible accelerator built by humans could reach the energies required for unification — but are there subtle phenomena which would emerge at energies reachable by either the LHC or its successors, or astronomical observations, which string theory predicts, but which lie outside the Standard Model?

At present I'm not aware of any. Are there any?

Planck's quantum hypothesis implied the photoelectric effect, which was observed. De Broglie's matter wavelength implied Bragg diffraction, which was observed. Einstein's general theory of relativity implied the bending of starlight around massive objects, which was observed. Quantum chromodynamics implied the Casimir effect, which was observed.

What slight but experimentally detectable effects does string theory imply? Are there any (which are not predicted by the Standard Model, that is)? If not, can we call it a scientific theory?

74. **Walt**

December 24, 2006

Does anyone else feel sorry for the Ptolemaic epicycle system?

75. **Jonathan Vos Post**
December 25, 2006

Excerpt from Pharyngula science blog
http://scienceblogs.com/pharyngula/2006/12/blank_post.php

(medieval): Nature abhors a blank post.

(modern): Blank posts are spontaneously filled by virtual posts and antiposts.

(postmodern): String Theory (strings of alphanumerics) has failed to make any useful predictions on a Blog Theory of Everything. Or, more properly, Character String Theory predicts a "landscape" of over 10^500 possible blogs in a blogmultiverse.

See, for instance,
Not Even Wrong

December 25, 2006

Walt,

Some commenter here pointed out that Ptolemaic epicycles are at least much better than string theory. They make loads of experimentally verifiable predictions.

77. **Jonathan Vos Post**
December 27, 2006

J.F. Moore's question, and the mention of ancient Greeks, and Ptolemaic astronomy are connected.

For instance, J.F., Aristarchus may not have been thought mad, but his heliocentric theory was ignored for a millennium, until Copernicus rediscovered it.

www-history.mcs.st-andrews.ac.uk/Mathematicians/Aristarchus.html

Democritus was not thought mad, and was seriously discussed by Epicurus (who sort of predicted chaos theory in cosmology) and Lucretius (so long ago that science was disseminated in poetry). But most people thought that atoms were only a philosophical construct, until Dalton updated them. Until Einstein's quantitative analysis of Brownian motion, many scientists STILL thought atoms a mere calculational convenience.

Odds are good that some other obscure ancient pre-Socratic Greek theorists will be rediscovered in some exciting future way. Those folks were actually in favor of experiments. That died out, for reasons unclear to me (Aristotle?) and ivory-tower theory dominated until the modern era.

The attack on String Thory is, in part, a historical analogy to the debate between pre-Socratics and later natural philosophers on the value of empirical methods.

I can't recall the author and title of a science fiction story about someone who created a hierarchical theory of genius. He systematically searched the trash heaps of insane asylums for ideas thought mad that turned out to be true, but ahead of their time. In the story, he found a few. Wasn't Grassman thought mad, and eventually accepted the claims, with his algebra filled with nilpotents. Turned out right, but ahead of its time.

78. **Jonathan Vos Post**
December 29, 2006

So the cosmos is not a dodecahedron embedded in a 5-dimensional composition of 4 elements plus Quintessence, but rather of strings of phlogiston?

And these string can be plucked in a Pythagorean mathematical harmony so as to become the electric fluid?

I have not the Humor to follow this, but wonder what the soothsayers determine from the portents on how long such a theory will be accepted.

As pointed to by Ars Mathematica, here's a wonderful quotation, and fascinating paper, on the
misapplication of scientific statistical methodology, which might just as well be applied to String Theory by its critics.

"… a potent but sterile intellectual rake who leaves
in his merry path a long train of ravished maidens but
no viable scientific offspring…."

From:
"The Earth is Round (p 'less than sign' .05)" by Jacob Cohen, 1994.
http://camargue.unibas.ch/cohen1994.pdf

79. **XPM**
January 1, 2007

> I can't recall the author and title of a science fiction story about someone who created a hierarchical theory of genius. He systematically searched the trash heaps of insane asylums for ideas thought mad that turned out to be true, but ahead of their time.

The story (or more precisely, a "review" of a fictitious story) "Odysseus of Ithica, New York." in Stanislaw Lem's *A Perfect Vacuum*.

Scott Aaronson For Sale

December 21, 2006
Categories: Uncategorized

Scott Aaronson has adopted a sensible attitude towards the controversy over string theory, announcing in a new posting entitled [Mercenary in the String Wars]() that his allegiances in this "War" are for sale to the highest bidder. I encourage all my extremely wealthy financial backers to take him up on this.

He seems to have reached this decision after enjoying an all-expenses-paid vacation in the Bay Area courtesy of the Stanford string theorists, despite having a great deal of sympathy for the criticisms being made of string theory. While there, he gave a talk for which he makes his notes available, on the topic of [Computational Complexity and the Anthropic Principle](). It's quite entertaining, although the fact that anyone is seriously debating the kind of issues Scott discusses is a good indication of how far off the rails string theory has gone.

Scott seems surprised to discover that, in private discussion, string theorists are far more reasonable than he expected from their writings, from the behavior of string theory bloggers like Lubos, and from his conversations with Greg Kuperberg, who is convinced that string theory critics are "intellectually non-serious" (I forgot to mention in my last posting that Kuperberg was someone else I had in mind when quoted in 02138). His experience agrees with my own, that in private conversation I find that most string theorists and I agree much more than one would guess. In such a context I've just about always found them more than willing to admit that the current situation of string theory is disturbing, progress has ground to nearly a halt, and that the whole landscape business is extremely problematic. That these attitudes are not well reflected in the public utterances of string theorists I think is due to several factors. Given the problems facing the theory, many find it best to just avoid being quoted publicly, and those who do talk to the press feel that their field is to some extent under unfair attack in the media and they should make their best effort to defend it. Those who spend their time vigorously defending string theory as a healthy research program, attacking its critics on blogs and elsewhere, often represent only a tail in the statistical distribution of views and behaviors of the string theory community.

I also suspect that one reason Scott found the Stanford string theorists behaving more reasonably than he would have guessed is that the last year or so has not been kind to their early hopes that statistical calculations would allow some sort of real predictions to emerge from the anthropic landscape. It has become increasingly clear that this kind of idea just can't work, for reasons that have been extensively discussed here.

I predict a lively discussion in the comment section over at Scott's blog, and encourage people to use that venue. Already John Preskill has weighed in with what he thinks is an unintentional double entendre about Susskind: "When I listen to Lenny Susskind, I really believe that information can come out of a black hole."

Update: Scott is pretty funny, but I have to admit that Lubos is completely [hilarious]().

Comments

1. **hack**
   December 21, 2006

   string theory critics are "intellectually non-serious"… this sounds alot like the language used by neoconservatives against critics of the Iraq war. Interesting parallel.

2. **M**
   December 21, 2006

   I think that

   a) judging string theorists from Lubos, and
   b) judging string theory from our anthropic vacuum

   are equally misguided approaches. One event is not enough to meaningfully test a statistical distribution.

3. **Peter Woit**
   December 21, 2006

   hack,

   Because of my desire to keep politics out of this blog I've avoided so far giving into the temptation to draw parallels between the string and Iraq fiascos, but it is hard to resist. In both cases most sensible people agree things are going badly, with those in authority resisting calls for pulling out and accusing their critics of not providing a tolerable alternative. Also, in both cases most people I know think not much is going to improve until Nov. 2008, when US presidential elections, and LHC experimental results, both promise about a 50% chance of some positive changes in the situation.

4. **stringhater**
   December 21, 2006

   It is easy to criticize a scientific endeavor, if it is speculative it is crazy, if it is not speculative, it is going nowhere, or it is not cutting edge, the speculations might or might not develop into facts, if they dont they an easy target, crazy speculations which were obviously never going to work, if they do, they are often incremental, something you can brush off as insignificant, it doesnt achieve all you had hoped, well that happens all the time, science is normally incremental, Peter Woit, you find it so easy to criticize the science of others, what about your own, has it progressed more than all those whom you so easily criticize? Oh, wait a minute, you don't seem to have any science, well that explains a few things.

5. **wazoo**
   December 21, 2006

   The anthropic principle seems to have weird effects on people. I wonder whether people really argue in those terms? And, at Stanford?

   What's going to happen when those graduates start reaching the higher rungs at Hewlett Packard? I don't know… I think those slides gave me a horrible hangover…

6. **Yatima**
   December 21, 2006

   wazoo said:

What's going to happen when those graduates start reaching the higher rungs at Hewlett Packard?

What do you _think_ will happen? The usual stuff: Winning contracts, eliminating co-workers, mooching and smooching, the odd superfluous management book; maybe some pretexting and an invitation to a board of enquiry. Business is quite unlike physics. It is even quite unlike engineering.

While "Computational Complexity and the Anthropic Principle" is certainly not a great contribution to string theory (IMHO of course), it certainly is fun reading. Though I'm not sure whether, assuming that "There is no physical means to solve NP-complete problems in polynomial time" holds in the universe (which I agree with), the sentence "There is no way to reach a solution to an NP-complete problem in polynomial time in the multiverse" is necessarily true or even meaningful. Where is Greg Egan when you need him?

…but for this evening I have the Complexity Zoo to admire.

7. **anon**
December 21, 2006

Scott Aaronson's talk mixing the everett multiverse and the anthropic principle is…breathtaking…Not-Even-Wrong "physics" of monumental proportions.

The huge complexity zoo makes it starkly clear that complexity theory is a very young field. Those guys need a classification theorem that will reduced the number of complexity classes by a factor of 10, at least.

8. **Scott Aaronson**
December 21, 2006

Those guys need a classification theorem that will reduced the number of complexity classes by a factor of 10, at least.

I've heard that complaint more often than I can remember, but I've never found it particularly well thought-out. Do chemists need a classification theorem that would reduce the number of elements — say, by collapsing nitrogen with helium? The bottom line is that there are a lot of complexity classes because there are a lot of models of computation. Furthermore, we *know* that collapse can't be the general rule of the Complexity Zoo — for example, since P!=EXP, we must have either P!=NP or NP!=PSPACE or PSPACE!=EXP (and most likely all three of them).

If you're serious about wanting a classification theorem, can you tell me anything concrete about what such a theorem should look like? This blog is no place for critics and naysayers — I want to see a positive proposal! 🙂

9. **Not Even Not Even Wrong**
December 21, 2006

Scott,
chemistry has the periodic table, which is a classification and probably just the sort of "reduction" that anon was talking about.

10. **Scott Aaronson**
December 21, 2006

Yes, but it's a *messy* classification, where some rows contain 2 elements, others 8, and others 18, and the properties of an element can be deduced from the column it's in except when they can't…

I could give you a "classification" of complexity classes in exactly the same sense. Here, I'll even start: P is to NP is to BPP, as E is to NE is to BPE, as EXP is to NEXP is to BPEXP…

11. **Chris W.**
December 21, 2006

Actually, Hack, neoconservatives have started directing the accusation of "non-seriousness" against the Bush administration. Don't ask me why it took so long. From "Neo Culpa" in Vanity Fair:

> **Kenneth Adelman**: "The most dispiriting and awful moment of the whole administration was the day that Bush gave the Presidential Medal of Freedom to [former C.I.A. director] George Tenet, General Tommy Franks, and [Coalition Provisional Authority chief] Jerry [Paul] Bremer—three of the most incompetent people who've ever served in such key spots. And they get the highest civilian honor a president can bestow on anyone! That was the day I checked out of this administration. It was then I thought, There's no seriousness here, these are not serious people. If he had been serious, the president would have realized that those three are each directly responsible for the disaster of Iraq."

12. **Arun**
December 22, 2006

Thomas Friedman, NYT pundit and pontificator, had a bunch of rules for the Middle East in his column, which I have presented here removing one sentence.

"Rule 1: What people tell you in private in the Middle East is irrelevant. All that matters is what they will defend in public in their own language. Anything said to you in English, in private, doesn't count. …. In the Mideast, officials say what they really believe in public and tell you what you want to hear in private."

I'm wondering whether Friedman Rule 1 is applicable in a wider circle than just the Middle East.

(w.r.t. "… in private conversation I find that most string theorists and I agree much more than one would guess.").

13. **Chris Oakley**
December 22, 2006

Stop! Stop! Enough politics! This is getting like Lubos's blog!

14. **Robert Musil**
December 22, 2006

Surely there can be few means of evidencing the "non-seriousness" of a scientific discussion than for its participants to decend into political analogies of which they generally have little expertise. "Not Even Wrong" is an admirable, serious discussion maintained by a remarkable man.

The political infection is a mistake. A very big mistake.

15. **Peter Woit**
December 22, 2006

OK, OK, no more politics. But at least no one has brought up global warming….

16. **A String Theorist**
December 23, 2006

Hi Peter,

In a comment above you indicate your belief in the possibility that experimental results from the LHC could lead to an improvement in the string theory situation.

Do you believe we might actually discover TeV scale strings, black holes, or extra dimensions?

It seems that if we "only" discover some kind of supersymmetry, or Higgs (even if it is not the standard Higgs but something more exotic), that will have no impact on string theory (other than sociological) because any such scenario can likely be embedded in some version of string theory.

To summarize: it's really hard for me to imagine any experimental result that would have an impact on string theory.

17. **Peter Woit**
December 23, 2006

A String Theorist,

What I meant about the LHC was not that it would have anything to say about string theory, but that it might tell us something exciting and unexpected, most likely about electroweak symmetry breaking. If this happens, many theorists would just drop string theory and work on whatever new direction the experiments are indicating. This would improve a lot the situation of particle theory, not the situation of string theory.

18. **Thomas Larsson**
December 23, 2006

To summarize: it's really hard for me to imagine any experimental result that would have an impact on string theory.

For almost 20 year, Ed Witten repeatly stated that string theory makes one prediction, supersymmetry (and one postdiction, gravity). Hence if SUSY is disproven at the LHC, there are two possibilities:

1. Witten was right and string theory is wrong. Then there seems to be no point in pursuing string theory.

2. Witten was wrong. Since Witten's enthusiasm was the main reason for being interested in string theory in the first place, there seems to be no point in pursuing string theory.

19. **Arun**
December 23, 2006

Perhaps the so-far-unsuccessful scientific effort to detect gravitational waves – which I think is at least as old as the first string revolution – can be examined for clues as to how patient one needs to be with respect to scientific discovery?

20. **no**
December 23, 2006

general relativity was proposed in 1915, made a firm postdiction for the perihelion of Mercury and a few firm predictions; the first one was quantitatively confirmed in 1919 (just after WWI, that caused some delay).

String theory predicts supesymmetry, maybe around the weak scale, maybe a bit above, maybe around the string scale (which could be anywhere below the Planck scale), maybe at any intermediate scale, maybe split, maybe super-split (on 1st April).

Arun, I think there is some difference.

21. **Arun**
December 24, 2006

no, I specifically mean LIGO!

22. **MathPhys**
December 24, 2006

Am I reading Lubos right? Is he preparing himself for leaving academia?

23. **YBM**
December 24, 2006

I'd guess that Lubos is actually searching desperately for an excuse, feeling he's likely to be fired soon.

24. **PPKR**
December 25, 2006

$2 for scott

25. **gw**
December 25, 2006

lubos's low-degree of psycosocial intelligence (esp., inability to detect sarcasm/clearly identifiable marks of non-seriousness) leads me to conclude that he has asperger's syndrome. he should be checked.

26. **Eli Rabett**

December 25, 2006

Two short comments. First, the interesting question about Motl is what next. He is not stupid, which either means he has some plan for the future that fits in with his behavior, or he is stupid (see a) or he has a cushy job lined up somewhere else (Czech Republic??) where his behavior and lack of production will not make a difference so he can indulge himself.

Scott Aaronson makes a fundamental mistake. While the periodic table may appear messy to a physicist, it is a huge reduction from the number of possible molecules, and the key organizing principle in chemistry. As a minor note, the original table, based on reactions with oxygen and hydrogen WAS rectangular, however there are a large number of other forms which may appeal to you (in roughly chronological order)

27. **Jonathan Vos Post**
December 25, 2006

"There is no way to reach a solution to an NP-complete problem in polynomial time in the multiverse" is necessarily true or even meaningful. Where is Greg Egan when you need him?"

Or Charles Stross, or Rudy Rucker, or Vernor Vinge, all of whom write great fiction about such questions.

28. **Hans**
December 25, 2006

I have Aspergers Syndrome myself and studying theoretical physics. And I can say, Lubos is a hard case of this desease.

I have run in similar problems on internet forums as he does on his blog.
When discussing about things in which feelings of other persons would be involved, everyone could see my "mathematical thinking style" unable to recover emotions of other people (at least as fast as a normal people should)

An extreme case, where this lack of empathy is seen, is this post of lubos:
http://mrigmaiden.blogspot.com/2006/08/zero-divergence-blogroll.html

Although the grandma of the poster has died, lubos attacks the physical ideas of this female student. He relies on physics having no connection to how the attacked person might feel.

From my experiences, I have learned, that it is best for a person with AS, only to comment seldom on things where feelings of toughts of others are involved. And when, then one has to put words like "I think" or "in my opinion" Or "maybe" or "as I understand" in ones sentences. This is, because the mathematical thinking style makes a person with AS believe, he/she knows the world for sure.

But this isnt. Since persons with AS have only a rather small connection to others feelings, and so, they miss important facts in their analysis.

One can live with AS almost without being seen as excentric. But only if one represses oneself on discussions that could be connected with others feelings.

If I would open a blog and discuss opinions of sociology or personal feelings on what others are doing (calling people working on LQG as crackpots is not a scientific statement), It would be my death.

But exactly this is the problem here:
It is correct, that LQG is not developed that far as string theory is (because of the lower number of researchers). So lubos is calling researchers in this field as crackpots. Because they are working on a theory that is not developed that much. His mathematical analysis leads to a conclusion and then he insults the researchers.

It is correct, that most females have not so much scientific interests than males. This statement can be based on sociological data as on brain functional analysis. Lubos sees this, and now tries to find more facts. He then looks for IQ studies of woman, and states this loudly. Without thinking, that he will insult some women. (But however, it is not intelligence, but different interests, (it can be shown that woman are, on the average, more interested in living objects), why, regrettably, so few woman study physics. Here lubos has lack of knowledge of sociological data, but he presents his poor evidence loudly as facts. With no care, of insulting anyone. Sentences, like "I think" or "Maybe it is" or "this might be an interesting result", or any sign of open-mindedness for other meanings are not present.

This is typical for AS. A person with a mathematical mind takes some data as axioms. And then, all other opinions are wrong.

And he will present his thinkings without any knowledge how others feeling.

I think for him it would be the best, simply to SHUT DOWN HIS BLOG IMMEDIATELY and concentrate himself working on some papers. He has ruined his life with his blog.

In Munich, I've heared Suesskind complaining personally about Lubos Blog! If Lubos would not have this blog, almost everyone would employ a former Harvard professor. (But of course, Lubos won't shut down his blog, because he thinks that he was always right, seeing no insults he has made. He writes that he "does not enjoy elementary human rights now", and this shows no insight, that he has done something wrong)

Lubos should furthermore only comment on sociological items, when he has thought of seriously, what others might think of his sentence.

This is something, one can expect from an intelligent man, even if he has AS or not.

And then, when he finds out, that he has no or not much ideas of, what others might think on his sentences, he should go to a therapist, who gives him some hints).
Then he should try to train this ability.

For Lubos, this is the only way to go.

A first check if he should go to a doctor is this test from Cambridge:

http://www.wired.com/wired/archive/9.12/aqtest.html

29. **Eeyk**
December 25, 2006

This kind of "diagnosis-at-a-distance" doesn't strike me as particularly serious. On the other hand autism, in any of its different forms and degrees, does not explain, for example, why should anyone write a long piece of gratuitous, deceitful publicity for Micros*ft in their own blog. Just plain stupidity of the garden variety is more than enough for that.

Demographically speaking, people afflicted with Asperger syndrome are relatively rare. Guys like Lubos, look for one and you'll find dozens.

30. **John A**
December 25, 2006

Hans, that's very insightful. I'd never thought of Lubos like that but it makes a lot of sense. Lubos does not recognize certain behaviors that he displays are exactly the same sorts of behaviors he criticizes in others.

I've had some run-ins with some climate scientists (and one or two journalists and mad bloggers) but I have never, ever wished them physical harm. The idea that Lubos could wish that of Peter Woit is beyond reprehensible, its inhuman.

I think Lubos could shut down the blog, if and only if, he could be convinced that the blog was detrimental to his work even if it is remarkably popular. If I was looking to employ Lubos, then I'd insist that he shut down the blog.

I know a professor at Harvard who told me that he is not allowed to run a blog nor respond to people on blogs. I've no idea how or why Lubos gets away with it.

There IS a crisis in physics and nobody knows how to begin to solve it. A theory of quantum gravity that makes testable predictions is as elusive today as it was in Einstein's time.

31. **Hans**
December 25, 2006

Eyek wrote
>Demographically speaking, people afflicted with Asperger syndrome are relatively rare.

No. It affects 0,05% in the general population.

Most of these people become mathematicians or physicists or engineers.
In physics they aren't rare. At least, they are as rare as people in academic positions on western universities whishing others to die because they have other opinions.

Again: This post here:
http://mrigmaiden.blogspot.com/2006/08/zero-divergence-blogroll.html
indicates behaviour that only someone without empathy can have.

For example, these points of behaviour would led to a diagnosis by a doctor (DSM-IV):

#1) Restricted repetitive & stereotyped patterns of behavior, interests and activities, as manifested by at least one of the following:
1A) encompassing preoccupation with one or more stereotyped and restricted patterns of interest that is abnormal either in intensity or focus.
(Lubos hates LQG and does String theory only. I think he is preoccupied with string theory to an abnormal intensity. Some would say he is a "String theory fanatic". That does count here.)

He fullfills one criteria of #1. so we go to step #2

2 The disturbance causes clinically significant impairments in social, occupational, or other important areas of functioning.

(When others think his behaviour is rude, or excentric, and telling him this often, and Harvard forbids him to write what he wants, this could count as a significant impairment. At least then, when Lubos becomes unemployed and does not get a job, because of his blog. It is to say here, that many professors with AS do not fulfill the point above. But this point is not present in many other diagnostic criteria. That is, we could use the criteria by Gilbert or ICD10, were this is not present, if we want him diagnosed)

3 There is no clinically significant general delay in language
(Lubos speaks fluently and theres no reason to believe he had suffered from language delay in the past)

4 There is no clinically significant delay in cognitive development other than in social interaction
(Lubos is a bright guy. Otherwise he would not be able to do string theory)

5 Qualitative impairment in social interaction, as manifested by at least two of the following

5A) lack of social or emotional reciprocity
(Aaronsons post was humour. This is seen by most healthy adults. But not by lubos, who lacks appropriate emotional reciprocity and takes Aaronsons post in fact by word)

To fully qualify for a diagnosis, he must now fulfill one of the following points:

5B) marked impairments in the use of multiple nonverbal behaviors such as and gestures to regulate social interaction
5C) failure to develop peer relationships appropriate to developmental level
5D) a lack of spontaneous seeking to share enjoyment, interest or achievements with other people

Of course, I cannot check B,C,D online! But I think he fulfills 1A, 2, 3, 4, 5A.

For a doctor, it would be important now, if he also fullfills 5b or 5c or 5d. He only needs to fullfill one point and then case closed.

Or one could look at maybe DSM-IV or ICD-10 where other diagnostic criteria are stated. Maybe there IS case closed then.

32. **MathPhys**
December 25, 2006

I must admit I was stunned to read Lubos' reaction to Aaronson's post. Something's wrong with that young man.

33. **woit**
December 25, 2006

Please, please, enough about Lubos's supposed psychological problems, this isn't on-topic or worth this much discussion, and mostly seems to me rather ill-informed anyway. I have no idea what he's alluding to about leaving academia. The most amazing thing about him has always seemed to me the fact that his string theory colleagues seem to consider him a serious scientist, the best young one they can hire, and to this day, as far as I know, have not taken any steps to try and bring his point of view on string theory into some sort of alignment with reality.

34. **woit**
December 25, 2006

Arun,

I don't really see any relation between LIGO and string theory. One has known what sorts of gravitational waves GR predicts for a long time, they have been indirectly observed in binary pulsars, and direct observation is a very tough technical problem. The current LIGO has always been known to not be sensitive enough to definitely see a signal.

35. **Hans**
December 25, 2006

Sorry, for these discussion about Lubos. It will never occur on this Blog anymore.

I made this post because people out there, who are to give him a new job, after his time at Harvard is over, can understand Lubos better.
Lubos may feel, that no one would give him a new job in academia because of his behaviour. He may feel, that he is in some sense "outside" of the community. And therefore, he writes that he looks forward to leave it.

It is important for future employers to recognize, that they deal with someone, whose papers should be read with greatest interest, but his insulting writings on other people are simply not to be taken seriously or as rude. It is important for employers, that Lubos does not intend to be rude, naive, or odd in any way.
I think, Lubos just thinks he makes (mathematically) correct statements.

One should judge him on his papers and on nothing else.

I would give him a research scientist position, were he can write papers without influence of anything social other than simple situations as lecturing, for example (here one speaks logically derived sentences to a silent audience. He will have no problems with lecturing).

It is important to have a non perturbative string theory. And this part of his research might be the reason for giving him a job at Harvard.

He should be given a position, were he can develop this further.

36. **Scott Aaronson**
December 26, 2006

Thanks, Hans — I have no idea if your analysis is correct, but it did help to put Luboš's apparent vitriol against me and others in a different light.

Scott Aaronson makes a fundamental mistake. While the periodic table may appear messy to a physicist, it is a huge reduction from the number of possible molecules, and the key organizing principle in chemistry.

In exactly the same sense, the "zoo" of complexity classes is a huge reduction in the number of possible computational problems, and the key organizing principle in theoretical computer science. The zoo and the periodic table are both relatively messy, but still much simpler than the alternatives.

37. **Graduate**
December 26, 2006

Hans,

No offense intended but maybe you should go post all this stuff on Motl's blog where he might have a think on it. Whether he has AS or not, you do seem to have some helpful insight into his behavior so maybe you will know how to get things across to him in a way that will help.

Cheers.

38. **Hans**
December 26, 2006

I think this won't help. He would simply delete my comments, without any thinking.

The problem is, that he belives he is strictly correct. He thinks simply:

String theory=most developed theory of Gravity
=>String Theory=Science
=>critics of String Theory=anti-scientists.
Anti scientists=crackpots
As a scientist one must fight against crackpots
=> one must fight strongly against any critique of String theory.

That is all. There is no space for other opinions, meanings and thinkings or even humour in his mental structure.

Maybe his colleagues tried often, to explain him, that there are allways different opinions out there. Maybe they have given up, because telling him this has no effect on him. (At least Susskind, who, in Munich, projected a big photo of a prof. Lubos Motl, Harvard, with his beamer, that was signed with the phrase "Susskind is senile", seemed to found it strange, that such statements are in a blog from a Harvard professor. I think, in Stanford, he won't get a job these days).

To say that there's a point in life, which he misses completely is, in my opinion best done by a friend (if he has such) or a colleague, whom he has some respect of. At best of course a String theorist.

And not an anonymous crackpot coming from a crackpot blog of the internet.

Also: In a one to one conversation, these problems might be not present. Since here, one has a wider context (as facial expressions), which makes it easier detect, if some words are not appropriate as in online writings.
It might be, that in a one to one conversation, he is seen by his colleagues as merely a "shy" man. So one could forgive his colleagues, when they dit not tell him something.

Also, I think although Lubos is not allowed by Harvard, to comment on "not even wrong", he even might read this postings here, just for couriosity. Here, he can read them twice, without deleting them.

Aaronson might complain to Harvard because lubos called him "the ultimate example of a complete moral breakdown of a scientist"
and "a corrupt piece of moral trash. "

I think such a complain should be made to Harvard. In it it should be emphasized, that no one can take Lubos seriously after reading his texts. Aaronson could write, that Harvard should protect Lubos from himself by shutting down his blog which continues to contain insults.

39. **Eeyk**
December 26, 2006

No. It affects 0,05% in the general population.

Five in ten thousand is what most people would call "relatively rare".

At least, they are as rare as people in academic positions on western universities whishing others to die because they have other opinions.

"Empathy-impaired" persons are not necessarily afflicted with AS. Many other conditions can lead to a lack of empathy. Even more so, non-empathic people are not necessarily mentally ill, just as non-musical people are not necessarily deaf.

I understand your viewpoint, and your opinion on this might well be correct, but I think it takes more than bad net.behavior and over-the-top blogposts to diagnose someone with a mental illness or personality disorder.

40. **Hans**
December 26, 2006

Well, I think this is rather going off topic here.
I simply wanted to give Lubos or employers of Lubos some advice. Not more. And this will definitely be the last reply on that topic.
We should discuss on physics now.

But to answer Eeyek shortly:
He wrote:
"non-empathic people are not necessarily mentally ill"

It is a spectrum. One says, that "non-empathic" people are ill, when they run into problems with environment or their lack of empathy is simply striking. That's all.

To answer the second point:
I have met people diagnosed with AS on internet forums. Unfortunately some hard cases behaved in a way, exactly with the same writing style (when it comes to social naivity, misunderstanding, (unfortunately) aggression, insults, fanaticism on topics, collecting data, repeating facts, repeating contents) as I see it from this Harvard professor. The reason for my conclusion comes from at least 70 samples with AS. The fact that I've seen exactly this behaviour only and I emphasize ONLY in harder cases with AS, is the reason for calling him unfortunately a "hard" case in the post above.

I don't want to go into detail here, even if I could do it easily, because this is a physics blog.

Maybe Lubos has no AS. But then he would be a very good imitator of a harder case of this disease. It is difficult to imitate a disability.

Just for fun: http://www.math.columbia.edu/~woit/wordpress/?p=111

41. **Hans**
December 28, 2006

Lubos now says, that he might go to Kenya
http://www.haloscan.com/comments/lumidek/6952878876388094292/?src=hsr#689412

Wonder, if they need there any sort of a stringtheorist. At least, it was Czech fighter jets which they definitely wanted in Kenya.
http://en.wikipedia.org/wiki/Corruption_in_Kenya
Would have cost them Sh 12.3 billion. Maybe they think Lubos gives a good warlord (or what so ever).

Well, as Lubos has some experience with countries whereis not much freedom of speech as was in former communist czech and as is in Kenya till today:
http://news.bbc.co.uk/2/hi/africa/4765250.stm

I don't think one really has to fear about him there.

42. **Chris Oakley**
December 29, 2006

> Lubos now says, that he might go to Kenya

Fine by me, especially if he has no access to the internet there.

43. **Hans de Vries**
December 29, 2006

> Lubos now says, that he might go to Kenya, "Wonder, if they need there any sort of a string theorist "

Do not underestimate Kenya's head of Internal Security Michuki. He knows very well that String Theory is currently our only hope for the development of gravity guns, or wormholes generators for rapid troop deployment, just to name a few.

Be sure that Security chief Michuki did read the literature and books on advanced physics directed to the general public. Without doubt he has the means and will to provide Dr. Motl with his own secret lab in the jungle to lay the basis for a grandiose vision of a great pan African empire.

For Dr.Motl, Africa will be just as good as any starting place to free the world of Climate fanatics, Islam, feminist, liberals, democrats, communist and worst of all: crackpots (String theory skeptics). There are already signs of an emerging united African front (including Mogadishu warlords) in the struggle against the latter.

Regards, Hans

Holiday Links

December 26, 2006
Categories: Uncategorized

A random collection of links, on the whole not having anything to do with the holidays:

A Stanford Physics Student in Berkeley is now An American Physics Student in England, and reports from the DAMTP Christmas party, where people were supposed to be wearing "Sci-Fi" costumes, that one physicist came in a black t-shirt with the following printed on the front:

The Anthropic Landscape of String Theory

Leonard Susskind. hep-th/0302019

As far as I can tell, of string theory papers written during the last four years, this is the second most heavily cited (the first is the KKLT one that inspired it). How dare these English people act as if this is some sort of joke?

Raymond Streater's Lost Causes web-site has always been a wonderful source of anecdotes and opinions. He has a new book coming out any day now from Springer entitled Lost Causes in and Beyond Physics which I've just ordered and am looking forward to reading. Streater's web-site also includes a pretty hilarious commentary on Lubos Motl's typically absurd review of one of Streater's earlier books, the deservedly famous PCT, Spin and Statistics and All That, written with Arthur Wightman. I had never realized I was in such good company.

From Streater's web-site I also found a link to an interesting talk by Guralnick on some of the history he was involved in of work on symmetry breaking in QFT during the sixties which ultimately led to the Glashow-Weinberg-Salam model and what is now known as the Higgs mechanism. The talk tells how leading physicists discouraged work on these ideas as "junk" that wouldn't lead anywhere and would ensure that one couldn't get a job. During these years the dominant opinion was that S-matrix theory was the route to future progress, with QFT a dead-end.

Back when I was a physics graduate student I remember every so often picking up a copy of the journal Foundations of Physics and flipping through it, trying to read some of the articles. From what I remember, at the time it struck me as a semi-crackpot phenomenon, mixing a few serious attempts at thinking about foundations with large heaps of nonsense. It seemed clear to me then that serious theorists worked on very different things, trying to understand gauge theories and the Standard Model. A friend of mine who was also a graduate student back in those days recently told me that now the current mainstream literature strikes him as much like that found in the old days in journals like Foundations. I don't know what this means for physics, but Springer recently announced that Gerard 't Hooft (one of the main creators of gauge theory) is taking over as editor-in-chief of the journal. Maybe in times like ours in which there is no experimental guidance, work on foundations should get new emphasis (I think this is one of the points in Lee Smolin's recent book).

If one wants an overview of recent developments in the interaction of math and physics, one could do a lot worse than read the proposal from various mathematicians and physicists in the Netherlands entitled The Fellowship of Geometry and Quantum Theory (via Klaas Landsman's web-site).

John Baez's student Derek Wise has a well-written paper about Cartan connections, and John provides some commentary in his latest This Week's Finds in Mathematical Physics. I've always been fascinated by Cartan connections, since they provide a framework linking very general ideas about geometry with Lie groups. As John notes, they provide a joint generalization of the Riemannian and Kleinian points of view about geometry. They also seem to provide a natural mathematical framework for thinking about the relation between GR and gauge theory. Besides the references given by Wise, one should also note that Kobayshi-Nomizu, the standard reference text among mathematicians on geometry from the point of view of connections, is very much inspired by the idea of a Cartan connection. It seems likely to me that if we ever figure out how to properly understand geometrically how to unify gravity and the standard model, these ideas will be part of the story (although much else will also be required, including an understanding of the role of spinors, and of the geometry behind quantization).

Finally, for comic relief, Kris Krogh pointed me to a talk by Michael Berry from a few years ago, where he describes his experience back in 1985 at CalTech when he was working on quantum physics and zeta-functions, and met up with some of the local string theorists:

I met one of them, who asked what I was working on. When I told him, he fixed me with a pitying stare. "Yes, we have zeta functions throughout string theory. I expect the Riemann hypothesis will be proved in a few months, as a baby example of string theory."

Update: Several people have pointed out that the Susskind t-shirt or the report about it contain a typo. The correct reference is hep-th/0302219

Update: There's an interview with me posted on Scienceline, the web-site of the NYU Science, Health and Environmental Reporting Program, with the title Stringing Up String Theory.

Update: Yet another interview, this one with Lee Smolin at IEEE Spectrum on-line, called Thread-bare Theories.

Comments

1. **andy**
   December 26, 2006

   I once talked to our librarians about the peculiar inclusion of "foundations of physics" with the other physics books because it appears to be a philosophy journal. Apparently the LOC decides where it is shelved for most libraries.

2. **Peter Shor**
   December 26, 2006

   Can I put in a plea for less scorn in physics? I don't really want to defend the foundations of physics, as much of the research in this field really was, and probably still is, junk. But the dismissal of the whole field as garbage by the vast majority of mainstream physicists is, in my opinion, a large part of the reason that the profound differences between classical and quantum computation weren't discovered earlier. The field of quantum computation was thus ignored by the mainstream and founded by crackpots, outsiders (such as me), and the occasioual genius who didn't care what other people thought. This, of course, was greatly to my benefit. (I've changed my mind. More scorn! More scorn!)

   If the string theorists are wrong, the scenario will undoubtedly be repeated in the case of quantum gravity. Is anybody paying attention to the work of Alain Connes, a genius *and* an outsider?

3. **Tony Smith**

December 27, 2006

Peter Woit said "… Kobayshi-Nomizu, the standard reference text among mathematicians on geometry from the point of view of connections, is very much inspired by the idea of a Cartan connection. It seems likely to me that if we ever figure out how to properly understand geometrically how to unify gravity and the standard model, these ideas will be part of the story (although much else will also be required, including an understanding of the role of spinors, and of the geometry behind quantization). …".

In that context, might it be useful to revisit the 1980s work of Meinhard Mayer, A. Trautman, et al, on the geometry of gauge theories, which work extended the 1960s Kobayashi-Nomizu material from a gauge physics point of view ?
Examples of such work include:
Hadronic Journal 4 (1981) 108-152;
and
New Developments in Mathematical Physics, 20th Universitatswochen fur Kernphysik in Schladming in February 1981 (ed. by Mitter and Pittner), Springer-Verlag 1981, especially the articles entitled
A Brief Introduction to the Geometry of Gauge Fields;
The Geometry of Symmetry Breaking in Gauge Theories; and
Geometric Aspects of Quantized Gauge Theories.

4. **Tony Smith**
December 27, 2006

Peter Shor asked "… Is anybody paying attention to the work of Alain Connes, a genius and an outsider? …".

Actually, Peter Woit has had at least two entries on this blog about Alain Connes:

December 2005 at http://www.math.columbia.edu/~woit/wordpress/?p=313
which has links to a Tehran interview and workshop

and

October 2006 at http://www.math.columbia.edu/~woit/wordpress/?p=482
The latter entry has links to
http://arxiv.org/abs/hep-th/0610241 (a paper by Chameseddine and Connes in which they calculate "… a Higgs mass around 170 GeV and a top mass compatible with present experimental value …", clearly (in my opinion) the type of results that superstringers would love to have but have been unable to get)
and
http://www.newton.cam.ac.uk/webseminars/pg+ws/2006/ncg/ (a Cambridge workshop on noncommutative geometry)
as well as
a link to an interview with Connes at
http://www.arte.tv/fr/connaissance-decouverte/science/Paroles_20de_20chercheur/1350636.html

Tony Smith
http://www.valdostamuseum.org/hamsmith/

5. **Paul Jackson**
December 27, 2006

Peter Shor is right; we need more tolerance in Physics. On the other hand, there may be wisdom in Henry Ford's aphorism: "History is bunk" (or did he mean Philosophy?). But the equivocal stance is a futile one. So I say — strength to Peter Woit, who is anything but equivocal.

There is also room in physics for folk like Eduard Prugovecki, a Toronto physicist-mathematician-philosopher who explored the prehistory of the String Wars (aka the Renormalisation Wars). A long and informative article of his is at:

http://individual.utoronto.ca/prugovecki/EpistemicPerspectives.html

It does not appear in the archives of this Blog, but should be more widely known.

6. **Michael**
December 27, 2006

Hi Peter,

[this is somewhat off-topic but closely related to your post]

You once blogged that Graeme Segal would conduct a seminar at Columbia during December. Has he held his seminar yet?

7. **woit**
December 27, 2006

Michael,

Segal gave a long lecture at a one day conference organized by Dennis Sullivan at the CUNY Graduate Center in December. He also gave a long series of lectures here at Columbia this past semester.

The lectures were about various topics in QFT, and he is writing a book on the subject. I've been trying to think of various tactics that might encourage him to get the book done more quickly. One of them would be to put my own notes from his lectures on-line, but given their state, I decided that that would be mean. Some of this material is already in lectures that you can find on-line written up by Segal himself.

8. **Matt**
December 27, 2006

First of all, I can name the Anthropically attired physicist, but I'm not sure if he would want to be "outed", so I'll just send him a link to the post.

Secondly, Andy said, “I once talked to our librarians about the peculiar inclusion of “foundations of physics” with the other physics books because it appears to be a philosophy journal.”

It’s a physics journal alright, just not one that only publishes papers that calculate the cross-section of somethingorother. I realize that makes it not recognisable as physics to a large section of the physics community. Compare with Stud. Hist. Phil. Mod. Phys. if you want to see what a philosophy journal looks like. In my opinion, creating artificial boundaries between “physics”, “philosophy”, “mathematics” and even “computer science” these days is part of the problem with modern physics. Foundational questions are studied mainly by philosophers, physicists and mathematicians, but they each bring a different approach to the subject and have different goals in studying it, so we’re best off treating it as an interdisciplinary subject rather than cordoning it off as “philosophy”. In any case, who cares where Found. Phys. goes in the library? Is there anyone left who wouldn’t prefer to access it on the web instead?

On the other hand, I agree that Found. Phys. has had a rather checkered history. It has gone through eras where editorial policy was particularly bad, but right now it seems to be more or less on track, so have a look at a recent issue and see what you think. I’d urge caution in judging it too harshly though. After all, even the esteemed PRL contains a large proportion of misguided papers. Even if technically correct, they often do not have the significance for the subject claimed by the authors. The main difference is that PRL covers technical work at the forefront of modern physics, so it is difficult for a casual reader to judge the quality of papers outside their field. On the other hand, Found. Phys. covers the foundations of subjects that any educated physicist ought to know something about, so it is much easier to spot the garbage.

9. **Doug Natelson**
December 27, 2006

Found. Phys. is not the only journal that has gone through, shall we say, interesting periods. Look up Nature **251**, 602 (1974) for an example.

10. **Perry**
December 27, 2006

If a paper uses the word epistemology, it is philosophy!

11. **Kris Krogh**
December 27, 2006

Michael Berry’s talk reminds me very much of Richard Feynman. The full text is [here](#).

12. **Chris Oakley**
December 28, 2006

Re: Streater/Wightman, I would be grateful if some kind reader of this blog would find it in their hearts to update the [Wiki entry for Haag’s theorem](#) with authoritative, up-to-date information. This is, after all, one of the main things tackled by this book.

Re: Eduard Prugovecki – thank-you, Peter Jackson, for drawing attention to Prugovecki, who arguments against renormalization are more learned and eloquent than my own. I was sorry to see that he died relatively young.

13. **Chris Oakley**
December 28, 2006

Sorry: Paul, not Peter Jackson.

14. **D R Lunsford**
December 28, 2006

This was very nice to see in print:

http://www.mth.kcl.ac.uk/~streater/EPR.html

The whole Streater page is just pure fun!

-drl

15. **D R Lunsford**
December 28, 2006

Peter Shor – I don’t see Streater as being scornful at all, just wickedly sarcastic, almost like H. L. Mencken. You get the strong feeling he has looked deeply into many of these lost causes himself and knows why they fail, and like any good explorer, is pointing out the potholes and cliffs to avoid.

His comments about quantum cosmology, wave fn of the universe, many worlds etc are however genuinely and rightfully scornful. Perhaps there is not enough scorn in physics!

-drl

16. **Mauricio**
December 28, 2006

the correct hep-th number of Susskind’s article is hep-th/0302219

17. **LDM**
December 28, 2006

Kobayshi-Nomizu is a standard reference and needs to be more widely known among physics students, but look as you may, you will not see semi-Riemannian manifolds discussed. Also it is somewhat weak in that this standard reference on geometry contains not one picture in either of its 2 volumes. It reminds one of the criticism of Lamb’s Hydrodynamics — you can read it and still not know that water is wet.
Volume 2 of Spivak is vastly superior for a physicsist in that it gives a good analysis and motivation of the different approaches to connections, which is more what a physicist needs…in other words, if you really want to understand the history and motivation of the subject, read Spivak.

18. **woit**
December 29, 2006

LDM,

I agree that Spivak is much more readable than Kobayashi-Nomizu. It's much longer and does things in much more detail and at leisure. However, one thing I noticed when teaching a course on this and using both as a reference is that there are some pretty sizable chunks of Spivak where the proofs are more or less directly copied out of Kobayashi and Nomizu.

On the whole, Kobayashi-Nomizu is not a good book to learn the subject from. But once you know what is going on, it is an excellent reference, with beautifully concise arguments.

19. **D R Lunsford**
December 29, 2006

peter – a friend pointed that out about the Feynman lectures – useless didactically, but invaluable once you knew what was happening. I never reconciled myself to this idea, having learned math from Klein and physics from Sommerfeld. There is no reason to be obscure when writing a text.

-drl

20. **Matt**
December 29, 2006

Perry said, "If a paper uses the word epistemology, it is philosophy!"

I know this is meant as a joke and I can assure you that the humor is not lost on me. Similarly, you can tell you are in a philosophy talk if the speaker ever talks about "cashing out" an idea.

However, you can find an increasing number of papers that use the word epistemology, or at least its cousin epistemic, in good old Phys. Rev., since they are beginning to take foundations seriously again in the wake of quantum info and quantum computation. That either means that Phys. Rev. is now publishing philosophy, or that it is genuinely possible to write a paper that bridges the gap. I'll leave you to decide which is the case.

21. **Louise**
December 29, 2006

If you can't see the stars from Manhattan, then check out ASTRONOMY magazine: "WHAT IF STRING THEORY US WRONG? If it is, the dark matter, dark energy and cosmic inflation are in big trouble."

22. **Peter Woit**
December 29, 2006

I'll take a look at the latest Astronomy, but dark matter, dark energy, and inflation really have nothing to do one way or another with string theory.

23. **anon**
December 29, 2006

Not sure where to post this, but you and your book were mentioned in a year-in-review episode of Talk of the the Nation's Science Friday. One of the panelists admitted to having written one of the most negative reviews of your book and spewed some ignorant nonsense. Thought you might enjoy listening to it and getting annoyed.

24. **Peter Woit**
December 29, 2006

anon,

Thanks, but I think I'll pass on the opportunity to hear more from K.C. Cole. Her review was by far the most amazingly bizarre one of the many I've seen. I made the mistake of wasting my time complaining to her that she had misrepresented what I wrote in the book about neutrinos. In response she wrote back to explain that she, unlike me, was an expert on neutrino physics and had lectured to physicists on the subject. Yesterday I was talking with someone who has worked her, but will resist the temptation to repeat what he had to say about her.

25. **Sebastian Thaler**
December 29, 2006

The webcast of the Science Friday segment to which anon refers above can be found at http://www.npr.org/templates/story/story.php?storyId=6696466 and the discussion of Woit's and Smolin's books begins at 30:40.

26. **LDM**
December 30, 2006

K.C. Cole is not a scientist — and certainly could not do a real neutrino calculation if her life depended upon it. NPR/sciencefriday should have its funds cut for exposing our children to her incompetence.

27. **Michael**
December 30, 2006

Peter,

[again, partially off-topic but relevant nonetheless]

Do you know when, approximately, Segal will post his notes on the arXiv and/or when his (presumed) book will come out?

Michael

28. **Peter Woit**
December 30, 2006

Michael,

I didn't get the impression Segal was close to having a book done, and I don't think he intends to write up notes from these lectures, so unfortunately I think it will be a while before this material appears in a finished, public form.

29. **Alejandro Rivero**
December 30, 2006

"Is anybody paying attention to the work of Alain Connes, a genius and an outsider?"

I am 🙂 and it is a very difficult work to follow, in the side related to gravity. He is up to conjuring all his previous experience on KMS states plus the new work with Marcolli on Qlattices, in order to get a vision of gravity "as symmetry breaking".

Is anybody paying attention? Yes. Will anybody dedicate the effort needed to follow him? I doubt it. At least in the gravity related issues. I am a bit more optimistic in the question of producing examples and or classification of spectral triples. And then there is the part about the standard model. Barrett at Nottingham was putting attention recently, and it receives sporadic attention from here and there, more or less at the level of any other GUT model.

30. **TomH**
December 30, 2006

K.C. Cole was a so-called "science reporter" for the Los Angeles Times a few years ago. I found nearly everything she wrote to be exceedingly annoying, both in style and content.

31. **fh**
December 30, 2006

From what I've seen people are very aware of Connes work, but nobody really knows what to do with it.

I know that there are a couple of guys in Denmark trying to apply Loopy techniquees to Connes style geometry, but it's tough from a technical point of view AND doesn't really seem to conect to the conceptual physical questions that seem appropriate….

Ah yes, the reference is:
hep-th/0601127

32. **Shantanu**
December 30, 2006

Peter and others, happy holidays. Have a look at Steinn's blog
http://scienceblogs.com/catdynamics/2006/12/dissed_by_the_best.php
on how he shifted from string theory to astrophysics

33. **a**
December 31, 2006

it would be interesting to have a presentation of Connes works in a style more accessible to physicists, focussed about their physical motivation and predictive power (does it restrict the QFT particle content and couplings?), rather than about applications to quantum gravity.

34. **Peter Orland**
December 31, 2006

I don't mean to be too discouraging, but I don't see what is
so exciting about Connes' approach to the standard model.
He takes a complicated, successful theory and makes
it even more complicated, just to facilitate his ideas. It
all seems badly motivated.

35. **D R Lunsford**
December 31, 2006

Peter – you actually should listen to Cole. I have never in my life heard such indescribable bullshit. How does this non-entity, who without doubt cannot even understand Aristotle, not to say Kepler or Galileo, much less Newton or Einstein or beyond, presume to tell an interested listener what physics is about?

It is extraordinary. Imagine if such a person gave medical advice, or piloting advice, or firefighting advice. "Well it's only physics." Wrong – physics is important. Most of modern life came from it.

I am stunned.

-drl

36. **Jonathan Vos Post**
January 1, 2007

Michael Berry's 1985 CalTech anecdote is extremely funny. But one shouldn't overgeneralize. Caltech has, for a century or so, been a place where there are always SOME Mathematicians who listen to what Physicists are saying, and vice versa. John Schwarz is not a universal template, and is a gracious host at swimming pool parties I've attended.

The intersection once included, to pick a few luminaries almost at random, Harry Bateman, Dr. Robert A. Millikan, Dr. Theodore von Karman, Linus Pauling, Feynman, Gell-Mann, Witten, Stephen Wolfram, Hawking, and at the moment includes Barry Simon and Kip Thorne. The fact that it produced people second rate in both, such as myself, should not be held against it.

37. **Peter Shor**
January 3, 2007

Peter Orland:
Connes actually has a prediction for the Higgs mass in his latest paper (hep-th/0610241). True, it seems to assume the probably incorrect "big desert hypothesis" that there's no new physics between the Higgs scale and the Planck scale, but I believe this is still more than any of the alternative approaches can achieve. So it seems to me

(who knows nothing about it) that Connes' approach must be introducing some new constraints somehow. And since I know Connes is really smart, my opinion is that it's worth paying attention to.

On the other hand, it looks very hard and I'm not planning to try to figure it out myself, so I probably shouldn't be criticizing other people for not trying to figure it out themselves, either.

38. **Peter Orland**
January 3, 2007

Peter Shor,

Please understand that though I admire Connes,
I don't find the prediction of one number especially
impressive. Fits are not physics.

One needs a new idea (or a dramatice experimental
result) which is fundamentally simple. This is different
from being mathematically or calculationally simple.
By fundamentally simple, I mean a theory with few
hypothesis leading to a strong consistent framework
(like Maxwell's equations or General Relativity).
Connes idea, to my way of thinking, is not simple
in this sense. No principle points to his non-commutative
scheme the way the principle of equivalence pointed
to Riemannian geometry into gravity.

39. **Peter Orland**
January 3, 2007

P.S. (by which I mean Peter Shor)

I think it is better to find an idea interesting and
not pursue it (as you are doing), than dismiss an
idea because you don't want to learn about it.
I hope that that is not what I am doing.

Many people in high-energy theory arrogantly
dismiss an idea as nonsense because they don't
want to make an effort to understand it. I only
add this remark because I do not want my writings
above to reinforce this contemptuous behavior.

40. **Peter Shor**
January 3, 2007

Peter Orland,

I didn't mean to imply that you are one of the people who arrogantly dismiss ideas because they don't understand them.

I have assumed that worrying about how to quantize space-time led to non-commutative geometry. Since I don't understand any of this, I could be completely wrong.

Peter Shor

41. **Peter Orland**
January 3, 2007

Peter,

I don't think that quantization of space-time definitely
implies that geometry is non-commutative. Non-commutativity
is just one proposal.

All we are sure of is that there is some cut-off scale less
than or equal to the Planck scale 10^{-33}cm, at which
GR breaks down. This may have no implication for the
standard model (I can't imagine how it wouldhave such an
implication).

Unless there is some fundamentally simple idea that
points to what should happen (by "fundamentally
simple", I don't mean easy to understand. See my above
remarks) there are lots of ways to cut off gravity.

Some schemes for cutting off gravity are more
philosophically attractive than others (depending
on your philosophy) but there is no compelling principle
yet which tells us how to chose. Some people would
chose string theory because of renormalizability or
finiteness, but it isn't clear to me that it's the only way.

An interesting problem would be to put in just a silly
momentum cut-off into gravity at the Planck scale and
ask if there are any observable consequences. For example,

there would be Planck-sized unitarity violation. That could conceivably imply some nonconservation of probability that one might be able to test. Maybe Kuzmin has thought about this, since he and his collaborators had suggested that violations of certain precepts at the Planck scale could have macroscopic consequences.

One aproach would be to ask what sort of cut-off scheme would naturally explain flatness. By this I mean both approximate cosmological flatness and the fact that space-time fluctuations don't seem to grow to macroscopic size (this is a problem in path integrals of random manifolds). I had a crazy proposal to solve this problem, which I called the "critical solid", but some of the assumptions of the proposal need to be changed slightly. I eventally would like to look at this problem again, but I am too busy with non-perturbative aspects of gauge theories.

42. **Peter Orland**
January 3, 2007

I just looked up V. A. Kuzmin's papers on SPIRES. It seems he has looked at violation of CPT at the Planck scale, but not of unitarity.

43. **Alejandro Rivero**
January 4, 2007

The requeriment of a "new idea" is sort of misleading. Gauge theories were stressed by Pauli, the nonabelian version from Yang-Mills can not score as a "radical new" idea, and the point of using SU(2) times U(1) would not score even as "new".
It is more about ideas evolving in paralell to experimental input, and in this sense Connes´s model is performing well: it transmuted ten years ago to go from electroweak to include colour, and now in transmutes again to include neutrinos. Still, it is not definitive, because it is not really exploiting the new mathematical setup (for instance, the fact of SU(3) being separated from the electroweak part in the bivector field formulation, as it appears in the red book, would add some insight about the quarks and it doesn't – yet).

44. **Peter Orland**
January 4, 2007

Alejandro,

I didn't say that I am skeptical of Connes's idea because it is not new. I am skeptical because it makes the standard model more complicated and solves no problems. In this sense I don't think the idea is a fundamental advance.

What Are You Optimistic About?

January 1, 2007
Categories: Uncategorized

Every year John Brockman's Edge Foundation asks a large number of people in science and technology to write a short piece answering a chosen question, and this year the question is [What Are You Optimistic About?]

Among particle physicists, the overwhelming thing to be optimistic about is the LHC. For instance, [Lawrence Krauss] writes:

I am optimistic that after almost 30 years of sensory deprivation in the field of particle physics, during which much hallucination (eg. string theory) has occurred by theorists, within 3 years, following the commissioning next year of the Large Hadron Collider in Geneva, we will finally obtain empirical data that will drive forward our understanding of the fundamental structure of nature, its forces, and of space and time.

Others who also mention the LHC include [Lisa Randall], [Charles Seife], [Lee Smolin], [Adam Bly], [Maria Spiropulu], [Karl Sabbagh], [Frank Wilczek], [Paul Steinhardt] and [Corey Powell].

Wilczek describes himself as optimistic that "physics *will not* achieve a theory of everything", taking the point of view that he hopes nature will continue to surprise us. He also denigrates the search for a fundamental theory of everything by noting what it has led to in the case of the string theory landscape:

At this point the contrast between the grandeur of the words "Theory of Everything" and the meager information delivered becomes grotesque.

[Alexander Vilenkin] on the other hand is optimistic about the multiverse and the anthropic landscape, saying it is implied by string theory, "our best candidate for the fundamental theory of nature", and that he thinks that statistical predictions will be possible.

The person I agree with most is [Gino Segre] who writes:

So why am I optimistic? Because I believe that controversy, with clearly drawn out opposing positions, galvanizes both sides to refine their opinions, creates excitement in the field for the participants, stimulates new ideas, attracts new thinkers to the fray and finally because it provides the public at large with an entrée into the world of science at the highest level, exhibiting for them heated arguments between great minds differing on questions vital to them. What could be more exciting?

That sort of optimistic point of view on the whole string theory controversy is one that I hope more theoretical physicists will take, with string theorists acknowledging that there are serious questions that have been raised and that are worth debating.

Personally I'm a lot more optimistic now than I was a year ago that a more realistic view of string theory has started to take hold in many quarters, and that perhaps particle theory will move towards a healthier state. Like the Edge contributors, I see the fact that the LHC is now not far off as a cause for optimism. Perhaps it will produce the sort of surprising new insight into electroweak symmetry breaking needed to show the way forward. Even if it doesn't do this, the likely failure to see superpartners or extra dimensions may encourage theorists to give up on ideas that don't work and try and strike out in other directions.

Comments

1. **mclaren**
   January 1, 2007

   With minds like this on the job, there's every reason to be optimistic about string theory:
   http://www.theonion.com/content/node/38718

2. **Renormalized**
   January 1, 2007

   That story from the onion has been floating around the internet for 5 years and was totally fabricated by a student.

3. **hack**
   January 1, 2007

   A fabricated article in the Onion? Say it isn't so!

4. **Tony Smith**
   January 2, 2007

   In his 2007 Edge answer to "What Are You Optimistic About?", Steve Grand said:

   "… The Strong Possibility That We've Got Everything Horribly Wrong

   The thing I'm most optimistic about is the strong possibility that we've got everything horribly wrong. All of it. Badly. …

   Sometimes we manage to convince ourselves that we have a handle on what is going on, when in fact we're just turning a blind eye to a mass of contradictory information. We discard it or ignore it (or can't get funded to look at it) because we don't understand it. It seems to make no sense, and it can take us a while before we realize that the problem doesn't lie with the facts but with our assumptions. Paradigm shifts are wonderful things. Suddenly the mists clear, the sun comes out and we exclaim a collective "aha!" as everything begins to make sense. What makes me so optimistic about science right now is that there are plenty of these "aha" moments waiting in the wings, ready to burst energetically onto the stage. We've got so much completely wrong … and I think a lot of our standing ideas and assumptions about the world are about to turn inside-out, just as our much older, religious ideas did during the Enlightenment.

   My guesses for prime candidates would include quantum theory and our understanding of matter, but those aren't my field …

   My field is artificial intelligence, but I'm sad to say that this subject started on the wrong page of the map many years ago and most of us haven't woken up to it yet. We keep our eyes firmly on the route and try not to look to left or right for fear of what we might see. … the digital computer has dominated the AI paradigm, through failure after dismal failure. …".

   I suggest that Steve Grand's selection of "quantum theory" as a "prime candidate" may be accurate,
   and

that the last paragraph in the quote from him would be just as accurate if
"artificial intelligence" were changed to "quantum theory"
and
"the digital computer" were changed to "superstring theory"
and
"the AI paradigm" were changed to "the high-energy theoretical physics paradigm".

It would be interesting to compare the sociology of theoretical physics and of AI studies over the past couple of decades or so.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

5. **normalized**
January 2, 2007

There is no cause for optimism. People shouldn't go into science if they're prejudiced, because nature doesn't conform to most prejudices. Ideally to the mainstream of the 19th century, the geological record should have turned out to support Biblical Creationism. It didn't. Tragic for all those mainstream guys.

String theory is insulated too well to be disproved directly, but if the predictions of an alternative theory were confirmed, then that would make string theory look a waste of time. Even though string theory can't be disproved, it would be discredited.

Therefore, it is guaranteed that all alternatives that might make contact with reality will be attacked most strongly as crackpot by the mainstream.

Weaker alternatives, which look as pathetic as string theory regarding experimental falsification, will be looked at slightly more tolerantly by the mainstream.

Similarly, lame attacks on string theory will be tolerated but convincing attacks will be answered with strong abuse. There is no way anything can improve. What if people don't like nature? Suppose string theory turns out wrong. What will stringers do? Call nature 'crackpot' and storm off in a huff? Obviously, they want to postpone that evil day indefinitely.

6. **Michael**
January 2, 2007

Question:

With the LHC about to begin its first run, and supposing that both the Higgs boson and superpartners are discovered, respectively, what then would theoretical physics look like for the next few years?

Answer, anyone?

7. **Ari Heikkinen**
January 2, 2007

Or, it could turn out that LHC does nothing but make the widely adobted we-need-a-bigger-accelerator syndrome even stronger.

My question about LHC is that has there ever been any realistic estimate of energies required to arrive at anything even remotely useful (I mean, worth the cost, considering the huge amounts of money these things cost to build) ?

To me it somewhat appears that everyone's just guessing and no one even knows what's it supposed to reveal.

8. **QM**
January 2, 2007

Ari, that's why research is more interesting than burocracy.

9. **nontrad**
January 2, 2007

Back in the day, when I was doing physics (around '97-ish) and listened to various pros and cons of matrix / M / this and that theory bandied about in various hallways, the killjoy phrase I heard most often was 'If LHC sees no SUSY then that'll be it for ST '. Almost invariably, once that card made it to the table even the most zealous proponents tended to stare down at their shoes while the conversation turned to other matters.

Most important for my young ears: This magic phrase didn't come from minor weights; some of the speakers had seen more then one 'revolution' in their time.

So….as far as I am concerned….based on my very limited experience….it's ALL about LHC. ALL about LHC.

10. **Seth**
January 2, 2007

To Notrad: what I've heard, most recently, is that the LHC can't prove String Theory and can't kill it either. You can always move the Supersymmetry up to a higher energy scale.

And speaking of killjoys, this isn't the year to be optimistic about LHC. We'll be months into 2008 before real data and analysis of energy frontier physics start to arrive.

11. **Hans**
January 2, 2007

In the 10 dimensional theory, ST is certainly supersymmetric. However: LHC won't see this length scale. The compactified theory that it faces to must not be supersymmetric.

But when SUSY is not seen at LHC, there would exist no clue at all, that ST is the correct way. "When we don't see SUSY at LHC, then we need good advice" said Dieter Luest.

So, LHC can't kill ST but in can reduce remaining hopes that one can describe physics with it, which can be observed.

12. **Yatima**
January 2, 2007

Tony Smith says:

It would be interesting to compare the sociology of theoretical physics and of AI studies over the past couple of decades or so.

This has probably been done somewhere. Sociology should be similar in a general sense. There are the 'Notable People': Minsky comes to mind. Apparently his paper on the limits of "perceptrons" was a major fator in funding cuts for artificial neural networks. Everyone piled into symbolic computation after which some new results and disillusionment with the symbolic approach led to a revival of the ANN approach etc. There are the 'SSC' programs like 'Ffth Generation' and 'Strategic Computing Initiative'. These yield little empirical data but generally lead to nowhere and/or mutate into something else due to changing goals and the realization that one has aimed too high.

Thing is, the problems are of fundamentally different nature. While ThPhys pulls into the direction of an overarching and hopefully elegant/compact description, "Intelligent System Studies" (to avoid the AI moniker, which has become overly stale lately) has given up the delusion of finding 'The Intelligence Algorithm' a long time ago. Said delusion has been called 'Physics Envy' – by whom I don't remember. Some still ride against qualia strawmen or sundry shadows in Searl's Room or they go off orthogonally into QM or whatnot (no disrespect to Penrose intended) but this gets tiresome quickly to anyone who remembers his brain is such a polynomial kludge that the may be unable to find his own socks in the morning.

I'm always ready to be surprised by fundamental shifts but at this point I would be surprised to be surprised if I may say so.

A paper about the "messiness" by Cherniak. Still good:

"Undebuggability and Cognitive Science," Communications of the ACM, 31 (1988) 402-412

My excuses for this digression into non-physics.

Happy new Year to Peter Woit … and the rest of the crew.

13. **nontrad**
January 2, 2007

Seth,

Thanks for the thoughts; see you after LHC 2007.

Best regards,

nontrad

14. **Chris W.**
January 3, 2007

As I recall, some time ago on Cosmic Variance JoAnne Hewett said that if the LHC doesn't turn up something pretty interesting within a few years then experimental particle physics in the U.S. is in for some very dark days. Actually, she may have said this in a comment. Perhaps she can offer a reprise (or a correction) here…

15. **from EU**
January 3, 2007

some time ago there was a post at CosmicVariance about this topic, and I was very surprised in hearing that apparently everybody thinks that the past and present situation in the US is fine, that SLD had been as successful as LEP, etc. Elsewhere one hears different opinions. Let me present two facts, that can be checked

1) A few years ago, many experimentalists in Europe didn't like that a large number of US experimentalists joined LHC without giving a proportionally large contribution to its construction. One of the arguments in favor of this decision was the danger of a collapse of the high-energy experimental community in US before LHC.

2) Tevatron, "the biggest accelerator in world", actually has a circumference smaller than HERA, than LEP/LHC, than the old SppS.

16. **Michael**
January 3, 2007

Don't worry if particle physics bites the dust within the next few years… there's Financial Engineering to go into for all those out-of-work young postdocs.

17. **island**
January 4, 2007

> Actually, she may have said this in a comment.

In *this* forum:

http://www.math.columbia.edu/~woit/wordpress/?p=445#comment-14668
If the worst case scenario plays out, and the LHC discovers nothing, then that is the end of particle physics as we know it. And that includes string theory. They may think they are immune, but they are not – they will fall due to lack of funding with the rest of us.

I can't wait, because I'm fairly certain that you'll be able to hear John Horgan's shouts of vindication from just about anywhere on Earth.

18. **Thomas Larsson**
January 4, 2007

If the aether wind does not turn up in the Michelson-Morley experiment, it just means that something like split aether theory is right.

19. **Chris W.**
January 4, 2007

Island,

Yes! I'm sure that's the one. Thanks for tracking it down.

20. **Steven H. Cullinane**
January 4, 2007

For a rather different "entrée into the world of science," see page 56 of this week's New Yorker (issue dated Jan. 8, 2007).

21. **Eli Rabett**
January 4, 2007

Steve I just put the NYorker cartoon up Great minds, etc…

22. **MDL**
January 4, 2007

I'm optimistic that someday one of these searches:

site:http://www.math.columbia.edu/~woit/ "minimum description length"
site:cosmicvariance.com "minimum description length"

or one of the first ten links (I gave up after that) returned from this search:

"string theory" "minimum description length"

will find a discussion of the relevance of the minimum description length (MDL) principle to the issue of the scientific status of string theory. MDL is, after all, a common criterion for selecting among theories in machine learning, when all of the theories can fit all of the data.

That discussion would likely start with the argument that — provided both theories can be made to fit all the data! — the criterion for preferring one physical over the other should be lesser size, as expressed in some reasonably primitive and unbiased representation in which all expressions can be reduced to bit strings. (See also Kolmogorov complexity.)

Someone then would doubtless speak up and claim that MDL sidesteps objections that the use of anthropic arguments destroys scientific criteria, then someone would object that having even one real number could make complexity unbounded, and someone would respond that this suggests that comparing the number of free real-number parameters in each theory is a better basis for preference than is MDL in the conventional sense. Then I would expect to see arguments about the status of real numbers, particularly the unbounded-complexity sort, no doubt leading someone to assert that all parameters are actually rationals, citing Pythagoras.

It will be a lot of fun to see all that, and to see where it leads. Maybe some day.

23. **J.F. Moore**
January 4, 2007

I can't wait, because I'm fairly certain that you'll be able to hear John Horgan's shouts of vindication from just about anywhere on Earth.

I think he is more reserved than that. For one, unless LHC science is a total bust, ILC will certainly follow, so that is another decade of pining enabled, with a couple of years for someone to win (or not) a Nobel Prize in time to resolve the Horgan-Kaku long bet:

http://www.longbets.org/12

24. **wab**
January 5, 2007

Let's say that all LHC finds is a very broad HIggs at well over 500 GeV. I would not bet on an ILC in that case.

25. **Ari Heikkinen**
January 5, 2007

Interesting comments from Kaku on that "longbets" link. Lot's of "if"'s and "might"'s tho.

26. **plank**
January 5, 2007

"Personally, I feel no need to prove the theory experimentally, since I believe it can be proven using pure mathematics." (Kaku)

Interesting indeed!

How does one prove a theory about reality using pure mathematics?

You may prove that it reproduces all phenomena you've observed by now at best. But for that there exist good theories already. So what is really needed is predicting something unknown and getting EXPERIMENTAL verification of that.

I for one would like to know how to prove, say Newton's laws of motion using only pure mathematics.

27. **Thomas Larsson**
January 6, 2007

You may prove that it reproduces all phenomena you've observed by now at best. But for that there exist good theories already.

There are many interesting numbers not explained by current theories, e.g. the spectrum of particle masses.

28. **plank**
January 6, 2007

"There are many interesting numbers not explained by current theories, e.g. the spectrum of particle masses."

Right, I wasn’t precise enough. I should have written that many theories explain a lot of the data we have. Those theories are “incompatible” but they still explain a lot.

So yes, retrodiction of unknown relations already experimentally verified, say mass ratios, mixing matrices constraints or something like that, would also be a breakthrough.

My point is, even if your objective is explaining all that has been observed, you can’t do it with pure mathematics alone. You need experimental data in order to check that theory. And if you predict anything new, to be “sure” you need to verify that too.

When a physicist writes “Personally, I feel no need to prove the theory experimentally, since I believe it can be proven using pure mathematics.” (and this seems like not a very uncommon idea among his peers) I think there is genuine reason to be concerned.

I understand that theoretical physicists need to be hardheaded.
Imagine if Galileo didn’t ignore air friction and all that! To this day we would have only Aristotelian Physics. A feather doesn’t fall like a stone. Everyone can see this on their daily experience. But, Galileo made an hypothesis (model) and verified that model experimentally with controlled conditions he though reproduced the assumptions his model made.

You can’t expect to say that the distance of falling bodies varies with time like the sum of the first n odd integers (he did say this, because $\sum_{k=1}^n (2k-1) = n^2$) and expect that reality conforms to your intuitions because the fact that summing the first odd integers you get a perfect square is so beautiful.

FY 2007 Funding Issues

January 5, 2007
Categories: Uncategorized

As mentioned here earlier, the last Congress decided to not pass most new FY 2007 spending bills before leaving town, putting these off until the new Congress convenes, and running the government on a continuing resolution, mostly at last year's spending levels. There is speculation that the new Congress may decide to not even try to put together and pass FY 2007 spending bills (the fiscal year started Oct. 1), instead just funding things by a continuing resolution for the rest of the year, mostly at FY 2006 levels. The Fermilab director Pier Oddone has issued a statement about the implications of having to run Fermilab at the FY 2006 funding level for the rest of the year. These would be dire, including having to take such measures as completely shutting down the lab and furloughing its employees for a month.

This would be extremely bad news for Fermilab, coming at a time when they have been having great success with getting the Tevatron to run at ever greater luminosity. The machine has just set new records for weekly luminosity, monthly luminosity, and initial luminosity (you can follow their progress here). While everyone is concentrating on the LHC, the Tevatron remains the only machine in the world running at the high-energy frontier, and the most likely source of any surprising new information about beyond standard model physics during the next couple of years. It would be a great shame if budget problems were to have a negative impact on this.

I don't have any information about what the impact of these budget problems might be on particle theory or on mathematics. For mathematics, the impact may not be so great since, after several years of sizable budget increases at the NSF, the FY 2007 budget request for mathematics at the NSF contained only a 3.2 percent increase.

There's a quite interesting interview in the latest (February) issue of the Notices of the AMS with William Rundell. Rundell was the director of the mathematics part of the NSF until last summer. He describes how during his tenure the NSF emphasized "single-researcher" or "PI" grants, saying that:

If you take any block of time from NSF's beginnings to now and you ask, what were the best years for the DMS single-investigator grants or for senior researcher increases?, the answer is the period of 2001 through 2005.

Rundell notes that during this time the number of grants went up by only a small amount, maybe 10 percent, but that the value of each grant "went up enormously". Before 2001, people were being given at most one month of "summer support", now junior people get two months, and senior people often a month and a half or two months. While inflation and average university raises have been around 2 to 3 percent, the academic star system has had stars (the people most likely to be getting these grants) receiving 6 to 7 percent raises, 10 percent promotion raises, and big hikes in salary when they move. So, the bottom line is that a lot more money has been going to a small segment of the mathematics research community.

The interviewer states that "Most mathematicians believe PI grants are the most important part of the DMS", but I wonder whether that is really true. Rundell also explains that the current system leaves most mathematicians with not much motivation to lobby for an increased NSF budget, especially if most of the increase is going to go to a small number of well-paid people:

I think it is probably true that the mathematicians who get the money aren't pulling their weight for justifying us to get more. And on the other hand, those people who are disenfranchised have no incentive to do that.

Personally I've never understood the logic of devoting such a large part of the NSF research budget in math or theoretical physics to increasing the salary of the best paid people in the field, although I hear that once one achieves such a status the reasons become much clearer. Besides the "summer salary" though, these grants do fund many things that are important for the health of university math departments, especially supporting graduate students. Rundell claims that over this same period the NSF has doubled its support for graduate students. This is probably reflected in the data contained in another article in the new Notices, an annual survey of new doctoral recipients. This survey finds the number of Ph.D.s awarded last year in mathematics to be 1245, the highest number ever recorded. Four years ago this number was at a local minimum, with 948 mathematics Ph.Ds awarded.

Also supposedly suffering from funding problems is the high energy theoretical physics group at Harvard, where, according to one of its faculty members, because of feminism the university has been unable to afford competent computer support. As a result the group has recently had to shut down its web server (schwinger.physics.harvard.edu), and evidently has had several of its machines broken into, with no administrator around to deal with this. There's a huge on-going problem with university computer systems which seems to be the same thing that happened at Harvard. Many groups of hackers have broken into a large number of insufficiently well-protected university unix systems, often installing trojanned versions of the SSH software. The trojanned SSH client programs then gather people's usernames and passwords as they are typed in when SSH is used to login to another system. These are used to break in to yet other systems. Since SSH is the fundamental tool used to manage logins between different machines at most universities, this is a very difficult problem to deal with.

One reason I've mentioned this is to warn people to be very careful about using SSH, especially using it to login from a system not at your home university, since the SSH program on the machine you are using may be trojaned. Better to use your own laptop, with its own SSH software. I'd like to discourage posting of comments about computer security here, since most such comments just spread misinformation of one kind of another, just making problems worse. There are many other places on the internet to get information about and discuss these issues.

Update: There's more about the 2007 NSF budget here.

Update: Today's NY Times has an article here. It seems that many other labs, including RHIC and Jefferson Lab, are facing similar problems.

Comments

1. **plank**
   January 5, 2007

   just regarding ssh. Try using private/public key (DSA for instance) authentication when possible and most of those problems go away. And don't login *from* a computer you don't trust (even when using keys)

   If LHC finds nothing people are expecting (SUSY, higgs) nor anything completely unexpected (my favourite) then budgets will get far more stringent in the future.

2. **Grammar Nazi**
   January 5, 2007

   "Congress may decide to not even try and put together and pass FY 2007 spending bills"

   "try and"? Shame

3. **Peter Woit**

January 5, 2007

OK, OK, Grammar Nazi,

When I proofread the posting I did think that the writing was worse than usual, but also that I was too busy to do much about it. And, hey, standards on internet blogs are low in general, right?

4. **Kevin**
January 5, 2007

Simply put, I do not believe Fermilab's Pier Oddone. Inflation is about 3%/yr. Thus, if 2007 funding is at 2006 levels, they will have to cutback by 3%, not close down for a month (an 8.3% decrease).

Besides, when was the last time Fermilab produced any good work? 1976? They have hardly established a good track record in the last few decades, and better they live within a budget than that my taxes go up.

5. **Peter Woit**
January 5, 2007

Kevin,

Oddone gives a detailed justification in his letter to the DOE. This far into the fiscal year there are strong constraints on what he can do to save money, especially since supposedly there are no major capital spending projects going on that could be stopped or slowed down. His estimate for what they can save by shutting down the lab for a month is 3 percent of the budget. You're not going to get an 8.3 percent savings since what you save by turning off the lights and furloughing people is only part of your operating costs. You'll continue to need some people to stay there, and you morally can't do things like shut off medical benefits to your furloughed employees.

If you really don't think Fermilab produces any good work, you shouldn't be arguing for saving $11 million by shutting the place down for a month, but for saving billions by shutting it down permanently (along with the rest of US HEP research, which hasn't done any better than Fermilab). And please, everyone, take the aggrieved arguments pro or con about taxation levels to other blogs hosted by people willing to tolerate them.

6. **Peter Orland**
January 5, 2007

In defense of Farm 'n Lab…. I agree that nothing earthshaking is has come out in a long time. An important consideration, however, is that there are standard nuts and bolts measurements, such as more accurate values for masses and widths, soft-scattering measurements, etc. This is physics, even if not the exciting kind.

I have a question for experimentalists or phenomenologists who might be reading. Will measurements at the Tevatron be useful for interpreting LHC data? I think they should, since the background at the LHC will be hard to subtract otherwise. Someone else would certainly know for certain.

7. **Peter Orland**
January 5, 2007

If Grammar Nazi is reading, there is no need to chastise me. Re-reading my last sentence fills me with shame.

8. **anonymous**
January 6, 2007

Kevin:
1976? For most of us, the discovery of the top quark was certainly good work. Perhaps you meant 1996? In any case, the Tevatron has put lots of limits on new physics, and has precisely measured a lot of Standard Model parameters. It also does good B physics.

Grammar Nazi:
"Try and" is perfectly grammatical in typical English usage. Surely you have better things to do than carry on a pedantic crusade based on arbitrary rules? For instance, you can go to [this post at Language Log] to see "try and" being used by a coauthor of the Cambridge Grammar of the English Language.

9. **pheno answer**
January 6, 2007

backgrounds have already been measured, and will be much worse at LHC.
Observing tops, Z, W… at LHC will help in calibrating LHC detectors.
People moving from Tevatron to LHC will bring their expertise.

The main goal of Tevatron was and is discovering something new just before LHC. This would have some scientific value, because Tevatron detectors and backgrounds are already understood. Nevertheless it seems to me an example of poor competition: Tevatron runII is not really needed for physics and needs a lot of resources. For comparison, CERN preferred to close LEP (despite the hints for a higgs, leaving the next strike to Tevatron) and go on with the next big project. Hopefully this will turn out to be a good and brave decision.

10. **Michael**
January 6, 2007

The more I read your blog the progressively more skeptical I become about a meaningful career in hep; maybe 'financial engineering' isn't such a bad move to make if you want a remote chance to make a decent living *AND* use all the new tricks and skills you pick up during your studies.

How say you, Pete?

11. **Chris Oakley**
January 6, 2007

> The more I read your blog the progressively more skeptical I become about a meaningful career in hep; maybe 'financial engineering' isn't such a bad move to make if you want a remote chance to make a decent living *AND* use all the new tricks and skills you pick up during your studies.

I am not any of the Petes, but I have done a fair amount of Financial Engineering after doing a PhD in HEP theory. What you need to be a Financial Engineer is knowledge of probability theory and the ability to solve PDEs. Also, programming skills are essential. However, you are unlikely to be using any techniques you learned after your first degree. The reason that employers choose PhDs is that there is hot competition for the jobs and PhDs look better on paper.

12. **D R Lunsford**
January 6, 2007

Peter – do you think there is a niche for physicists/mathematicians with professional-level computer knowledge to run these university systems? I would think such a person could better serve the needs of physics/mathematics faculty.

-drl

13. **Peter Woit**
January 6, 2007

drl,

I do think it is a good idea for physics/math departments to consider having their systems managed by a permanent person with a Ph.D. who teaches and has some sort of faculty position. This has worked well here in the Columbia math department, with me and my predecessor (but then I would think that..). The main problems I've seen with departmental computer systems occur when one tries to run them with grad students or poorly paid/part-time computer administrators, who don't stay in the job very long. If you want a reliable computer system, you need to have someone smart in charge of it who is around long-term, and has the authority to enforce standards and spend the money needed to ensure reliability. The security and spam difficulties associated with running mail servers and multiuser unix systems are huge, and the day is long gone when a faculty member or grad student could set these things up and get them working reliably in their spare time.

14. **Peter Woit**
January 6, 2007

Michael,

I think Chris is right that most "financial engineering" jobs don't use that much sophisticated mathematics. But they certainly are much better paid, with much better job prospects than in academia, especially if you want to live in a place like New York or London. At the moment half of all personal income in Manhattan comes from the financial industry, and extrapolating from past trends, that should soon approach 100 percent. Not clear to me what the future holds…

Mathematics is a perfectly healthy field, theoretical physics much less so, with the problems I discuss ad nauseam here. Experimental HEP in the US has serious questions about its future. For both theory and experiment, the future should be a lot clearer 4-5 years from now after initial results from the LHC. If the LHC doesn't find something that disagrees with the standard model, experimental US HEP will be in big trouble, theoretical physics will also be in huge trouble if it continues down the same road it has been following.

15. **C**
January 6, 2007

Hi Peter Orland,

"Will measurements at the Tevatron be useful for interpreting LHC data?"

"Tevatron-for-LHC Report: Preparations for Discoveries," hep-ph/0608322, has some information about this.

Regards,
C

16. **ssh?**
January 6, 2007

Peter, sorry for asking a question about computers, but maybe you are in a unique position also for this issue. I would like to understand if forbidding direct ssh access (to everything, including the http server) is an exaggeration. To users like me it seems more annoying than having some hackers, but our professional administrators have a different opinion, and, being not competent enough, I cannot understand if they are right, or if they like to have a too easy life.

17. **Peter Orland**
January 6, 2007

C,

Thanks!

18. **Peter Woit**
January 6, 2007

ssh?,

Unfortunately, at the present time there is a good case to be made for severely restricting people from logging in to accounts that can run a shell from machines that one doesn't trust. There are just too many compromised machines out there, and if someone logs in from one of them, a group of hackers now can and will get into the account. From a shell account, even if they don't know much they can cause significant trouble. If they are very knowledgable they can probably get root access and cause huge amounts of trouble (compromising many accounts on the system, trojaning ssh so they can get into other systems, trojaning the system software so that the server needs to be completely rebuilt, etc. etc.).

Security is always a balancing act between making it convenient or at least possible for people to do things over the network that they need to do, and protecting systems by minimizing the number of potentially dangerous network connections. There's no easy answer to this…

19. **Ari Heikkinen**
January 6, 2007

"I do think it is a good idea for physics/math departments to consider having their systems managed by a permanent person with a Ph.D. who teaches and has some sort of faculty position."

That wouldn't work. Having someone who teach as system administrator "when they have time" only means the systems will basicly be left unmanaged and the only thing they end up doing is add or remove a few accounts now and then.

It's a full time job trying to keep up to date with security updates and especially trying to anticipate any possible future attacks (then again, just avoid windows and you'll automatically avoid most of the security problems of today).

20. **Peter Woit**
January 6, 2007

Ari,

"That wouldn't work."

Well, my experience is definitely that it can work. My colleagues here in the Columbia math department seem to be quite happy with how the computer system runs, and it's basically run by me, at the same time that I teach one course per semester (some semesters a seminar for the graduate students giving them practice teaching, which requires little preparation). Before I took over this job, it was done on a similar basis by someone else, and people were also happy then with how it worked. It would not work if the person involved had a much larger teaching load. It also can take quite a few years to get a computer system stabilized, secured, and working in a reliable, secure and easy to maintain manner.

And no, avoiding Windows is not the solution to all problems. The problems the Harvard theory group seems to have had which required shutting down their systems had nothing to do with Windows. And Windows/Mac/Linux arguments and evangelism are completely off topic. Don't even think of it…

21. **Ari Heikkinen**
January 6, 2007

Just to add to my previous post, I use them all. There's different sets of problems each one solves the best.

22. **Chris W.**
January 7, 2007

Regarding computer and network security see this sobering article:

Attack of the Zombie Computers [botnets] Is Growing Threat
(NY Times, 1/7/2007)

(Windows XP Home Edition, not to mention Windows 98, has for years been considered a botnet disaster waiting to happen.)

23. **Bastard Operator from Hell**
January 7, 2007

Ok, Peter's idea to take discussion about security issues elsewhere sure is a good thing:

1) "trojanning" is a wrongly spelled verbing of a bastardization of "installing a trojan horse program". What happens is that the SSH client is either replaced or "debugged" by something that captures password information. Thus, "compromising the SSH client" is the phrase to use.

2) Plank says: "Try using private/public key (DSA for instance) authentication when possible and most of those problems go away." They do not and DSA is NOT a recommended algorithm for public key cryptosystems. However, "two-factor authentication" will alleviate some problems.

3) Ari says: *'Having someone who teach as system administrator "when they have time" only means the systems will basicly be left unmanaged'* Ab-so-lutely. It's fun to do half-assed system administration from time to time (don't we all love to tinker) but how can you ever dot the i's and cross the t's on a network with more than a handful of servers, workstations and users ? This is a high-dimensional space and the inevitable random walk will quickly take you into the regions that are labelled 'here be downtime'. Not to be insulting but I have noted that often people are somewhat optimistic regarding the true state their network is in, especially if they have an academic background. Ah the good old times when all our data was on a single harddisk under the teaching assistant's desk (no, it was not in the backup pool either).

Also…where's the documentation?

4) Two words: *Tripwire* or *Radmind*.

Bu enough of this, enjoy the Sunday.

24. **Eeyk**
January 7, 2007

"trojanning" is a wrongly spelled verbing of a bastardization

It's interesting how wrongly spelled verbings of bastardizations can be absolutely clear and meaningful. "Trojanned ssh" simply says it all in just two words…

25. **CD318**
January 7, 2007

I can speak to life sciences. An NSF proposal on which I was PI scored in the top 15% was declined; less than 10% of submissions can be funded at present (in recent years around 20% have been funded). Fortunately we can scrape by for awhile on other funding sources but for others this will be the difference between surviving and not.

26. **CD318**
January 7, 2007

Kevin typed: "Simply put, I do not believe Fermilab's Pier Oddone. Inflation is about 3%/yr. Wellllll… belief != data, and the Consumer Price index != inflation of scientific equipment and supplies (which are increasing faster), or of the cost of electricity required to run the experiments. Moreover, the cost/time of running a scientific experiment is not constant, even in constant dollars. In addition, nothing in the above post indicates that Fermilab itself is going to see a 3% cut. It is common, even when agency budgets are flat to implement across-the-board cuts that are considerably more severe.

In other words, it is obvious that you are operating in a severely data-deficient state, and that your beliefs, while strongly felt, are not based on much beyond strong feelings. Finally, I would note that the Republican congress and the President were planning to DOUBLE the NSF physical science budget over the next several years, and I doubt that the Democrats will scuttle that particular plan. So you might want to avoid getting too excited about a one-year 3% cut. Over the longer term, what you want is simply not going to happen.

27. **Peter Woit**
January 7, 2007

    OK, OK, will fix the bad spelling…

28. **Who**
January 7, 2007

    I suggest
    trojan'd

    the double n doesn't look right—it puts the stress on the second syllable
    but neither does **trojaned**.

    Verbing is just fine in this case.

29. **Jimbo**
January 7, 2007

    So how much funding for the Tevatron would be required to keep it running until the new budget is cranked out ? I'm guessing on the order of ~500 M$$…..
    Perhaps Jim Simon could talk to Bill Gates, Steve Ballmer, Matt Lesko, Sir Richard Branson, and other high-tech philanthropists, and they could in turn network to their peers….shortly, in a geometric progression, the bread might be made available if these parties were made aware of how dire the straits are….?

Astronomy Posting

January 8, 2007
Categories: Uncategorized

When I was young, my main scientific interest was in astronomy, and to prove it there's a very geeky picture of me with my telescope on display in my apartment, causing much amusement to my guests (no way will I ever allow it to be digitized, I must ensure that it never appears on the web). By the time I got to college, my interests had shifted to physics, and since that time I've hardly at all kept up with what is going on in astronomy. Like everyone, I'm still fascinated by the amazing pictures coming out of the field, and like most particle physicists, I'm deeply jealous of astronomers for the fact that they have a wealth of exciting new data to work with, together with promising prospects of lots more to come.

This week there's a big meeting of the American Astronomical Society going on in Seattle, producing lots of astronomy news. Many bloggers are in attendance, including Rob Knop, Steinn Sigurdsson, Phil Plait, and C.C. Petersen. Rumors that celebrity couple Sean Carroll and Jennifer Ouellette were there turned out to be partially unfounded. Lots of press releases are being generated, including one from the University of Washington full of the usual overhyped claims about cosmic superstrings.

This week's Science has a special issue on particle astrophysics, with lots of articles worth reading, including a nice summary of the exciting things happening in the field by Adrian Cho. He reports that many experimental particle physicists have moved into the field, partly because of the opportunities there, partly because of the difficult situation of experimental particle physics, especially in the U.S. Michael Turner is quoted explaining that the particle physicists have brought to the field some ambitious ideas, due to their habit of "thinking big":

These are not people who are afraid to ask for big things, and they're used to people saying yes.

An example of this is the IceCube neutrino experiment being put together under the ice in Antarctica, employing 400 researchers and costing $271 million.

Turner also has an article summarizing the situation in cosmology, where he notes that many string theorists are now pinning their hopes on making some connection to the real world in this context:

Nowhere in particle physics are the stakes higher than for string theory. If string theory is to live up to its billing as "the theory of everything" rather than, as some say, a theory of nothing, it needs a home run. Because most of its current predictions exceed the reach of terrestrial laboratories, many string theorists are pinning their hopes on a cosmological home run, such as a fundamental understanding of inflation (or a more attractive alternative), a solution to the puzzle of cosmic acceleration, or insight into the nature of the Big Bang itself.

For something truly bizarre, check out the cover story of the February issue of Astronomy magazine, entitled "What if string theory is wrong?" (mentioned earlier here). It confirms me in my opinion that I shouldn't write about things I don't know much about, like astronomy, since it's by an astronomer who clearly knows very little about particle physics, especially about supersymmetry:

Supersymmetry is a mathematical principle that allows force-carrying particles, such as photons and gluons, to transform into one another. It also allows the unification of gravity with other forces because its particle, which some call the graviton, can transform into one of the other force-carriers…. If extra dimensions don't exist, then supersymmetry doesn't either… Without supersymmetry, some physicists have proven that the energy of empty space would be so enormous the universe would instantly collapse. Only by understanding physics beyond the standard model can we hope to understand how the vacuum works and the universe's dark side. And only string theory appears able to serve as a reliable mathematical guide to that larger universe.

Lenny Susskind provides the usual over-the-top outrageous quote:

It is hard to find a serious paper about particle phenomenology that doesn't in some way use the tools of superstring theory.

The author seems to believe that there's some sort of experimental evidence of string theory and that it is just like general relativity:

While string theory is sparse on experimental validation, the situation is not so different from general relativity in its early days, when difficult mathematics made calculating a prediction extremely challenging.

and somehow thinks that string theory is the only hope for the future of physics:

Without superstring theory, we'd lose the intriguing prospects for the multiverse, with its infinite and eternal creativity in spawning new universes… More immediately, dark matter and dark energy would remain imponderable enigmas, shorn of any clues about where they come from. Astronomers can live without knowing the quantum properties of gravity. But to learn that 96 percent of the cosmos is unknowable would be a bitter pill to swallow. It would be even worse for physicists. Without a logical framework in which to pose and answer questions, our inquiries into the fundamental aspects of the physical world would devolve into semantic quibbles.

Some days I think that there's definitely a more realistic view of string theory out there, other days I'm not so sure…

Update: It seems that Edward Witten is attending the AAS meeting, although not speaking there. See the comment from David Cobden, and Steins Sigurdsson's blog entry from the conference Trendspotting, where he reports:

On a completely unrelated note, Ed Witten was spotted wandering the halls…
Now there is always some cosmic string or quantum cosmo thingy going on here, but what we ask (and, yes, I did actually ask), was he doing in the extrasolar planet session?

Ed likes exoplanets!
Dood.

Update: Science a Gogo has an article about this, String Theory? Knot!, which uses my characterization of Susskind's quote as "over-the-top", but then uses the wrong quote, using something from the Astronomy magazine article which wasn't written by Susskind.

Update: The University of Washington press release on cosmic superstrings, based upon a poster presented at the AAS meeting, has made it to Fox News (via Lubos).

January 9, 2007

Google Translate

Translate Text

Original text:

> Without superstring theory, we'd lose the intriguing prospects for the multiverse, with its infinite and eternal creativity in spawning new universes…

Breathless Popular Science Hype to English

> Superstring theory requires more than 3+1 dimensions, which is unfortunate as there is no compelling reason to believe that there *are* any extra dimensions.

3. **M**
January 9, 2007

maybe all your quotes are meant to be somewhat overhyped, so I should not add that IceCube was built thanks to the experimentalists who spent many years developing the necessary technology with smaller experiments (from Baikal to Amanda), and because astrophysics suggests that a km^3 detector is needed to probably start seeing neutrino events from astrophysical sources.

4. **Tommaso Dorigo**
January 9, 2007

Thank you for the quotes from Astronomy. I have always preferred Sky and Telescope to it, but it does not harm to be given additional good reasons now and then…

Cheers,
T.

5. **John A**
January 9, 2007

> While string theory is sparse on experimental validation, the situation is not so different from general relativity in its early days, when difficult mathematics made calculating a prediction extremely challenging.

General Relativity: published 1915.
First exact solution (Schwarzschild)- 1916
Prediction of perihelion shift of Mercury – c. 1916
Bending of spacetime by gravity (Eddington) 1919
Gravitational Red Shift (Pound/Rebka) 1959

String Theory: [this line unintentionally blank]

6. **Bee**
January 9, 2007

It is hard to find a serious paper about particle phenomenology that doesn't in some way use the tools of superstring theory.

What exactly might he mean with 'the tools of superstring theory'?

7. **LDM**
January 9, 2007

Susskind, by making such unfounded statements, must realize he only succeeds in destroying any scientific reputation he may have enjoyed.
As far as Physics is concerned, if he truly believes his statement and is not just engaging in some form of self-promotion, then he is truly delusional.

8. **Ari Heikkinen**
January 9, 2007

"Without superstring theory, we'd lose the intriguing prospects for the multiverse, with its infinite and eternal creativity in spawning new universes…"

Actually, you don't lose anything. I don't need string theory (or any other theory or even any math) to conclude that we're in a bubble called the "universe" (or anything you want to call it) and anything (if anything) out there outside this "bubble" could be called another "dimension" (again, whatever you like to call it).

And even with this purely philosophical reasoning I'm not going to be any more right or wrong than any other reasoning of whatever might be out there or not.

It's kind of like what's going to happen after death. There's lots of theories of what might happen with each one as likely to be right or wrong, as no one's came back to tell what really happened.

So my message to all physicists who happen to read this is: instead of wasting all your life on theories which aren't even remotely useful for anything practical why not instead do something useful, like figure out how to get fusion reactors working (and when it comes to funding, this is where the money should go).

9. **Thomas Love**
January 9, 2007

Lenny Susskind said:

It is hard to find a serious paper about particle phenomenology that doesn't in some way use the tools of superstring theory.

Obviously Susskind doesn't know how to do a literature search.

10. **Chris W.**
January 9, 2007

But to learn that 96 percent of the cosmos is unknowable would be a bitter pill to swallow.

Is Susskind referring to the multiverse here? If so, shouldn't that be "99.9999999…. percent of the cosmos is unknowable"?

11. **Dan**
January 9, 2007

Dear Peter & co,

How successful has been string cosmology, including Randall's & Sundrum braneworld models? How successful has loop cosmology been? I understand that there probably isn't much in the way of hard quantitative predictions, but what about soft or generic predictions, that would differ and be potentially observable, from current SM+GR? (i.e I am aware string cosmology offers SUSY-partners as DM candidates. Anything else?)

curious
Dan

12. **Peter Woit**
January 9, 2007

Dan,

As far as I know, none of "string cosmology", braneworld models, loop cosmology make any predictions, hard, soft, generic or whatever. The SUSY dark matter candidate is a feature of SUSY, not of strings, branes, loops…

13. **Dan**
January 9, 2007

Hi Peter,
Ok thanks. When I google there are a lot of hits, such as arxiv.org/abs/astro-ph/0303499 and arxiv.org/abs/astro-ph/0303499 but I am unsure what real astronomers think

14. **Robert Musil**
January 9, 2007

"[T]o learn that 96 percent of the cosmos is unknowable would be a bitter pill to swallow. It would be even worse for physicists. Without a logical framework in which to pose and answer questions, our inquiries into the fundamental aspects of the physical world would devolve into semantic quibbles."

Perhaps the author is suggesting that if string theory must be abandoned for whatever reason, its cultists will (must!) Drink The Coolaid instead of soldiering on in a purposeless world! The IAS as Jonestown! Well, in that case, maybe it will be sherry, not Coolaid.

15. **Peter Orland**
January 9, 2007

Paul Says:
January 9th, 2007 at 6:03 pm
a) If three-dimensional space (let's omit the "fourth dimension of time", for a moment, reason given below) is "curved" by gravity, what is it curving into? For example, if you place a bowling ball on a bedspread, it is curving *from* the second dimension *into* the third dimension.

Paul,

The answer to your question is very subtle. To understand curved
space, it isn't necessary to curve that space into anything. This was discovered by Gauss and Riemann, and is a fact of "intrinsic geometry".

To see how this works, imagine a curved sheet of rubber. Draw
coordinates (that is a graph) on the rubber. Now mash it flat into the plane. The coordinates will remain on the sheet, but won't be
flat. The intrinsic curvature is still there, due to the stresses
rubber. On the other hand, if you take a flat piece of rubber
and bend it (without otherwise straining it), it remains intrinsically
flat, though there is now what is called extrinsic curvature.

Einstein's equations of gravity relate the intrinsic curvature of
spacetime to matter. They say nothing about extrinsic curvature,
i.e. how space-time is embedded in some space of more than
four dimensions.

Implicit in your question is another about curvature of
three-dimensional space, as opposed to four-dimensional
space-time. Many popular books incorrectly explain
gravity as being due to curvature of space. The bowling-
ball/bedspread picture is NOT really the right way to think
about gravity. In the most natural (either comoving or
Schwartzchild) coordinates, the spatial curvature is
extremely small. Newtonian gravity is not at all related to
spacial curvature, in these coordinates, but in space-time
curvature. There is some curvature of three-dimensional space, responsible for some of the shift of the perihelion of mercury,
but it is very small.

The physical way to think about gravity is this… In so-called
comoving, or inertial coordinates, space falls into energy
(which by E=mc^2 includes matter). Particles in this space fall
with it. The bedsheet is slightly curved by the bowling ball, but
Newtonian gravity is due to the bedsheet being sucked into the

bowling ball!

One can choose other coordinates, where spacial curvature
is big, but they are not particularly useful.

16. **anonymous**
January 9, 2007

Dan, there are plenty of specific models of inflation in string theory. They can involve things like a brane and an anti-brane in the extra dimensions which move toward each other and annihilate. While they move, the universe is expanding (inflation); when they annihilate, lots of particles are produced. Contrary to what Peter says, any specific model of this type does make specific numerical predictions for things like the CMB power spectrum. The trouble is that there are a lot of models of this type, and not enough numbers measured well by experiments to select among them, at least so far.

17. **woit**
January 9, 2007

Please Peter O. and others. This kind of discussion of the basics of GR is off-topic and has nothing at all to do with the posting. This is not intended as a general physics discussion forum, which is something I have no interest in hosting or trying to moderate.

anonymous,

Again, there is no such thing as a "prediction" of string cosmology, or a "prediction" of brane world scenarios about cosmology. These ideas cannot tell you what the next generation of experiments is going to see, or the one after that. There are so many variants of these models and lots of parameters, so much so that these ideas are vacuous in terms of making anything anyone would call a legitimate prediction. If you disagree, tell us what "string cosmology" or brane-world scenarios says the next generation of CMB experiments will see, and be willing to agree that string theory is wrong if they don't see this.

18. **Aaron Bergman**
January 9, 2007

Specific models make specific predictions. Nothing's going to say that string theory is wrong, but various scenarios make unambiguous predictions and are falsifiable.

19. **Peter Woit**
January 9, 2007

Aaron,

"string cosmology" is not falsifiable
"brane world cosmology" is not falsifiable
I have no idea about loop cosmology.

Sure, you can come up with highly complicated, highly speculative models that don't really explain anything about observable physics but make "predictions". I could make up a "scenario" which involves God writing the lyrics to Lucy in the Sky With Diamonds in Morse code and imprinting these in the CMB at a certain amplitude. This would make definite predictions, and be completely falsifiable.

20. **Robert Musil**
January 10, 2007

I'm not an astronomer, but I sent your quotes to the astonomers I know (there are not that many – but they do include people working at Harvard-Smithsonian). They weren't even aware that string theory offered any explanation whatsoever for Dark Energy and Dark Matter. They tell me the most likely candidate for Dark Matter is "axions", which are hypothetical particles that arise from supersymmetry in the standard model (no strings there). The most likely candidate for Dark Energy is said to be some kind of small positive vacuum energy due to something about the vacuum or fields that we don't understand (again, no strings needed). These astronomers agree that while positive vacuum energy many constrain string theory, there are no constraints of any sort from string theory to observations.

For the record: The astonomers I asked are actually now directly involved in observation projects regarding Dark Energy and Dark Matter. Just thought I'd mention that.

21. **LDM**
January 10, 2007

Aaron Bergman,

"Nothing's going to say that string theory is wrong."

Please. Look up the definition of the science method somewhere and then rethink your statement.

There is another quote by Pauli, lesser known, but perhaps with more scientific content and less sarcasm than the title of Peter's book. Pauli pointed out that there is always a *continuum* of theories that agree with a given phenomena, but the test of a theory is that it predicts something new.

Note Pauli did not say postdict.
Note that string theory fails this test miserably.

Pauli arrived at this observation, in my opinion, because his genius was so great that he could and did easily discover alternate formulations and approaches.

There is so far no compelling reason to believe string theory in its current form and considerable reasons not to, that is unless you are like Susskind and have invested your professional identity with it…and also consider yourself one of the fathers of the theory.

22. **anon y mus**
January 10, 2007

Dan & other anonymous,

models with parallel branes in extra dimensions have been studied hoping that a) their potential energy naturally gives the flat potential needed for inflation; b) their final collision generates the particles we see.

However a) turned out to be false, after that the size of the extra dimensions is stabilized. Furthermore b) when inhomogeneties in the matter density can be computed, their spectral index comes out very tilted, unlike the observed one. And c) in any case the idea that some God liked to start the Universe putting two perfectly parallel branes looks as naive as the ancient oriental cosmology where the Earth stays above a turtle above a turtle…

23. **anon y mus**
January 10, 2007

correction: probably this cosmology is not naive from the modern point of view of String Naturalness: perfectly parallel branes can be justified by invoking the Anthropic Principle.

I am sorry, but for a moment I forgot that Susskind told us that we must use the tools of superstring theory to do something serious.

24. **r hofmann**
January 10, 2007

Dear Ari,

`So my message to all physicists who happen to read this is: instead of wasting all your life on theories which aren't even remotely useful for anything practical why not instead do something useful, like figure out how to get fusion reactors working (and when it comes to funding, this is where the money should go). '

I agree with you. All philosophizing about mere matters of belief,
such as the multiverse, is even culturally irrelevant if our very culture won't survive the looming climatological catastrophe we
will have to face in the absence of a viable alternative to the present way of fueling or energy needs. I personally believe that fusion with
magnetically confined plasmas will be viable if we manage to
apply genuine knowledge gained about electroweak symmetry breaking (theoretically and at the LHC) to this problem.

High regards.

25. **Lee Smolin**
January 10, 2007

Dear Dan,

Regarding loop quantum cosmology, this is a class of models, not yet the full quantum field theory. Nonetheless within them, there is a universal mechanism for eliminating the initial singularity. That mechanism implies modification of the power spectrum, at a level that may be observable in future CMB observations, as argued in astro-ph/0411124. Whether this leads to predictions from the full theory rather than models is the subject of ongoing work, see for example astro-ph/0611685.

26. **Dan**
January 10, 2007

Dear Lee Smolin & both anonymous

thanks. It seems string cosmology is also a class of models as is loop cosmology? Incidentally Lee, I've been hoping you and Bilson publish a followup preon paper 😉

27. **Aaron Bergman**
January 10, 2007

"string cosmology" is not falsifiable
"brane world cosmology" is not falsifiable
I have no idea about loop cosmology.

Sure, you can come up with highly complicated, highly speculative models that don't really explain anything about observable physics but make "predictions".

Actually, some of them aren't particularly complicated, and they do make honest predictions. I don't understand what your problem with this is. The models can be ruled out.

28. **Landscape vegetable**
January 10, 2007

How long will it take to rule out 10^500 models? How many per second can be ruled out? To do it within 1000 years (3*10^10 seconds) would mean ruling out ~10^490 models per second. The universe is only 4*10^17 seconds old, so to do it over the age of the universe would require ruling out only ~10^483 models per second.

It reminds me of SDI in 1985. Objectors to SDI dismissed it by working out that all the computers needed to shoot down Soviet missiles would take thousands of years to program. It's too bad that nobody influential is using this argument against the Landscape.

29. **anonymous**
January 10, 2007

Peter says the models "don't really explain anything about observable physics," but for most of us having a reasonably simple model of how inflation could work is pretty nice. As for what "anon y mus" says, I suggest reading more of the literature — it's not always about exactly parallel branes, and there are some viable scenarios. It turns out one doesn't even necessarily need slow-roll, brane inflation has suggested scenarios where the kinetic term matters more than the potential. Anyway, Dan, yes, brane cosmology suggests various models, which as Aaron says are falsifiable. What it doesn't do is suggest a unique model, but neither did old, field-theoretic inflation. So I don't really know what Peter's so worked up about.

30. **LDM**
January 10, 2007

anonymous ,

If string theorists have to resort to an extremely speculative idea like inflation as evidence for an even more speculative idea, string theory, than that itself is telling. I do not consider such models meaningful.

31. **Lee Smolin**
January 10, 2007

Dear Dan,

Loop quantum cosmology must be a set of models for two reasons: 1) they incorporate diffrerent models of the inflaton. 2) They describe reductions to different homogeneous cosmologies, i.e. FRW, Bianchi I, Bianchi IX etc. These are harmless, they do not represent different low energy theories or low energy phenomenologies as do the string cosmologies. Moreover there are no fine tunings in the main results, such as the removal of singularities or corrections to the CMB spectrum.

At the same time, one would like to do better and know if the predictions found are genuine predictions of full quantum gravity rather than a quantization of a reduced set of degrees of freedom. This is the aim of some current work.

There is also a more speculative direction of work in which we postulate that, if geometry emerges from a low energy limit of a purely quantum geometry it may do so in a phase transition which leaves observable signatures. This work is very recent, see hep-th/0604120, and hep-th/0611197, but it appears that one can make distinct predictions for CMB observations on the basis of a few simple assumptions about that conjecttured phase transition, see astro-ph/0611695.

Thanks re preons. Work is presently underway, in collaboration with several people.

Thanks,

Lee

32. **Peter Woit**
January 10, 2007

Aaron,

"I don't understand what your problem with this is. The models can be ruled out."

You decided to not quote the part of my comment that answers this, here it is again:

"I could make up a "scenario" which involves God writing the lyrics to Lucy in the Sky With Diamonds in Morse code and imprinting these in the CMB at a certain amplitude. This would make definite predictions, and be completely falsifiable."

There's more to doing science then coming up with "scenarios" based on pure speculation, you actually need some sort of evidence for them. What string theorists are doing now is saying that string theory can't tell us anything about low energy physics, but it is science because it can tell us about cosmology. When asked what it tells us about cosmology, the answer is "in general, nothing, but it leads to all sorts of scenarios". And the only evidence for these "scenarios" is that they are somehow compatible with the idea of string theory unification, determining low energy physics. The whole thing is kind of absurd.

33. **Peter Woit**
January 10, 2007

anonymous,

I just don't see how introducing branes improves the situation at all as far as "having a reasonably simple model" is concerned. It seems to do quite the opposite.

34. **Aaron Bergman**
January 10, 2007

There's more to doing science then coming up with "scenarios" based on pure speculation, you actually need some sort of evidence for them. What string theorists are doing now is saying that string theory can't tell us anything about low energy physics, but it is science because it can tell us about cosmology.

Not everything has to be seen through this prism of string theory, spawn of satan or harmless diversion. If I just called them string inspired models, would that be ok? Take DBI-inflation, for example. Outside of its string theory inspiration, is there anything that makes it worse than other models for inflation?

35. **Peter Woit**
January 10, 2007

Aaron,

Working on speculative ideas that really have nothing to do with string theory, and justifying this not because of evidence for the ideas, but because they are "string-inspired" doesn't seem to me like a healthy way to do science. It's also kind of intentionally misleading, intended to get people believing that "string theory makes predictions", and writing completely absurd articles for Astronomy magazine.

36. **anon y mus**
January 10, 2007

Dear anonymous-who-wants-literature-for-problem-a): see pages 22,23 of hep-th/0610102 for a short review. In my opinion the fact that the generic idea does not help is more important than the fact that one can avoid some problem by cooking up specific models.

37. **Aaron Bergman**
January 10, 2007

Working on speculative ideas that really have nothing to do with string theory, and justifying this not because of evidence for the ideas, but because they are "string-inspired" doesn't seem to me like a healthy way to do science.

People aren't working on string-inspired models because they're string-inspired, but because they are new models. There are lots of models for inflation, some string-inspired, some not. I think they're all worth investigating, don't you?

38. **Aaron Adams**
January 10, 2007

If ever there was a gauntlet thrown at the feet of an apartment visitor with a cellphone camera, this is it:

> "…there's a very geeky picture of me with my telescope on display in my apartment, causing much amusement to my guests (no way will I ever allow it to be digitized, I must ensure that it never appears on the web)."

39. **Ari Heikkinen**
January 10, 2007

I don't think it's entirely fair to say that just because you're not making any predictions you're not doing science.

Take early days of aerodynamics, for example. All they were doing was trying to understand what's happening in their wind tunnels, that is, trying to understand real world phenomena.

Even though they weren't making any predictions (at the time), everyone in the field still seem to think they were doing science.

40. **kuos**
January 10, 2007

Susskind is right.

String theorists occasionally use algebra, hence algebra is one of the "tools of superstring theory".

Very few serious particle phenomenology papers avoid the use of algebra. QED.

41. **Peter Woit**
January 10, 2007

Ari,
Experimentalists don't need to be making predictions, but theorists are supposed to, and it's theorists I was talking about.

Aaron B.,

Well, in general I don't think all possible models (of inflation, or of anything else) are equally worth investigating. One is supposed to be concentrating on those for which one has a good scientific reason. If your only reason for deciding to work on one class of models is that it's "string inspired", that seems to me to be a problem.

42. **wow**
January 10, 2007

This discussion of inflation is quite interesting. I can't think of *any* development that was important in yielding the eventual standard models of cosmology and particle physics, that Peter couldn't criticise along the same lines.

Gauge theory? Just a model. Can't make a unique prediction, because it isn't a unique model. Since you can't falsify gauge theory, its not science.

Einstein's theory of gravity? Has an infinity of solutions. If your favorite FRW cosmology doesn't match data, you could choose a different solution. Thats not science.

In both cases, people chose a framework, built models as best they could, and eventually found that ONE describes nature pretty well. For gauge theory that happened to be 3-2-1. For Einstein gravity, initially, the flat FRW solution (which has since been augmented). Other people chose other frameworks, tried to build good models, and failed. String theorists are working in exactly the same way: they choose a framework, and try to build a model that is itself predictive and falsifiable. Smolin uses his framework. Thats fine. As long as each model is testable, there is no problem with the plethora of models being suggested.

Claiming that these are string theory models of inflation, is no more or less misleading than saying that the various Lambda CDM cosmologies (specified by many parameters) are all simple versions of GR + the standard model. The model is far from unique. So what?

43. **Chris W.**
January 10, 2007

(from Ari) *All they were doing was trying to understand what's happening in their wind tunnels, that is, trying to understand real world phenomena*.

And that doesn't involve making predictions? I don't mean predictions of the "future," but just predictions of, say, what velocity field you'll get in the neighborhood of an specific airfoil positioned in a certain way in the wind tunnel. You may have such observations already in hand, which you try to reproduce with an application of the Navier-Stokes equations or some less general model. If you succeed, then you say, okay, let's *predict* what will happen if we reposition the airfoil or change its shape in a certain way, whose presumed effects we know how to calculate. It's the results of this follow-up testing that are of the greatest interest; we want to know if the initial agreement was merely a fluke.

Admittedly, the results of such tests may reflect more on our methods of approximating a solution to the model, or on our choice of relevant free parameters, than on the fundamental assumptions of the model itself, but that's part of the problem of testing the model—find ways to confront the central assumptions with *crucial* tests, ie, tests whose evaluation is not overly dependent on incidental aspects of the model's formulation.

String theory seems to have evolved in such a way that crucial observational tests, as opposed to tests of internal consistency or correspondence to (at least some) important aspects of the Standard Model, are impossible to formulate. The best criticism then becomes a meta-criticism—that string theory seems *designed* to make such testing impossible or in some sense beside the point. (Of course the apparent freedom to choose a background spacetime has played an essential role in all this.)

In the face of this situation one can continue to imagine that one has understand something about nature that wasn't understood before, but the same can be said of any number of metaphysical ideas. Susskind seems to be protesting the abandonment of this "opportunity" to understand nature. Perhaps there still remains such an opportunity in string theory, but the current situation demands a much deeper response than a proliferation of convoluted variants on Kaluza-Klein models, an interminable exploration of the Landscape, invocations of the Anthropic Principle, or exploration of the vast array of mathematical ramifications of the theory's formalism.

44. **Peter Woit**
January 10, 2007

wow,

Sorry, but I find these claims that there is no difference between the predictivity problems of string theory, and those of gauge theory or GR to just be absurd, and I can't believe that anyone makes these claims seriously.

For about the 100th time, the difference is not hard to understand. Gauge theory and GR are quite simple, rigid structures, and at the time they were suggested, they correctly postdicted huge amounts of observed physics, and made huge numbers of predictions, some of which were quickly testable.

String theory unification, whether applied to particle physics or cosmology postdicts virtually nothing and predicts nothing. Unlike the case of gauge theory or GR, there simply is no scientific evidence for the idea, nor any plausible prospects for getting any soon. Unlike the case of gauge theory or GR, attempts to connect string theory unification to real world physics aren't based upon solid predictions that follow logically from certain simple principles. Instead there's a whole industry of complicated and ugly Rube Goldberg constructions which don't explain anything, but are are designed purely to avoid contradicting the rules of logic or what is already known about physics.

45. **dan**
January 10, 2007

Dear Lee Smolin,
I am aware that the symmetry reduced loop quantum cosmology may have good semiclassical description but not LQG.

Incidentally would you mind if I cut and paste your comments to wiki here

http://en.wikipedia.org/wiki/Loop_quantum_cosmology?

A hobby of mine is to update wiki's entries on LQG
(I.e I added material on preons and Kodama state, for example)

http://en.wikipedia.org/wiki/Loop_quantum_gravity
http://en.wikipedia.org/wiki/Preon

46. **David Cobden**
January 11, 2007

I heard about something quite funny and moderately relevant today at the AAS meeting. One of our newer students was giving a poster on detecting gravitational waves from cosmic strings. He described to me how someone with a high-pitched soft voice came up to talk to him, and how the other students around him suddenly went completely silent. The stranger was quite interested and said something like "you've got to look at radiation from cusps". Student: "Kinks?" Stranger: "No, cusps." Student: "You seem to know quite a lot about string theory." Audience: smiles! Yes, the man himself, on the lookout for experimental verification!

47. **F.**
January 11, 2007

It seems strange that every harmless motion and remark of a
prominent physicist seems worth commenting on here.
What happens?
F.

48. **woit**
January 11, 2007

F.,

Well, one role of this blog is to retail gossip and keep people up to date on the activities of the celebrities of our field, and for those of us interested in particle theory and mathematics, Witten is bigger than Britney Spears, Paris Hilton and Lindsay Lohan all rolled into one. He has a very large influence on the direction of the field, so for instance if it turns out he has given up on particle theory and decides to devote himself to the study of exoplanets, that would be explosive news. No, I don't think it's happening. More likely, like many of us, Witten just thinks a lot of this astronomy stuff is cool.

49. **David Cobden**
January 11, 2007

Dear F.,

What seems strange to me is that anyone could think that EW's remark was the point of the comment. Oh well.

Dave

50. **FFF**
January 11, 2007

Can Witten go to the toilet while attending a string theory seminar without worrying that it might be interpreted as an explosive news?

51. **wow**
January 11, 2007

Actually, gauge theory (and field theory as a whole) was criticized in much the same way as you are criticizing string theory, for about 20 years following the original Yang-Mills paper. This culminated in the bootstrap/S-matrix movement where the irrelevant technical "rube goldberg" details of field theory, which was itself not unique and far from well defined, could be swept under the rug.

Of course this was badly misleading. Field theory is difficult and nonunique. It is also deep, beautiful, and correct. My guess is that this is true of string theory as well. A difference seems to be that string theory is unique, but has many solutions, while field theory is fundamentally non-unique. But this is not an important difference.

52. **D R Lunsford**
January 11, 2007

Peter,

Like you I started with astronomy and dropped it in college. Recently I acquired a good 10″ telescope and let me tell you, the thrill is still there! You'll enjoy having one, I recommend it. It's also more fun now that I understand light and the universe a lot better than I used to.

-drl

53. **D R Lunsford**
January 11, 2007

Tommaso,

“Astronomy” has always been a miserable sensationalist rag. It also had the bad effect of debasing Sky&Telescope by forcing them to compete on a more glossy level. In a sense it annihilated with the old S&T and they both disappeared in a burst of advertising dollars.

-drl

54. **woit**
January 11, 2007

wow,

The difference between QFT and string theory has nothing do with questions about uniqueness. The simplest QFT in the class of gauge theories (QED) accurately describes nature to absurd precision, makes an infinite number of non-trivial predictions, all of which turn out to work when you test them. This remains true of the only slightly more complicated non-abelian gauge theories and the standard model.

People did not argue against QFT that is was untestable, they were testing it all the time. They argued that it couldn’t describe the strong interactions, and that appeared to be the case until the discovery of asymptotic freedom. There has never been any time when people studying QFT were claiming that it was impossible to get predictions out of it because there were too many QFTs.

If you want to make an argument that string theory will someday triumph the way QFT did, you could try and claim that someday we’ll better understand string theory, and realize that it has some surprising property like asymptotic freedom that will make its current problems describing nature go away. Maybe, but there’s no evidence for that now.

55. **woit**
January 11, 2007

drl,

I still have an old 8″ telescope, don’t get to use it very much in New York City though…

56. **wow**
January 12, 2007

The history of qft is not as you say. There were two periods of significant “discouragement” due to people who thought the structure should be easier and more unique than it is.

If you read about QED (see Dysons many accounts), it is clear that by the mid 40s, after 15-20 years of worrying about relativistic quantum mechanics, most of the old heroes of qm (Dirac, Schrodinger,…) Thought a fundamentally new structure to replace qm (not QED) was needed. It was the new generation (feynmanm schwinger etc) that saw that the old complicated theory, could indeed be made to work. They needed rube goldberg contraptions to explain loop effects and it took 25 years before the correct wilsonian understanding of renormalization was attained.

Then, later, the chicken littles appeared when the theory of strong interactions required novel features of qft.

The analogy is quite clear. Understood poorly, qft is very difficult, nonuniqe, and even seems ambiguous (due to misunderstandings of renormalization). The aesthetic worries were irrelevant (science doesn’t demand uniqueness, just that one avatar of the theory be a good approximation of nature).

57. **Thomas Larsson**
January 12, 2007

Wow: Funny, I used exactly this summary of the history of QFT in the introduction to my contribution to this book. However, I don’t see how it can be construed to support string theory. Adding tons of unconfirmed (and increasingly unlikely) “new physics”, like susy, extra-dimensions, fundamental extended objects, 496 gauge bosons, or 10^500 universes is more like the new physics that Oppenheimer and others thought was necessary to cure the infinities of QED.

58. **Peter Woit**
January 12, 2007

Wow,

I have read a bit about the history of QFT… Earlier I was referring to the post 40s history of the subject, but I don’t think your interpretation of the earlier history holds water.

From the very beginning in the late 1920s, QED had a huge amount of experimental backing. First-order perturbation theory was well-defined, and gave extremely accurate, testable predictions of a huge variety of experimentally measurable effects. The problems with higher order perturbation theory were a matter of principle, but practically of little significance. The measurement of the Lamb shift made clear that higher-order effects were real and the theory had to explain them, which was rather quickly done.

It’s true it took 15-20 years to sort out the problems of how to renormalize QED, but for a large chunk of this period, most physicists were either trying to save their skins or working on war-related projects. People were worried that QED might very well be inconsistent, but I don’t know of anyone who was worrying that it was consistent, but experimentally untestable.

And the reason people took seriously Feynman and Schwinger’s renormalization methods, whether or not they found them to be of a “Rube Goldberg” nature, was that these methods gave extremely accurate and experimentally confirmed predictions for things like the anomalous magnetic moment of the electron. If Feynman and Schwinger had been doing higher order perturbation theory calculations using complicated methods, but getting no predictions out of them, just a bunch of excuses for why QED couldn’t make predictions, absolutely no one would have taken them seriously.

59. **wow**
January 12, 2007

I haven’t actually heard any string theorists say the theory will not lead to predictions, once (by whatever fortuitous experiment) the correct class of solutions is found. I have heard you say this many times, but apparently the rather large community of technical experts on string theory, does not believe your statement. To me, this looks like what critics of field theory would have been saying in the 30s and 60s. And the response of the string theorists, is similar to what the wise folks who kept working in the natural extension of existing theory (QFT) did.

The absence of data at the relevant energy scale is indeed different. This is not a problem of string theory, and has haunted beyond SM physics for 20 years. To attack string theorists and not the huge number of phenomenologists who worked on supersymmetry, technicolor, large extra dimensions, randall sundrum scenarios, little higgs models, or whatever, seems silly to me. One could just as easily make ad hominem remarks about the 10s of thousands of papers there with no experimental confirmation of the ideas. And these remarks would be just as silly: the goal of the endeavor is to divide up the space of models so * when interesting signatures are SEEN *, one will know what this means about where we live in theory space.

String theorists do the same thing with their framework. If Smolin had a framework I imagine he would also do this, though I have never understood in what sense he does have one.

60. **Peter Woit**
January 12, 2007

wow,

I'm sure people working on string theory hope that it will some day lead to predictions, but there aren't any now, and the problem is that at this point there's not a plausible scenario for how this is going to happen. You seem to be saying that you believe in a "fortuitous experiment" that will indicate that the string theory landscape picture is correct by providing evidence for a certain class of string theory solutions. That's logically possible, but I don't see any evidence for this scenario other than wishful thinking based upon a firm conviction that string theory has to be true. Yes, this judgement about the plausibility of your scenario is a personal one, but I'm pretty sure that it is shared by a large fraction of particle theorists who are not string theorists.

Beyond the standard model particle phenomenology has, like string theory, had very little success over the last 20 years. With no experimental guidance, it's a very hard problem. Like string theory, some ideas about particle phenomenology are overhyped by their enthusiasts. But I just don't see the same unhealthy domination of the subject by a single idea that is not working. Phenomenologists are at least trying lots of different ideas (even if none of them are especially promising). The idea of getting beyond the standard model physics out of some kind of string/M theory on a 10/11 space has not just failed to work out the way people hoped, but it continues to dominate a large fraction of particle theory research. Given the lack of any other successful ideas, there's no reason some people shouldn't work on it, but people who do so should acknowledge that things are not going well, and that probably other quite different ideas are needed.

The day technicolor models are pursued by large groups of theorists who create institutes devoted their study, won't hire people who don't work on these models, write books and TV shows about the glories of technicolor, and start up blogs devoted to calling anyone who doesn't believe in technicolor an imbecile, I'll start writing postings pointing out the problems with what they are doing.

61. **Thomas Larsson**
January 12, 2007

To me, this looks like what critics of field theory would have been saying in the 30s and 60s. And the response of the string theorists, is similar to what the wise folks who kept working in the natural extension of existing theory (QFT) did.

"The critics are right. We have no single prediction of string theory that is verified by observation. Even worse, we don't know how to use string theory to make predictions. Even worse than that, we don't really know what string theory is."
-Steven Weinberg

62. **anonymous**
January 12, 2007

"and start up blogs devoted to calling anyone who doesn't believe in technicolor an imbecile"

Hey, I bet Ken Lane can be persuaded to do that!

"But I just don't see the same unhealthy domination of the subject by a single idea that is not working. Phenomenologists are at least trying lots of different ideas (even if none of them are especially promising)."

Wah? I guess by one idea you mean "the right theory is a string theory." At the same level of generality phenomenologists generally go from the idea "the right theory is a QFT for which the SM is a low-energy effective theory." There is of course lots of diversity in what phenomenologists do, but at the same time there is diversity in stringy model-building (intersecting brane models, flux compactifications, etc.). I don't see what you're doing as an apples-to-apples comparison.

63. **M**
January 12, 2007

wow, many phenomenologists are interested in if/which new physics keeps the weak scale naturally small (supersymmetry or technicolor or…?) because colliders are now exploring physics at the weak scale. This is not only an important issue, it also is an issue that will be clarified, probably soon at LHC. The present attempts could be right, or could be wrong, but cannot be not-even-wrong.

64. **wow**
January 12, 2007

M:

Many of the things explored by model builders (including the most influential ideas of the past decade or so) were either directly or indirectly but obviously influenced/inspired by string theory ideas. I am not saying this as "an arrogant adherent of string theory" — this is a fact that the originators of the models would freely admit. It is true of the Randall/Sundrum works on warping and anomaly mediation; it is true of the large dimensions works which not coincidentally blossomed right after D-brane gauge theories became a topic of interest; it is true of new ideas in SUSY model building which took off from Seiberg's classic works, which in turn were inspired in part by thinking precisely about string theory moduli spaces. It is true of the recent resurgence of interest by cosmic string theorists, who see the reasonable motivation for new possibilities of strings with smaller tension that play a very subleading role in structure formation. It is true of most attempts to build models relevant for Planck, that would show measurable non-Gaussianity or gravitational waves (specially the former; ideas about the latter go back to the origin of inflation, but have been considerably influenced by theoretical considerations of quantum gravity more recently).

So, M, even the things that you say are defensible because in some very short term they are "relevant" to near term experiments, have a history that shows the value of the more formal research going on in particle/string theory.

65. **Chris W.**
January 13, 2007

The aesthetic worries were irrelevant (science doesn't demand uniqueness, just that one avatar of the theory be a good approximation of nature). (- wow)

Right, I got it; that's good. So, one should make sure that one's theory has as many "avatars" as possible, with as much diversity as possible, to maximize the likelihood that one of the them will be a good approximation of nature. After all, nature can be anything at all, and science is fundamentally trial and error, so we want to make sure the options available for those trials really cover the bases. Works for me. It looks like string theory and its offshoots are doing a heckuva job then.

(Karl Popper used to talk about how important it was for a theory to *restrict* the observations that one might anticipate making. Man, what a crock of s*** that was…)

[🙂]

66. **M**
January 13, 2007

wow, what you say about extra dimensions is true, and probably their connection with strings also is the main reason why these ideas attracted so much attention. Experiments will tell if it was worthy.

I prefer to look at physics rather than at physicists: recent decades will be likely remembered for the following fundamental discoveries: the cosmological constant, inflationary cosmology and structure formation, solar neutrino oscillations, atmospheric neutrino oscillations. Strings played no role there.

67. **Kyrie**
January 14, 2007

> recent decades will be likely remembered for the following fundamental discoveries: the cosmological constant, inflationary cosmology and structure formation, solar neutrino oscillations, atmospheric neutrino oscillations

I would add to this list the definitive observational proof of the existence of dark matter. And maybe also the experimental proof of the CKM model of CP violation.

68. **M**
January 19, 2007

I hope that next years will be the crucial ones for both topics.
Dark Matter could be seen in direct detection experiments and produced at LHC.
The second topic you suggest could be part of a more general issue: since 30 years theorists think that the SM must be replaced at the weak scale by some new physics that solves the hierarchy problem, but since 30 years experiments (colliders, CP,…) fail to find it. If this negative trend continues at LHC, I would consider it as a fundamental discovery, more fundamental than e.g. supersymmetry. But I don't know how this could be explained to funding agencies…

69. **Ari Heikkinen**
January 23, 2007

"cosmic superstrings"

So any "fluctuation" whatsoever on whatever measuring device and it's evidence for cosmic superstrings? Come on, even Hoagland would have more reasoning for his theories than that.. 🙂

Various Stuff

January 11, 2007
Categories: Uncategorized

This week I'm getting ready for the start next week of the spring semester. I'll be teaching the second half of our graduate course on Lie Groups and Representations, something I also did a few years ago, at which point I wrote up some notes and put them on-line. This year, since the students covered somewhat different material during the first semester, I'll be covering some different topics, hoping to both write up some notes on the new topics, and improve the older notes. We'll see how much of that I have time for. Throughout academia, others are also trying to figure out what they'll be talking about during the new term, for example see Clifford Johnson's recent posting. He's teaching a course on string theory, something about which he seems to be a tad bit defensive. Actually his outline syllabus doesn't really indicate what he will cover, referring to aspects of perturbative and non-perturbative string theory, gravity and quantum field theory, which pretty much includes most of modern physics. Perhaps, like some of the rest of us, he hasn't quite yet decided what exactly to talk about…

A future course that some people might be interested in is a summer school to take place in Seattle on Lattice QCD and its Applications.

An American Physics Student in England has a review of QFT textbooks for beginners. He neglects to mention a couple of my favorites (maybe just because they are ones I learned from during my student days): *Quantum Field Theory* by Itzykson and Zuber, and Pierre Ramond's *Field Theory: A Modern Primer*.

I saw the above link first at Dorigo Tommaso's blog, which also contains all sorts of news about interesting results coming out of the Tevatron, including a new, more accurate value of the W-mass. See for instance here, here, here, and here. About the new W-mass measurement, there's also a Fermilab press release, and an article in Nature. It may yet turn out that the Tevatron is the place where the Higgs is first seen.

Also in Nature is an interesting article by Frank Wilczek about recent lattice QCD results showing that QCD leads to a nucleon-nucleon potential with hard-core repulsion.

Notes from the talks at last week's Gottingen Winterschule on Geometric Langlands are now available.

From Peter Teichner's web-site, a new preprint by him, Hohnold and Stolz describing 8 different models for real K-theory, one of which is in terms of supersymmetric quantum mechanics. The paper is dedicated to the memory of Raoul Bott, whose periodicity theorem is a large part of this story.

From Michael Douglas's web-site, there are slides from his recent colloquium talk here at Columbia on Supersymmetric Gauge Theory: an overview. He also has a new preprint out with Denef and Kachru entitled Physics of String Flux Compactifications. The autthors go over the arguments for the Landscape and devote significant space to discussing whether or not string theory is testable. They explain why hopes that one could use a statistical, anthropic argument to predict whether supersymmetry breaking happens at low or high scales haven't worked out. There's a somewhat mystifying claim that "in fact string/M-theory does predict a definite distribution of gauge theory and matter contents", referring to various papers which don't contain anything like a definite string/M-theory prediction of such a distribution.

As for the testability of string theory, the authors first note that while there are all sorts of exotic phenomena that one might imagine finding that are consistent with string theory, none of them are required by string theory, so:

Thus, while string theory can offer experimentalists many exciting possibilities, there is little in the way of guarantees, nor any clear way for such searches to falsify the theory.

They then go on to give what they see as four possibilities for testability:

1. "Swampland" arguments showing that string theory can't possibly lead to a low energy effective theory that agrees with what we see. Unfortunately, there seems to be no such plausible argument, with all arguments of this kind so far only ruling out string theory as a source for very different physics than what we observe.

2. String theory must be true because there is no other possible theory of quantum gravity. They completely ignore LQG, but do admit that "one should not take this too seriously until it can be proven that alternatives do not exist", mentioning the possibility of finiteness of N=8 supergravity.

3. Maybe the LHC will discover new physics that clearly is the result of a string theory compactification.

4. Maybe they will be able to make statistical predictions using the landscape.

These seem to me extremely weak and problematic arguments. 3 appears to be little more than wishful thinking that a miracle will happen and save the day, and all efforts over the last few years to pursue 4 seem to lead to insuperable difficulties for very fundamental reasons. In the end, the authors acknowledge this, writing "ultimately convincing evidence for string theory will have to come from observing some sort of exotic physics", and putting their hopes in string cosmology, especially the hope of seeing networks of cosmic superstrings or signals in the CMB corresponding to non-linearities in the DBI action.

After this dismal summary of the situation and of prospects for the future, the authors decide to end with conclusions more or less directly opposite to the ones their arguments naturally lead to:

We conclude by noting that while the present situation is not very satisfactory, there is every reason to be optimistic… There are many well-motivated directions for improving the situation, and good reasons to believe that substantial progress will be made in the future.

Update: One more. There will be a public debate over the anthropic principle later this month, involving David Gross, Lenny Susskind, and others. More information here.

Comments

1. **A.J.**
   January 11, 2007

   American Physics Student in England also forgot to mention Zinn-Justins's *Quantum Field Theory & Critical Phenomena", which about as good a QFT textbook as currently exists. I always appreciated the fact that they explain Wilson's perspective on effective field theory in the introduction, before doing even a gaussian integral.*

2. **Mark**
   January 11, 2007

   Hi Peter,

   Whats your favorite reference for Lie algebras? I remember you once mentioned Bourbaki.

3. **Peter Woit**

January 11, 2007

Mark,

Kind of depends what you want to do with them. Bourbaki is unusually readable, but better might be a standard mathematical textbook, best-known algebraic one may be Humphreys. More for geometers, there's Fulton and Harris. If you're just learning the subject, a concise discussion is in the first part of the short book by Carter, Segal and McDonald. For physicists, who don't care about arbitrary fields and really want to compute things, there are lots of references, and they might find Fulton and Harris readable. The beginning chapter on Lie algebras by Jurgen Fuchs in his book Affine Lie Algebras and Quantum Groups is nice, lots of computational details in Howard Georgi's book.

4. **Thomas Love**
January 11, 2007

I cut my teeth on Robert Hermann's Lie Groups for Physicists (which I really cannot recommend) and Robert Gilmore's Lie Groups, Lie Algebras and Some of their applications (now from Dover). Gilmore has a new version at:

http://www.physics.drexel.edu/~bob/LieGroups.html

Thanks, Peter, for making your notes available. I'll read them soon. My major complaint about most books on Lie algebras is that they deal with matrix reps and ignore reps via differential operators as is done is courses in differential geometry.

5. **Chris W.**
January 11, 2007

In line with the variety of items above, I thought I would pass along a blog posting about a new open access journal, mentioned in a comment on CV:

PhysMath Central

(..open access, but *commercial*.)

6. **Thomas Larsson**
January 12, 2007

As a student, I preferred Ramond over Itzykson and Zuber because it wasn't so prohibitively big. IZ is a better reference, though.

A second drawback of IZ, which I have become increasingly aware of during recent years, is that small print is unfriendly to middle-aged eyes.

7. **Peter Orland**
January 12, 2007

The book by Sattinger and Weaver on Lie groups and algebras is not bad. It's pretty rigorous, and much of it is in language physicists can understand. The best thing about it is that it's short. The chapters on classification of semi-simple Lie algebras are pretty good (except the proof of Engel's theorem is impenetrable – I had to find that someplace else).

I also second Peter W.'s endorsement of Segal's lectures, in the book with Carter and MacDonald.

8. **amused**
January 12, 2007

A minor quibble with Wilczek's nice article: When he mentions the limitations of the calculation of Aoki & co (e.g. quark masses larger than their physical values) he neglects to mention that the calculation is also "quenched", i.e. fermion determinant in the path integral is set equal to 1 and hence the effects of vacuum polarisation by quark-antiquark pairs are ignored. I've no idea to what extent this affects the result; presumably its qualitative features – in particular the hard core repulsion – would remain, but quantitatively the inter-nucleon potential could be quite different. At any rate, going from quenched to full (unquenched) QCD certainly affects the results for hadron masses, reducing the discrepancies with experiment from ~10-30% to ~1-2% in the high-precision lattice calculations that Wilczek mentions (but surprisingly doesn't give a reference to). The problem with having to do calculations at larger quark masses is not so serious since one can extrapolate to physical values (via chiral perturbation theory), but there is no similar solution for unquenching – you just have to get a powerful enough computer and do unquenched calculations from the beginning. So this seems a more serious challenge as far as removing the limitations of Aoki & co's work goes.

Btw Peter, do you ever think about returning to the lattice? There are interesting things going on these days, including mathematical things. E.g. it is now understood how to formulate fermions on the lattice with chiral symmetry, exact chiral zero-modes etc, so the notion of index makes sense and one can ask whether it coincides with the (your!) lattice topological charge of the background gauge field, as it should (for sufficiently smooth fields) according to index theorem. Numerical studies indicate that this is the case, but there is no analytical proof so far. So if you ever feel like returning to this topic there's a research problem for you right there.

9. **liealgebras**
January 12, 2007

Jacobson's old book on Lie algebras is quite readable and very cheap (its a Dover). It also goes into more depth than most the current standards (it's an algebra textbook not a geometry textbook).

10. **Peter Woit**
January 12, 2007

amused,

I actually got interest in the things I've been working on for many years when I started thinking about chiral lattice fermions. It has always seemed to me that which lattice gauge theory does a beautiful job of taking advantage of the geometric nature of gauge fields, the discretization of fermions completely ignores the geometry of spinors, and maybe there is a better way of doing things.

Anyway, this led me to other questions and problems I'm still struggling with, going back to the lattice problem to see if anything I've learned about spinor geometry can be useful there is on my ToDo list, something I should try and find time to work on.

11. **a**

January 12, 2007

Off topic, but talking about books, does anyone know a good introduction to differential geometry? Last time I looked at the first chapter of Do Carmeno, it seemed to have bunch of errors. Spivak is very nice, but perhaps a bit thick. Any other suggestions?

12. **amused**
January 12, 2007

Peter,

Sorry if this is getting off-topic, but chiral fermions on the lattice are in pretty good shape these days in the overlap/Ginsparg-Wilson formulation. It certainly doesn't have the obvious beauty and naturalness of the lattice gauge field formulation, but on the other hand, given the obsticle of the Nielsen-Ninomiya no-go theroem, it might be as good as it gets. At any rate, many things work out as they should, including chiral gauge anomalies and their relation to families index theory. People haven't tried to describe general aspects of spinor geometry in this formulation though – it's all been usual spinors coupled to gauge fields on flat spacetime so far.

13. **Peter Orland**
January 12, 2007

Peter,

As amused said, the problem is solved for QCD. The status of spectra and some other numbers of QCD is actually looking very good.

On the other hand, regularizing the standard model with the lattice is in poor shape. Genuine chiral fermions are a problem. The Nielsen-Ninomya theorem is a potential problem with any cut-off, not just the lattice (in fact, Nielsen and Ninomiya did not use a lattice). It may be that this problem points to some new physics beyond the standard model.

14. **anonymous**
January 13, 2007

Peter (Orland),

Can you elaborate on that? I was under the impression that Nielsen-Ninomiya comes from some index theorem based on putting the theory on a torus. So it looks to me like it has more to do with IR regulation than with UV regulation. So couldn't you just take the finite-volume regulator to be on some other topology with a different value of the characteristic class appearing in the index theorem, and take the infinite volume limit of that?

(I realize I might have some major misunderstanding here, since I've only heard the Nielsen-Ninomiya theorem discussed briefly a couple of times.)

15. **Jimbo**
January 13, 2007

Neither American Student in England, nor any of the respondees has mentioned the new player in town, by Mark Srednicki, chair of the physics dept. at UCSB: http://www.physics.ucsb.edu/~mark/qft.html

In my humble opinion, it will shortly blow Peskin & Schroeder Out of the proverbial water. Our QFT instructor, immediately upon discovering Srednicki's new text, not even due out until Feb., dropped P&S immediately in favor of it. Check it out !

16. **amused**
January 13, 2007

Peter Orland,

It is true that the lattice formulation of the Standard Model hasn't been accomplished yet, but nevertheless I still consider the lattice formulation of chiral gauge theories (not just vector ones like QCD) to be in relatively good shape. The fundamental obsticle represented by the N.-N. no-go theorem has been overcome by the overlap/Ginsparg-Wilson approach, and it has been shown to correctly reproduce the anomaly structure of the continuum formulation. What remains is to construct the chiral fermion measure (or "perfect phase" in the overlap terminology) such that the lattice theory is gauge invariant when the usual (continuum) anomaly cancellation conditions are satisfied. This has already been done for gauge group U(1) but not yet for the nonabelian cases (including Standard Model). There are no fundamental obsticles to accomplishing this; it is "just" a hard technical problem. The prospects of this being sorted out any time soon are bleak though since no one seems to be working on it. (Some of us would like to but then we'ld soon be out of a job…)

17. **Peter Orland**
January 13, 2007

Amused,

I am not so sure that the non-Abelian case is just a technical problem. Also the U(1) solution is very complicated, and it is not so clear that it is satisfactory.

18. **A Rivero**
January 13, 2007

I-Z was my textbook, and I do not like it. Actually I wonder if someone learning mainly from it got to do research on QFT. It was a transition book, for a generation who was too late to use the Bjorken et al books and too early to enjoy the new books.

19. **Chris Oakley**
January 13, 2007

Re: Srednicki, I too thought it was better than average, and it is nice to find a QFT reference that is more the thoughtful, useful pedagogical text and less of the cookbook.

Having said that, I did feel the need to send an e-mail to the author pointing out a problem with the common SL(2,C) conventions used in the supersymmetry community. As in some other areas, I seem to be the only one who worries about these things, but this particular problem cost me at least a day of my not-very-valuable time when I was a graduate student.

20. **amused**
January 13, 2007

Peter O.,

"I am not so sure that the non-Abelian case is just a technical problem."

All I can say is that it's my strong impression after having worked on it and tallked to others who have worked on it.

"Also the U(1) solution is very complicated, and it is not so clear that it is satisfactory"

If you have found something unsatisfactory in Martin Luscher's argument I suggest you write and tell him about it. (It seemed fine to me when I studied it.)

21. **Peter Orland**
January 13, 2007

amused,

Just so I understand what you are saying….

Are you stating that it has been resolved that chiral fermions, e.g. neutrinos have a good lattice formulation?

22. **Peter Orland**
January 13, 2007

… and that everything works when coupling said particles to gauge fields?

23. **Peter Orland**
January 13, 2007

I am looking over Luescher's papers to say exactly what he says.

24. **amused**
January 13, 2007

Peter O.,
Before coupling to gauge fields, chiral fermions such as neutrinos do indeed have a good lattice formulation now. And they continue to do so if you couple to U(1) gauge fields in an anomaly-free representation. For coupling to nonabelian gauge fields the situation is still unresolved at the nonperturbative level. (At the perturbative level things have in fact been resolved and everthing is fine.) As I mentioned above, the remaining problem in this case is to construct a chiral fermion measure such that the theory is gauge-invariant when the fermions live in a representation of the gauge group which satisfies the usual (continuum) anomaly cancellation conditions. (There is a priori an arbitriness in the phase of the chiral fermion measure, and the challenge is to determine a suitable phase factor (as a function of the lattice gauge field) such that the chiral fermion determinant becomes gauge invariant.) Actually there has already been substantial progress on this for electroweak gauge group U(1)xSU(2) but not yet a complete solution. It's a difficult technical problem – as you mentioned, the U(1) case itself is already pretty complicated – but i don't see any fundamental obsticle to things working out.

This is getting quite off-topic from Peter W.'s original post, I hope we aren't testing his patience too much… Anyway I have to go to bed now (it's 4am here) so won't be able to get back to this until tomorrow…

25. **Louise**
January 15, 2007

Dr Woit, you may enjoy Sharon Begley's column in the WSJ January 5: "Giant Swiss Collider May Reveal Secrets About Origins of Mass"

"If the LHC creates superpartners, the results will be spun as fiercely as a political campaign debate. String theory, which asserts that the basic constituents of matter are tiny vibrating strings that exist in 11 or 12 dimensions, requires supersymmetry. Thus stringsters may hail signs of superpartners as their long-sought vindication. But rival theories posit superpartners too, so if the LHC finds them it wouldn't uniquely support string theory."

"Supersymnetry is a vital part of string theory, so if the LHC doesn't find it, that would argue strongly against string theory," says physicist Lawrence Krauss of Case Western Reserve University, Cleveland. "If it is observed, you can say that string theory has not been disproved, but not that it has been validated."

The article also contains quotes by Lee Smolin. I can post the whole thing if you wish.

26. **lostsoul Ph. D.**
January 15, 2007

More or less off topic – Anjana Ahuja (the London Times 15th Jan.) flags up NEW (and Lubos' Reference Frame) as an 'exciting arena for gladitorial spats … over string theory'. Somehow, she manages to make the Sage of Harvard appear to be the more reasonable of the combatants: his mildest ever invective ('crackpot') is paired with what must ahve been Peter Woit at the end of a very hard day.

27. **King Ray**
January 15, 2007

Chris Oakley: thanks for posting a link to your explanation. I will have to think about this some more. Do you have a link or reference for Penrose's conventions? I don't have his book handy. I want to make sure that my conventions are consistent.

If we take the contravariant symbol to be the inverse of the covariant symbol (a la the metric in GR), which would make them negatives of each other when viewed as matrices, we have eps^(ab)*eps_(bc) = delta^a_b. Then we have eps^(ac)*eps_(cd)*eps^(bd)=delta^a_d*eps^(bd)=eps^(ba)=-eps^(ab). Thus it doesn't seem that having them be inverses of each other and obtaining each other by raising and lowering indices are consistent, assuming raising and lowering are done with the second index. I hope my notation is clear. contravariant indices are preceded by a ^, and covariant indices by a _. I think if you had them not be inverses of each other, but be the same then you would get eps^(ab) by raising the indices of eps_(ab). Is that what Penrose does?

28. **Peter Woit**
January 15, 2007

For those wondering what "lost soul" is referring to, see

http://www.timesonline.co.uk/article/0,,20909-2547760,00.html

The quote is from here

http://www.math.columbia.edu/~woit/wordpress/?p=490

and taken out of context. It was part of a response to commenters who wanted me to remove links to Lubos's blog because of the racist nonsense he spews.

29. **Chris Oakley**
January 15, 2007

I think that String Theorists should be grateful to Lubos for his efforts in keeping public interest alive in a subject that might otherwise die for lack of experimental support. It would appear that many of them are.

King Ray: I will try and keep this short, but Penrose's handling of SL(2,C) – which is of course a pre-requisite to twistors – I got from lecture notes, not a text book, although I am sure that there will be printed references somewhere. The notes on my web site spell out my understanding of this matter. The covariant-contravariant relationship does not require the ε identities as you give them – it only requires that the transformations under group action are inverses of each other. Your identities in fact almost apply with Penrose's conventions, apart from a few sign differences. Yes, obtaining ε^{AB} by raising the indices of ε_{AB} is the thing that matters, and it is indeed what Penrose's conventions guarantee. My point is that if one does not have the same rule for raising/lowering indices of preserved tensors as other tensors, then all hell will break loose.

30. **King Ray**
January 15, 2007

Chris, if the covariant and contravariant 2D Levi-Civita symbols are not inverses of each other, and you use the second index of each to raise or lower indices, then if you raise a spinor's index and then lower it you get back the same spinor. If your LC symbols are not inverses of each other (i.e., are the same), then you get the negative of the spinor you started with (like a complex structure squared acting on the spinor since eps^2=-I). I think the way others are doing it is ok so long as you know that when you raise the indices of the covariant LC symbol you get the opposite of the contravariant LC symbol. Maybe they should have two different symbols. Maybe all could be made good if you raise with one index and lower with the other and make covariant and contravariant LC symbols equal? I'll have to see what Penrose does.

31. **King Ray**
January 16, 2007

I looked up Penrose's raising and lowering conventions in Penrose and Rindler, Spinors and space-time, Vol. I, and Penrose has covariant and contravariant LC symbols the same, and lowers with the 1st index and raises with the 2nd. I guess a good mnemonic would be L1R2.

32. **King Ray**
January 16, 2007

Chris, thanks for bringing up this issue. I may adopt Penrose's convention. The only problem I have with it is remembering which issue to raise with and which to lower with, which is why I always preferred to raise and lower with the 2nd index.

In summary, I think Srednicki's conventions are consistent, you just have to keep in mind that eps contravariant is not gotten from raising the indices of eps covariant. I can't see any problems if you keep that straight.

It must be 20+ years since I looked at Penrose's book, so thanks for getting me to do that. I also saw a nice set of identities in there that are all worked out. Penrose and Rindler also have a nice appendix on spinors in n dimensions in Vol. II.

33. **Chris Oakley**
January 16, 2007

King Ray – right. But one must have ε_{AB} = ε^{AB} or the bad things alluded to in my note will happen. See also here, eqs. 3.31-3.35.

34. **Chris Oakley**
January 16, 2007

> In summary, I think Srednicki's conventions are consistent, you just have to keep in mind that eps contravariant is not gotten from raising the indices of eps covariant. I can't see any problems if you keep that straight.

Yes, but that means that ε_{AB} is not a tensor. I would definitely call that a problem. It means that every time you raise or lower its indices you have to remember to change the sign as well.
PS: If you are who I think you are (I have only just twigged), then I apologise for a somewhat brusque reply to an earlier post from me. Peter, fortunately, deleted it.

35. **King Ray**
January 16, 2007

Chris,

Thanks for the link to your document, I will look at it more carefully later.

I agree with you 100% in that it is an abuse of notation to use epsilon for both contravariant and covariant LC symbols if you use Srednicki-like raising and lowering. Like I said above, they really should have different symbols in that case, but using the same symbol is ok if you don't assume that they are related by raising and lowering indices. Penrose's convention is definitely less confusing as far as that goes, although harder to remember since you raise and lower with different indices.

I did not see the post you referred to, so no harm was done. I am not sure who you think I am, but I am probably not that person unless Peter told you who I am. I prefer to be anonymous, one reason for which is that I have many friends and acquaintances in the string community. In the past, I have gone on long walks with Penrose and Newman on a number of occasions.

36. **King Ray**

January 16, 2007

Also, yes, you must have eps^(AB) = eps_(AB) in Penrose's convention as I alluded to previously. Otherwise raising and then lowering gives you a minus sign as I stated above.

37. **peter_pan**
January 17, 2007

Peter,
I don't follow your blog, so there's no way that I know whether you know or you don't know about the following workshop in KITP. with both string theorists and numerical GR and looooooooooooooooooooooooooooopists.
Here is the link:

News From All Over

January 16, 2007
Categories: Uncategorized

Last summer the entire editorial board of the prestigious journal Topology resigned, in protest over the high prices that Elsevier was charging. It was announced today that a new journal called the Journal of Topology is being launched by many of the same people. It will be published by the London Mathematical Society, printed and distributed by Oxford University Press, and the first issue should appear in January 2008.

There's a recent report from HEPAP evaluating how far along the field is towards reaching certain set "long-term goals" (where "long-term" here is not a very long time-scale).

The New York Times Science Times section has a new columnist, John Tierney. Tierney has been with the paper for a long time, writing columns about New York and on the Op-Ed page, typically from a consistently Libertarian perspective. He also has a blog (where he promises to "rethink conventional wisdom about science and society") and explains his conversion to science journalism by writing that he "always wanted to be a scientist but went into journalism because its peer-review process was a great deal easier to sneak through."

The Templeton-funded magazine Science and Spirit, dedicated to bringing science and religion together, has a new issue out. It contains an interview with Max Tegmark about the Foundational Questions Institute. There's also an article called The World on a String about the anthropic landscape and the problems with string theory. Susskind and Wilczek are quoted saying positive things about the multiverse, Krauss and I on the other side of the question. Finally there's a review of my book by David Minot Weld with the title Stringing Us Along. It's pretty accurate, although it's not true that the book describes string theory as "totally without scientific merit" (that would be the string theory anthropic landscape…). Weld appears to be the son of ex-Massachusetts governor William Weld.

The Templeton foundation has a new web-site, and has announced a moratorium on new proposals over the next few months while they change their grant-making process. The web-site gives various information about the grants they have made in the past. I hadn't realized that they make grants in mathematics. There was one last summer for about $16,000 to W. Hugh Woodin for research in mathematical logic.

New institutes devoted to "foundations" appear to be popular, with Templeton Prize winner Paul Davies starting up one at Arizona State University to be called *Beyond: Institute for Fundamental Concepts in Science*. This was announced by ASU president Michael Crow, who before he left for ASU was Executive Vice Provost here at Columbia and in charge of overseeing research and various "strategic initiatives".

In the bookstore this past weekend I saw a new glossy book from National Geographic called Theories For Everything: An Illustrated History of Science. Lots about physics, but as far as I could tell, no mention of the Standard Model, Glashow, Weinberg, QCD, etc, but a whole page about string theory. In their version of physics history, one skips from Feynman to black holes, Hawking and string theory.

The coverage of string theory in popular media these days is decidedly mixed. A couple weeks ago I attended a performance of the play "Strings" by Carole Bugge, for a review, see here. It wasn't bad as a play, and reminded me of another similar one from a couple years back, String Fever. But I'm kind of dubious that this sort of thing actually communicates any accurate understanding of physics to anyone. The play deals with themes of adultery, loss and 9/11 with a plot based on the train ride supposedly during which Steinhardt and Turok came up with the ekpyrotic scenario (the play's train ride is jazzed up with a woman cosmologist, who is sleeping with the two other physicists). Unfortunately the playwright's understanding of all this seems to be based on little more than watching a British TV show on the topic. In the pamphlet distributed to the audience various popular books on string theory and physics are recommended, together with much more dubious sources, like the film "What the Bleep Do We Know?"

There does seem to be a much more skeptical take on string theory getting out into the media these days. A recent episode of Numb3rs featured Judd Hirsch telling his genius mathematician son Charlie that string theory is "bogus", more or less the same insight into the universe as that of late sixties hippies, everything is "vibes". String theorist Larry has been shot off into earth orbit for some reason.

As mentioned here and at Cosmic Variance, the New Yorker recently actually ran a cartoon about the string theory controversy. If that's not an indication that something has made it into the zeitgeist, I don't know what is. Besides the New Yorker, string theory features in Zippy the Pinhead and recent Doonesbury cartoons, as well as one from Rodrigo Alonso entitled Pulling Strings that he sent me recently.

Update: What is it with Harvard string theorists and climate change?

Comments

1. **Peter Orland**
   January 16, 2007

   As I skimmed Tegmark's interview, I learned that he hopes his foundation will merit new Einstein's. It reminds me a bit of Smolin's question as to why there are no new Einsteins, indicating that the current scientific environment discourages ultra-creative people.

   What strikes me as misguided about all this is that the real Einstein met obstacles every inch of the way until 1905 (when he published all his results in a mainstream journal). I don't see today's scientific environment as being worse than 1905's. I think it's much better. In 1905, many people who did science had to be independently wealthy (not most of the people we read about – they were lucky enough to have their talents recognized).

   I also wonder how these people would react if a new Einstein finds some breakthrough in an area of physics other than quantum gravity or multiverses?

2. **island**
   January 16, 2007

   Davies is an atheist… just to clear the air of any possible misunderstanding.

   Interesting factoid:

Davies has pre-released and then withdrawn the book that you reviewed Peter, on two separate occasions now, in the U.S.

It is now scheduled for its third release sometime in mid-April under then new title of, **Cosmic Jackpot: Why Our Universe Is Just Right for Life:** instead of **The Goldilocks Enigma**, like it was in the U.K. and elsewhere.

http://www.amazon.com/Cosmic-Jackpot-Universe-Just-Right/dp/0618592261/sr=1-1/qid=1167149428/ref=pd_bbs_1/002-8082944-3852846?ie=UTF8&s=books

3. **hack**
   January 16, 2007

   Thompson is indeed a string theorist from Harvard, but a cursory glance does not reveal any obvious tendencies towards Lubos style crackpotism on the issue of climate change. It would be interesting to hear what he has to say on the issue.

4. **Jason**
   January 17, 2007

   On climate change I don't see how Lubos is a crackpot. He clearly knows more about it than Al Gore for example.

5. **Anti-Lubos**
   January 17, 2007

   On climate change I don't see how Lubos is a crackpot.

   Hahahahahaha. Hahahahahahahahahaha. Hahahahaha.

6. **Ari Heikkinen**
   January 17, 2007

   "On climate change I don't see how Lubos is a crackpot."

   Ok, seriously, that must be the funniest thing I've ever read here. I'm actually laughing. 🙂

   Would actually be interesting to hear what Thompson has to say about the climate change considering in another Harvard string theorist's dimension greenhouse effect apparently don't exist at all while that same person apparently considers himself the allknowing expert on the subject dismissing actual experts in the field as charlatans and anyone who disagrees with his conclusions a crackpot.

   Surely if Thompson's that bad I'll never take anything anyone from Harvard says seriously no matter what degrees they might have.

7. **Peter Woit**
   January 17, 2007

   I don't know anything about Thompson, and have no reason to believe that he has anything other than sensible and well-informed views on climate change. It just seemed remarkable that there's this much interest in climate change in the fairly small community of Harvard string theorists.

8. **Ari Heikkinen**
   January 17, 2007

   I actually have a question about this:

   Can string theory actually be used to (or tell) anything about the earth climate, perhaps temperature changes as correlated to measured amounts of greenhouse gases in the atmosphere considering known amounts of carbon dioxide emitted due to burning of fossil fuels worldwide (according to EIA in the US that was 27000 million metric tons of carbon dioxide worldwide total in 2004) ?

9. **Peter Woit**
   January 17, 2007

   Ari,

   No.

10. **Chris W.**
    January 17, 2007

    Looks like some young string theorists are keeping their options open, and working on something whose relevance is unquestionable. More power to 'em…

    (LM, on the other hand, is probably consulting for Exxon-Mobil.)

11. **anonymous**
    January 17, 2007

    Ari and Peter,

    Dave is a very bright guy who had an interest in environmental issues long before coming to Harvard. While I can't speak for him, I do know that he is a very reasonable fellow and, as far as I could tell, has a sensible take on climate change.

12. **Clark**
    January 17, 2007

    Cal State's eccentric Professor Larry Fleinhardt (Peter MacNicol) is moonlighting as senior presidential advisor on the new season of 24, which is also a Numb3r.

13. **Robert Musil**
    January 17, 2007

    I don't think a diversion here into climate warming is a good idea. And I don't think calling anyone a "crackpot" is going to be any more effective a rhetorical technique for commenters on this blog than it has been for Lubos. That's the kind of weapon that mostly backfires.

For what's its worth, Harvard has pretty high profile people on various sides of the climate warming issue. For example, Willie Soon and Sallie Baliunas, both at Harvard Smithsonian, have published papers suggesting that solar variability is more strongly correlated with variations in air temperature than any other factor, even carbon dioxide levels. Obviously, this is not a view held by a majority of climate scientists. But these people are far from "crackpots."

Here's a Wikipedia article with some links:

http://en.wikipedia.org/wiki/Sallie_Baliunas

Of course, I don't want to be construed as endorsing her views. But I do want to be construed as opposing calling people "crackpots" without justification far exceeding what Lubos or his critics have mustered to date and further opposing bringing up global warming here in the first place.

14. **Aaron Bergman**
January 17, 2007

Soon and Baliunas? Seriously?

15. **Peter Woit**
January 17, 2007

Please, all. The global warming debate is definitely off-topic here, unless you have a specific insight into the interest certain string theorists are taking in it.

From what I can tell, there's a long list of other blogs where those interested in this debate can discuss it, sometimes even with people who actually know something about the subject. Please take such discussion there.

16. **Jonathan Vos Post**
January 17, 2007

Close, but no cigar, Clark.

The school on the hit show where professors include Charlie Eppes (David Krumholtz), Dr. Larry Fleinhardt (Peter MacNicol), and Amita Ramanjuan (Navi Rawat), is 'Cal-Sci' (based on Caltech). Caltech's IP attornies were ready to approve this; but CBS legal staff had last-minute cold feet and invented 'Cal-Sci' which, in any case, is not "Cal State." I'm quite clear on this, as I was a Physics-turned-Math graduate of Caltech, one of my professors was NUMB3RS's Math Advisor Gary Lorden, and my son is about to graduate with a double B.S. in Math and Computer Science from Cal State L.A.

Oddly enough, in real life, Judd Hirsch (who plays Alan Epps) has a bachelor's degree in Physics! At least, that's what he told me…

17. **nontrad**
January 17, 2007

Yikes,

In an attempt to get back on topic, (and this may be off topic…sort of reaching out on a limb here) did anyone read Banks' most recent lanl posting http://arxiv.org/abs/hep-th/0701146 discussing entropy in the early universe? I ask since this paper repeatedly discusses various 'beliefs' and 'religions', which seems relevant to Peter's post above.

Now, I only ask since I do and have, to some degree, followed Bank's work for reasons related to some of his early work in nuclear physics and some vaguely related matters…

Prior to reading / skimming Bank's recent article (which I went over very early this morning), I was unaware that a certain someone posted on their blog about this article. So this might be hot water to raise this topic. And forgive me if I'm stirring the pot here by raising this subject: That's not my intention.

Instead, in reading this article I was reminded of the time when (over a decade ago) Coleman, Polchinski, Susskind and others wrote articles about the 'Attack of the Giant Wormholes' and 'Revenge of the Giant Wormholes' etc in NPB. A time when…well things didn't look promising at all.

Even Banks states in his article that there are concerns about 'calculating the number of angels that dance on the head of a pin' in these matters. By comparison, the recent HEPAP report seems far more cogent, sober, constrained, rational and realistic…

Aren't these two very very different in nature?

18. **woit**
January 17, 2007

nontrad,

I also took a look at the article by Banks, but decided it wasn't worth the time needed to try and figure out exactly what he was talking about, life is too short. This kind of absurdly speculative discussion of anthropic/cosmological topics seems to me highly unlikely to ever lead anywhere, and it's questionable whether it's science at all. I also noticed that at times Banks appeared to be to some extent making fun of the subject, which is encouraging, because the whole thing does seem a bit nuts.

Anyway, sorry but I can't help you understand this paper. There's always Lubos, but his endless posting about this appears to just be the usual stew of misinformation about physics and claims that anyone who disagrees with him is stupid. I wonder what Banks thinks about how his student turned out…

19. **Peter Orland**
January 18, 2007

nontrad

Banks did not do nuclear physics in the old days. He worked on lattice gauge theories (and did primarily analytic, not numerical research).
This subject is part of nonperturbative, relativistic quantum field theory.

20. **Steve Myers**
January 18, 2007

I glanced at Banks paper. Immediately I thought of Wells' "Dr. Moreau" & the monkey-man's Big Thinks & Little Thinks. It seems real science has more to do with the little thinks than those Big Ideas.

Does it come to this: Second Law implies no low entropy implies no consciousness implies no me. But I only know that because I am; therefore, I am not if and only if I am. Will that get me a Templeton grant?

21. **CapitalistImperialistPig**
January 18, 2007

Tierney a science columnist? I predict that he will vigorously contest with Gregg Easterbrook for lamest science columnist award – if his political columns provide any hint.

22. **Ari Heikkinen**
January 19, 2007

If there's a transcript or perhaps audio (mp3?) somewhere of that Thompson's talk perhaps post a link here? Thanks.

23. **Ari Heikkinen**
January 19, 2007

"While teaching at Harvard, he developed software that allows blind students to read papers in physics and mathematics. As the lead researcher in Harvard's Alternative Fuel Vehicle Project in 2001, David assembled recommendations that led to the use of environmentallyfriendly biodiesel in all of Harvard's trucks and buses."

I'm sure he's a very reasonable guy based on all this and I acknowledge it's unreasonable to prejudice solely based on another person's musings on the subject.

24. **Maynard Handley**
January 21, 2007

"But I'm kind of dubious that this sort of thing actually communicates any accurate understanding of physics to anyone."

I think most physicists would agree that the way in which "relativity" transmuted to "relativism" in the first half of the 20th C
(a) had buggerall to do with physics
(b) provided apparent support for a set of occasionally dubious ideas, which, right or wrong, should have stood on their own, unbuttressed by big words hijacked from physics.

OK, we all agree with this — and yet we are supposed to cheer, or at least shut up, when other physics ideas (entropy, chaos theory, string theory, [coming up next: phase transitions and spectroscopy]) are misused as hooks for artworks. Personally I think the tolerance of the scientific community for this sort of thing is quite daft.
If you can write a kickass play about phase transitions, well you're obviously some sort of genius and good for you. But if what you are writing is a play about how life is sort of like phase transitions as you misunderstand them, well let's leave it to the theater critics to talk about the play part, but we, the physicists, should be criticizing misunderstood physics wherever we see it not be, with with the subtle condescension of diminished expectations, praising a playwright for using some of our words, and look, he almost got them in the right order, how precious.

Simile and metaphor have their place in art, fine, but we don't tell botany students to make a special point of reading "My love is like a red red rose".

2006 Topcites

January 18, 2007
Categories: Uncategorized

Every year the people running SPIRES put together a list of the most heavily cited papers in their database. I've discussed here in the past the listings for 2003, 2004 and 2005. Up until 2003 these appeared with a discussion by Michael Peskin of many of the papers on the list and their significance, but he hasn't done this for the past couple years. This year, instead of waiting for the SLAC people to put together the list, I decided to generate one myself. I'm not enough of an expert with SPIRES to get it to just give me the list for 2006, but it was an interesting exercise to go through the lists generated by various searches just using their "topcite 50+, topcite 100+, etc…" feature, together with restrictions on dates. I think I was able to compile a complete list of papers with 150 or more citations, and post-1990 papers with 100-150. I was just looking at papers in particle theory (hep-th, hep-ph, hep-lat), not experimental (hep-ex) papers or astrophysics (astro-ph) papers, and was not counting survey articles. I've put the full list on a separate web-page, Most Heavily Cited Theoretical Particle Physics Papers 2006.

There are of course lots of caveats about any conclusions drawn from counting citations, but these numbers do give some solid data about what is going on these days in particle theory research. Two topics from nearly a decade ago continue to dominate these citation counts: AdS/CFT and brane-world models. By far the most heavily cited paper is the original 1997 one by Maldacena (546 citations), and the number of such citations has actually increased significantly over the number in 2004 (451) and 2005 (436). Research into AdS/CFT heavily dominates current particle theory research, but, remarkably, this research has not led to any recent heavily-cited papers on the subject. After a flurry of activity in 1998-2000, the only 21st century paper on the topic with over 100 citations in 2006 is the 2002 paper on pp-wave backgrounds by Berenstein et. al.

Overall, the list provides a very depressing view of the first six years of 21st century theoretical particle physics, with only eight post-2000 papers getting over 100 citations. These break up neatly into 4 hep-th string theory papers and 4 hep-ph phenomenology papers. Besides the 2002 pp-wave paper (hep-th/0202021) the other three string theory papers are all about the landscape, with the KKLT paper (hep-th/0301240) getting by far the most citations (238), followed by hep-th/0105097 (Giddings, Kachru, Polchinski) with 150, and Susskind's hep-th/0302219 ("The Anthropic landscape of string theory") with 109.

The heavily cited phenomenology papers are mostly compilations of theoretical fits to experimental data: hep-ph/0201195 (parton distributions, 193 citations), hep-ph/0405172 (neutrino oscillations, 133 citations), hep-ph/0406184 (CKM matrix, 118) and hep-ph/0506083 (neutrino mass matrix, 103 citations).

While getting this list together, I also accumulated some other data, including lists of recent papers with citation counts in the range of 50-100, and will try and put this together and write about it sometime soon.

Some other data one might want to take a look at is the arXiv monthly count of submissions (I found out about this from a posting at physicsforums). It shows the number of HEP submissions growing until about 2002, more or less flat since then, although each of the last two years have shown slight declines.

I'll avoid the temptation to make extensive editorial comment on the meaning of these numbers, but I find it hard to believe that anyone could claim that they reflect a healthy field. The domination of non-phenomenological particle theory research by landscape studies is especially disturbing.

Comments

1. **Tony Smith**
   January 18, 2007

   Peter said "… a posting at physicsforums). It shows the number of HEP submissions growing until about 2002, more or less flat since then, although each of the last two years have shown slight declines. …".

   2002 was the year that the Cornell arXiv began (or greatly expanded) its blacklisting actvity. A 14 October 2002 e-mail message from register-query@arXiv.org (not addressed to me, but it was forwarded to me which is how I know the quote is accurate) referred to:
   "… a large pool here – typically flagged by reader complaints …".

   Without regard to whether or not any particular person (me or any other) should have been blacklisted,
   it appears that 2002 marked the establishment of a policy of using "reader complaints" as a basis for rejection of submissions from people in the "large pool".

   I am not surprised that the establishment of such a policy coincides with a flattening of the number of submissions, followed by slight declines.

   I (for the record I am not disinterested in such matters) feel that this does indeed not "reflect a healthy field".

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

2. **anon**
   January 18, 2007

   As far as I know, which is very little, there are a few "referees" working ad-honorem for the arXiv. Submissions are not evaluated in detail but, rather, by their abstracts. The number of preprints actually rejected is allegedly extremely low, and consists of obviously nonsensical submissions. I don't think those very few rejections should have any impact on the global statistics of a given research field.

3. **student**
   January 18, 2007

   Hi Peter,
   "Overall, the list provides a very depressing view of the first six years of 21st century theoretical particle physics, with only eight post-2000 papers getting over 100 citations."

   I'm not sure how you did the search but you somehow missed all these papers with over 100 citations:

   hep-th/0011089, hep-th/0109152, hep-th/0308089,
   hep-th/0308055, hep-th/0309187, hep-th/0404257,
   hep-th/0404116, hep-th/0403047, hep-th/0312171,
   hep-th/0301006, hep-th/0301006, etc.

   So, it's not so depressing 🙂

4. **anon**
January 18, 2007

"…with only eight post-2000 papers getting over 100 citations" during the year 2006.

For example, the famous paper by Maldacena got 546 citations in 2006, and 436 in 2005.

5. **woit**
January 18, 2007

student,

I was talking about number of citations/year, specifically the number in 2006. For instance, the first paper you mention has more than 100 citations, but over more than six years. It looks like during 2006 it had only 7 citations.

6. **matt visser**
January 18, 2007

Peter: When did you compile your data from Spires? — There was an (unannounced) bug with their database search routines for most of Wed 17 Jan which caused large numbers of articles to be unfindable using the standard search interface… As "student" points out:

"I'm not sure how you did the search but you somehow missed all these papers with over 100 citations:

hep-th/0011089, hep-th/0109152, hep-th/0308089,
hep-th/0308055, hep-th/0309187, hep-th/0404257,
hep-th/0404116, hep-th/0403047, hep-th/0312171,
hep-th/0301006, hep-th/0301006, etc."

Spires now seems to be functioning normally, and it would be worth double-checking your searches.

7. **woit**
January 18, 2007

Matt,

I did the searches the evening of the 17th, and a few this morning (the 18th). Earlier in the day I had been trying various things on SPIRES and once or twice noticed some anomalous behavior. But while I was doing the searches, SPIRES seemed to be fine, and all the numbers I was getting appeared to be consistent. In particular I was going through the 2005 topcites list as a starting point, and the 2005-2006 numbers tend to be similar with a couple interesting exceptions (interest in pentaquarks dropped like a stone in 2006…).

Again, this is 100 citations/year, not total citations. If anyone can point to a paper that isn't on my list that got over 100 citations, please let me know.

8. **anonymous**
January 18, 2007

Peter, why do you think lots of recent papers should have over 100 citations in a year in a healthy field? It's not at all clear to me that this is a measure of the health of a field. One could argue the opposite, that it's a sign of a healthy diversity of research topics.

Also, it seems to be a stretch to say that non-phenomenological theory is "dominated" by landscape studies. A quick look at the past week of hep-th shows about 4 or 5 landscape-related papers (things like moduli stabilization) out of 66 total papers. That is hardly "domination."

9. **Yatima**
January 18, 2007

Dont' know whether this link has shown up already, but here goes:

Interview with Lee Smolin in the IEEE Spectrum Magazine:

http://www.spectrum.ieee.org/jan07/4812

Nothing unusual.

10. **woit**
January 18, 2007

anonymous,

Particle theory has always been a field where promising new ideas quickly attract a lot of attention, with lots of people soon writing papers trying to exploit the new idea and see what they can do with it. I just don't see any evidence for the claim that what is going on here is that there are as many promising new ideas as there used to be, but people are not pursuing them, rebelling against particle theory's traditonal trendiness and going for diversity. It seems to me that the evidence is overwhelming that the post 2000 period for particle theory has been characterized by an historically unprecedented dearth of new ideas.

The dominance of landscape studies that I was writing about is not an absolute dominance in terms of numbers of papers being written, but a dominance in the area of new ideas that the community has chosen to pursue. The data about which recent papers are getting most heavily cited is unambiguous.

To put it crudely and bluntly: sure, lots of people are not working on the landscape, far more are working on AdS/CFT or on other topics. But they're not writing papers that many other people think contain promising ideas worth pursuing. The landscape people are the only ones recently to be writing papers that inspire many others to follow them and work on the same thing.

11. **Who**
January 18, 2007

anonymous, here is something to help you decide about the health issue that concerns you
in year 2000 there were **twenty-one** recent string papers (papers that appeared in the past five years 1996-2000) which got 100+ cites in 2000

in year 2006 by Peter's list there were **three** recent string papers (papers that appeared in the past five years 2002-2006) which got 100+ cites in 2006

we are talking healthy field and comparing. You ask:

Peter, why do you think lots of recent papers should have over 100 citations in a year in a healthy field? It's not at all clear to me that this is a measure of the health of a field. One could argue the opposite, that it's a sign of a healthy diversity of research topics…

Maybe it will help make it more clear to you if you compare 2000 with 2006 and see if there is a more healthy diversity of research topics now in 2006 than there was in 2000, since the cite numbers are so much less.
I think if you go back and look at the titles and abstracts of some of those 21 papers you will decide not. But here is the 2000 list if you want to try.

http://www.slac.stanford.edu/library/topcites/top40.2000.shtml

12. **anonymous**
January 18, 2007

It's unfortunate that we don't have a good database of complete particle theory citation counts stretching back to the 40s or earlier; I strongly doubt that it's always the case in any given year that there are lots of good new ideas that get *over 100 citations* in one year, within a year or a few of their publication.

The "100 citations" mark is a bit high to extract meaningful information from, I think. Let's look at one recent paper that "many other people think contain[s] promising ideas worth pursuing": Intriligator, Seiberg, and Shih, hep-th/0602239, already has 52 citations. Surely by any reasonable standard this is a paper that has inspired other people to follow up on it. Other recent trends, just off the top of my head, include the study of energy loss in quark-gluon plasma, integrability in N=4 SYM, and trying to understand general constraints on infrared modifications of gravity. There are plenty of papers on all of these topics, but not necessarily one extremely highly-cited and very recent paper that kicked off the trend. They don't meet your criteria for what is trendy, but I think most people in the field would say they are healthy trends.

For that matter, hep-ph/0507005, "Bootstrapping multi-parton loop amplitudes in QCD" by Bern, Dixon, and Kosower, has 57 citations. That might not match your standards, but 57 citations in a year and a half for a highly technical paper is impressive, and I don't think *anyone* can argue that this is not good and highly relevant physics.

13. **anonymous**
January 18, 2007

Who, your comment appeared as I was writing mine: I don't think it's fair to expect any given year to match the explosion of work that followed AdS/CFT and the beginning of extra-dimensional model building. The fact that a few major new ideas appeared at that time doesn't mean that more recent new ideas are completely useless. For that matter, many of the most important papers in the history of theoretical physics failed to provoke the sort of flurry of new papers that AdS/CFT did. AdS/CFT is a sociological anomaly.

14. **woit**
January 18, 2007

anonymous,

Personally I happen to think the various work you quote is among the best work going on in particle physics, but it's not very promising that it will ever lead to important progress in the field. That's just my opinion, and you're welcome to dismiss it as such, and instead claim that in your opinion the best current work in particle theory is every bit as promising as that of any other period.

But the numbers I'm discussing here are not matters of opinion but solid facts about exactly how particle theorists are voting with their feet about what's an idea worth working on and what isn't. If you have facts to back up your claims, let's hear them. SPIRES data does go quite a ways back, I just noticed that they now have "topcites" lists going all the way back to 1974. If you look at any of the lists from before the last few years you'll see large numbers of recent papers amongst the most heavily cited ones. For something really dramatic, take a look at the first one, 1974. The overall number of papers was much lower, with the most heavily cited papers getting 150-200 citations, unlike the 3-500 we see now, but virtually every paper on that 1974 topcite list is a recent one from the previous six years.

1974 was an unusual year, just after the birth of the standard model, but the data for more than 30 years is there. If you can find some evidence in it to support your claims, lets hear it.

15. **woit**
January 18, 2007

anonymous,

If you think 2000 is an unfair year to pick, pick any other one. For instance pick 1997, right before AdS/CFT. Of the 6 most heavily cited theory papers, guess how many were written during the previous 4 years? ALL of them.

16. **Graduate Student**
January 19, 2007

It seems that the paper by Minahan and Zarembo hep-th/0212208 has around 100 citations in 2006.

17. **woit**
January 19, 2007

Graduate Student,

My SPIRES search gave 94 citations for the Minahan-Zarembo paper in 2006.

18. **Bee**
January 19, 2007

Overall, the list provides a very depressing view of the first six years of 21st century theoretical particle physics,

That's probably because you've excluded astro-ph?

Anyway, looking at your list I should have cited at least half of the papers you listed at one point or the other, not sure if I actually did though. E.g. the PYTHIA, CTEQ, global neutrino fits etc, it's fairly easy to accidentally cite a paper referring to an older version, and those guys usually don't complain. Its still puzzling me why journals have no policy on what has to be cited and what hasn't. Admittedly, I think it would be as important to have a policy on what papers are not to be cited. There are just too many people who cite papers that have only a vague connection to their work, or because they know the authors, or because the author is one of those who will sent you an email saying 'I want to draw your attention to MY VERY INTERSTING PAPER… '

Interesting post, thanks.

Best,

B.

19. **Kasper Olsen**
January 19, 2007

Peter,

your measure seems quite arbitrary; for example, some new ideas generate a lot of new papers since many "relatively simple" things can be worked out in the beginning (like what has happened with AdS/CFT), other ideas take longer to generate new papers since the ideas can involve things which at least **some** people have a harder time understanding (like with the geometric Langlands program).

So,
(1)how would you quantify your claim, that *"but I find it hard to believe that anyone could claim that they [those numbers]reflect a healthy field*.?

(2)Have you compared with another field of research which you consider as being "healthy"?

(3) Have you tried to do the same "statistical" analysis in some sub-field of mathematics, for example? And what would then be your conclusion?

-Kasper

20. **Peter Woit**
January 19, 2007

Bee,

Sure, astrophysics and cosmology are quite healthy subjects, unlike particle physics. While I was making up this list, I was looking at papers that appeared in astro-ph that had large numbers of citations to see if any had much relevance to particle physics. The only candidates were papers about the vacuum energy and things like "phantom energy". It's certainly true that astrophysical observations of a CC pose a serious challenge to fundamental particle physics, but unfortunately I don't think anyone has a promising idea about what to do about his.

Kasper,

I very explicitly quantified my claim: a healthy field is one that is generating significant numbers of promising new ideas, and the best objective standard I can think of is to look at what work people are citing in their current work, and how much of it is recent. If you have a better objective standard, let's hear it and let's see some objective evidence that particle theory is doing well these days.

Your conjecture seems to be that maybe the current situation is different than the one of the past in that now there is plenty of progress and promising ideas out there, but, unlike in the past, few people are working on these ideas. I don't believe this, and don't see any evidence for it. If you have some evidence that this is what is going on, that this explains the difference in numbers between now and the past, let's see the evidence.

I'm a great fan of the recent work on geometric Langlands, but I don't think large numbers of people are going to work on it anytime soon. This is not because it is difficult (which it is), but because it doesn't appear to show any obvious promise as an idea about solving particle physics problems.

If you want an example of a healthy field, as Bee suggests look at astrophysics. I don't have time to generate numbers, but if you look at the 2005 SPIRES topcites list, you'll see that most of the astrophysics papers listed there are recent ones.

I haven't tried to do the same exercise in mathematics, it would be complicated because there are lots of sub-fields, lots of overlap of sub-fields, and much smaller communities working on the same problems. Mathematics definitely has more and less healthy sub-fields; one could probably identify some that are pretty moribund, with few promising recent ideas. The subfields of math that dominate major research universities appear to be quite healthy though, with for instance the solution to the Poincare conjecture and Fermat's Last Theorem in recent years. I know of no reason to suspect that you would see a big difference in the fraction of heavily cited papers that are recent now versus in the past in most subfields of math.

21. **Michael**
January 19, 2007

I recently read that Steven Weinberg considered the most important task ahead in theory research was to understand better the various effective field theories in hadron physics. He felt deep insights – and perhaps important new physics – lay within these structures.

I'm wondering if any theorist(s) are paying much attention to his views (sufficiently more than to AdS/CFT research)?

Michael

22. **Michael**
January 19, 2007

Oh, and by the way, I was curious about another issue:

Besides string theory research, were there any other theory paper(s) [hep-th, hep-ph, hep-lat, or (also) math-ph] that generated interest within the field?

I think the era of effective field theories is beginning to dawn on the research horizon. Any comments to this view?

Michael

23. **Peter Woit**
January 19, 2007

Michael,

Weinberg's views about the importance of effective field theories are the dominant paradigm in particle physics, and this has been true for 30 years or so. There is no danger that these views (or others of Weinberg) are being ignored.

24. **wow**
January 19, 2007

Hi:

Actually, if you look for *why* the so-called landscape papers you mention are well cited, the reason is not much to do with what you regularly bash as "landscape studies."

A few of the citations are from papers about anthropics or the multiverse.

The vast majority are from papers that try to build realistic models: that is papers that are trying to achieve realistic inflation, or particle physics, or both, in a concrete string model. While you can call this "landscape studies," most people would probably call it model building. One can argue about whether one should try to build models of realistic physics all the way from the planck scale down using string theory, but this is a pretty traditional goal of particle physics (starting with GUTs where speculations about ridiculous energy scales became fashionable). Arguably almost all papers on SUSY are motivated by this goal also (with unification being one of the pillars that drives SUSY model building).

25. **Graduate Student**
January 19, 2007

So Minahan and Zarembo are almost there. Nevertheless I think this is an active area of research in hep-th. I don't know if you consider this area to be part of string theory (via AdS/CFT) or QFT…

26. **foo**
January 19, 2007

If you think arXiv rejects papers which are obviously nonsense, search for papers by Mueckenheim. I've spotted a few others, but can't remember right now.

27. **woit**
January 19, 2007

wow,

One of the papers is Susskind's anthropic manifesto. Sure, the citations of the other two often come from "landscape" model-building that doesn't necessarily involve anthropics. But I still think this kind of model-building is highly problematic. The models are inherently complicated and ugly, unmotivated by any physical evidence that points to them, and seem able to reproduce virtually any extension of the SM that one wants, leading to a real question about whether this kind of model-building is normal, falsifiable science at all.

28. **gunpowder&noodles**
January 19, 2007

"There are just too many people who cite papers that have only a vague connection to their work, or because they know the authors, or because the author is one of those who will sent you an email saying 'I want to draw your attention to MY VERY INTERSTING PAPER… '"

I don't see anything particularly harmful in this. I'm sure you know how irritating it is when people who ought to cite you fail to do so, and I just don't want to be one of *those* people who only cite the works of famous people. Look at the cites for Witten's Geometric Langlands papers: most of them just seem to think that having that name on their paper will miraculously render it more likely to be published. That is pathetic, but, again, what harm does it do? There is a lot of talk these days about how there are too many bad papers on the arxiv. By people whose papers are, of course, uniformly excellent.

29. **Michael**
January 20, 2007

Peter,

If this is the case – that Weinberg's view(s) have remained, and continue to remain, the most important paradigm in particle theory – surely his research program is worth persuing for young grad students and postdocs. Why spend so much of ones efforts on 'string theory' and such when (arguably) the most important research direction is staring us in the face? Am I [simply?] missing some information / insight into the field or does such a view seem quite obvious and relevant; I still don't know why SO MANY of the brightest in the field spend time with strings and other highly speculative ideas when EFT may be the most important direction of research for the current generation (to perhaps the next or beyond) of physicists.

Any idea, feedback, etc?

Also, would you happen to know where CP violation studies currently stand? Is CP violation studies directly related to EFT research?

Michael

30. **David I. Santiago**
January 20, 2007

Peter, I am somewhat puzzled that you did not consider theoretical condensed matter physics papers. After all, they are not only an important part of theoretical physics, but they have for a long time been influenced
and have influenced particle theory and quantum and conformal field theory.

31. **woit**
January 20, 2007

David,

One reason for this is that condensed matter theory papers aren't in SPIRES, but more importantly, I just don't know very much about the subject, which seems to be a good reason for me not to write about it.…

Michael,

Most "string theory" papers ARE effective field theory papers. Effective field theory is an extremely general idea which almost everyone is using. The problem in this field is that nobody has a good idea WHICH effective field theory will get us beyond the standard model (which most people believe is an effective field theory itself).

32. **Michael Bacon**
January 20, 2007

Daved Deutsch is joining the debate as well regarding string theory. In the December 9 issue of New Scientist he comments on string theory as follows:

"I think it's unlikely that a research programme of that kind can work. Even if you found the right mathematical object, you probably wouldn't even recognise it because you wouldn't know how it corresponds with the world. For example, if someone had invented quantum theory purely as a mathematical model, how would they ever guess that its multi-valued variables correspond with quantities that we measure with single values? After all, it assigns multiple values to observable quantities simultaneously. I would warn against expecting the answer to come from a new mathematical model. It should be the other way around: first find what you think might be the solution to a problem, then express it as a mathematical model, then test it."

33. **woit**
January 20, 2007

About the Deutsch quote. I haven't looked at the original article, but if he's really refering to string theory, I don't think his argument makes any sense. To defend string theorists, they are not working with "purely mathematical models", with no idea how to connect them to quantities we can measure. Their problem is quite different: when they do try and use string theories to model a unified theory of gravity and particle physics, the simplest forms of string theory are inconsistent with what we observe, and making the theory more complicated to get around this makes the theory consistent with almost anything and thus unpredictive.

34. **anonymous**
January 20, 2007

Michael wrote: "I recently read that Steven Weinberg considered the most important task ahead in theory research was to understand better the various effective field theories in hadron physics. He felt deep insights – and perhaps important new physics – lay within these structures."

Do you have a link or a reference for this? I feel like there's a miscommunication between you and Peter in this discussion, because I don't think Weinberg would say that the most important task ahead is for people to understand "effective field theory" in the general sense Peter is interpreting it as. Pretty much everyone in the field understands that. I expect Weinberg means *particular* effective field theories (hence, "in hadron physics"), probably formalisms like SCET.

35. **Peter Orland**
January 20, 2007

Peter,

I know that this is not your meaning, but to many people the number of times a paper is cited is the main indicator of how valuable the work is. I would not dispute that the number of citations is a parameter which has some use, but the emotional reliance on this number is, in itself, unhealthy. Are we to evaluate ourselves the same way chairs, deans and provosts evaluate us?

I was at a large string theory conference some years ago and one speaker who had been giving many talks "challenged" the audience with the question, "What will be the next string theory paper to garner 500 citations?". Everyone seemed highly animated and thrilled by this disgusting, prurient line of thought. I mentioned to a young string theorist, who had been very excited by this question, that the number of citations is much less significant than an experimental prediction. He replied that if this were to happen in string theory, he would switch to pure mathematics. I interpret this to mean he was actually indimidated by the thought of confronting real science.

I realize that you are trying to make a particular point with SPIRES and the time-dependence of citations. Part of the reason for the phenomenon you mention is that people to believe that highly-cited papers must be good, so those are the papers which garner more citations. This is symptom of the short-term scholarship in our field.

36. **Chris W.**
January 20, 2007

Speaking of citations, would you believe a spill-over of eternal inflation and the multiverse into evolutionary biology? See [q-bio.PE/0701023](q-bio.PE/0701023):

> … I argue that the many-worlds-in-one version of the cosmological model of eternal inflation implies that emergence of replication and translation, as well as

> the major protein folds, by chance alone, as opposed to biological evolution, is a realistic possibility and could provide for the onset of biological evolution.
> …

37. **M**
January 21, 2007

Nobody presently knows what future good physics is, and citations allow to do a democratic pool. It will be interesting to wait some decades and measure the correlation between good physics and highly cited physics. Probably the result will be what Feynman described as:

"Nobody was permitted to see the Emperor of China, and the question was, What is the length of the Emperor of China's nose? To find out, you go all over the country asking people what they think the length of the Emperor of China's nose is, and you average it. And that would be very "accurate" because you have averaged so many people. But it's no way to find anything out; when you have a very wide range of people who contribute without looking carefully at it, you don't improve your knowledge of the situation by averaging."

38. **Q**
January 21, 2007

M, *it is more democratic to take a consensus by averaging guesses* than by imposing a particular person's guess. At least this process has the benefit of eliminating all extreme guesses, which are crazy enough to have a chance of being correct.

39. **M**
January 21, 2007

Q, ultimately some experimentalist will decide for everybody, and many top-cited papers will end up in the trash. Science is not democracy.

I agree that in the meantime citations might be a good alternative, but without forgetting its limitations, like the one you mention. Quoting Winston Churchill: "democracy is the worst form of government except all the others that have been tried".

40. **Kyrie**
January 21, 2007

> Nobody presently knows what future good physics is, and citations allow to do a democratic pool.

I guess you meant a "demographic poll"? But I agree with you: since nobody knows yet what new physics is going to be, citations reflect what most people in the field is working on, but not necessarily *where* the good physics is.

> and many top-cited papers will end up in the trash. Science is not democracy.

Once a paper has a few thousand citations, it will remain in the top cited list for a very long time. If it's more than 2000, then it will remain there for decades to come, maybe even forever…

Funny thing is, if susy and/or extra dimensions are not seen at the LHC, several papers on either subject will be stuck in the top-cited list in HEP, even though nobody is going to be working on that anymore…

41. **Kyrie**
January 21, 2007

On a related note, there's not only the list of top-cited papers. I read in the December issue of Physics Today that there are *five* new books on susy and/or susy phenomenology. I don't doubt all of them are very good books. I wonder how many good books on susy and its phenomenology are there now in the market. One dozen? Several dozens?

In this respect, I think there are two scenarios for LHC physics, and both look equally ludicrous to me.

In the first scenario susy is observed at the LHC. The idea that the discovery of new particles has not only been predicted, but actually preceded by more than a dozen books about them is definitely preposterous.

Just imagine that between 1946 and 1976 people had been very busy writing *large numbers of books* about the Upsilon and b physics… does that make sense from a historical perspective? It'd be like a movie played backwards, and equally hilarious 🙂

The second, no less ludicrous, scenario is that susy is not observed at the LHC. Then, what are historians of physics going to make of the last 30 year period? What are they going to have to say about an entire community working for decades on a field, to the extreme of writing several dozen books about it, when actually there will be no hint of the relevance of that field to nature? Again, it'd be a very funny situation…

42. **Peter Woit**
January 21, 2007

I'd like to make clear that it certainly is not my opinion that number of citations indicates a paper's value. These citation numbers are interesting purely for providing an objective measure of what topics particle theorists are working on, and what past ideas people have decided are worth pursuing and are using to write new papers. It's no secret that I think there's a serious problem with the choices that are being made and would like to see very different ones….

43. **Amos Dettonville**
January 21, 2007

Regarding the Deutsch quote, I think he may have been trying to make a more general point, since he referred to "a research programme OF THAT KIND". He apparently thinks string theory is (or at least was) a research program whose modus operendi was to rely heavily on purely mathematical criteria in seeking a "mathematical object" that corresponds with the world. I guess it's debatable whether the string program fits that description, but this seems to be the KIND of program that Deutsch thinks is unlikely to be successful.

As I understand it, Peter thinks this criticism doesn't actually apply to the string program. Rather, he says, the string program has been driven by empirical factors, and those factors have falsified the notions arrived at by purely mathematical criteria, so the program can't be criticized for total reliance on abstract criteria, ignoring empirical facts. He thinks the problem with the string program is in how it has responded to the (what he sees as) empirical falsification, by introducing so much flexibility that it becomes essentially unfalsifiable – thereby rendering it incapable of making any definite predictions.

I think the comments of Deutsch and Woit describe two different problems that can afflict a research program. The string program has probably suffered from both at different times. The fundamental premises underlying the string model, with the extra dimensions, etc., seems (to me) to have been motivated largely by abstract considerations of the kind that Deutsch argues are unlikely to lead to genuine increased understanding of physical phenomena. But I also agree with Peter that, at the present time, the string model seems to have morphed from what once was hoped (and hyped) to be a rigidly unique structure into an almost infinitely flexible curve-fitting formalism (like Ptolmey's epicycles and deferants) that could be fit to just about any conceivable set of facts.

I suppose, in a way, the two problems are related, i.e., any program devoid of new physical ideas and relying heavily on mathematical criteria, is likely to arrive (at best) at a more sophisticated curve-fitting model.

As an aside, I don't think there is necessarily anything wrong with devising a better curve-fitting formalism for expressing physical theories. My problem with the string program is that I think a lot of its prominence and funding, etc., has been and still is driven partly by the aura generated by the original hype, which presented string theory as having this marvelously rigid and unique structure, e.g., it ONLY works in this many dimensions, and it REQUIRES this and that, so the impression was given that this program was leading to the unique logically viable structure, which must therefore be true. It isn't surprising that this prospect got a lot of people (even those with no knowledge or expertise in physics) excited, and the news was on the "front page" of the popular press. Now, decades later, very few people in the field would make those such claims, but the retractions and back-pedaling have much less loudly publicised than the original claims. As a result, I think the string program has continued to benefit from some residual public excitment and hype that, in retrospect, was not justified. So, I think the books of Penrose, Smolin, and Woit are useful in countering some of that effect, and highlighting the fact that the feature of the string program that was originally its main selling point (unique prediction of the logically necessary structure of the universe!) is now very much in doubt.

44. **King Ray**
January 21, 2007

String theory is definitely Ptolemaic… it is to the standard model as Ptolemy's cycles and epicycles are to Kepler's laws and Newton's theory of gravity. The ultimate theory is supposed to be simpler than the standard model…

45. **Chris W.**
January 21, 2007

I must say I think Deutsch is right on target in the following sense: At this point in the development of string theory, the problem has become, at best, *a combination of* (1) "what mathematical structures should or must the theory contain" and (2) "what is the right way to set up a correspondence of these structures with observations we can make, or theories that have already tested [ie, the Standard Model]". The theory has evolved in such a way that it allows enormous latitude for fiddling at both levels, as if its developers imagined that such room for fiddling is what one ought to have in a good theory. In short, the apparent conclusion has become that there is a vast multiplicity of options, any one of which might become "the flavor of the month" as observations come in, ad infinitum.

The seeds for this situation arguably existed in the theory from the start, inasmuch as it began as a stab at understanding the strong interaction, and evolved—based on some formal features of the theory—into an approach to unification and quantum gravity. A clear *a priori* motivation for the relevance of those formal features to the new context has never been articulated. Similarly, the linking of internal symmetries and spacetime (Poincare) symmetries formally described by supersymmetry has never been understood physically.

In contrast, Einstein's motivations for replacing the spacetime of Minkowski by a Riemannian spacetime were clear, because he took pains to make them so. He tried very hard to minimize the arbitrariness of his choices. Neither experiment nor mathematical insight (much less mere technical virtuosity) is enough for this. What Einstein had at that time, it seems to me, was a *deep insight into what physics was about*. An essential aspect of such insight is appreciating the empirical facts of prior theories' successes, while knowing that these theories cannot be fundamentally correct.

46. **Thomas Larsson**
January 22, 2007

What Einstein had at that time, it seems to me, was a deep insight into what physics was about.

It might be added that the really big breakthroughs of the previous century (SR, GR, QM and renormalization) all involved thinking deeply about observers and observability. I see no reason why QG should be different.

47. **Jester**
January 22, 2007

One could look at these results from an optimistic side. Apparently, there was recently no hype that could fool a large part of the community (like the 2004 paper about split supersymmetry, hep-th/0405159, 104 citations in 2005).
But seriously, i really think there is more interesting work going on now than in the last few years, though it does not pass the 100+ trigger. Two examples from my domain: a composite Higgs of hep-ph/0412089, 47 citations in 2006, and a bottom-up approach to AdS/QCD, hep-ph/0501128, 53 citations in 2006.

48. **Travis**
January 23, 2007

Good to see that you are making use of the SPIRES database, however, as someone else mentioned, there was an anomaly in our citation data for about 12 hours during the time you were searching. This was due to an error in some new code that we had to release to be able to track citations to the upcoming new arXiv.org ids, as well as tracking other citation forms. For this reason I would be a bit suspect of your data, and I'm sorry that our unfortunate bug caused a problem at the wrong time for your analysis. Beyond that bug there can be some other anomalies, since data mining the database can actually be a bit tricky and it helps to really understand the data and the system.

This year we plan to release the topcites lists on the 31st of January, so your wait will not need to be too long. In the future, if you (or anyone reading this) have some statistical questions like this that we don't answer via the regular lists, feel free to contact us directly at spires AT slac.stanford.edu and we can often generate such lists and statistics much faster, and more accurately than you can via the web interface. We can't devote too much time to these things, but we can certainly help when we can. See http://www.slac.stanford.edu/spires/play for examples of this sort of thing.

Best Regards,
Travis
SPIRES Database Manager

49. **Peter Woit**
January 23, 2007

Thanks Travis,

I've spot-checked the numbers I found earlier, and the ones I checked seem to agree with what SPIRES reports now. Looking foward to seeing your results. I did also gather data on theory papers from the last few years with citations in the range 50-100 in 2006. Before writing about that I guess I'll wait and see if your numbers are any different than mine.

Various and Sundry

January 22, 2007
Categories: Uncategorized

Later this week there will be a mini-workshop at City College organized by some of the CUNY particle theorists, on the topic of Yang-Mills Theories: nonperturbative aspects. The schedule of talks is here, I'm planning on attending some of them.

Also this week, Witten is speaking at the IAS on Wednesday with the title "Operator Expansion Product of 't Hooft Operators". I'd like to go down to Princeton to hear this, but have to teach here around the same time, so won't be able to attend the talk. Maybe someone who does attend will tell us about what Witten had to say.

There's an interesting new particle theory blog, called Resonaances, and written by someone in the CERN Theory Group (who for now is operating anonymously as "Jester", also commenting here). It includes reports of talks at the recent Winter School on Strings, Supergravity and Gauge Theories, discussion or recent ideas about supersymmetry breaking using metastable vacua, and scary photos from the Christmas party, which included someone playing a Borat/Theorat character and Wolfgang Lerche as the string pope, intoning the following prayer:

Our Witten, which art in Princeton,
Hallowed be thy name.
Thy Nobel come,
Thy will be done,
In CERN as it is in the US.
Give us this day our daily string,
And forgive us our theory,
As we forgive those who do phenomenology.
Lead us not into experiment,
And deliver us from tests.
For thine is the arXiv,
Hep-th and math-AG,
For ever and ever,
Amen

Over at Tommaso Dorigo's blog, he's spreading wild rumors about a Higgs signal seen by CDF. He does acknowledge that this "signal" is not the sort of thing one should take seriously, almost certainly a statistical fluctuation. With the Tevatron getting closer to the point where it might actually see the Higgs, and the LHC sooner or later starting to produce data, I look forward to the prospect of lots of rumors being put out by bloggers of Higgs or SUSY signals. I remember many years ago that there were always new rumors of things being seen at experiments, which just about always turned out to not actually be there. In recent years the large experimental collaborations have done a better job of acting responsibly and not letting wild rumors get out. Maybe the blogging phenomenon can play a useful role in getting the irresponsible rumor game going again. Any CDF/D0 people who want to send me rumors that I can then irresponsibly help propagate are encouraged to do so.

I just got a copy of a new textbook about Lie groups and their representations, called Compact Lie Groups, by Mark Sepanski. I had been frustrated that there wasn't a book out there of just the right level with the same perspective I'm taking during the next few weeks of my graduate course, but Sepanski looks just right. From what I've seen so far of it, I recommend it highly as a place to learn about things like the Peter-Weyl and Borel-Weil theorems.

Another interesting book I recently acquired is Terry Gannon's Moonshine Beyond the Monster, which is highly readable as well as entertaining, and contains a wealth of information about affine lie algebras, "modular moonshine", vertex operator algebras and conformal field theory, and much more.

There are two new textbooks now out about string theory and attempts to get the a unified theory of particle physics out of it, by Michael Dine, and by Katrin and Melanie Becker and John Schwarz. I haven't had a chance to look at either very carefully, but they both seem to neglect to mention that this idea doesn't work. The thing that most amazes me though is Dine's choice for one of the three luminaries of the field to get a blurb from that might convince people to buy the book: Lubos Motl.

Update: John Conway, the CDF experimenter whose potential Higgs signal was mentioned here, has joined the Cosmic Variance team, and his first post is one of a series giving the details of this story.

Comments

   January 22, 2007

   🙂 spreading rumors is fun indeed!

   But I will defend strenuously my reputation if put to trial on this one! I just about posted blessed results (shown at conferences) of a reasonable analysis observing a 2-sigma bump _somewhere_ in one spectrum… I am not guilty, your honor!

   Of course, part of the fun in discussing these kind of bumps lies in the fact that usually only those who know better understand that a 2-sigma bump like that has _zero_ significance (because the mass is unknown, and a bump _has_ to happen somewhere).

   All others, who are fascinated by the chance that a higgs is there, of course want to dream on, and I let them do so by presenting some additional suggestion… I claim innocence on this count too, your honor.

   Cheers,
   T.

2. **yagwara**
   January 22, 2007

   Thanks for the pointer to Terry Gannon's book.

   On lie groups, do you dislike Brocker and tomDieck for some reason? I ask because I have been wanting to go back and (re)learn some of this stuff and that was one of the books I was planning to use.

3. **Peter Woit**
January 22, 2007

yagwara,

Brocker, tomDieck is probably my favorite book among the older ones, although unfortunately it doesn't discuss Borel-Weil theory. The Sepanski book is in some ways similar to Brocker, tomDieck, but simultaneously shorter, covering fewer things that are not so important, and getting to Borel-Weil theory.

4. **kuos**
January 22, 2007

Lot's of SUSY/String textbooks coming out, each one destined to become a classic. Perhaps a last ditch effort to cash in before LHC makes 20 years of theoretical research obsolete?

5. **wolf**
January 23, 2007

Regarding the Cuny workshop, it seems to be entirely devoted to two spatial dimensions. Maybe with an eye on applications to critical phenomena/statistical mechanics?

6. **Shantanu**
January 23, 2007

Peter did you find anything interesting/controversial at the KITP workshop
on singularities at : http://online.kitp.ucsb.edu/online/singular_m07/

7. **Peter Woit**
January 23, 2007

wolf,

I don't know if there are any applications of 2+1d YM to stat mech. I think the main reason people are interested in 2+1d YM is as a toy model for trying to solve 3+1d YM non-perturbatively. In 1+1d YM is exactly solvable, in 3+1d there's very little we know how to do analytically. 2+1d is intermediate in difficulty…

Shantanu,

My main interest is in particle physics, so I fear the kind of quantum gravity discussions going on at that workshop just aren't something I'm interested enough to follow closely. The workshop does appear to have both LQG and string theory people participating on an equal footing, so I guess that's something worth noting.

January 23, 2007

Congratulations ??? What a lazy bum! I have 670 posts out and I've been around for a third of the time…

Of course… Hehm… My posts are not quite as interesting, and… Hhruumph… They get a hundredth of the traffic…. And hmmm… I do not have a tenth of the comments to answer. Oh well.
Congratulations, Peter!

T.

10. **Who**
January 23, 2007

Yes! Congratulations on reaching the 500 mark, Peter, with a blog that clearly makes a uniquely valuable contribution.
Also must say I was very glad to see the home-made 2006 topcites. I wouldn't be surprised to learn that their appearance accelerated Spires and prompted them to decide on bringing out the official list by 31 January, the date Travis mentioned in this post:

http://www.math.columbia.edu/~woit/wordpress/?p=508#comment-21399

11. **Peter Woit**
January 23, 2007

Thanks T. and T., although you may be slightly premature, I think there might be two posts that are in both categories…

Just upgraded the blog software to WordPress 2.1. If anyone notices any anomalies, let me know.

12. **z3**
January 23, 2007

Heads up on Distler and Rothstein's paper in the upcoming issue of PRL discussing possible LHC tests of string theory, or rather it's generic assumptions — analyticity, unitarity, and Lorentz invariance — through W boson scattering events.

13. **stevem**
January 23, 2007

As regards the CUNY Yang-Mills workshop, what exactly is the current status of non-perturbative analytical calculations of things like mass gap, string tension and confinement? I had heard/read somewhere that the string tension can be estimated for (2+1) YM and is comparable to values obtained from lattice sims. The talks will probably cover such things. Hopefully, they will appear online as the first one looks especially interesting. Or maybe someone attending will report on them. The emphasis seems to be on (2+1) YM. It still seems unlikely that (3+1) YM for SU(3) can ever be solved exactly. Maybe a string dual can be found to pure qcd, but again this seems unlikely, at least right now. Also, does anyone know if any progress has been made on the YM millennium problem? I presume you would have to prove existance of quantum YM and a mass gap strictly in (3+1) and not in (2+1)?

14. **wolf**
    January 23, 2007

    z3, those generic assumptions of string theory — analyticity, unitarity, and Lorentz invariance — look vaguely familiar to me. Could it be that I have seen them some place else? Maybe some theory not involving strings?

15. **Peter Orland**
    January 23, 2007

    Stevem,

    There will be several things discussed at the CCNY meeting.

    Right now, what most people are doing in 2+1 dimensions are new strong-coupling methods. In 2+1 the strong-coupling mass gap is proportional to the coupling squared, and the string tension (determined by working out the vacuum state) is proportional to the coupling to the fourth power. These results were shown by lattice strong-coupling methods (not computer simulations) a long time ago, but some new mathematical methods which are quite interesting have been developed to study them.

    I will also present some work I have been doing for the last few years
    on a weak-coupling method for understanding confinement, which
    works only in 2+1 dimensions. The method used two coupling constants, which are arbitrarily small in units of the UV regulator. The
    gauge theory studied this way is not rotation invariant, but quarks
    are confined and adjoint sources are not (for a finite number of
    colors. There is also an interesting picture of string excitations.

    I think what most people hope to gain from the meeting (at least I do) is an approach to confinement in 3+1 which works for weak bare coupling constant.

    Since Peter W. will be going to some of the talks, perhaps he can give
    his evaluation of the meeting.

16. **z3**
    January 24, 2007

    Wolf, these principles are not shared by all theories of QG. So a test of them amounts to a weak test of string theory, in that there's a very low probability string theory would be falsified thru an observed violation of these requirements, but the lack of any violation also only increase our confidence in string theory by a negligible amount. There is quite a bit of publicity stunt in calling this a test of string theory, but there is some physical motivation in it as well.

17. **John Conway**
    January 24, 2007

    "Wild rumors" ??

    I gave the talk at the Aspen particle physics conference where we broke the news of the results of our search. I was the one who "let the wild rumor out."

    We showed what we saw, pure and simple. It's not anything to get excited about statistically, clearly. People did get excited, though, because this is about the Higgs after all!

    You try to suggest it's "irresponsible" to show your results honestly in public, and discuss them afterwards in the hallway or blogs or wherever…well, that's just irresponsible of you. So there.

    And, T., there certainly does not *have* to be a bump somewhere. For us we would only expecet such a thing about 2.5% of the time; we are working on refining that number, as I said at Aspen. It's tricky, as you know.

    What are results do show is that *if* the Higgs is there, at an enhanced rate at high tan beta, we could nail it at the Tevatron before the LHC (on which I also work) does. Now wouldn't that be interesting?

18. **Peter Woit**
    January 24, 2007

    John,

    My comments about Tommaso's posting were a bit tongue-in-cheek. I do think HEP experimentalists are behaving incredibly responsibly these days, rarely if ever promoting signals of marginal statistical significance. Maybe I'm wrong, but I remember this happening much more often 20-30 years ago. I admit to a bit of nostalgia for this kind of activity, for seeing people get excited by possible signals (even if they almost always have their hopes dashed later). So I think maybe a bit more irresponsibility would be a good idea, and I was trying to encourage any inclinations in that direction that Tommaso might have. The only problem is how to keep it out of the science coverage in the press that goes out to the general public…

19. **Tommaso Dorigo**
    January 27, 2007

    Yes, John, the mentions of "rumors" and "irresponsibility" were made with half-joking tone, both above and in my blog.

    As for the significance, I totally agree, it is tricky indeed. My opinion is that the CDF signal would be the typical way a 160 GeV Higgs would show up in a statistically-limited analysis such as ours, but it is just as well the typical bump due to a weird fluke in the data.

    We search the Higgs in tens of different mass distributions, in various final states. We HAVE to have a 2-sigma bump somewhere at some point! Of course, you can shrug your shoulders and claim that you are only concerned with your own analysis, but as long as rumors spread only when signals grow above the (say) 2-sigma mark (or if more vocal people start crying wolf at 1.5-sigma, as in LEP II – hruuumpf), we are giving the world a wrong perception of the data if we do not qualify those 2-sigmas.

Not your job, of course, so no criticism is implied to you, but rather on the way we publicize our scientific output.

And I agree with Peter when he says these days we are a bit over the mark with our “protection” of our own data. We’ve been colleagues for 14 years, and you certainly have a very well informed opinion on how I think of the whole matter… Just think of the superjet affair 😉

In any case, congratulations for your intriguing result, John!

Cheers,
T.

20. **Tommaso Dorigo**
January 27, 2007

And, Peter, the problem of discussing results among peers without the matter getting known by newspapers is not solvable.

During the last four months I have been contacted to comment or explain new results posted in my blog by no less than five journalists from Nature, New Scientist, Physics World, Scientific American, Physics Today… (And as you know I am grateful for your directing traffic to my blog now and then, without which I would be a lesser known blogger).

These people do look for “leaks” in the blogosphere. They have grown smart!

That, combined with the tough bylaws of my experiment, totally prevents me from real leaks in my blog. What I can do is to hint at things to come. As I did in the post on John’s signal, where I hinted at the fact we will bless a Z->bb signal in CDF soon, and that a few tens of higgs decays could be there if the MSSM signal were true…

Cheers,
T.

21. **Peter Woit**
January 27, 2007

Tommaso,

One solution of course is that if you can’t leak on your blog, you could write me, and I could then spread rumors from my blog… If journalists called me I would deny everything, claim I just made it up.

A major problem with this whole blogging thing is that some of the best rumors I hear from friends and colleagues I just can’t use, mainly because it would be too obvious where they came from, and the people involved would get annoyed and never tell me anything again. My hopes to become a leading physics/math gossip columnist are unfortunately difficult to realize.

Physicists Develop Test For "String Theory"

January 24, 2007
Categories: This Week's Hype

Press releases claiming that a "test for string theory" has been found appear with some regularity, notwithstanding the fact that no one actually knows how to test string theory. The latest one comes from the University of California at San Diego, where the press office today put out a press release entitled Physicists Develop Test For "String Theory". The story has been picked up by the media, appearing here and here and probably soon in many other places.

This latest claim about a "test for string theory" is quite remarkable and even more bogus than usual. It is based on a paper which has nothing to with string theory and doesn't do a string theory calculation at all. The paper first appeared on the arXiv last April with the title Falsifying String Theory Through WW Scattering, and was extensively discussed here. In October a new version of the paper was put on the arXiv, with a changed title Falsifying Models of New Physics via WW Scattering (and this was discussed here). I'm guessing that the removal of the claims about string theory from the title was due to a referee at PRL not being willing to go along with such a title, although maybe there's more to the story and if so I'd be curious to know what it is.

The year is just beginning, but I'm already willing to award this press release the title of "most outrageously misleading string theory hype of 2007". It is going to be extremely hard for anyone else to match it.

Update: The Distler et. al. overhyped press release continues to spread misinformation to the public, getting more and more ridiculous as it spreads. The blog Tech.Blorge.com reports about string theory that:

Until now, experimental verification has not been possible; but researchers at the University of California, Carnegie Mellon University, and the University of Texas are planning a definitive test with the future launch of the Large Hadron Collider…

This then made it to Slashdot, which put out a story under the headline String Theory Put to the Test, which starts off with:

…scientists have come up with a definitive test that could prove or disprove string theory. The project is described as…

and then goes on to give a description of the LHC project.

I think the people responsible for this should be ashamed of themselves.

Update: Not to be outdone by UCSD, Carnegie-Mellon has also issued a press release about this. More also here and here.

Update: More at Digg, SpaceDaily, Science Frontline, etc., etc.

Update: Yet another major university issues a misleading press release about this: from the University of Texas Team of Theoretical Physicists Develop a Test for String Theory.

Update: The Resonaances blog has a posting explaining what is actually in the Distler et. al. paper, while describing the press releases, with their pretensions that the authors have found a way to test string theory at the LHC, as "hilarious".

Update: Sabine Hossenfelder wrote in to point out that New Scientist now has an article about this, with the title New particle accelerator could rule out string theory. The article quotes hype from string theorist Allan Adams as well as from Distler, ignoring Distler's co-authors and describing him as "leader of the team" that solved the problem no one else had been able to solve, figuring out how to test string theory at the LHC. Funny, but as far as I can tell, this great advance in the testability of string theory is not being covered at any of the string theory blogs. I wonder why…

Comments

1. **andy.s**
   January 24, 2007

   The authors are saying it tests Lorentz invariance, analyticity, and unitarity, the ingoing assumptions for ST.

   I guess the first one means relativity is valid, the last one means all operators are unitary (?); I have no idea what analyticity means.

   Are any of these likely be violated at the LHC?

2. **r hofmann**
   January 24, 2007

   In general, unitarity of the S matrix puts a bound on the growth of cross sections with energy, the so-called Froissart bound. In particular, if the SM-calculable bound is heavily violated by experiment (LHC) then the SM is inferred to be embedded into something more general which takes over at high energies. Personally, I strongly believe that the latter will happen on grounds that have nothing to do with susy, Xdim, and string theory for that matter.

3. **Jester**
   January 24, 2007

   It's a pity the authors chose to advertise this way since, after all, they did a very interesting work. Most of us used to think that in a low-energy effective quantum field theory any higher-dimensional operators consistent with the symmetries are allowed. Now we know that at least the signs of certain operators are constrained by very general arguments. Only very bizarre theories could violate these constraints (and string theory is not bizarre enough). There is also the earlier paper by Arkani-Hamed et al. [hep-th/0602178], which discusses these matters from a somewhat more general perspective.

4. **Bee**
   January 24, 2007

   You have a funny typo there, never heard of WWW Scattering 🙂

   In October a new version of the paper was put on the arXiv, with a changed title Falsifying Models of New Physics via WWW Scattering (and this was discussed here).

5. **Peter Woit**

January 24, 2007

Thanks Bee. I guess I thought the author's paper has more to do with scattering bogus claims via the World Wide Web than scattering W particles…

6. **Tony Smith**
January 24, 2007

The UCSD press release by Amy Pavlak and Kim McDonald has as its title
"Physicists Develop Test for 'String Theory'"
The press release said in part:
"… "Since we don't have a complete understanding of string theory, it's impossible to rule out all possible models that are based on strings," said Rothstein. …".

The title and the statement by Rothstein seem to be contradictory.

Further, the press release said that the "… test sets bounds on … three mathematical assumptions –
Lorentz invariance (the laws of physics are the same for all uniformly moving observers),
analyticity (a smoothness criteria for the scattering of high-energy particles after a collision) and
unitarity (all probabilities always add up to one). …",
so
it seems that the press release could just as well be entitled "Physicists Develop Test for 'Bootstrap Theory'",
about which Peter Woit said in blog comments in July 2006:
"… the bootstrap program … was wrong, and wrong in very much the same way that string theory is … If you look at Chew's writings from that era, there's a lot of the same kind of wishful thinking you see in string theory. Not knowing about asymptotic freedom of gauge theory, you could argue that the bootstrap was "the only game in town" … To some extent, lots of people who had worked on the bootstrap and early versions of string theory just picked up where they had left off when string theory came back into fashion in 1984. There really only was a period of about 10 years (1974-1984) when QFT was completely dominant. …".

It is also interesting that Ed Witten studied under David Gross and
David Gross studied under the leading advocate of bootstrap theory, Geoffrey Chew.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

7. **A quantum diaries survivor**
January 24, 2007

Well, the first link quoted above is a rather imprecise but not dishonest account IMHO. In particular, I appreciated the sobering quote by Distler:

"If the bounds are satisfied, we would still not know that string theory is correct," said Distler. "But, if the bounds are violated, we would know that string theory, as it is currently understood, could not be correct. At the very least, the theory would have to be reshaped in a highly nontrivial way."

Of course, there is a small step still needed to fill the gap from what Distler acknowledges and the fact that nobody really takes seriously any theory implying violation of those three principles, and the article fails to make it.

T.

8. **Peter Shor**
January 24, 2007

So does this mean that now any test of general relativity is now also going to be a test of string theory? And that Hulse and Taylor received their Nobel prize for a successful test of string theory?

9. **Ari Heikkinen**
January 24, 2007

I guess it's not just a string theory problem, I mean, how do we know that any "new breakthrough" that'll be claimed even on LHC will be anything but a desperate attempt to make something out of some nonsense just to give even some justification for all the money spent on building it?

10. **Tony Smith**
January 24, 2007

Ari Heikkinen said: "… how do we know that any "new breakthrough" that'll be claimed even on LHC will be anything but a desperate attempt to make something out of some nonsense just to give even some justification for all the money spent on building it? …".

LHC is almost certain to produce results with respect to Higgs and the Tquark that will substantially improve understanding of the Standard Model.
The Standard Model is very far rom "nonsense".
Increased understanding of it is very important with respect to real (i.e., testable by experiment) physics,
and (in my view at least) fully justifies the cost of building the LHC so that its enegy/luminosity regions can be explored and better understood.

As to "how do we know" claimed results of LHC will or will not be "nonsense",
it is the same as with all accelerator experiments:
You read the papers, look at the data, and study the analysis techniques. If you find something that doesn't look right to you, then say so and if your criticism is correct it will eventually become part of the results.

There WILL be data that if properly analyzed WILL increase our understanding of the Standard Model, and, since that is what the LHC was designed to do, it WILL be worth the money spent on it for that purpose.

There is a big difference between deciding to spend money on a machine to do a specific task (for the LHC, to explore the Standard Model in a given region of energy and luminosity)
and
spending 90% of high energy theory money on something that is substantially divorced from experimental results, and has produced no such results for decades, and is sociologically operated like a private club.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

11. **Peter Woit**
January 24, 2007

Tommaso,

I think there actually is an honesty problem with the Distler quote. His paper does not involve any string theory calculation in any way, so claiming a "test of string theory" is very problematic. In addition, as far as I can tell, what seems to have happened with that paper is that a PRL referee made them change it to remove the claim from the title about having a "test of string theory". If this is right, to issue a press release about the PRL paper describing it as a "test of string theory" takes real chutzpah. If there's another explanation for why the paper's title was changed, I'd like to know what it is.

12. **Peter Woit**
January 24, 2007

Ari and Tony,

Please try and keep your comments on-topic.

13. **anonymous**
January 24, 2007

Tommaso said:

"the fact that nobody really takes seriously any theory implying violation of those three principles"

But at least a few people take seriously loop quantum gravity, which as I understand it does violate at least one of these principles….

14. **A quantum diaries survivor**
January 24, 2007

Ok, I confess I did not read the paper 🙁 shame on me!

I guess I am getting dangerously close to having to rely on incorrect press accounts to know what is going on, at least in string theory.

As a matter of fact, I remember discussing in my blog (guess with who, with Jacques Distler) the very issue of theoretical papers being too cryptic for a "normal" experimentalist to even conceive reading. If I recall correctly, he claimed that it was not string theory's fault, because it has never been easy for experimentalists to read cutting-edge theoretical papers.

T.

15. **Peter Woit**
January 24, 2007

Tommaso,

Actually that paper is pretty readable, partly because it doesn't involve string theory. Some experimentalists might actually find it more readable than many theorists, since it is a story about the behavior of scattering amplitudes. This is closer to what experimentalists have real experience with these days, unlike theorists who often spent much of their careers working on more speculative stuff.

16. **Ari Heikkinen**
January 24, 2007

Peter,

The point I was trying to make (ok, perhaps it was badly worded as an example) was that upfront announcements of scientific "breakthroughs" is nothing new. It's been done throughout the history by scientists, the media and by others, not just by string theorists.

Speaking of the announcement in question, don't they claim this one could only prove string theory wrong, not right (Quote: "But, if the bounds are violated, we would know that string theory, as it is currently understood, could not be correct.") ?

So if they think they can prove string theory wrong this way then what's the problem? Also, the pdf you link (on arxiv) still reads "Falsifying String Theory Through WW Scattering" so what's wrong with that?

17. **Peter Woit**
January 24, 2007

Ari,

I put two links there. One is to the original version of the paper, with the claim about string theory in the title, the second is to a revised version of the paper uploaded several months later, where the title has been changed to remove the reference to string theory. Given the timing of this, it seems likely that the revised version is the refereed one, and that the referee is responsible for insisting on the changed title.

You might want to go back and read the extensive discussion about this whole topic that occurred here and that I linked to, involving one of the authors of the paper. I don't want to repeat all those arguments, but the gist of the matter is that the assumptions made by these authors are actually the fundamental ones made in QFT. So, what is actually true is that if their bounds are seen to be violated, it is QFT, not string theory that is falsified. These same assumptions apply to perturbative string theory, but since one doesn't really know what non-perturbative string theory (M-theory) is, they don't apply to string theory in general.

18. **onymous**
January 24, 2007

My attempts to comment anonymously keep getting rejected, I'm not sure why.

Here are two things that are being overlooked in this discussion:

1. Yes, both QFT and string theory have these basic properties, but not necessarily every theory does. LQG, for instance, is sometimes claimed to violate Lorentz invariance.

2. These bounds reveal ways that low-energy physics is sensitive to very high-energy physics. It is true that in QFT these positivity criteria are always satisfied, so QFT would be falsified by violations of them. However, it's not the case that in low-energy *effective* QFT these criteria are always satisfied. So what is falsified is that at very *high* scales, the theory describing our world is not a QFT. But we already know that, because of gravity! So QFT is already falsified. Given that QFT is falsified, we can ask what are other sensible theories of high-scale physics. One is string theory. Violation of these positivity conditions would, then, falsify string theory. This is not trivial. They would not necessarily, for instance, falsify LQG.

19. **Peter Woit**
January 24, 2007

onymous,

Sorry about your problems with the spam filter (Akismet). The new version of WordPress has a newer version, which may have different behavior. Unfortunately it is is completely unconfigurable, and it does sometimes tag comments as spam for no obvious reason (sometimes it does this to MY comments…). I do generally check the spam queue once or twice a day, so if you just wait a while, your comment should appear after a while.

I just don't think it's accurate to say that violation of these bounds would falsify string theory (and, if you look at the wording in the published version of the paper, I think you'll see the authors don't say this, perhaps because a referee wouldn't allow them to). What might be falsified is perturbative string theory (and presumably this is what the authors mean by the locution "generic models of string theory" used in their paper), but that is already falsified. One needs some sort of non-perturbative string theory or M-theory to get the kind of string theory backgrounds needed to get realistic physics. Not knowing what this M-theory is, you don't know if it will satisfy the relevant assumptions.

20. **Ari Heikkinen**
January 24, 2007

Ok, I got your point, the first three versions of the paper in question are titled "Falsifying String Theory Through WW Scattering" and claim "If no light resonances are found, then a measured violation of the bound would falsify string theory.".

But in the fourth version of the same paper the title was changed as "Falsifying Models of New Physics via WW Scattering" and the claim was changed as "As a corollary, if no light resonances are found, then a measured violation of the bound would falsify generic models of string theory.".

As far as I can recall from Greene's book, there wasn't any mention of "generic models" of string theory, so exactly what's meant by that?

21. **Peter Woit**
January 24, 2007

"generic models" of string theory doesn't actually have any well-defined meaning, as far as I know. It's a bizarre locution I've never seen anywhere else, and was presumably introduced here to satisfy a referee who told the authors that their assumptions were not obviously satisfied by all string theory models.

As I explained in my previous comment, the problem is that only for perturbative string theory (and some unrealistic non-perturbative versions) do you have any kind of definition of the theory, and thus can check whether it satisfies the assumptions being made. For the kind of fundamental theory that string theorists hope exists and produces standard model physics, the existence of such a theory is purely conjectural, and one doesn't know if it will satisfy the assumptions.

22. **mclaren**
January 24, 2007

Yes, I was just about to post about this misinformation. You have to admire the sophistry involved in these kinds of press releases. Since string theorists claim that string theory susbsumes all the rest of physics, it therefore follows that any test which confirms any theory anywhere in physics necessarily confirms string theory.

Good thinking. That kind of incisive reasoning will surely get us to a Theory Of Everything "real soon now"…that is, if we don't experience The Singularity first. Or find WMDs in Iraq…

23. **Aaron Bergman**
January 24, 2007

In related news, I recently saw a non-black non-raven.

24. **Jack Lothian**
January 24, 2007

I have not read the paper (& probably would not understand it) but the press release reads as a form of lying to me. In the release, facts are selectively stated in such a way as to mislead people who are not experts in the field. The release is written in such a way that they encourage the layman to jump to erroneous conclusions. In my opinion, here is an analogy of what they are doing.

I claim that I have an investment strategy that can return your investments plus 100% in as little as 2 months. Furthermore I have a scientific test that was used to validate my strategy. It showed scientifically that the return on your investment will always be positive. Of course some investors will be more successful in using my strategy than others. So just send me a few thousands dollars & I will give you my scientific investment strategy.

Is this a form of fraud? I say yes & the press release uses a similar argument to imply the test will validate string theory when in fact it will just show string theory is one many different possibilities and outcomes. And one of the possibilities that will be still open is that string theory is not even wrong.

25. **Johan**
January 24, 2007

Why would LQG be Lorentz-invariant? It's not a theory of flat spacetime. For an enlightening discussion, see http://www.lns.cornell.edu/spr/2003-11/msg0056792.html . Someone well known to NEW readers makes a cameo appearance.

26. **gunpowder&noodles**
January 24, 2007

I guess what people mean by "Lorentz invariant" is "Lorentz invariant in the limit of flat spacetime". By the way, are you sure that that thread is not some kind of forgery designed to suggest that LM doesn't understand basic GR?

27. **student**
January 25, 2007

GR (as well as string theory, which is also generally covariant) contains Minkowski spacetime as a solution. On the other hand, it is not clear if LQG can produce a flat Minkowski spacetime as a solution. In fact, there is a claim that the DSR is a limit of LQG and that the Lorentz violating effects in DSR can be tested experimentally (Lee Smolin keeps mentioning GLAST and other experiments). Hence, if the Lorentz violating effects are found experimentally it would be an indirect evidence of the LQG. The Distler, et. al. paper claims that the Lorentz violating effects can be tested at the LHC as well. If such effects are found the perturbative string theory would be invalidated. If they are not found, theories like LQG and DSR would get a big blow but string theory would still survive, although this would not "prove" string theory.

28. **Garbage**
January 25, 2007

I find rather amusing Peter's insistence on the inquisitor referee cutting off any reference to ST. It looks as if he was that referee ;). The paper was finally accepted with a revised title AND (quote from the latest version): "argument completely revisited, stronger and more pertinent bounds given".
This version thus make stronger connection to tests of New Physics at LHC, via WW scattering, including ST and any other candidate for a High Energy completion of the SM which obeys LI, Unitarity and Analyticity. There are a few technicalities which are not the case to discuss now (like a heavy Higgs scenario). However, as a matter of principle, the logic I think is clear.
Namely, tests of GR are of course tests of low energy ST (and also low energy LQG), but also tests of any other *classical* theory of spacetime and low energy physics. What's propossed in this paper is a test of the high energy behavior of scattering amplitudes and hence of high energy ST, since the latter is one of the few theories (and some claim perhaps the only one) we have to complete the SM (including gravity) in the UV. Furthermore, if the way out of ST (as Peter claims) is thru a yet non-existent M-theory, violations of the bounds will put strong constraints on the possible non-perturbative definitions of ST, which by itself is, needless to say, extremly important/interesting.

January 25, 2007

The old filter in WordPress was triggered by multiple links or some notorious subject lines.

The new Akismet goes after comments that have multiple exclamation marks. It also filters out very short posts that look like they were bot-generated for driving up ranking of single website (typical one is "interesting point, I agree")

30. **Thomas Larsson**
January 25, 2007

I guess what people mean by "Lorentz invariant" is "Lorentz invariant in the limit of flat spacetime". By the way, are you sure that that thread is not some kind of forgery designed to suggest that LM doesn't understand basic GR?

From what I recall of that spr thread (you might be able to find some comment by myself there, I don't remember), this was one of the few occasions when I agreed with LM. He disagreed with people who claimed that diffeomorphism symmetry is empty just because you can choose curvilinear coordinates in Newton theory. Like a theory with global phase symmetry is a gauge theory, because you can choose different coordinate systems in different fibers 8)

A freely falling observer sees a Minskowki spacetime. GR has a local Lorentz symmetry in this sense.

31. **press release**
January 25, 2007

Garbage, the fact that the test needs a heavy Higgs is not a tecnicality, since data suggest a light Higgs.

Anyhow, violations of unitarity etc at the Planck scale would give effects 1000000000000000000000000000000000 smaller than what LHC can measure.

Furthermore, hep-th/0602178 presented the basic idea earlier and correctly.

32. **Matti Pitkanen**
January 25, 2007

For quite an interesting idea about a possible reduction of Poincare group to its subgroup as a fundamental symmetry (implying that CP also ceases to be a symmetry) see the [Very Special Relativity] of Glashow and Cohen. See also the little article [here].

34. **Arun**
January 25, 2007

Is this the reasoning?

Suppose the Standard Model is an effective theory valid upto some scale A.

We can add higher-dimension terms to the SM Lagrangian and put bounds on the coefficients of these terms.

Suppose those bounds are found to experimentally violated, and suppose our assumption that the SM effective theory is valid to some scale A is still true, then it must be that one or more of Lorentz invariance, analyticity of the S-matrix, etc., is violated and string theory is cannot be true.

The assumption that the SM effective theory is valid to some scale A and not some lesser scale B is presumably checked by the same set of experiments that find violation of the bounds on the coefficients of the higher-dimension terms?

Thanks in advance for clarifications!

35. **Peter Woit**
January 25, 2007

Please, this is not the place to discuss various people's confusions about the role of the Lorentz group in GR. In the paper in question here the Lorentz group has to be a global symmetry, this is not the case in GR.

36. **Peter Woit**
January 25, 2007

Garbage,

So, it's true that a referee wouldn't allow the paper to be published with a title claiming that its authors had a test that could falsify string theory? If so, don't you see a bit of an ethical problem with the authors having their universities issue press releases based on publication of the paper in PRL entitled "Physicists Develop Test for "String Theory""?

37. **press release**
January 25, 2007

Arun, these constraints come from Quantum Field Theory. So, if LHC can only probe energies at which some QFT applies (the Standard Model or whatever else), these constraints are automatically satisfied. To test if quantum gravity violates locality/unitarity/etc, one must do experiments sensitive to quantum gravity. But if we knew how to directly test quantum gravity, we would have no need of inventing indirect tests.

38. **onymous**
January 25, 2007

Trying again to post this:

"So, if LHC can only probe energies at which some QFT applies (the Standard Model or whatever else), these constraints are automatically satisfied."

No, this is not true, unless I misunderstand what you're getting at. An effective QFT can perfectly well describe everything happening at LHC energies, but the constraint can still be violated because the UV completion is something more exotic. In that case the effective QFT will have some unusual signs, but this doesn't mean it's not a valid effective QFT for low-energy physics. This is sort of the whole point of this type of study, as emphasized in the Adams et.al. paper (hep-th/0602178): analyticity tells you about how far-UV properties manifest themselves in IR behavior. In this way it is possible (but not likely!) that properties of quantum gravity could make themselves known at much larger distances, very indirectly. Unfortunately this only happens if the theory of QG is exotic enough.

Also, above: "Anyhow, violations of unitarity etc at the Planck scale would give effects 1000000000000000000000000000000000 smaller than what LHC can measure." This isn't clear to me either: do you have some particular example of a nonunitary theory in mind? In general modifying quantum mechanics is dangerous, e.g. the Banks/Peskin/Susskind argument that superficially plausible-looking modifications of QM lead to order-one violation of unitarity even at low energies (http://www.slac.stanford.edu/spires/find/hep/www?j=NUPHA,B244,125).

39. **amused**
January 26, 2007

onymous's point in his first comment above seems fair enough: Basically, if I understand rightly, if physics at high (Plank scale) energies is described by a quantum theory (of point particles, strings, or whatever) then Lorentz invariance, analyticity and unitarity imply certain positivity constraints in effective QFT descriptions at lower energies, and in particular in the Standard Model. These can apparently be tested in WW scattering, and if they are found to be violated it implies that a quantum theory description at Plank scale (with the aforementioned 3 properties)doesn't exist. Since string theory is supposed to have these properties, it in particular gets invalidated. Peter's objection that string/M-theory hasn't been constructed yet (at least at the nonpertubative level) is strictly speaking correct, but to me it seems excessively trench warfare-like. If the constraints are found to be violated in WW scattering it would certainly be a heavy strike against string theory as a road towards describing Plank scale physics.

Kudos to the authors for coming up with this interesting and potentially important result. But the string-hype way in which it is being presented in the press is lamentable. Casual readers will come away with the impression that string theory has finally made a testable experimental prediction, just like e.g. electroweak theory predicting the vector bosons and their masses. The limited nature of the "prediction" in this case should have been emphasized, and the authors can't escape some responsibility for this not having been done.

40. **amused**
January 26, 2007

"…imply certain positivity constraints in effective QFT descriptions at lower energies, and in particular in the Standard Model."

Er, I guess that should have been "…and in particular at energies above the standard model ones but still accessible at the LHC."
The SM itself, being a QFT, automatically satisfies the positivity constraints…

41. **Garbage**
January 26, 2007

"Anyhow, violations of unitarity etc at the Planck scale would give effects 1000000000000000000000000000000000 smaller than what LHC can measure."

As pointed out by onymous (although the reference to Banks et al. deserves further comments on), this is by no means totally clear. For instance, violations of LI generates dim

42. **Garbage**
January 26, 2007

Peter,

I posted a longer comment. Not sure what happened. There is something strange going on here. Unfortunately I posted it as I wrote it and I dont really feel like writting it again. Hope it can be retrived, otherwise it will be left to the reader's as an exercise to fill the (much longer) gap…

43. **press release**
January 26, 2007

Let us assume that quantum gravity is at the Planck scale (10^16 TeV) and violates unitarity/analiticity/causality/etc: it would give effects suppressed by 10^16 TeV.

But LHC is sensitive to new operators suppressed at most by 100 TeV. Operators induced by quantum gravity are too small to be seen. Whatever is their sign, it can be approximated with zero: LHC is not testing quantum gravity. LHC is testing QFT. Any QFT (whether or not it comes from strings and whether or not it is the Standard Model) predicts no violation of causality, no Vedic spirits, etc.

Discovering Vedic spirits at LHC would be very interesting, but a paper that tells "if LHC sees Vedic spirits we would have to rethink string theory" is not very interesting.

44. **N. Nakanishi**
January 26, 2007

I'd like to comment that Lorentz invariance can be violated spontaneously in the ordinary framework of local QFT based on the manifestly Lorentz-invariant action. As is well known, the regulator theory can remove all ultraviolet divergences, but it is usually rejected as unphysical because it violates the unitarity of the physical S-matrix. However, this belief is not true if the regulator masses are complex. That is, what is violated in the relativistic complex-ghost field theory is not unitarity but Lorentz invariance! This fact was found 36 years ago. Please see N. N., Prog. Theor. Phys. 116 (2006) 873 or hep-th/0609206. Earlier references are contained therein.

45. **Arun**
January 26, 2007

These can apparently be tested in WW scattering, and if they are found to be violated it implies that a quantum theory description at Plank scale (with the aforementioned 3 properties)doesn't exist.

To which I add : doesn't this argument assume that there is nothing beyond the standard model until the Planck scale? If WW scattering at LHC shows something new, then (in the absence of string theorists) wouldn't we be normally looking for new particles at the LHC energy or a little higher rather than drawing implications for the Planck scale?

46. **Peter Woit**
January 26, 2007

Sorry about that G, but the rest of your comment seems to have vanished into the ether. I'm afraid that this blog software, like most others, has problems when you try and use the "less than" symbol. It inteprets it as opening an HTML tag, which never gets closed, so I guess it just deletes the symbol and everything after it. If someone knows of some way the software can be modified to not behave like this, let me know. Otherwise, people should just be warned to be very careful using "less than" or "greater than" symbols, realizing that WordPress may do something very undesirable when it encounters them.

47. **Chris Oakley**
January 26, 2007

Hi Garbage,

One can of course use < for < and > for > as per standard HTML.

48. **amused**
January 27, 2007

Arun,

As I understand it, the argument in the paper doesn't make any assumption about where the new physics shows up; it could be anywhere between the SM and Plank scales (although it shouldn't be too close to the SM scale, otherwise some complications arise according to the paper). The point is that if the physics at some or other high energy scale scale is described by a quantum theory with S-matrix having the usual properties, then that alone implies certain constraints on the effective QFT descriptions of physics at lower energies (specifically, on the coefficients of a couple of terms in the general expression for a chiral Lagrangian describing a spontaneously broken electroweak gauge theory provided the Higgs mass isn't too light). These bounds can apparently be probed by WW scattering at the LHC. Say the bounds are found to be violated in some future experiment at energies above the SM. That would imply that the physics at any higher energy scale, and in particular at the Plank scale, can't be described by a quantum theory with S-matrix having usual properties (otherwise the bounds wouldn't have been violated). Since string theory is supposed to be (a road towards) such a quantum theory, it would be pretty much dead as a consequence.

"press release",

I don't get your point in your last comment. The paper doesn't claim to be saying anything specific about the structure (operators etc) of whatever theory describes physics at the Plank scale.

49. **press release**
January 27, 2007

amused,

here are a few other observations that would similarly falsify current theories (including string theory): a 4th generation of quarks only, a W that moves faster than light, new vectors that do not fill an adjoint representation, perpetual motion, an anti-commuting boson, a new lepton doublet without its neutrino, nonconservation of energy, antigravity, time machines, a fundamental particle with spin 3, etc.
Why do you think that WW scattering is more interesting?

50. **Arun**
January 27, 2007

The abstract says:

"We show that the coefficients of operators in the electroweak chiral Lagrangian can be bounded if the underlying theory obeys the usual assumptions of Lorentz invariance, analyticity, unitarity and crossing to arbitrarily short distances. **Violations of these bounds can be explained by either the existence of new physics below the naive cut-off of the the effective theory, or by the breakdown of one of these assumptions in the short distance theory.** As a corollary, if no light resonances are found, then a measured violation of the bound would falsify generic models of string theory. "

I repeat what I posted earlier, that in the absence of string theorists, we'd greet the violation of the bounds with gleeful cries of new physics below the naive cut-off.

51. **Amos Dettonville**
January 27, 2007

I must say this is an ingenious approach to establishing the falsifiability of a theory, one that I had not thought of before. I wonder if Popper ever thought of it, or commented on it. There are some extremely fundamental premises underlying essentially all scientific thought, and so an observed violation of one or more of those premises would automatically falsify just about every scientific theory. For example, according to my theory, the electrostatic force of a charged particle falls off (at least approximately) as the square of the distance, so if someone discovered that it actually falls off as the cube of the distance, my theory would be falsified. Likewise, according to my theory, it's impossible to construct a perpetual motion machine, so if someone ever constructs a perpetual motion machine, my theory is falsified. I can dream up endless "tests of my theory" this way… but does this really count as falsifiability in the sense of a robust scientific theory?

Maybe the notion of falsifiability should include an extra condition: If a particular empirical finding would falsify not only my theory, but also virtually every other theory, then it shouldn't be counted as a test of my theory in particular. For example, a test of Lorentz covariance, or analyticity, or anything of this fundamental nature, ought to be simply described as tests of those properties. It seems inappropriate to label such tests as "tests of string theory".

I'm actually surprised that the press releases haven't taken the opportunity to call these "Tests to Falsify Einstein's Theory of Relativity!", since a violation of Lorentz covariance would surely be more significant as a violation of relativity (an actual existing theory) than of "string theory" (a hypothetical theory that may or may not actually exist, and that may or may not actually be falsified by this result, depending on what, if anything, the theory turns out to be).

52. **Aaron Bergman**
January 27, 2007

I repeat what I posted earlier, that in the absence of string theorists, we'd greet the violation of the bounds with gleeful cries of new physics below the naive cut-off.

I'd think you'd find that, if you were to talk to string theorists, they would be extremely excited if new physics, any new physics, would be found.

—

[If something would falsify] virtually every other theory, then it shouldn't be counted as a test of my theory in particular.

I'd think a modicum of research would show that there are plenty of attempts by people to construct theories that violate most subsets of unitarity, Lorentz invariance and analyticity. Lee Smolin, to pick an example, seems to believe (at least some portion of the time) that LQG is not Lorentz invariant.

53. **Amos Dettonville**
January 28, 2007

It doesn't take any "research" to know that people have examined the possibility that (for example) Lorentz invariance might be violated. Indeed, Lorentz himself theorized about this. But surely Lorentz invariance is (and has been for quite some time) accepted as one of the best supported empirical facts, and it is implicit in all the *standard* (for lack of a better word) modern theories (as opposed to research porgrams or ideas for theories) of physics. I'd think a modicum of thought would suffice to realize that if Lorentz invariance were ever found to fail, any implications it may (or may not) have for the highly speculative research program known as "string theory" (or LQG etc) would be utterly insignificant compared with the implications for the very foundations of modern physics, i.e., actual theories that actually exist today. A falsification of relativity would be staggering news… but not because of what it does or doesn't say about "string theory".

My point is that it's silly to tout failure of Lorentz invariance as falsification of the hypothetical "string theory" (whatever that may or may not turn out to be), when in fact it would falsify the foundations of all the successful EXISTING theories of physics.

54. **amused**
January 28, 2007

press release,

The odds are against any of those things turning up, don't you think? If it turns out, as many people seem to expect, that string theory can accomodate whatever new physics is found at the LHC, then these bounds at least give one way that it could still potentially be falsified.

Arun,

"I repeat what I posted earlier, that in the absence of string theorists, we'd greet the violation of the bounds with gleeful cries of new physics below the naive cut-off."

If the violation isn't accompanied by the mentioned "light resonances" then the conclusion about breakdown of one of the assumptions on the short-distance theory is inescapable. (And existence of string theorists was not one of those assumptions…)
If the light resonances are there, then the bounds would need to be modified – that's what I was alluding to in the "some complications arise" part of my last comment.

"

55. **N. Nakanishi**
January 28, 2007

One should not confuse the Lorentz invariance of the fundamental action with that of the physical S-matrix. As I emphasized previously (January 27, 2007 at 6.14 am), Lorentz invariance can be violated SPONTANEOUSLY in the ordinary framework of QFT without contradicting the fundamental principle that the action integral is Lorentz invariant. Therefore, this theory can be a theory which coincides with the standard theory in lower energies. Furthermore, if one accepts the violation of Lorentz invariance, it is possible to remove all ultraviolet divergences without violating the unitarity of the physical S-matrix.

56. **woit**
January 28, 2007

Amos,

I think that pretty much everyone except Distler et. al. who has ever thought about what it means to test a scientific theory understands that your test of the theory is supposed to involve characteristic features of that theory, and that you're supposed to actually do a calculation involving such characteristic features in order to come up with anything that can legitimately be called a "test".

The way some string theorists recently seem willing to throw out the most basic things about what it means to do science in order to make rather absurd claims for their research never ceases to amaze me.

57. **Garbage**
January 28, 2007

Peter & Amos,

I disagree with the claim that the bounds are not a test for whatever New Physics (NP) is out there in the UV. The magic of the EFT formalism is that one doesnt really need to know what is it like but what sort of basic principle respects. If the bounds are violated these principles must be re-thought, or the other possibility is NP at a much lower scale than we think.
To partially answer press release at the same time. If these basic assumptions break down naively at the Planck scale, it isnt a priori true that they wont show up at lower scales. For instance, the breaking of LI could generate operators in teh EFT which are not Planck supressed (This is easy to understand once the 1/Mpl gets killed with the UV cuttoff scale).
Unitarity in the other hand goes tied to the notion of evolution. Therefore, it is also possible that Planck scale violations get enhanced by
a mixture of its time and energy dependence (recall the disp relation will not get thru unless SS*=Id).
Yet another possibility is that the fall off of the scattering amplitude does not obey the Froissart bound and, as in the cae of LI, small violations will get amplified by the cutoff scale.

In spite of all the possible scenarios we could come out with, the EFT spirit tells us we can still do some predictions based on simple assumptions without a complete knowledge of the UV completion. If the bounds are violated we will know one or more of these assumptions are wrong, or there is a light resonance out there we havent found. This is a robust prediction which will falsify all the models of NP which rely on such premises. All we know so far of ST falls into that class. LQG or others, might not. This is a non trivial test of the High Energy behavior of scattering amplitudes, needless to say does not conflict with classical GR since, for instance, the assumed LI in LQG are of quantum origin. As such, this is a test of quantum gravity or GUT if you wish, for which ST claims to give a description of…

G

58. **confused**
January 28, 2007

I don’t understand what you’re all so upset about with this paper. The authors note that not all low energy effective field theories can be UV completed to some string theory. This is important and it runs contrary to what most anti-string people claim. Furthermore, it’s not true that any quantum theory of gravity which anyone takes seriously will automatically satisfy unitarity, lorentz invariance, etc – LQG doesn’t. So this seems to provide some nontrivial information about physics beyond the standard model. Obviously this can’t be used to verify string theory but it could, in principle, falsify it (modulo assumptions which look quite reasonable to me). This is EXACTLY what you guys are always complaining about: string theory can’t be falsified. But when somebody presents some small progress in the direction of showing that string theory can be falsified you people all complain about it, rather than praise the authors for at least trying.

As for the hype, yes, of course, the title somewhat overstates the claim but it’s not an outright lie (they don’t need to do a full string theory calculation to know that string theory respects unitarity, etc). All the authors have done is what everybody does: try to motivate people to actually read their paper. Do you also have “ethical” objections to giving your paper a playful/funny title in an attempt to attract attention?

59. **Peter Woit**
January 28, 2007

confused and Garbage,

My problem is not with the actual content of the paper. The authors are claiming to have some bounds which, in the extremely unlikely event they are violated, would indicate the existence of some new physics. The problem is that this is very different than having a “test of string theory”. They don’t actually use string theory in any way at all in their paper, in particular they don’t show that string theory satisfies the assumptions they are making (and no one knows if whatever non-perturbative string theory is, whether it will satisfy these assumptions). It’s quite simple: the paper is simply not about string theory at all, so it can’t in any sense be “progress in the direction of showing that string theory can be falsified”. There’s nothing wrong with trying to show string theory can be falsified, there is something wrong with claiming you can show this when you can’t.

“All the authors have done is what everybody does: try to motivate people to actually read their paper. Do you also have “ethical” objections to giving your paper a playful/funny title in an attempt to attract attention?”

Unfortunately the title of the press release doesn’t seem to be a joke, although it really is one. Yes, I do see an ethical problem with giving a paper a misleading, dishonest title in order to get people to read it and it appears that a PRL referee had the same problem. I see an even bigger problem with issuing misleading and dishonest press releases, which is what the authors have done here.

60. **onymous**
January 28, 2007

no one knows if whatever non-perturbative string theory is, whether it will satisfy these assumptions

You keep saying this, but we do know that string theory is a theory satisfying the rules of quantum mechanics, so I don’t see how unitarity could *ever* be violated by nonperturbative effects. It also seems hard to believe that analyticity would ever be violated, because it encodes causality properties. Lorentz invariance, you might be able to raise questions about, I suppose (maybe you can turn on a small background B field or something?). So if you were going to try to argue that a realistic string theory could violate one of these principles, I guess that Lorentz invariance would be the place to start. In any case, within the paradigm of string theory on 4D Minkowski space times a compact manifold, the assumptions seem pretty much unimpeachable, right? No matter what nonperturbative physics is happening to stabilize the compact manifold, it doesn’t change the far short-distance properties of the theory. “Nonperturbative” doesn’t automatically mean “we have no clue.”

61. **Peter Woit**
January 28, 2007

onymous,

Getting 4D Minkowski space X a stabilized compact manifold is just one aspect of what you hope your non-perturbative string theory, whatever it is, will look like at large distances. You don’t know what is going to happen at arbitrarily short distances. With very little trouble you should be able to find many places where prominent string theorists such as Gross, Witten, Seiberg, etc. go on about how understanding non-perturbative string theory will require us to give up our conventional notions of what space and time are. I don’t see how you can reconcile this with claiming that you know that non-perturbative string theory involves a 4D Minkowski space structure and associated analyticity properties down to arbitrarily short distances. It seems to me that Gross, Witten, Seiberg, etc are saying the exact opposite, and that they would be happy to claim that violation of the bounds in question is evidence for string theory, not that it falsifies it.

62. **Amos Dettonville**
January 28, 2007

Just to be clear: I don't dispute that the violation of Lorentz invariance would falsify one of the basic premises of any theory or any research program that takes Lorentz invariance as one of its basic premises. I'm just observing that this includes essentially all *existing* successful theories, as well as many/most research programs for new theories. Lorentz invariance is a very fundamental feature of existing physical theories, and the fact that its violation would undermine some speculative directions of research into future theories ("new physics") strikes me as secondary to the fact that it would falsify the foundations of all existing theories.

Perhaps one can take the phenomenological view that existing theories are not based on any degree of Lorentz invariance beyond what has been experimentally verified, so if a violation were found outside those limits, it wouldn't affect existing theories. But that seems like a rather obtuse interpretation of current theories. Surely the point of a scientific theory, like relativity, is not just to be a catalogue of known empirical results, but to predict things beyond what has already been measured, and to place the phenomena in a coherent conceptual framework. If a measurement conflicts with the prediction of a theory, even in a region beyond what has been tested before, then the theory is falsified. We may still accept that the theory "works" approximately within a limited range, but it is nevertheless falsified in its previous sense.

I hope we can all agree that relativity predicts that Lorentz invariance is never genuinely violated (more or less by definition), so if a violation is found, relativity is falsified. All I'm saying is that, to me, the falsification of relativity itself would be far more significant than the undermining of one or more speculative research programs based on (among other things) relativity. Notice that the paper in question points to Mattingly's 2005 paper in Living Reviews in *Relativity* for a discussion of possible Lorentz invariance and its implications.

Note to N. Nakanishi: You commented about something that might be termed "violations of Lorentz invariance" in existing QFT, but the authors of the paper in question seem to conceed that the kind of Lorentz invariance they are talking about would in fact conflict with QFT, so they seem to be talking about what I would call a genuine violation of Lorentz invariance (see Mattingly's paper for the meaning of "genuine").

Note to confused: I'm uneasy about giving playful/funny titles to scientific papers "in an attempt to attract attention". I suppose if the title is understood to be an inside joke, then it would be okay, but I don't think it is being presented as a joke when reported in the popular press. Reporters don't seem to "get" the fact that it is a joke, i.e., that the falsification being discussed would undermine not just some avenues of string research but essentially all existing theories of physics. My objection to this practice is that it doesn't just attract attention, or serve as an amusement, it also seems to mislead. I'm all for whimsy, but I think we should strive to avoid using whimsy to mislead people… and there seems little doubt that people have been misled in this case (see all those press releases).

63. **Garbage**
January 28, 2007

"…It seems to me that Gross, Witten, Seiberg, etc are saying the exact opposite, and that they would be happy to claim that violation of the bounds in question is evidence for string theory, not that it falsifies it."

At least not the kind of ST we have so far and that's definitely a powerful claim. If the bounds are violated, and ST wants to stay up there, better start taking those 'give-up' ideas seriously.

In the other hand, there is people who would say ADS/CFT provides a
non-perturbative definition of ST. If that is the case, violations of the bounds would certainly throw that option out of the window, since we know the FT side is well behaved (In fact that is what convinced Hawking that BH evaporation was unitary after all. Although that might not be the case).

The paper uses assumptions about the UV completion of the SM. So far ST is *perhaps* the only theory at hand, which happens to obey these in most of its current forms. Therefore, the bounds are a test for what we know or hope of ST. I agree there is too much of a hype behind this, but yet I see no incorrect statements in the paper nor in the authors' claims in the press.

I would be happy to see more paper like this coming out, and certainly it would be great if the bounds are violated and the string community starts to 'give-up' in any way 🙂

64. **Garbage**
January 28, 2007

Amos,
LI can be violated in the vacuum (or a given state) and yet be there as a full symmetry of the action. In LQG the starting action is Einstein theory, its quantization introduces the foamy structure which might break LI. The LQG people would claim Einstein theory is recovered in the (h goes to 0) classical limit. The same people would tell you that the space of physical state is invariant under the whole diff group, and gauss law (local Lorentz). The same could happen to Unitarity depending on the choice of time variables even though there is an underlying unitary theory.
For the scattering amplitudes, String theory so far doesnt seem to violate LI nor the other assumptions (see the original Adams et al. paper).

G

65. **woit**
January 28, 2007

Garbage,

"At least not the kind of ST we have so far and that's definitely a powerful claim"

The "kind of ST we have so far", perturbative string theory, AdS/CFT, and a few versions of M-theory in special backgrounds, are already falsified. You can't get the standard model as low energy physics out of any of them. Claims that string theory can lead to the standard model have to invoke some hoped for, but not yet understood non-perturbative theory. The question of "is string theory falsifiable" is only non-vacuous if it refers to conjectural versions of string theory that solve the problems of known versions of string theory. For these conjectural versions you can't say one way or another whether they satisfy the conditions at issue.

66. **onymous**
January 28, 2007

"Claims that string theory can lead to the standard model have to invoke some hoped for, but not yet understood non-perturbative theory."

You do know about the work of Braun et al on the heterotic MSSM, yes? Or of Verlinde and Wijnholt? There's not exactly "not yet understood non-perturbative theory" that's crucial there. There's no mystery about the short-distance physics. The models aren't perfect yet, true, but they're not as far from reality as you seem to think.

(Cosmology might require not-yet-understood physics, but I don't see any obvious connection to the short-distance questions we're talking about here.)

67. **woit**
January 28, 2007

onymous,

The models you discuss involve an ad-hoc choice of background, in particular an ad-hoc choice of a 4d Lorentz invariant background. This background is supposed to be determined by the unknown non-perturbative theory fundamental theory. As far as I know, they are not yet successful at reproducing the standard model.

The question is not whether people have looked at models with 4d Lorentz invariance, the question is whether string theory has to lead to models with this invariance, and there is no argument for this.

68. **Garbage**
January 28, 2007

"The question is not whether people have looked at models with 4d Lorentz invariance, the question is whether string theory has to lead to models with this invariance, and there is no argument for this."

There will be if the bounds are violated….forget about it….

G

69. **Bob McNees**
January 28, 2007

I know I'm late to the party, but I feel like I need to comment on this. There are four versions of the paper available at the arXiv. None of them contains the phrase "test of string theory". They do, however, refer to the potential for "falsifying string theory".

I'm going to assume that everyone here understands the difference between these two things.

The "press release" appears to have been put together by UCSD's news service and subsequently picked up by their counterparts at CMU and UT. In fairness, I can see how some of the quotes, taken without reference to either the rest of the press release or the actual paper, deserve to be argued with. But Peter's "most outrageously misleading string theory hype of 2007″ also contains these quotes:

"If the bounds are satisfied, we would still not know that string theory is correct," said Distler. "But, if the bounds are violated, we would know that string theory, as it is currently understood, could not be correct"

"In other words, string theory—as articulated in its current form—would be proven impossible."

Wow. So basically, the most outrageously misleading statement about string theory for 2007 is that an experiment can not confirm string theory, but it can falsify it. How did such a radical idea ever make it through the peer-review process?

I can't imagine why Peter – who is, of course, free to delete this post if he likes – would be upset by the prospect of a legitimate proposal for falsifying string theory (Yes, I know … along with several other theories). I mean, it's not like he's getting royalty checks from a book whose title implies that this is not possible, even in principle.

70. **N. Nakanishi**
January 28, 2007

Reply to Amos Dettonville: You seem to misunderstand my claim.
There are two, mutuall equivalent, perturbation theories, "old" and "Feynman". The latter is manifestly covariant, that is, if the action is Lorentz invariant then the "Feynman" S-matrix is automatically Lorentz invariant, as long as no new situation is encountered. The necessary new situation encountered is the introduction of complex delta function. This is not an artificial procedure. Indeed, if one calculates the S-matrix by means of the "old" perturbation theory, one obtains exactly the same Lorentz-noninvariant result without introducing any new concept.

71. **Amos Dettonville**
January 28, 2007

Reply to N. Nakanishi:

Maybe you can help me understand what you're saying if you would comment on the following quote from Mattingly's 2005 review paper on Lorentz Invariance (which is cited in the "string falsification" paper):

"As we have seen, over the last decade or two a tremendous amount of progress has been made in tests of Lorentz invariance. Currently, we have no experimental evidence that Lorentz symmetry is not an exact symmetry in nature. "

Do you agree or disagree with this statement? Are you saying there IS evidence of violation of Lorentz Invariance? Or are you saying current theory entails such violation, even though it has not yet been detected? Or are you saying something else completely? If the latter, could you explain the relevance to the subject under discussion?

72. **N. Nakanishi**
January 29, 2007

Reply 2 to Amos Dettonville:
I never positively assert the violation of Lorentz invariance, but I think that the main subject of this debate is the possible violation of Lorentz invariance. I believe that the spontaneous violation of Lorentz invariance is much more probable than the extra dimensions, string theory, etc. My aim is to remind people of the fact that even if LHC experiment indicates the violation of Lorentz invariance, it is still possible to explain it in the framework of the manifestly Lorentz-covariant QFT.
(As an experimental evidence of the possible violation of Lorentz invariance, some people point out the observation of extremely high-energy cosmic-ray particles, because they should collide with 3K cosmic background photons.)

73. **woit**
January 29, 2007

Bob,

You totally ignore the scientific argument repeatedly made here that the Distler et. al. paper does not provide a way of falsifying string theory (an argument that the PRL referee seems to have agreed with). While ignoring the scientific issue, your only argument is to make a sleazy accusation that I'm just trying to make money.

Completely pathetic.

74. **Bob McNees**
January 29, 2007

I don't ignore the argument, I disagree with it. Perturbative string theory gives you an S-Matrix with well-defined properties. If you demonstrate a violation of these properties, you have falsified the theory. Yes, a lot of other things go along for the ride. If you see the kinds of violations they discuss, it would be hard to reconcile those observations with conventional QFT. One way of falsifying string theory is showing that properties it should have at all scales are violated at the scales you have just gained access to.

That is a scientific argument. You are free to say "they should come up with something that targets string theory more precisely, as opposed to such a wide-swath of theory space". Sure, that would be great. But it doesn't make their argument unscientific.

Is it the press release you disagree with? The way it might be interpreted in the popular media? Because that's where I think you are being hypocritical. Where was your indignation when the press releases were being issued on your behalf? You just wrote a book describing your views on string theory, and you gave it a title implying that string theory cannot be falsified. The publisher issued press releases and advertisements, as publishers are wont to do, claiming that you *show* that string theory cannot be falsified. I read your book and considered your complaints, and I don't agree that you have demonstrated a "lack of falsifiability". Why do you get to announce that in a press releases?

I don't think you are "just trying to make money". I think you genuinely want people to know what you think about string theory. You just chose a forum that uses advertising and press releases to drum up interest, and now you're upset that it might cut the other way. At least people can download and read the peer-reviewed article for free.

75. **Peter Woit**
January 29, 2007

Bob,

You continue to ignore the scientific argument I was making. Perturbative string theory is already falsified, it makes predictions that disagree with experiment.

I gave my book a title implying that string theory cannot be falsified, because, in its current state, the way it is being pursued, it can't. I'm willing to stand by that claim, and have spent a lot of time discussing and defending it here and elsewhere and will continue to do so.

The marketing materials prepared by a publisher trying to sell a book are not directly comparable to a press release issued by a university on behalf of one of its faculty members, but if you want to make that comparison, fine. I don't think I've seen everything the marketing people at my two publishers have written and may be using, but I am willing to stand behind everything that they've shown me and asked me to look over. This is mainly the jacket copy on the books. I argued with the US publisher and insisted that they use language that, while it was not the way I would want to present my arguments, was language that I could stand behind and back up. I assume that the authors of this paper similarly are willing to stand behind what has been issued in their name. If they're not, it would be a good idea for them to say so publicly.

It's a very simple distinction: String theory IS "not even wrong", it is not testable in its current state, and honest researchers in the field acknowledge this.

76. **D R Lunsford**
January 29, 2007

Bob McNees said

None of them contains the phrase "test of string theory". They do, however, refer to the potential for "falsifying string theory". I'm going to assume that everyone here understands the difference between these two things.

This is just sophistry. There is no difference other than one of language. I am going to assume you know the difference between actual physical experimentation and the vagaries of language.

-drl

77. **Jack Lothian**
January 29, 2007

My wife has had hundreds of press releases issued in her name & she has read everyone of them before release & edited most of them before release. This is a pretty common practice. The idea that press releases are generated by faceless gnomes who never communicate with the so-called authors of the release is not a true picture of how most press releases are issued. Shame on you for suggesting this, even our lowest politicians know that they can not get away with this kind of defense. It ranks right up there with the dog ate my homework excuse. I believe the odds are that these authors saw this press release before it was sent out & they approved it. Thus the authors publically endorsed the view that their paper presented a "test of string theory".

I agree with Lunsford that your arguments are a form of sophistry.

78. **urs**
January 30, 2007

Peter wrote:

🙂

79. **Q**
January 30, 2007

The first […] is 'is already falsified,'
The second […] 'that disagree with experiment'.

It's supersymmetric unification scheme predicts a massive cosmological constant.

The SU(3) force predicted by string for low energy, using the known SU(2) and U(1) force strengths, is wrong by current experimental data (four times outside the experimental standard deviation).

Should Peter have called his book simply ‘Wrong’? ‘Not Even Wrong’ refers only to the non-falsifiable ‘predictions’ like unification of all forces at an energy of 10^19 GeV, extra dimensions rolled up in Planck scale manifolds, prediction of gravitons, superpartners, branes, etc., that can’t be checked falsifiably by experimentation…

80. **woit**
January 30, 2007

Urs,

If you actually have an argument, it would be helpful if you would make it. I’ve made one: purely perturbative string theory doesn’t give standard model physics, it’s wrong. Attempts to get around this by invoking complicated backgrounds, generated by non-perturbative effects like branes are non-predictive and not even wrong. If you have an answer to this argument, let’s hear it.

81. **Thomas Larsson**
January 30, 2007

Wrong, completely wrong, not even wrong.

Bosonic string, superstring, M-theory.

82. **John Gonsowski**
January 31, 2007

Let’s say Gross comes up with some very good math to link string theory to QCD (perhaps giving QCD it’s own emergent spacetime while string theory has some other spacetime)… would this then allow Gross to justifiably claim QCD as a test of string theory?

83. **Peter Woit**
January 31, 2007

The “test of string theory” discussed here has nothing to do with a string theory dual for QCD. There may very well be such a thing, and if it can be shown to be exactly dual to QCD, then every test of QCD would be a test of that string theory. The claims in the Distler et al. paper are not about this, but about testing the idea of string theory as a unified theory of particle physics and gravity

84. **Arun**
February 2, 2007

What’s your opinion of this “verification of string theory” method?
http://link.aps.org/abstract/PRL/v98/e051301

85. **woit**
February 2, 2007

Arun,

I haven’t looked at the paper very carefully, but I guess Shiu/Underwood. are claiming that in certain brane-inflation models, for certain ranges of parameters, you can in principle see effects of the warped compactification on the CMB. I have no idea whether these effects are something one could imagine practically measuring anytime in the forseeable future for realistic parameter values.

They don’t claim in the PRL paper to be able to “test string theory”, but they have issued a press release, which seems to me an unwise thing for theorists to do to promote this kind of very speculative result:

http://www.news.wisc.edu/13422.html

The press release is entitled “Physicists find a way to “see” extra dimensions”, which is nowhere near as misleading as the Distler et. al. press releases. It does contain claims about string theory that are likely to mislead people, especially Shiu’s quote that “This provides a rare opportunity in which string theory can be tested.” It would have been a good idea for him to make clear that string theory is not being tested, but a very specific “string-inspired” model of extra dimensions, and that not seeing the effects they study (which is extremely likely) doesn’t in any way provide evidence against string theory.

This is kind of like the endless claims one heard after Randall-Sundrum that the LHC would “test string theory” since in principle extra dimensions could be of TeV scale, and in principle they could come from string theory. People seem to have stopped making that particular “test of string theory” claim for one reason or another.

It will be interesting to see how many inaccurate press stories are generated by this press release.

Too much going on, hard to keep up with all the things that seem worth mentioning. Here are some quick ones:

There was a meeting on Geometric Langlands involving mathematicians and physicists last week at the Schrodinger Institute in Vienna. David Ben-Zvi has notes for the talks.

There's an interview with John Baez and Urs Schreiber, partly about blogging. I personally take credit for first referring to him as a "proto-blogger", thus making him feel bad (although it was intended as a compliment…) and encouraging him to modernize:

So, I started getting a little frustrated about being called a 'proto-blogger'. I would joke that I felt like being introduced as like, 'Homo erectus: Very smart for its time, with the first stone tools'. It made me feel sort of old!

Victor Rivelles reports from the Latin American String School in Bariloche. Notes are online.

Michael Creutz has a new paper claiming that rooted fermions are not just "ugly" or "bad", but "evil". See here for some commentary on The Evil That is Rooting.

William Fulton is giving an excellent series of lectures here at Columbia every Friday afternoon, on the topic of *Equivariant Cohomology in Algebraic Geometry*. Ex-Columbia undergrad Dave Anderson, now Fulton's student at Michigan, is writing up notes.

There's a proposed new newsgroup "sci.physics.foundations", which some readers here might find interesting, and which would be a better place for a lot of the discussions which people try to start here, which I then try and stop because I don't want to moderate them. More about this here, and some discussion here.

   Most ironically, perhaps, the Earth's axis of evil (the stuff of mankind, no doubt) is spilling over into the greater realm of Universe. God only knows, I suppose.;)

2. **Jay R. Yablon**
   January 25, 2007

   Thanks, Peter, for letting folks know about the new Usenet group "sci.physics.foundations" which we are seeking to start up in the near future.

   A primary goal of our group is to use the power of the internet as a platform for scientific collaboration on an international basis among serious physics researchers seeking to gain a deeper understanding of nature. We are hoping that this group will evolve into a model of enlightened, mutually-supportive scientific collaboration, going beyond the "gotcha" and one-upsmanship mentality that has so pervaded many other physics discussion groups.

   The moderators and proponents all believe that conservative scientific method is fundamental to scientific discovery and advancement. This includes the persistence to conduct trials, the courage to make and admit errors, the open-mindedness and flexibility to correct errors, and the recognition and acceptance that in the end, nature, not personal philosophy or predisposition, popular fashion or paradigm, or greatest availability of research funding, is the ultimate arbiter of whether our theories are correct. In part, nature presents herself via other knowledgeable people of good will who are willing to look at someone else's theories-in-trial, collaboratively point out what nature has already validated to be true which is possibly being overlooked or contradicted, and kindly suggest corrective measures. As such, with the goal of contributing to the advancement of scientific knowledge, sci.physics.foundations will make use of the newly-available power of the internet to augment "feedback" to serious research during its formative, stages of trial, error, and correction, from people of like-interest around the world.

   Please review our RFD at http://vacuum-physics.com/spf/, post your support at http://groups.google.com/group/news.groups.proposals/browse_frm/thread/aa4bfd6d8bf61111/6f20a6d40961a4b6#6f20a6d40961a4b6, and then join us the collaboration once sci.physics.foundations begins.

    The problem is obvious. The comment in question was travelling at very nearly the speed of light.

Short Items

January 30, 2007
Categories: Uncategorized

Discover Magazine has just announced a competition, calling on people to submit videos to them that "clearly explain perhaps the most baffling idea in the history of the world: string theory". The challenge is called String Theory in Two Minutes or Less, and the winner gets featured in an upcoming issue of Discover. In related news, one of my correspondents suggested making my postings available as YouTube videos, but I think I'll resist any temptation to go that route.

Michael Peskin was here at Columbia yesterday, giving the physics colloquium, which was mainly about prospects for detecting at the LHC the kind of supersymmetric WIMP that is supposed to make up dark matter. On his web-site there are slides which more or less correspond to the talk he gave. The bottom line is that he believes that over the next 5-10 years we'll be seeing evidence for such a WIMP from all of three different sources: astronomy (GLAST), direct detection experiments, and the LHC. The claim is that the LHC should be able to detect the existence of such a particle (although it's not easy…) and maybe even measure the mass to 10 percent.

Experimental HEP bloggers keep putting out gripping multi-part stories about what it's like to be dealing with collider data that is not conclusive, but has anomalies that promise the possibility of something new and exciting. See the latest from John Conway and Tommaso Dorigo.

There's a new mathematician's blog out there, John Armstrong's The Unapologetic Mathematician. He promises "I'm sure I can come up with a good rant once a week or so. Actually, I'll set that as a goal."

NPR's last Science Friday program dealt with experimental HEP physics, featuring David Barney (CMS), Jacobo Konigsberg (CDF) and Barry Barish (ILC).

I managed to get to a few of the talks at last week's City College workshop on non-perturbative Yang-Mills that was mentioned here recently. Unfortunately I couldn't get up there on Friday and missed talks by Maldacena and Freidel that I would have liked to see, but did make it to some of the talks on Thursday and Saturday. It appears that progress in 3+1d remains limited, but quite a lot of work is going on with new analytical methods for dealing with 2+1d, which can be tested by comparison with extensive results from lattice gauge theory computer simulations.

Max Karoubi has a new paper on the arXiv, Twisted K-theory, old and new. It traces the origins of the subject back to nearly 40 years ago, explaining the original mathematical motivations, old and new results, and relations between them.

Over at edge.org, my friend Nathan Myhrvold has his photos and an essay about penguins. OK, besides Nathan's background in the quantum gravity business, this has nothing to do with math or physics. But the things are damn cute…

Update: A commenter points out that I should also advertise a bit an event taking place downtown here in New York next week. I'll be talking at the Cafe Scientifique, which will take place at 7:30 next Tuesday evening, at the Rialto Restaurant in Soho.

   January 30, 2007

   Peter-

   Another item worth mentioning for the benefit of your readers in the NYC area: a certain critic of string theory is scheduled to appear at Cafe Scientifique in lower Manhattan on the evening of February 6th. It should be a good time; the speaker has an interesting blog….

6. **woit**

January 30, 2007

Thanks Sebastian,

I'd forgotten that I did intend to mention that again here, will add something on to the posting.

7. **mclaren**
January 30, 2007

Really, this sounds like Monty Python's "Semaphore version of Wuthering Heights."

8. **Chris Oakley**
January 31, 2007

Peter –

I would love to go to your talk, but unfortunately will not be in New York on that day. This title: "Not Even Wrong: The Failure of String Theory And the Search for Unity in Physical Law" is a bit of a mouthful. Is it too late to change it to just "Is String Theory bullsh*t?"

9. **Bee**
January 31, 2007

well. that's how progress is made. why study a decade when you can just look at some 2-min videos at YouTube, and everything is explained? it seems to me the adjective 'baffling' was very carefully chosen.

Thanks for the penguin-link 🙂

10. **Thomas Love**
January 31, 2007

I thought the objective was to put the entire final theory on the back of a T-shirt.

11. **Seth**
January 31, 2007

As a student on ATLAS, I'm curious what you meant by your comment that "it's not easy" to detect the existence of supersymmetric WIMPs at the LHC. I admit it's very possible I'm missing something, but I had thought that simply finding WIMPs was a much easier (and quicker) study than many others at the LHC.

It's true in some sense that nothing in particle physics is easy, but as the slide in Peskin's talk notes (on page 58), we do think we have a handle on kinematic variables that will point to the existence of such particles. In particular, the effective mass (usually the scalar sum of missing transverse energy and the top four jets) plots often look rather different than the Standard Model, even with relatively little data.

There's a lot of active work being done on how best to do these studies. There are refinements that may improve the situation considerably, like playing with the details of the cuts or the exact variable one plots. There are also problems that need to be understood better, in particular having a firm estimate of the standard model background and the error on that estimate.

The search for heavy non-interacting particles is one that can be done even with fairly early LHC data, and might yield promising results quite quickly. Other studies, like the ones analagous to the Tevatron "bump-hunting" that you've linked to, will require much more care and better estimates of systematic errors, and so would seem to be much harder.

Figuring out what kind of WIMP we're dealing with, and maybe measuring its mass—now *those* things will be hard.

12. **Peter Woit**
January 31, 2007

Seth,

The reference to "not easy" was just a reference to the general difficulty of extracting this kind of signal, not a claim that it was difficult compared to lots of other signals people are looking for, which are even harder. Peskin in his talk was emphasizing the huge sizes of the backgrounds to be dealt with at the LHC (perhaps because he does want people to keep in mind the case for the ILC).

Thanks for your informative comment about this!

13. **Tommaso Dorigo**
February 2, 2007

From Chad Orzel's blog:

"You'll be happy to know that Peter Woit has already bowed out (suggested concept: standing in front of a whiteboard, hopping up and down, and yelling, "It's crap! Crap crap crap crap crap!" for two minutes)."

Where did you suggest that Peter ? I must be missing something.

Cheers,
T.

SLAC 2006 Topcites

February 1, 2007
Categories: Uncategorized

A couple weeks ago I generated a list of the theoretical physics papers that were most heavily cited during 2006, according to the SLAC database, and discussed it here. Today the people at SLAC put out their own lists for 2006, which are quite interesting to go through. Their data is quite consistent with mine, although the numbers are very slightly larger, since a small number of new citations have been added into the database over the last couple weeks, I think mainly from papers which for example appeared on the arXiv in January 2007, but carried 2006 dates (e.g. write-ups from 2006 conferences).

The main list covering all HEP papers is dominated these days by astrophysics-related papers. Out of the 50 papers on the list I count only about 15 particle theory papers, and 3 review articles. The only post-1999 hep-th paper that makes the list is the KKLT landscape paper. To make the top 50, a paper needed to get 152 citations or more.

The list I put together goes deeper, down to papers with 100 citations, but SLAC has also put out something even better: 2006 lists of 50 most-heavily cited hep-th and hep-ph papers. To make the hep-th list, a paper had to have 62 or more citations. Looking over the 20 or so post-2000 papers on this list gives a good idea of what topics have been popular in recent years: the landscape, dark energy, and various aspects of AdS/CFT, and a small number of other topics. There are also several review papers on the list. Anyone interested in understanding what topics are attracting attention in particle theory research these days should find it quite interesting to go through this list, and spend some time taking a look at and learning about any of these papers that are unfamiliar.

   February 1, 2007

   thought you might be interested, in case you haven't yet seen

   New particle accelerator could rule out string theory
   22:04 01 February 2007
   NewScientist.com news service

2. **Peter Woit**
   February 1, 2007

   Thanks Bee, I hadn't seen that particular piece of string theory hype, will add it to the relevant posting. To relate to the current topic, the paper in question has been cited a total of 5 times since it appeared last April.

3. **gunpowder&noodles**
   February 1, 2007

   Do many string theorists really deny that the subject is in poor shape these days? The only one I can think of is Clifford Johnson. Most of the ones I know freely admit that there is a stalemate, but claim [I think rightly] that there is no alternative on the market……

4. **woit**
   February 1, 2007

   gunpowder,

   I've found the last few years that when I speak to string theorists privately they're willing to admit that things are not going well, but they are very loathe to say this publicly. The active string theorists with blogs (Clifford/Jacques/Lubos) all publicly claim that things are fine with string theory, that at most what is going on is that the field is a bit less active than at some other times.

   I agree there's no obvious alternative on the market (as far as particle theory goes, for quantum gravity there's LQG). If there were a promising alternative idea particle physics unification, string theorists by now would be willing to jump ship. The problem is how do you encourage people to do the kind of work necessary to come up with alternatives?

5. **Garbage**
   February 2, 2007

   "To relate to the current topic, the paper in question has been cited a total of 5 times since it appeared last April."

   Well, the final (published) version if I recall right came out in october…LHC yet to come!
   Nevertheless, it is kinda fun Peter makes such remark. I cant even imagine the type of ranting he would spit out if it had more than 100+ by now 🙂
   The article in the New Scientist is however really poor I admit. If it makes it into 'the economics' then I would start to worry 🙂

   G

6. **Pindare**
   February 2, 2007

   Those who think there is no alternative on the market should perhaps have a closer look at the recent work of Connes, Chamseddine, Marcoli, Barrett, Cartier…

   http://arxiv.org/abs/hep-th/0610241
   http://arxiv.org/abs/hep-th/0608221
   http://www.ihes.fr/IHES/Scientifique/Seminaires/seminaire.php?theme=3

   In a recent video interview available here
   http://www.arte.tv/fr/connaissance-decouverte/science/1350636.html

   Connes says (chapter 18 at 3:50, translated from french): "[…]when you look at the table which I have made […] you realize that the dimension of a point is not zero, it is six! […] This is somehow consistent whith what people do in string theory *but* they look for an ordinary space of dimension 6 while the space that one finds with the formula is not an ordinary space, it is a non-commutative space, so they could not find it. […] it is of metric dimension 0 but of dimension 6 in the sense of K-theory […]"

He then says they make predictions (Higgs, Top) which must be tested in two years time by LHC data to see wether or not their model is right.

7. **Who**
February 2, 2007

as a way to track the quality of string research activity we can count the number of recent string papers that made the "top 50" list last year and compare this with how many made it in previous years.

As you mention, in 2006 only one recent string paper made the top 50. By recent I arbitrarily mean published in the last five years: 2002-2006.

However in 2000 I count TWENTY that made the top 50 list. Here by recent, published in the past five years, I mean a 1996-2000 publication date. Going from twenty down to one is a remarkable decline.

8. **Peter Woit**
February 2, 2007

Who,

To be fair, only in recent years has SPIRES included the astrophysics data. If you exclude astrophysics papers, I suspect a couple more particle theory papers would make the top 50. Still, the change since 2000 has been extremely dramatic.

9. **mclaren**
February 2, 2007

"The active string theorists with blogs (Clifford/Jacques/Lubos) all publicly claim that things are fine with string theory, that at most what is going on is that the field is a bit less active than at some other times."

That parrot's not dead! He's just sleeping!

lovely and apt Pythonism 🙂
John Cleese: This is an EX-PARROT!
http://www.mtholyoke.edu/~ebarnes/python/dead-parrot.htm

11. **woit**
February 2, 2007

I can't resist referring to an ancient piece of creative writing of my own:

http://www.math.columbia.edu/~woit/wordpress/?p=9

12. **Who**
February 2, 2007

From the looks of it, astrophysics has been included since 2001 (and in Peskin's reviews for 2002 and 2003 what gets top billing is already cosmology, after which neutrinos. So I think it is fair to compare the years
2001-2006 (the top 50 have been determined on about the same basis in each year)

2001: 14 recent string papers in top 50
2002: 13 papers
2003: 8 papers
2004: 3 papers
2005: 3 papers
2006: 1 paper, the one you mentioned by KKLT.

recent defined as published in the past five years, e.g. in 2001, published sometime in 1997-2001
Over this time period I don't think the decline can be ascribed to the inclusion of astro-ph because that was done throughout.
Good point though. I will exclude 2000 and earlier, since on quick inspection astro doesn't seem to have been included before 2001.

Shameless Enthusiasm

February 1, 2007
Categories: Uncategorized

The write-up of Larry McLerran's summary talk at Quark Matter 2006 has now appeared. This talk created a bit of a stir since McLerran was rather critical of the way string theorists have been overhyping the application of string theory to heavy-ion collisions.

McLerran explains in the last section of his paper the main problem, that N=4 supersymmetric Yang-Mills is a quite different theory than QCD, listing the ways in which they differ, then going on to write:

Even in lowest order strong coupling computations it is very speculative to make relationships between this theory and QCD, because of the above. It is much more difficult to relate non-leading computations to QCD… The AdS/CFT correspondence is probably best thought of as a discovery tool with limited resolving power. An example is the eta/s computation. The discovery of the bound on eta/s could be argued to be verified by an independent argument, as a consequence of the deBroglie wavelength of particles becoming of the order of mean free paths. It is a theoretical discovery but its direct applicability to heavy ion collisions remains to be shown.

McLerran goes on to make a more general and positive point about this situation:

The advocates of the AdS/CFT correspondence are shameless enthusiasts, and this is not a bad thing. Any theoretical physicist who is not, is surely in the wrong field. Such enthusiasm will hopefully be balanced by commensurate skepticism.

I think he's got it about right: shameless enthusiasm has a legitimate place in science (as long as it's not too shameless), but it needs to be counterbalanced by an equal degree of skeptical thinking. If shameless enthusiasts are going to hawk their wares in public, the public needs to hear an equal amount of informed skepticism.

Another shamelessly enthusiastic string theorist, Barton Zwiebach, has been giving a series of promotional lectures at CERN entitled String Theory For Pedestrians, which have been covered over at the Resonaances blog.

Zwiebach's lectures are on-line (both transparencies and video), and included much shameless enthusiasm for the claims about AdS/CFT and heavy-ion physics that McLerran discusses. His last talk includes similar shameless enthusiasm for studying the Landscape and trying to get particle physics out of it. He describes intersecting D-brane models, making much of the fact that, after many years of effort, people finally managed to construct contrived (his language, not mine, see page 346 of his undergraduate textbook) models that reproduce the Standard Model gauge groups and choices of particle representations. Besides the highly contrived nature of these models, one problem with this is that it's not even clear one wants to reproduce the SM particle structure. Ideally one would like to get a slightly different structure, predicting new particles that would be visible at higher energies such as will become available at the LHC. Zwiebach does admit that these contrived constructions don't even begin to deal with supersymmetry-breaking and particle masses, leaving all particles massless.

He describes himself as not at all pessimistic about the problems created by the Landscape, with the possibility that there are vast numbers of models that agree to within experimental accuracy with everything we can measure, thus making it unclear how to predict anything, as only "somewhat disappointing". He expects that, with input from the LHC and Cosmology, within 10 years we'll have "fully realistic" unified string theory models of particle physics.

The video of his last talk ran out in the middle, just as he was starting to denounce my book and Lee Smolin's, saying that he had to discuss LQG for "sociological" reasons, making clear that he thought there wasn't a scientific reason to talk about it. I can't tell how the talk ended; the blogger at Resonaances makes a mysterious comment about honey…

Finally, it seems that tomorrow across town at Rockefeller University, Dorian Devins will be moderating a discussion of Beyond the Facts in Sciences: Theory, Speculation, Hyperbole, Distortion. It looks like the main topic is shameless enthusiasm amongst life sciences researchers, with one of the panelists the philosopher Harry Frankfurt, author of the recent best-selling book with a title that many newspapers refused to print.

Update: Lubos brings us the news that he's sure the video of the Zwiebach lectures was "cut off by whackos" who wanted to suppress Zwiebach's explanation of what is wrong with LQG.

Update: CERN has put up the remaining few minutes of the Zwiebach video.

Comments

1. **Robert**
   February 2, 2007

   I am not saying that everything is solved in intersecting brane worlds and I would agree that they are only understood as long as susy is unbroken. But if you say that all particles are massless you should say the same about the all the fermions in the standard model. Only the Higgs has a genuine mass terms.

   But just as in the standard model, there are yukawa type couplings between the higgs and the fermions in intersecting brane worlds. Once the Higgs takes a vev (and this is allowed by the equations of motion) the fermions are massive.

   It is one of the features of intersecting brane worlds that left and right handed fermions and the higgs all live at different intersections of pairs of stacks of branes and there is a triangle of branes which has these three particles living at its corner. You can stretch a (euclidean) string (instanton) over this triangle and this gives the yukawa coupling in the low energy theory proportional to exp of minus the area of this triangle. As the families are supposed to arise from multiple intersections of the stacks as they wrap around the torus where all this is living, triangles of roughly equal geometric area give rise to exponentially different yukawa couplings, a feature many find attractive.

   You can say many things about why intersecting brane worlds are not realistic (susy, loads of scalars from bulk moduli) but the mass pattern is one of the pros of these models.

2. **D R Lunsford**
   February 2, 2007

   "String Theory for Pedestrians"

   I suppose this is a typically post-modernist reference to "Lie Groups for Pedestrians", the semi-famous and mega-annoying book by Harry Lipkin. I remember thinking the title offensive, did not regard myself as any kind of pedestrian, and didn't need a boy scout to escort me across the street of math-physics to the far curb of understanding. I think that book was the beginning of the end of my positive attitude about modern mathematics and its practitioners. Instead I decided to learn from fellow pedestrians Lie and Klein.

-drl

3. **D R Lunsford**
February 2, 2007

Looking through the transparencies, one finds the following typical example of sophistry in action:

The String Theory Landscape

String theory shares with Einstein's gravity a problematic feature.

Einstein's equations of gravitation admit many cosmological solutions. Each solution represents a consistent universe, but only one of them represents our observable universe.

Hmm, the last time I checked, this is just an initial-boundary value problem for a set of differential equations combined with a set of massively iffy assumptions about the early conditions in the Universe. What this has to do with the metaphysical ethos of the string landscape is beyond my pedestrian ability to understand. Hey! what did I just step in? TAXI!!

-drl

4. **urs**
February 2, 2007

But that's precisely what that "landscape" is: a space of solutions to something generalizing Einstein's equations.

5. **Peter Woit**
February 2, 2007

Urs,
That's great news. Perhaps you can let us know exactly what the equations are that generalize G=8piT so we can use them to make predictions about the results of experiments.

6. **urs**
February 2, 2007

A string vacuum is a certain 2dCFT. "Geometric string vacua" describing 2dCFTs that can be written as sigma-models are determined by what is called the "string background field equations", which are something like Einstein-Dilaton-Maxwell gravity with various other fields — like those infanmous "fluxes" — and various higher correction terms.

In principle, the "landscape" is the space of solutions of these field equations.

Like in any KK-like theory, physics in 4d is sdetermined by how these solutions look like in the compact directions. There are many such solutions, hence many ways to have physics in 4d.

7. **woit**
February 2, 2007

urs,

From your description, it appears to me that not only do you not know what the exact equations in question are, but you don't even know what exactly what space the equations live on. Perhaps, instead of just telling us that the equations that determine a string background are called the "string background field equations", you could write them out explicitly, or point us to somewhere where this has already been done.

8. **The man**
February 2, 2007

Hey Peter,

Urs is spewing nonsense, but your sneering attitude towards him in the last few posts can't help but remind me of Clifford's attitude towards you in his "tempest" posts.

9. **woit**
February 2, 2007

The man,

Thanks for the good advice.

I do get frustrated by the continuing mystification that surrounds the issue of the current state of attempts to get unified particle physics out of string theory. Opinions can reasonably differ about hopes for the future, but the question of what is now known about string theory ground states is a straight-forward one, and string theorists should stop "spewing nonsense" on the subject.

10. **Q**
February 2, 2007

Asking questions for clarification is not sneering. Clifford, Lubos and Jacques certainly attack because they can't psychologically face string theory's failure as physics.

If you want to see real sneering, ask one of those string theorists about alternatives like Smolin's work.

11. **z3**
February 2, 2007

Another “test of string theory” paper appearing on PRL, by Gary Shui et al. This time, it’s using CMB data to measure the geometry of compact dimensions.

12. **woit**
    February 2, 2007

    z3,
    See my comment about this week’s “test of string theory” in the other thread.

13. **paul**
    February 3, 2007

    Has anyone read this article?
    http://www.ccnmag.com/news.php?id=4789

    Sounds very promising!

14. **Ari Heikkinen**
    February 3, 2007

    You actually make a very good point about the “mystification” issue.

    As far as string theory is concerned, if you ask for something with actual equations, they’d give you a long list of big (and expensive) books to read and then suggest no one would understand them anyway unless they take 5-10 years courses in somewhere like Harvard (and it works, I’m still curious about what’s so special there in string theory math).

    So my question still remains: is there any single (self contained) book (or whatever) with equations, say something like 500+ pages that would explain what’s in Greene’s book with actual equations? There’s been many suggestions, but buying them all would surely be waste of money..

15. **a.n. onymous**
    February 3, 2007

    No, it wouldn’t be a waste of money from the perspective of the authors of those books. You can’t have too much learning…

16. **woit**
    February 3, 2007

    Ari,

    I haven’t actually seen the book, but from its table of contents the new Becker-Becker-Schwarz book sounds like the closest thing to what you are looking for. It is 700 pages of difficult material, and really understanding this is definitely a multi-year project. Then there’s the problem that the book doesn’t actually seem to really explain how bad and generic the problems of this research program are, or that any contact with experiment is at best far in the future, at a time-scale that is receding into the distance…

17. **luzo**
    February 3, 2007

    “It should be said at the outset that, as of yet, there has been no experimental verification of string theory. Also, no sharp prediction has been derived from string theory that could help us decide if string theory is correct.”

    Quote from Zwiebach’s book (chapter 1.3 right at the beginning).
    This seems very reasonable to me and in stark contrast with say Kaku’s claim that one could prove string theory using only pure mathematics.

    The part I’ve seen from his lecture at CERN follows the same spirit as this quote from the book.

18. **Uncle Enzo**
    February 4, 2007

    About this CMB test of string theory, first of all you need sensitive enough data. Let’s suppose you have this. Doesn’t the article assume there are extra dimensions in the first place? Obviously you can come up with another explanation for the CMB patterns which don’t assume extra dimensions. Plus, let’s suppose you narrow down the possibilities of geometries with the data. If the resulting 4D physics (at low energies) doesn’t match what we observe, then there’s a piece of evidence falsifying string theory.

19. **Q**
    February 4, 2007

    ‘If the resulting 4D physics (at low energies) doesn’t match what we observe, then there’s a piece of evidence falsifying string theory.’

    But string theorists can take all falsification to be a mere ‘anomaly’, as they already do with failures of string theory already (supersymmetry falsely suggests a really massive cosmological constant, for example). Science doesn’t come from experimental disagreement, because the theory gets modified, just as general relativity getting a small positive CC in 1998 to fit observations:

    ‘Scientists have thick skins. They do not abandon a theory merely because facts contradict it. They normally either invent some rescue hypothesis to explain what they then call a mere anomaly or, if they cannot explain the anomaly, they ignore it, and direct their attention to other problems. Note that scientists talk about anomalies, recalcitrant instances, not refutations. History of science, of course, is full of accounts of how crucial experiments allegedly killed theories. But such accounts are fabricated long after the theory had been abandoned. … What really count are dramatic, unexpected, stunning predictions: a few of them are enough to tilt the balance; where theory lags behind the facts, we are dealing with miserable degenerating research programmes. Now, how do scientific revolutions come about? If we have two rival research programmes, and one is progressing while the other is degenerating, scientists tend to join the progressive programme. This is the rationale of scientific revolutions. … Criticism is not a Popperian quick kill, by refutation. Important criticism is always constructive: there is no refutation without a better theory. Kuhn is wrong in thinking that scientific revolutions are sudden, irrational changes in vision. The history of science refutes both Popper and Kuhn: on close inspection both Popperian crucial experiments and Kuhnian revolutions turn out to be myths: what normally happens is that progressive research programmes replace degenerating ones.’

    – Imre Lakatos, ‘Science and Pseudo-Science’, pages 96-102 of Godfrey Vesey (editor), ‘Philosophy in the Open’, Open University Press, Milton Keynes, 1974.

20. **Robert**

February 5, 2007

In case anybody is really interested in how to compute corrections to G=8pi T here is what you have to do: Write down the sigma model for a string propagating in an arbitrary background geometry given in terms of G,B and phi (let's take RR fluxes to be 0 for the moment or use Berkovitz' formalism). Then do a world sheet loop computation (i.e. expansion in alpha' which plays the role of hbar in that theory) of the beta functions (in terms of G, B, and phi). For any order of alpha' this is a well defined procedure and there is no arbitrariness. Then you get the background equations of motion by requiring the beta functions to vanish. This is explained in detail in GSW Ch. 3.4 at the one loop level (i.e. the first alpha' correction) and has been computed if I am not mistaken up to four loops.

This should answer your question of how string theory generalised the Einstein equation. I described a perturbative computation but this is not any worse than elsewhere in particle physics.

21. **woit**
February 5, 2007

Robert,

The problem with the perturbative calculation you suggest is that it doesn't lead to something realistic with broken supersymmetry and stabilized moduli. For this you need non-perturbative phenomena: where are branes in your calculation?

This is the difference between string theory and standard QFTs used in particle physics. In string theory the perturbative ground state doesn't give you what you want, so you make some assumptions about what possible ground states may come out of the full theory, ending up with an incredibly complex set of possibilities. In the Standard Model, the electroweak ground state is exactly the unique perturbative one, which you understand well, and for the QCD ground state you have a well-defined non-perturbative theory that you can use to calculate numerically what it is, and get a unique answer.

What if you didn't know how to formulate QCD non-perturbatively, perturbative QCD didn't correspond to anything observed, and people went around claiming that non-perturbative QCD, whatever it was, led to a huge number of different possible ground states, so many that you couldn't use the theory to predict anything. Would anyone take this seriously?

22. **andy**
February 5, 2007

I really "liked" this comment of Lubos's, in reference to Zwiebach's lectures:

The goals of high-energy theorists have always been, are, and will be much more ambitious and abstract than a particular dirty experiment, whether or not an unrefined and uncultural observer of science likes it or not. Barton's focus only reflects the experimental character of the location where he gave the lecture.

23. **Thomas Larsson**
February 5, 2007

The problem is not that string theory disagrees with a particular dirty experiment, but that it disagrees with pretty much **every** dirty experiment, to the extent that it says something about reality at all.

I realize that I might sometimes sound wacky, but in one respect I am very conservative: I simply don't think that disagreement with experiment is a good thing.

24. **andy**
February 5, 2007

I hope it's clear that "liked" = ROTFL!

25. **Thomas Larsson**
February 5, 2007

Andy, sorry!

26. **andy**
February 5, 2007

Thomas, no problem. It's hard to be nuanced on a blog.

27. **wolf**
February 5, 2007

much more ambitious and abstract than a particular dirty experiment,

Delubosional… 🙂

28. **Coin**
February 5, 2007

> They're trying hard, using various tools from Germany of the 1930s they can find, to hide the simple fact that every informed person knows about the status of that theory, namely that loop quantum gravity almost certainly doesn't work – and the two recent popular books are cheap porn for undemanding consumers. It has become effectively impossible to both report about the actual current status of physics as well as to keep the talk publicly available.
>
> I wonder what percentage of the talks will have to be doctored, preordained, or censored before other people start to realize that there is a problem. Be sure that once more than 50% of talks are doctored or censored, it will already be too late because those who don't exactly believe that science should be made by free scientists who are not intimidated will already be in charge.

Huh?

29. **woit**
February 5, 2007

"cheap porn for undemanding consumers"

People have complained that the book is too hard for the average reader, maybe I should get the publisher to put the above blurb from Lubos on the back cover.

30. **Robert**
February 6, 2007

Peter, I don't understand your reply. I fail to see how the choice of vacuum influences this beta function calculation which is in some sense local at a point on the world-sheet. It is one way to obtain the low energy field equations and all discussions of KKLT etc of the many vacua actually talk about the _solutions_ of these equations. There is little doubt about the equations.

I had thought the standard line of attack here would have been to mention that the corrections are alpha' corrections and are thus important only if center of mass momenta get close to the Planck scale and are thus unlikely to observe in the real world soon. Which is followed by a philosophical discussion if this theory is really a different theory from GR from which it doesn't differ at everyday energies.

31. **woit**
February 6, 2007

Robert,

You can choose any background you want and try and do perturbative string theory on it, but string theorists keep telling us that string theory is a unique theory with no adjustable parameters. The theory is supposed to tell us what the possible lowest energy (or metastable) states of the theory are. Doing this requires a full non-perturbative string theory, and no one knows what this is.

32. **urs**
February 6, 2007

> Doing this requires a full non-perturbative string theory…

That might be.

But, by definition, the "landscape" of string theory is the space of "perturbative vacua" which, in string theory, is a space of certain 2d CFTs. For a subset of these (the geometrical ones), this space is the space of solutions of a generalization of Einstein's equations.

DRL's quote, which got this discussion started, is therefore accurate in the realm of perturbative string theory.

33. **woit**
February 6, 2007

Urs,

The "landscape" of string theory is supposed to be the set of all vacuum states (or metastable states) of string theory, this is what is physically relevant. Again, you can't actually know what this set is until you have a non-perturbative string theory.

34. **Robert**
February 6, 2007

Peter, you are moving the goal posts. The question was

> Perhaps, instead of just telling us that the equations that determine a string background are called the "string background field equations", you could write them out explicitly, or point us to somewhere where this has already been done.

I gave you the answer and now you complain that I did not answer the different question "What are the vacua of string theory?". The corrections to Einstein's equations can be computed without knowing the answer to the second question.

35. **Peter Woit**
February 6, 2007

Robert,

These are questions about physics, so what I was asking for is something that answers a question about physics. I don't doubt that you can write down equations that no one knows how to connect to physics, I'm claiming you can't write down equations that answer physical questions.

In particular, I don't believe that, from string theory, without knowing which vacuum state we're in you can write down a universal modification of Einstein's equations. Without knowing the vacuum state you don't even know how many large dimensions there are or what the string coupling is.

As Lisa Randall once pointed out: "sure, string theory predicts GR… in 10 dimensions".

36. **urs**
February 6, 2007

Since it seems we are arguing about a definition, let's look at the literature to see what people actually do when they say they study the "landscape".

The review
Fux Compactifications
http://arxiv.org/abs/hep-th/0610102

by Douglas and Kachru might help.

They go through lots of examples, write down the generalized Einstein actions of string theory background fields and find the solutions to their equations of motions.

For instance take the first example, p. 29. The generalized Einstein-Hilbert action of relevance is equation (36), the ansatz for solving its equations of motion (finding its extrema) starts in equation (41).

You can search for "Einstein equations".

They also do discuss (p. 4) that invoking "nonperturbative effects" is one aspect done in this business, but necessarily so. So if you don't believe in these nonperturbative effects there is still a lot of ordinary landscape remaining.

Finally, maybe one comment: unfortunately this review does seem to take that as granted, but it might be worth pointing it out: the very reason for calling these solutions to the string background equations — which, recall, determine conformal sigma-models — “vacua” is that given any such 2-dimension CFT in perturbative string theory we imagine regarding its n-genus correlators to be the n-loop amplitudes of a perturbative expansion of something about that very “vacuum”.

37. **Peter Woit**
February 6, 2007

urs,

The equation you point to has an undefined term in it that the authors call “S_loc” which they don’t specify other than to say that this is where you can put in things like D-branes and orientifold-planes. A non-perturbative theory is ultimately required to know what consistent choices can be made for such terms, as well as to understand whether these equations actually correspond to a valid approximate calculation in a ground (or metastable) state of the theory.

38. **urs**
February 6, 2007

I’d think D-branes and orientifold planes would still be part of the perturbative landscape, in that they are captured just by looking at 2-dimensional CFT: backgrounds with these features still correspond to points in the space of 2-dimensional superconformal QFTs with central charge 15.

But I do completely agree that whenever some author invokes aspects of “nonperturbative string theory” it might at best be a well-motivated guess.

I also agree that it might be that perturbative string theory is phenomenologically unviable, that there is no hope to get reasonable physics from studying the “perturbative landscape”, i.e. the space of c=15 2d SCFTs. Might be.

All I wanted to say is that the “perturbative landscape” of string theory — despite its silly name and the fact that we have no good real understanding of it at all and no matter how much we trust its prospects regarding phenomenology — is a well defined mathematical entity — and that many points in this space do indeed correspond to solutions of (natural) generalizations of Einstein’s equations.

39. **Robert**
February 6, 2007

The number of large dimensions or the value of the coupling constant are properties of the solutions to these equations not of the equations. And these equations definitely hold outside the branes in the bulk. And this equation is easy to check: just create some Planck scale curvature using some mass/energy distribution, and measure the graviational (and other) fields. Then you can check if they obey these alpha’ corrected equations. This should be independent of the vacuum you select at infinity. And if the coupling (in terms of the dilaton) is not too big, non-perturbative corrections should as well be controlable (being of order e^-1/g or smaller).

40. **Peter Woit**
February 6, 2007

Robert,

So, your modification of Einstein’s equations depends on which ground state you’re in, but knowing what these ground states actually are depends on knowing what non-perturbative string theory is (which you don’t).

What people are talking about often when they talk about a”string theory background” is some sort of semi-classical approximate ground state built on a specific 10d geometry, adding branes, fluxes, etc. The problem is, without knowing the underlying non-perturbative theory, you don’t know how well these reflect an actual ground state of the theory. You can argue that for special regions of parameter space you expect the semi-classical approximation to be good, but generically there’s no reason to expect this.

So, the equations you are trying to sell as analogous to G=8piT come in an infinite number of sets of equations, you don’t know what space parametrizes this infinite number, and whatever it is, on most of it these equations reflect an approximation which is probably no good and has nothing to do with physics.

I still think there’s a problem with the analogy of solutions in GR and string backgrounds….

41. **Aaron Bergman**
February 6, 2007

So, your modification of Einstein’s equations depends on which ground state you’re in, but knowing what these ground states actually are depends on knowing what non-perturbative string theory is (which you don’t).

How exactly did you go from what Robert said to that?

42. **woit**
February 6, 2007

Aaron,

Actually this discussion has gone far from the original origin which was Urs’s claim that the Landscape is just like solutions to G=8piT.

As for what I wrote, is it or is it not true that the modification of Einstein’s equation in string theory depends on the background (i.e. ground state)?

43. **Aaron Bergman**
February 7, 2007

In the perturbative string? No. The condition is just that the sigma model be conformal. You write down a general sigma model and write down the beta-functions. It’s done in Polchinski I.3.7, for example.

44. **urs**
February 7, 2007

And the beta functions one gets are, incidentally, for strings in pure gravitational and dilaton backgrounds, those used by Perelman to complete Hamilton’s program of solving the Poincaré conjecture.

45. **Peter Woit**
February 7, 2007

Aaron,

I know the argument in Polchinski, which deal with backgrounds large compared to the string scale. My question is whether this holds once you introduce other structures a la KKLT to stabilize the moduli.

46. **Aaron Bergman**
February 7, 2007

The perturbative string should properly be thought of as giving equations on the set of 2D QFTs of which sigma-models are only a part. The solutions to these equations are the 2D CFTs. (This is background independent on the classical level. To do background-independent quantization is trickier.)

When you start talking about moduli stabilization, however, one is talking about the 4D effective theory. This, by necessity, depends on the choice of compactification. Nonetheless, the theory is what you get from compactifying the string theory equations on your choice of CY. The final issue is the question of nonperturbative corrections. These are dealt with on a somewhat ad hoc basis in string theory because we a nonperturbative formulation of string theory in general. These do depend on the choice of background, ie, solution to the equations of motion. But this isn't particularly different than how one deals with instantons in ordinary QFT.

47. **Amos Dettonville**
February 7, 2007

Is Lorentz invariance optional in any of the known approaches to string theory? J. Distler's paper implies that Lorentz invariance (among other things) is a necessary attribute of string theory, or at least of what he calls "canonical string theory", whereas others seem to argue that string theory could be pursued in a non-Lorentz-invariant context. Can anyone clarify this? Does the "landscape" of possible string theories include some in which Lorentz invariance does *not* hold?

A related question: Is the "landscape" outside of what Distler calls "canonical string theory"? If so, at what point would the "landscape" become canonized?

48. **Nature**
February 8, 2007

"and that many points in this space do indeed correspond to solutions of (natural) generalizations of Einstein's equations."

Urs, what do you mean by 'natural'?

49. **urs**
February 8, 2007

> Urs, what do you mean by 'natural'?

On the one hand, nothing deep. I just added this remark to indicate to those who didn't know it that its not a bunch of weird generalizations in all kind of silly directions, but just the natural kind that you would expect: everything remains generally covariant, with various fields (p-forms, spinors, etc) all appearing coupled to GR in terms of scalar invariants cooked up from covariant derivatives.

While I think there is a also a deeper sense in which the string background equations are "natural", this is here not the place to discuss that. Suffice it to say that these generalizations are not chosen by hand but all appear automatically from an underlying principle. And not just in string theory #.

50. **Robert**
February 8, 2007

Urs, while I agree with your notion of naturalness you should not forget to point out that the naturalness is of the form of the equations but there are numerical coefficients for which a range of values would be natural but which get specific values in string theory. How many of them there are depends of course on the symmetries you assume your theory to have (for example N=8 susy fixing a lot of relations).

51. **Peter Woit**
February 8, 2007

Urs and Robert,

You both insist on discussing features of string theory backgrounds that are known not to correspond to the real world. The real world is not N=8 supersymmetric. It's highly misleading when you promote string theory by promoting aspects of it that are known to be completely inconsistent with its use as a unified theory that corresponds to the real world.

52. **urs**
February 9, 2007

Robert,

right. I vaguely indicated that there is more to the effective string background action than just being a form of GR coupled naturally to various sorts of matter. As you indicate, it is not just any coupling of dilaton, p-forms, spinors, etc to gravity, but a very particular one.

53. **urs**
February 9, 2007

> You both insist […]

We are just ansering a technical question:

"In which sense is a point in the landscape like a solution of Einstein's equations."

Answer: "From the point of the perturbative formalims: in every sense."

Clarifying this technical question is independent of evaluating its implications for phenomenological physics.

> It’s highly misleading when you promote string theory […]

I think in this thread neither Robert, Aaron nor me has done any promotion. I need to promote string theory no more than I need to promote, say, the tricategory 3Grp.

In order to clarify facts (facts like: “what *is* a point in the landscape, *technically*“) it helps to pause for a while with promoting this or that.

54. **Robert**
February 9, 2007

Maybe Peter is right and there is no point of discussing technical facts about theories. Maybe it’s better to make just claims and not discuss if details of these claims are right or wrong.

But still, just for the record, since there still seems to be some confusion: You have to differentiate between the theory (i.e. the equations of motion) and the state. All we are saying is that there are certain parts of the theory that are considered to be well understood (here: corrections to the classical equations of motion) while Peter keeps saying “but you don’t know the state” which is true but irrelevant for the first question as we try to argue. In addition, I see no reason why the world cannot be in a state with completely broken supersymmetry of a theory which has N=8 susy.

All the trouble with (absence of practically performable) experimental checks of string theory is that generically low energy questions depend crucially on the state (which as I said is unknown) while high energy questions (e.g. Regge scaling, higher curvature corrections) tend to be less dependant on the vacuum you are in.

55. **Peter Woit**
February 9, 2007

Robert,
I never said there is no point in discussing technical facts about theories. My only point is that if you are going to make claims about how the equations of string theory are “natural” and much like the equations of GR, you need to make clear if you are talking about some approximate version of string theory that can be rigorously shown to have nothing to do with the real world, or about a version of string theory that is a candidate for a unified theory.

Urs did helpfully reference a precise source for the equations he was discussing as “natural”. I pointed out to him that those equations contain explicitly an undefined term the authors call “S_loc” where they put in ad hoc contributions which are necessary to stabilize moduli, and which I don’t believe can reasonably be called “natural”.

As for you argument that string theory predictions at high energy don’t depend on the state, I don’t buy it. There seems to be an ideology among string theorists that the vacuum state, which governs what we can actually m easure, is a non-perturbative phenomenon (and thus we don’t know what it is), but that higher energy states (at energies we have no hope of probing) can be studied perturbatively. I see no reason for this to be true about the universe other than wishful thinking.

56. **onymous**
February 9, 2007

There seems to be an ideology among string theorists that the vacuum state, which governs what we can actually measure, is a non-perturbative phenomenon (and thus we don’t know what it is), but that higher energy states (at energies we have no hope of probing) can be studied perturbatively. I see no reason for this to be true about the universe other than wishful thinking.

Why not? It’s true of plenty of field theories. A lot of the nonperturbative stuff invoked for moduli stabilization is really just ordinary field theory (e.g. gluino condensation).

57. **Peter Woit**
February 9, 2007

onymous,

It’s not true for theories like QCD where the vacuum state is a truly non-perturbative phenomenon, and you can’t understand the higher energy states just using perturbation theory.

There are other arguments for why you won’t necessarily see 10d weakly-coupled string behavior (Regge trajectories) at high energy. What about M-theory? What about black holes?

The problem is that, not knowing what non-perturbative string theory is, string theorists are invoking it when perturbative string theory gives them something that disagrees with observation, then saying it can be ignored when they claim they can make predictions (safe from ever be confronted with experiment) at high energy.

58. **Anon**
February 9, 2007

“It’s not true for theories like QCD where the vacuum state is a truly non-perturbative phenomenon, and you can’t understand the higher energy states just using perturbation theory.”

The high energy behavior of QCD isn’t given by perturbation theory?

Really?

59. **Amos Dettonville**
February 10, 2007

On the question of whether Lorentz invariance is necessary for string theory, here’s what Smolin says in Ch 14 of The Trouble with Physics, where he talks about the possible breakdown of special relativity:

“String theory predicts that no matter how distant their sources are from one another, photons of different frequencies travel at the same speed. As we have seen, string theory does not make many predictions, but this is one; in fact, it’s the only prediction of string theory that can be tested by present technology… [[Interesting that Smolin wrote this prior to the recent announcements about the possibility of testing string theory]] …

“Would string theory survive…? Certainly all known string theories would be proved false, since they depend so heavily on special relativity holding. But might there still be a version of string theory that could be consistent with [the breakdown of Lorentz invariance]? Several string theorists have insisted to me that even if special relativity were seen to break down or be modified, there might someday be invented a form of string theory that could accommodate whatever the experiments see… There are a lot of ways to change the background of string theory so that there is a preferred state of rest… What puzzles me is why string theorists think this helps their cause… To me it’s more an indication that string theory is unable to make any predictions…”

Well, not being a specialist in this field, I must say that while I appreciate Smolin at least addressing the question directly (which hardly anyone else seems willing to do), the answer is slightly odd, because Smolin has worked in the area of string theory, and yet his only way of even trying to answer this fundamental question is to refer to what some un-named string theorists have insisted to him. The way he phrases it, it seems clear that he himself doesn't feel qualified to answer this question, although he does add the remark that "there are a lot of ways to change the background so there is a preferred frame". If this is true, then why does he need to rely on the un-named string theorists to "insist" to him that it is possible?

I suppose this just illustrates that one can't ever really falsify a research program, since a program can also change course and accommodate new information. Theories may be falsified, but research programs just fade away if and when people lose interest. Still, I find it troubling that even respected specialists in string theory don't know such a fundamental thing about their theory, as whether or not it must be Lorentz invariant.

One other comment: Smolin says the known versions of string theory ASSUME Lorentz invariance. He does not say they predict it, nor have I ever heard anyone else claim that string theory predicts Lorentz invariance. We don;t start with a tabula rosa, and miraculously deduce Lorentz invariance from the string principle (or some such thing). Rather, Lorentz invariance is simply assumed, as a postulate. Hopefully it's clear that the possibility of falsifying a postulate or assumption of a theory is quite different from falsifying a prediction of a theory. Likewise, when one says "string theory makes no falsifiable predictions" this is quite different from saying "the known string theories don't assume any physical principles that can be falsified". The former is the charge of the critics of string theory, whereas Distler et al are really only addressing the latter, which is at best only tangentially relevant to string theory.

60. **woit**
February 10, 2007

Anon,

Yes, really. The spectrum of states in QCD above the ground state consists of protons, neutrons, pions, etc., not free quarks and gluons. This spectrum is the analog of the Regge trajectories people claim that string theory predicts.

Asymptotic freedom and the ability to use perturbation theory to study scattering in certain high energy regimes is a different issue.

61. **anon.**
February 10, 2007

The spectrum of states in QCD above the ground state consists of protons, neutrons, pions, etc., not free quarks and gluons. This spectrum is the analog of the Regge trajectories people claim that string theory predicts.

In fact, the spectrum of QCD *does* at least approximately consist of Regge trajectories, if you go to large N_c. But real-world QCD has 3 colors, and violations of quark-hadron duality die off: at large s, rho(s) ~ constant. So in real-world QCD, perturbation theory does work at least for many quantities at large momentum, whether Euclidean *or* Minkowski.

(This is not to say that perturbation theory is any good for things like the total proton-proton cross section at high energy, of course. But you said the spectrum.)

62. **woit**
February 10, 2007

anon,

I was giving QCD as an example of a QFT where non-perturbative QFT determines both the ground state and the states above the ground state. Perturbative QCD just doesn't work at all here, for either the ground state, or for the states above the ground state (these states cannot be understood in terms of gluons and free quarks).

Whether QCD states can be understood in terms of perturbative string theory is a completely different issue. The problem there is not that you don't know the ground state because it is determined non-perturbatively, the problem is that you don't know what the string theory is.

63. **anon.**
February 10, 2007

By "higher energy states", I assumed you meant "states well above the QCD scale", since that's what the other Anon seemed to be talking about. And perturbation theory is perfectly good there, in a precise sense.

The states in QCD are, obviously, created by gauge-invariant operators acting on the vacuum. A two-point function of gauge-invariant operators can be expressed in terms of a spectral function rho(s). For s >> Lambda_QCD, perturbation theory calculates this up to small corrections by analytically continuing the Euclidean result and taking the discontinuity across the cut.

Of course resonances appear at small s and are not calculable in perturbation theory. But large s is perturbative. So it is not true that perturbative QCD doesn't tell you about states above the ground state, if you go to sufficiently high invariant mass.

64. **Peter Woit**
February 10, 2007

anon,

I don't think

"the vacuum state is a truly non-perturbative phenomenon, and you can't understand the higher energy states just using perturbation theory."

or

"The spectrum of states in QCD above the ground state consists of protons, neutrons, pions"

was in any way ambiguous. I was talking about the states of the theory above the ground state, precisely the analog of the low-lying states in Regge trajectories that string theorists always say are a prediction of string theory, despite the non-perturbative nature of its ground state. The question of what happens at very large invariant mass is a quite different one. I was obviously not making claims that there is no kinematical regime in which perturbation theory is useful in QCD, but was referring explicitly to a regime where it clearly isn't.

Again, I seem to never be able to get string theorists to address this point: if the ground state is determined by some unknown non-perturbative string theory mechanism, why do string theorists often claim that they can reliably use perturbative string theory to predict the energies of the low-lying states (the ones lying on a Regge trajectory) above the ground state?

65. **Moshe**
February 10, 2007

Strong feeling of deja vu, but let me try…if the string coupling is zero there are a bunch of massless modes (moduli) and a bunch of massive modes lying on Regge trajectories, giving characterisitc soft scattering etc. etc., This is the picture to zeroth order in the string coupling.
\
Working in small but non-zero coupling and including the tiny corrections due to instantons, gluino condensation, small fluxes etc. all those masses shift a tiny bit. This does not change the picture much, except that the would be massless modes are now massive, with a tiny mass compared to the string scale.
\
The analogy to QCD is misleading since the coupling is small, and consequently all non-perturbative effects are tiny. The vacuum and all massive modes are still approximately the perturbative ones.

66. **Peter Woit**
February 10, 2007

Thanks Moshe,

One comment is just that your argument assumes very small string coupling, for generic values of the string coupling there's no reason to believe that Regge trajectories etc. persist.

But I'd really like to understand exactly what the status of the KKLT backgrounds is. Besides the effects you mention, they need to invoke the introduction of a specific set of anti-D3 branes. With these, is everything really under control? Gross seems to be fond of claiming (see his remarks in Toronto a couple weeks ago) that since one doesn't understand non-perturbative string theory, there is no reason to believe that these constructions give you consistent vacuum states, especially in a cosmological context. Is he wrong? If he's right, and non-perturbative effects can destabilize these states, how do you know they won't destabilize higher states?

I'm willing to accept that it's possible that string theorists can come up with a self-consistent scenario involving vacuum states whose properties are under control, modulo some assumptions about the true non-perturbative theory, and in such a scenario you get Regge trajectories, etc. But even so, this is just going to then be a small corner of the landscape. Generically you're not going to have perturbative control, so can't claim that "if we just had a big enough accelerator, string theory predicts we'd see Regge trajectories".

67. **Moshe**
February 10, 2007

I am not sure what Gross referred to, I would have to look at the talk. It is true that one is always limited to constructions with calculational control. In such perturbative constrcutions Regge behaviour is a robust feature. Even if there are non-perturbative corrections invalidating the claims about the vacuum, the Regge behavior would still be there as long as the coupling is small.

68. **Peter Woit**
February 10, 2007

Moshe,

I'm not sure I'm convinced that if non-perturbative corrections make your vacuum state no longer a vacuum state they won't have significant effects on higher energy states. And, if unknown non-perturbative effects need to be understood to find the true vacuum state, in general I see no reason why they might not affect the Regge behavior of higher states.

Gross's comments were in the context of a public debate over anthropics. He said what he has said in many other talks: no reason to accept the landscape since we don't know what string theory really is, suspect that space and time are emergent phenomena but don't know what they really are, don't understand time-dependent backgrounds necessary for a consistent cosmology.

69. **Arun**
February 10, 2007

You may want to listen to Nima Arkani-Hamed's Perimeter seminar of Feb 8, where the claim is that given the small positive cosmological constant and the neutrino masses where they are, and the Standard Model in 3+1 dimensions, there is a landscape of vacua with one dimension compactified. i.e., given the Standard Model Lagrangian, you cannot compute the ground state.

70. **Peter Woit**
February 10, 2007

Arun,
I did watch the beginning of that talk, but didn't have time to watch the whole thing. Not clear to me what the point was, perhaps that you can ruin the Standard Model and make it as useless as string theory by replacing our 3 large flat spatial dimensions by various compactifications. Just seems like a good demonstration of why you shouldn't study these kinds of backgrounds.

71. **Arun**
February 11, 2007

Peter,

My initial reaction was the same as yours. But!

If the arguments hold up, it means if given } a 3+1D QFT + General Relativity + small positive cosmological constant + massless/light degrees of freedom like the Standard Model (i.e., the photon, graviton and light neutrinos)}, then that model has an infinite number of compactified vacuums, apart from the 3 large flat spatial dimensions vacuum. I presume that the only reason we didn't see this before is because we didn't look, we assumed that the 3 large flat spatial dimensions vacuum is the natural and the only vacuum solution.

I also gathered that this is not a generic problem with QFT + GR, but rather a problem with models that are like the Standard Model at low energy and that have a small positive cosmological constant. In other words, we are fine-tuned to have a landscape in the Standard Model!

Without any reference to string theory, the Standard Model + GR has a landscape problem. Of course, the anthropic solution is simple in this case, it involves only one choice, we pick the vacuum with the large flat spatial dimensions, because that is the one we live in, and that is that. But unless there is a physical/mathematical argument that rules out the compactified vacua, philosophically, we are not very far from the string theory landscape issue.

-Arun

72. **Q**
February 11, 2007

'… the Standard Model + GR has a landscape problem. Of course, the **anthropic solution is simple in this case, it involves only one choice, we pick the vacuum with the large flat spatial dimensions, because that is the one we live in,** and that is that. But unless there is a physical/mathematical argument that rules out the compactified vacua, philosophically, we are not very far from the string theory landscape issue.'

I disagree; the case of knowing the right solution from observations (three flat spatial dimensions) is not an anthropic selection. That's observational input, not anthropic reasoning.

Anthropic solutions are entirely different. Suppose a metastable vacuum which produces the SM is discovered in the string theory landscape. You would defend that solution by the anthropic argument, not because you have directly observed the Calabi-Yau manifold on the Planck scale and determined the right solution by direct observation.

Anthropic solutions are based on *indirect reasoning* not directly observing the type of dimensions. I.e., Hoyle said predicted the cross-section for the triple alpha fusion to create carbon because he ruled out other paths and knew carbon exists, not because he observed the triple alpha process in the lab.

There's no similarity between the anthropic selection of a SM from the string theory landscape, and the landscape of GR or SM where you aren't using the anthropic principle to select a solution, you are using direct empirical evidence about the dimensions etc. to choose a solution.

73. **student**
February 11, 2007

"I disagree; the case of knowing the right solution from observations (three flat spatial dimensions) is not an anthropic selection. That's observational input, not anthropic reasoning."

To me the "observational input" argument sounds just like the anthropic agrument. Here is why: We know the right solution from observations because we can make those observations in the first place. If the SM vacuum were AdS_3XS_1 instead of dS_4 we would not be here to make those observatons and use the three flat spatial dimentions as the input.

In other words, the "observational input" argument still DOES NOT EXPLAIN "Why?" the SM vacuum is dS_4 and not AdS_3XS_1. "Observational input" must have an explanation, don't you think?
According to Nima, the SM Largangian plus Gravity with a tiny CC has a huge landscape of vacua. Finding a selection mechanism, other than "observational input", such that the dS_4 vacuum is selected by dynamics would be a much more compelling answer.

74. **Amos Dettonville**
February 11, 2007

I agree with "Q" that the GR and SM solutions are based on direct empirical observation, not on indirect anthropic reasoning. On the other hand, I think Arun's comment highlights the need for one other ingredient, namely, Occam's razor. We can't claim that if there were compactified dimensions we would be able to directly observe them. If they existed, we would only be able to infer their existence indirectly, by the effect(s) they have on observable physics. Now, we have not, so far, observed any physical phenomena that imply the existence of compactified dimensions, but it doesn't follow that we can confidently extrapolate this to make predictions about new (previously unexamined) phenomena. I guess what Arun is saying is that, lacking some kind of generic argument ruling out compactified dimensions, the ability of GR/SM to make *predictions* outside out existing base of experience is placed in doubt. I understand that argument, but I don't think it carries much weight against GR/SM, because they adhere fairly closely to Occam's razor, i.e., they propose the simplest vacuum consistent with observation. Granted, we *could* postulate more complicated vacuua with unseen dimensions, but we choose the simplest one that works. This choice is fairly unambiguous, and although it is vulnerable to falsification (i.e., we can't be absolutely certain that the results extrapolate into new territory), this falsifiability is a good thing. Each time GR and/or SM avoid falsification in a new observation, it is justifiably counted as a success for those theories.

In contrast, if we have a theory that is intrinsically committed to the existence of many unobserved compactified dimensions, but which provides no unambiguous criteria for specifying those dimensions, then we are in a much more problematical position, because we are precluded from applying Occam's razor to simplfy down to a falsifiable theory. We face a hugh number of highly complex theories, with no clear way to choose between them. This is especially disappointing considering that the original excitement surrounding string theory was that it seemed to be leading toward a unique mathematically consistent theory. I know some people still hold out hope that a unique solution may emerge (a position that Susskind has characterized as "faith-based"), but as it stands today, it seems that the most salient attribute of string theory is its NON-uniqueness.

75. **woit**
February 11, 2007

Arun,

I still think that trying to claim that the most successful physical theory ever developed, which makes an absurdly large number of very non-trivial predictions which all agree completely with experiment, is on the same footing as a theory which predicts nothing is just silly sophistry.

I've made this point repeatedly, but here it is again in this context: the point is that the SM vacuum state is exceedingly simple and symmetric. It is not some random background of huge complexity based on choosing a complicated compactification, fluxes, D-branes, etc., etc. It is this simplicity that makes the theory predictive. There would be a compelling string model worth taking seriously if a simple choice of background led to something that didn't disagree with what we know about physics. The problem with string theory is that getting it to look like the real world involves adding in a Rube Goldberg-like array of complicated mechanisms designed to evade the fact that simple mechanisms don't work. This is the hallmark of what happens when you start with a wrong theory and try and make it agree with experiment.

Sure, you can ruin the predictivity of the Standard Model and make it not agree with experiment by putting it in a complicated background. So what???

76. **student**
February 11, 2007

"I don't think it carries much weight against GR/SM, because they adhere fairly closely to Occam's razor, i.e., they propose the simplest vacuum consistent with observation."

SM +GR do not propose/select the vacuum. The observational fact that we live in dS_4 is used as input but not explained. To me, the Occam's razor argument would select a 4D Minkowski vacuum as the simplest, not a dS with a tiny cosmological constant – indeed, a very unnatural choice!

"Sure, you can ruin the predictivity of the Standard Model and make it not agree with experiment by putting it in a complicated background. So what???"

Peter, what exactly do you mean by the "complicated" background?

Is 4d Minkowski less complicated than dS_4? So, why do we live in dS _4 and not in Minkowski vacuum? The "absurdly large number of very non-trivial predictions which all agree completely with experiment" would be "ruined" if our vacuum were AdS_3XS_1 instead of dS_4, according to Nima. The point is that there is no dynamical mechanism in the SM + GR which would select the vacuum. So, the ony option so far is to use the "observational"/anthropic argument to "explain" it.

77. **student**
February 11, 2007

Correction:

The "absurdly large number of very non-trivial predictions which all agree completely with experiment" would NOT be "ruined" if our vacuum were AdS_3XS_1 instead of dS_4, according to Nima.

78. **woit**
February 11, 2007

student,

As I wrote, I didn't watch all of Arkani-Hamed's talk, and I still have no idea whether he had a more serious point to make than the silly one about "the standard model has a landscape problem just like string theory" which is all I was getting from Arun's summary.

deSitter space is not that much less simple than Minkowski space, (it's also a homogenous space).

79. **student**
February 11, 2007

Peter,
The statement that "the standard model has a landscape problem" is not silly. Nima's discovery that the SM is just as happy to live in AdS_3XS_1 as opposed to dS_4 with a very tiny CC begs for an explanation as to why we ended up in the latter. To me, a 4d Minkowski vacuum seems to be a more "simple"/"natural" outcome than either of the two choices above. This "SM landscape" problem may be in the same category as the "string landscape" problem. It is the question of identifying a correct vacuum selection mechanism.
There is nothing "silly" about this question. If one can find such a mechanism for the SM+GR, the same mechanism may apply for the string landscape.

80. **Peter Woit**
February 11, 2007

student,

The "string landscape problem" is just caused by the fact that people have taken an idea that doesn't work (string theory based unification), added huge amounts of structure to it to evade the fact that it doesn't work, and now are trying to find some way out of this mess other than the obvious one (admit this doesn't work and try something else).

There certainly are specific choices that go into the standard model that distinguish it from other equally simple theories: why the specific dS cosmological background we are in (rather than AdS3xS1 or whatever)? Why SU(3)xSU(2)XU(1)?, etc. If you can solve any of these problems you'll be very famous. And not because you've figured out something that may help understand the string theory landscape…

81. **Amos Dettonville**
February 11, 2007

student,

I don't understand what you mean when you say GR does not propose a vacuum (specifically 3+1 dimensional spacetime, with a cosmological constant very close to zero). In alleged contra-distinction to this, you assert that "The observational fact that we live in dS_4 is used as input but not explained." Well, that's true, but it doesn't conflict with what I said. It's just repeating what I said. To "propose" is not to "explain". And we're in agreement that this proposal is based on observational facts. Indeed this is the whole point: the attributes of a theory like GR can be pinned down rather fully by observable facts. GR doesn't contain a large amount of free structure that is unconstrained by observable facts. I think Peter's point is that, in contrast, string theory has taken on a great deal of structure that is unconstrained by observable facts. This is what makes it problematic.

You wrote:
"To me, the Occam's razor argument would select a 4D Minkowski vacuum as the simplest, not a dS with a tiny cosmological constant -indeed, a very unnatural choice!"

Well, if 4D Minkowski spacetime was sufficient to save all the phenomena, I imagine it would be the preferred model. But it is pretty much impossible to reconcile the equivalence principle with mass-energy equivalence in the context of 4D Minkowski spacetime, so these observationally-based principles motivate a more general spacetime, and this generalization allows for the possibility of a non-zero cosmological. The economy, logical coherence, and connection to observable fact of general relativity is a far cry from the extravagant constructions of string theory.

Having said that, there's no denying that general relativity is an incomplete theory, as Einstein himself often emphasized. The stress-energy tensor is really (at best) just a place holder for some more meaningful representation of the non-gravitational constituents. Also, being a differential theory, GR obviously requires the specification of boundary conditions of some sort, and the imposition of energy conditions, etc., things the theory itself doesn't seem to constrain. So nobody would argue that GR is the last word. But I do think it presents a striking contrast to string theory.

82. **Anon**
February 11, 2007

"The 'string landscape problem' is just caused by the fact that people have taken an idea that doesn't work (string theory based unification), added huge amounts of structure to it to evade the fact that it doesn't work"

The existence or nonexistence of a large number of vacua of a theory is a property of the theory, not of the motivations of those studying it. If I understand correctly, Nima claims that the existence of a large number of vacua is a property that the SM+GR shares with string theory.

If so, then you can't wish the landscape away, by blaming it on the nasty string theorists.

83. **Q**
February 12, 2007

'The point is that there is no dynamical mechanism in the SM + GR which would select the vacuum. So, the ony option so far is to use the "observational"/anthropic argument to "explain" it.' – Student, February 11th, 2007 at 2:54 pm

Observational facts are just not anthropic arguments, and shouldn't be confused with them. The string landscape effort is based on neither observational facts nor anthropic predictions. The anthropic argument says that one set of observed facts (eg, the existence of carbon) predicts something else (eg, the rate of fusion of three alpha particles into carbon) which can be checked and confirmed in the lab.

For example, Hoyle used the anthropic principle to correctly predict a nuclear energy level at 7.6 MeV, which was then confirmed!

" "Most anthropic insights are made with the benefit of hindsight. We look at the Universe, notice that it is close to flat, and say, 'Oh yes, of course, it must be that way, or we wouldn't be here to notice it.' But Hoyle's prediction is … is a genuine scientific prediction, tested and confirmed by SUBSEQUENT experiments. Hoyle said, in effect, 'since we exist, then carbon must have an energy level at 7.6 MeV.' THEN the experiments were carried out and the energy level was measured. As far as we know, this is the only genuine anthropic principle prediction…"

– http://www.novanotes.com/jan2003/anthro1.htm

Even if a solution to the string theory landscape which was in ad hoc agreement with the SM was found, that is not an anthropic prediction. To get an anthropic prediction, you would have to find a solution to the landscape which is not merely consistent with the SM, but which says something further than can be checked in the lab.

With as many as 10^500 solutions, if any do include the SM, there would have a wide spectrum of nearby solutions which also do that, but which have variations regarding the extra physics they include that can be checked. So the problem will persist that the theory is sufficiently vague (due to having so many slightly different solutions) that it won't be falsifiable by the method of Hoyle's successful anthropic prediction.

84. **Arun**
February 12, 2007

I think I appreciate better Peter's and Amos' points, after some thought. The SM has a few dozen things put in by hand, if we have to add another, a vacuum selection principle, no big deal, we still have a theory from which we get a lot more back than we put in. We have a predictive theory.

If the anthropic principle led to a theory from which we get out more than we put in, I don't think anyone would be complaining very loudly. However, with the landscape, to put it dramatically, the sum total of human knowledge is insufficient to determine the vacuum.

85. **Peter Woit**
February 12, 2007

Anon,

"If so, then you can't wish the landscape away, by blaming it on the nasty string theorists."

I don't wish the landscape away, I'm agnostic about it. Gross thinks the calculations that lead to it are not reliable, other string theorists think they are. My point is that if you believe that you have reliable calculations that show that your theory has extremely complicated "backgrounds" in it, that the simple ones don't look at all like the real world, so you have to go to very complicated ones just to evade contradiction with experiment, it means your theory is wrong, and scientific ethics say you should abandon it.

This is the landscape problem, and any claim that the SM has the same problem is just sophistry.

86. **Anon**
February 12, 2007

"My point is that if you believe that you have reliable calculations that show that your theory has extremely complicated "backgrounds" in it…"

What does "extremely complicated" have to do with it? ("complicated", being very much in the eyes of the beholder)

I thought the "landscape problem" was that the theory has a large number of vacua. Period. No qualifiers about how "complicated" they are.

87. **Peter Woit**
February 12, 2007

Anon,

"I thought the "landscape problem" was that the theory has a large number of vacua. Period. No qualifiers about how "complicated" they are."

The number of vacua is not really the point, the problem is the nature of the vacua combined with their number. If the theory had one free parameter and you could calculate everything in terms of this parameter, you could say it had "an infinite number of vacua", but this would not be a problem. You just need one measurement to fix this and get a predictive theory. If there were a small number of complicated vacua, you could separately calculate things in each vacuum, compare to experiment, and see if one matched.

It is the combination of the complexity and the large number of vacua that both allows the string theory landscape to evade being confronted with experiment, and makes the whole setup non-predictive.

And no, "complicated" is not purely in the eye of the beholder.

88. **anon**
February 12, 2007

"It is the combination of the complexity and the large number of vacua …"

I don't see what the alleged complexity has to do with the issue.

If your theory has a large number of inequivalent vacua and if the low-energy physics is different in these different vacua, then you run the risk of losing predictivity.

I don't see why it matters whether these vacua are "simple" or "complicated."

89. **Peter Woit**
February 12, 2007

anon,

"If your theory has a large number of inequivalent vacua and if the low-energy physics is different in these different vacua, then you run the risk of losing predictivity."

You're ignoring the example I gave of a simple set of an infinite number of vacua. Again, the problem is not inherently the number of vacua, it's the combination of large number with their complicated structure. Simple versus complicated matters because simple situations are easier to do calculations in than complicated ones.

The other reason "complicated" matters is because "complicated" is what happens when you try and evade failure. If you start out with a simple model, find it disagrees with experiment, then add new more complicated structure to evade this, as you keep doing this it becomes more and more clear that your starting point was wrong. That is exactly what has happened as people have constructed more and more complicated string theory backgrounds.

90. **anon.**
February 13, 2007

It's kind of puzzling that you're so hostile toward Nima's talk. I guess you stopped watching before he explained that there are new ways to access deSitter solutions that don't involve the usual picture of tunneling and eternal inflation?

91. **Anon**
February 13, 2007

"Again, the problem is not inherently the number of vacua, it's the combination of large number with their complicated structure. Simple versus complicated matters because simple situations are easier to do calculations in than complicated ones."

If you need to compute the physics of 10^500 vacua, before you can determine which one we live in, and extract predictions for low-energy physics, then it really doesn't matter whether each individual vacuum is "simple" to do calculations in.

Conversely, if you can extract predictions without going to such extraordinary lengths, why does it matter that each individual vacuum is "complicated"?

" … failure …"

I think you are mixing up your personal distaste for anything related to "string theory" with whatever scientific point there is to be made about Nima's lecture and the landscape.

92. **woit**
February 13, 2007

anon.,

My hostility to the talk was just due to the claims about "the standard model has the same problem as the landscape". Perhaps there was some actual substance to the talk, I haven't heard any from the commenters here. A "new way to access deSitter solutions" sounds more substantive, but just isn't the sort of thing I'm especially interested in, maybe other people are.

Anon.,

You seem to just be unwilling to acknowledge that I've given you an example showing that in cases of simple theories a large or infinite number of vacua is not a problem at all. The point is simple: simple theories are simpler to calculate in, for complicated theories, the calculations are, well, complicated…

93. **Anon**
February 13, 2007

"You seem to just be unwilling to acknowledge that I've given you an example showing that in cases of simple theories a large or infinite number of vacua is not a problem at all."

Your example, with a continously degenerate vacuum, is in flat contradiction with experiment (because it contains a massless scalar field with dangerous couplings to ordinary matter, exactly as in a string compactification with unfixed moduli). Therefore, it is relevant, neither to the discussion of Nima's talk in particular nor to the landscape problem in general.

"The point is simple: simple theories are simpler to calculate in, for complicated theories, the calculations are, well, complicated…"

A tautology which, again, is irrelevant to the landscape problem.

94. **Peter Woit**
February 13, 2007

Lots of theories have parameters in them, my example is only "in contradiction with experiment" if you want to insist on the string ideology that your unknown non-perturbative string theory will have no free parameters. If you want to make my example consistent with the ideology, just have the free parameter only take discrete values. The issue is whether observable physics depends in a simply calculable way on the parameter, not whether it is continuous or discrete.

Again, the landscape problem is not that there are lots of vacua, as the above example shows, it's that the vacua are very complicated, it's difficult to calculate relevant physical observables reliably in them AND they come in essentially infinite variety.

95. **Anon**
February 13, 2007

"If you want to make my example consistent with the ideology, just have the free parameter only take discrete values."

A theory with free parameters (whether or not those parameters take on only discrete values) is not the same thing as a theory with many (discrete) vacua.

So, no, your example doesn't shed any light on the landscape problem.

“Again, the landscape problem is not that there are lots of vacua, as the above example shows, it’s that the vacua are very complicated,…”

That’s not what everyone else , including Nima, means, when they use the phrase “the landscape problem.”

Thanks for clarifying that thats what you mean.

96. **Peter Woit**
February 13, 2007

Anon,

If you don’t like my calling them “free parameters”, replace “free parameters” with “vacua” and read what I have to say again.

When I repeatedly write here that the landscape problem is due to both the number and complexity of the vacua, your deleting one half of this (about the number), putting what I have to say in quotes and saying that my definition of the landscape problem is different than other people’s is just a ridiculous tactic.

Since you seem to be on first-name basis with Nima and invoke him in everyone of your comments, perhaps you might want to contact him and ask him if all there is to the landscape problem is that the number of vacua is large.

97. **Lee Smolin**
February 13, 2007

Dear Q,

The Hoyle argument is not a “prediction” of the anthropic principle. The Hoyle argument is based on a fallacy in which an extra statement is added to a correct argument, without changing its force. The correct argument is as follows:

A The universe is observed to contain a lot of carbon.
B That carbon could not have been produced were there not a certain line in the spectrum of carbon.

Therefor that line must exist.

To this correct argument Hoyle added a statement that does no work, to get:

U Carbon is necessary for life.
A The universe contains a lot of carbon
B That carbon could not have been produced were there not a certain line in the spectrum of carbon.

Therefor that line must exist.

You see that U does no work. One way to see it is that if the prediction turned out to be wrong one would not question U, one would question the calculations leading to B.

I have found that every single argument proported to be a successful prediction from the AP has a fallacy at its heart. See my hep-th/0407213 for details.

What has been so disheartening about the current debates re the landscape is that all this was thought through a long time ago by a few of us and it has been clear since around 1990 what an appeal to the landscape would have to do to result in falsifiable predictions. The issue is not the landscape per se but the cosmological scenario in which it is studied. The fact that eternal inflation can’t yield anything other than a random distribution on the landscape is the heart of the impass, for that leads to the AP being pulled in in an attempt to save the theory and that in turn leads to a replay of old fallacies.

Thanks,

Lee

98. **Anon**
February 13, 2007

‘If you don’t like my calling them “free parameters”, replace “free parameters” with “vacua” and read what I have to say again.’

I did. Now it makes no sense at all.

“Since you seem to be on first-name basis with Nima and invoke him in everyone of your comments, perhaps you might want to contact him and ask him if all there is to the landscape problem is that the number of vacua is large.”

Nima’s argument is that fairly generic theories (like the Standard Model), when coupled to gravity, have a landscape of vacua.

You want to claim that what Nima finds is not a landscape because all those vacua are “simple,” whereas, in the landscape, the vacua are “complicated” (whatever the heck that means).

Clearly that means that you and he disagree about the definition of “landscape.” I’m just pointing out that the majority of high energy theorists, who use the term, are referring to his definition, not yours.

99. **woit**
February 13, 2007

Anon,

I didn’t define what the landscape is (everyone agrees we’re talking about the space of vacua of a theory), I was telling you what the landscape PROBLEM is. You believe the problem is the large number of vacua, not their complex properties, I’m telling you that it is both.

For the N’th time: If the landscape consisted of an infinite number of vacua, labeled by a discrete parameter (say an integer), and we could calculate all physical observables easily in terms of that integer, there would be a landscape, but no landscape problem. You just would have to compare the result of that calculation to observation, and see if, for any integer, the results matched. An infinite number of vacua is not inherently a problem, the problem is whether you are able to calculate things and match to experiment.

I don’t know what Arkani-Hamed’s “landscape of SM vacua” looks like and whether it’s one in which you can easily do calculations or not, and thus whether or not it suffers from the same problem as the string theory landscape does. Whether or not it does, claiming that "the SM has the same landscape problem as string theory" is sophistry.

100. **Q**
February 13, 2007

Dear Lee,

Thank you. As you write, the observation that people exist does not go into Hoyle's prediction, so the anthropic argument is not involved in the actual prediction.

The observations of the amount of carbon and of the beryllium bottleneck (that prevents significant carbon being formed by reactions other than the fusion of alpha particles) are no more anthropic than other astronomy or nuclear physics observations.

Hoyle's prediction was claimed to be 'the only genuine anthropic principle prediction', according to John Gribbin and Martin Rees's *Cosmic Coincidences*, quoted at http://www.novanotes.com/jan2003/anthro1.htm

Your link to http://arxiv.org/abs/hep-th/0407213 is extremely helpful and it surprises me that, in fact, there aren't any genuine anthropic predictions that have been confirmed. I thought it was just weak physics but not it looks like rubbish. My motto in future will have to be *nullius in verba*.

101. **Anon**
February 13, 2007

And, for the N'th time, the problem has nothing to do with the alleged complexity of the individual vacua in question.

"If the landscape consisted of an infinite number of vacua, labeled by a discrete parameter (say an integer), and we could calculate all physical observables easily in terms of that integer, there would be a landscape, but no landscape problem. … An infinite number of vacua is not inherently a problem, the problem is whether you are able to calculate things and match to experiment."

In your alleged non-example, one can calculate, once and for all, the values of all physical observable in these different vacua as a closed-form function of a single (or several) integer(s).

If that's your definition of "simple," then I'm afraid that there are no simple theories of any physical relevance to the real world.

Some quantities (super-renormalizable couplings, like the cosmological constant) will vary wildly between different vacua, even if (as Nima and others have argued) other, renormalizable, couplings do not vary appreciably.

There are plenty of field theory examples (much simpler than the Standard Model) that exhibit this behavior, when coupled to gravity.

I'm sorry that this observation causes you such psychological distress.

102. **woit**
February 13, 2007

Anon,

You are completely devoted to missing the point here. Obviously my example was over-simplified, but the fundamental point is simply that of whether or not you can calculate things and compare them to experiment, i.e. do science.

In the SM you can, extremely successfully. In the string theory landscape people have failed utterly to calculate anything that can be compared to experiment in any way. Examining why that is might be worthwhile, claiming there's no real difference is absurd.

Thanks for your concern about my psychological well-being, I assure you that I'm feeling just fine, the only psychological distress coming from mild annoyance that I'm wasting my time trying to have a serious discussion with someone who doesn't seem interested in this.

103. **urs**
February 14, 2007

> In the string theory landscape people have failed utterly to calculate anything that can be compared to experiment in any way.

While I don't want to disagree with the general statement that there are no useful predictions yet, the above statement is not quite strictly true.

One thing that is rather easily determined for most vacua is for instance the gauge group of the effective 4-dimensional theory. That can be compared to experiment.

And that's one of the main properties that people in string model building (= landscape point finding) check. They discard lots of vacua with the wrong gauge group and find vacua with gauge groups that come closer to the real thing by passing from simple to more involved vacua.

It is true that those vacua with the right gauge group that have been found so far are rather involved, as far as their "algorithmic complexity" goes (i.e. concerning how many pages you have to fill to define it). Although that does not preclude (nor suggest, of course) that there might not be a complicated looking Rube-Goldberg vacuum which is later realized to be "algorithmically non-complex" in that it, say, is the unique one with a certain property, whatever.

Please note well: I am not discussing whether or not we should be happy or non-happy with string theory and its space of solutions. We all know each others opinion on that already. All I want to address here is a technical point, namely if or if not people have managed to compute from a given string vacuum something that can be compared with the real world.

104. **woit**
February 14, 2007

Urs,

You're well aware that one can get just about any gauge group one wants out of the landscape. When I wrote about comparing theory with experiment, I was referring to the standard scientific notion of testing one's theory by making experimental predictions and checking them, something that is impossible in the landscape situation.

105. **Thomas Larsson**
February 14, 2007

Urs, would you say that a negative, or at least non-positive, cosmological constant is a falsifyable prediction of AdS/CFT?

106. **urs**
February 14, 2007

Peter, Thomas,

let me recall what I was commenting on:

Peter described how to proceed with a physical theory that has more than one solution

(http://www.math.columbia.edu/~woit/wordpress/?p=514#comment-22316)

> [for each solution] […] calculate all physical observables […] compare the result of that calculation to observation, and see if, […] the results matched [observation]

Then he remarked that

(http://www.math.columbia.edu/~woit/wordpress/?p=514#comment-22319)

> [for string theory solutions] people have failed utterly to calculate anything that can be compared to experiment in any way #

I was just pointing out that this is not quite true.

Lots of string solutions are known, lots of properties have been computed for them, like gauge group, number of generations, particle content in general, number of large dimensions.

Most choices one has tried don't match observation. To match even these basic properties with observation one has to look for rather peculiar solutions. (Some that do match these basic properties do exist, though. Most famously maybe the solution by Braun et al.)

I do agree with you all, though, that no useful prediction has come out of string phenomenology so far.

107. **woit**
February 14, 2007

urs,

If you look at the history of this, I think you'll find that what has been going on is not at all what I was talking about: computing the predictions of a theory, comparing to experiment, and admitting failure if they don't match. It has been something rather different: computing gauge groups + representations in simple examples, finding they don't match the observed SM, choosing more complicated examples, computing again, finding they still doesn't match, etc, reaching a present point of working with complicated examples that still are very unphysical, and not even having any idea whether the gauge groups + representations one has laboriously made match by ad hoc methods are even the ones that you want (what if the LHC discovers a new force or new particles?).

108. **urs**
February 14, 2007

Peter,

in your example,

http://www.math.columbia.edu/~woit/wordpress/?p=514#comment-22316

how many integers would you check before you "admit failure"?

I should say that I agree very much that checking lots of convoluted examples, one by one, with no guarantee that there is at least one that works is not particularly uplifting.

What is, at times, much more enjoyable are more bottom-up approaches, where one tries to identify some hidden underlying structure of our standard model, which maybe suggests where to look for a UV completion.

I am particularly thinking of Connes' way of encoding the entire standard model in the data of a spectral triple – and now rather elegantly so.

http://golem.ph.utexas.edu/category/2006/09/connes_on_spectral_geometry_of.html

Sometimes I imagine that if I were a model builder, I would try to use that information to look for string backgrounds that have a chance of reducing to Connes's spectral triple.

Notice that string backgrounds do tend to ordinary spectral triples on target space in the point particle limit:

Riordan Review of The Trouble With Physics

February 3, 2007
Categories: Uncategorized

Lee Smolin's *The Trouble With Physics* will be out soon in the UK, available February 22 according to Amazon.uk. This month's Physics World has a very good review of the book by Michael Riordan, under the title Stringing physics along. Before his current incarnation as an historian of science, Riordan worked as an HEP experimentalist for many years, going on to write one of my favorite books about the development of the Standard Model, The Hunting of the Quark.

The review is very well done, and I especially like his description of string theory as not a theory, but "instead a dense, weedy thicket of hypotheses and conjectures badly in need of pruning." The one place where I really disagree with Riordan, is where, like many other people, he explains the landscape issue and characterizes the problem with string theory as "it got caught up in its own mathematical beauty." I don't think that that's the problem with string theory in general, and it's certainly not the problem with the landscape arm of string theory research, which is explicitly devoted to the idea (see for example Susskind's book) that the universe is something of spectacular mathematical ugliness.

Riordan goes on to make the claim that the way string theory is being pursued is of danger to science in general, since its continual evasion of any possibility of confrontation with experiment is of the same nature as "intelligent design". Riordan writes "To me, string theory and intelligent design belong in the same speculative, unproveable category." He ends with the recommendation "*The Trouble With Physics* deserves a wide, careful reading by all physicists concerned about the future of our discipline."

Comments

1. **Keith Thompson**
   February 3, 2007

   Speaking of string theory:

   A cartoon.

2. **Thomas Larsson**
   February 3, 2007

   Science Fashions and Scientific Fact
   Michael Riordan
   Physics Today, August 2003, page 50

3. **woit**
   February 3, 2007

   Keith,
   That cartoon appears as a graphic in the Riordan article.

4. **Aaron Bergman**
   February 3, 2007

   To me, string theory and intelligent design belong in the same speculative, unproveable category, and Smolin apparently agrees.

   I think I've already used this line somewhere, but the fundamental difference between string theory and intelligent design is that string theory aspires to be science.

5. **woit**
   February 4, 2007

   Aaron,

   It's not that simple, intelligent design also aspires to be science.

   I do agree there's a fundamental difference: physicists should know better.

6. **Aaron Bergman**
   February 4, 2007

   Intelligent design pretends to do so, but we all know that it's a facade.

7. **mclaren**
   February 4, 2007

   ",,,the fundamental difference between string theory and intelligent design is that string theory aspires to be science.."

   Alas, all pseudoscience aspires to be science. The difference twixt science and pseudoscience is that genuine science offers us a reliable guaranteed way of detrermining whether those aspirations are destined to be fulfilled.

   I keep asking the same question over and over again, but no one ever gives a credible answer — specify the experimental results which can be performed and will categorically disconfirm string theory's predictions.

8. **John Gonsowski**
   February 4, 2007

   Physicists should know better than to go too much past what the known math is saying. Philosophers can go wherever they want but the two disciplines should be kept more separate than they sometimes are.

   String theory is an attempt to link some fairly well known ideas. If the math to do this linking was well known, there'd be plenty of existing experiments to use. Adding extra stuff has to either explain new things or link old things. String theory seems to be overly trying to find new ways to verify old things that they hope to link to other old things some day. That’s kind of not all that important at this point (except maybe for public relations if it gets interpreted to be more than it is).

9. **mclaren**
   February 4, 2007

   “String theory seems to be overly trying to find new ways to verify old things that they hope to link to other old things some day.”

   Occam’s Razor.

10. **King Ray**
    February 5, 2007

    There seems to be an Orwellian (1984) aspect to string theory…

11. **amused**
    February 6, 2007

    I’m no string lover but have to take issue with Peter’s description of Riordan’ review as “very good”. From the review:

    “To evade comparisons with dross reality, for instance, string theorists have invoked an unseen “metaverse” of parallel universes corresponding to the “landscape” of 10^500 possible solutions that might exist”

    No, the landscape was a derived consequence of the theory, not something invoked or put in by hand to “evade comparisons with reality”. I’m sure most string theorists would have much preferred there to be a unique vacuum from which unique predictions could be derived. (And yes, I hate the landscape just as much as everyone else here, but that’s beside the point.)

    “But at least these ideas [loop quantum gravity and others] lead to firm, testable predictions by which they can be judged and – if found lacking – rejected. This is science”

    String theorists talk about the possibility of evidence for ST from cosmic strings — I don’t want to defend the credibility of that, but are the “firm, testable” predictions from LQG any more credible?
    Also, has it been shown that LQG doesn’t have a landscape problem similar to string theory? Has it been shown that LQG can be coupled to matter in such a way that a unique low energy effective theory is obtained which contains the Standard Model in Minkowski spacetime?

    Riordan writes “To me, string theory and intelligent design belong in the same speculative, unproveable category.”

    Having once called on string theorists to denounce Lubos for comparing ST to the theory of evolution (see here for the outcome 😉) I now feel obliged to denounce Riordan for comparing ST to ID, and also Peter for his uncritical reporting of it. Nothing good will come from this derision of the research efforts of serious scientists who are following their best judgement in a difficult situation. (Disagreeing with their judgement is quite different to mocking them by comparisons to the ID nutters.) Much better imo to keep hammering the stringers on their weakest point: the unearned hegemonic position of ST in formal particle theory, and the ills that follow from it. Such as string theorists having been hired into faculty positions “at a disproportionally high level not necessarily commensurate with ability in all cases” (to quote SLAC’s JoAnne Hewett), with some of them having chosen ST for the reason that “well, you know, that’s the way things are going” (an actual quote from an acquaintance of mine who switched to ST as a postdoc and got a good faculty position out of it. I can hardly blame him, he had a family to support…)

12. **woit**
    February 6, 2007

    amused,

    I didn’t intend to imply that I support everything Riordan writes, some of it is highly oversimplified.

    Actually I don’t think Riordan has it completely wrong to say that the Landscape arises from trying to avoid problems with experiment. The point is that simple string backgrounds have massless moduli fields and so predict new long range forces. If we saw these, this would be considered a huge confirmation of string theory. But they’re not there so people have constructed more and more complicated “backgrounds” to stabilize the moduli, leading to the landscape problem.

    As for ST and ID, I don’t agree with Riordan’s broad-stroke characterization of string theory, there are plenty of string theorists who are not fanatics and are intellectually honest. But there are also some who are highly intellectually dishonest and/or complete fanatics, as bad as any of the IDers (and this includes the two most prominent string theory bloggers). The anthropic landscape is no more based on legitimate science than ID is, and the way that research program has gained serious attention is disturbing.

13. **amused**
    February 7, 2007

    Peter,

    “The anthropic landscape is no more based on legitimate science than ID is”

    The anthropic landscape isn’t science in the usual sense, but is still quite different from ID. String theorists who work on this can reasonably claim that they are simply following to its logical conclusion what in their judgement was the best road forward in particle physics at the time. Our response to that would be that they were following what in hindsight was a bad road, and should try to find another one. But still, the fact remains that the anthropic landscape, although not science itself, was nevertheless arrived at in a reasonably scientific way by serious scientists. In contrast, ID is nothing more than a cover for promoting religion.

14. **Aaron Bergman**
    February 7, 2007

    It’s not as if string theorists put the landscape of vacua into the theory by hand; it’s always been there.

    I really think you should reconsider your characterization here. It is both false and tremendously offensive. What you’ve never seemed to realize is that the vast majority of the people working on landscape related things have done so for the express purpose of being able to make predictions. Now, you might not like their philosophy, and maybe you think they’re out to destroy science in order to save string theory, but to compare them to the intellectual dishonesty that is ID is something I’d hope you would think long and hard about before doing.

15. **Peter Woit**
    February 7, 2007

Aaron and amused,

Yes, the anthropic landscape was arrived at by standard deductive scientific arguments. The problem is what happened when people got to it. Many physicists have properly acknowledged that if your theory leads to something grotesquely ugly and complicated that can't provide legitimate scientific predictions, you have to acknowledge that your theory is wrong and try something else, and that this is the conclusion the anthropic landscape forces on one. Some people refuse to acknowledge that this is what has happened, and I don't see their behavior as fundamentally different than that of the IDers. They are giving up on the standard scientific method because it conflicts with their ideology.

I've repeatedly made the scientific argument about why the anthropic landscape is not science, I don't see any point to trying to make claims about what is in the hearts of either string theorists doing this or IDers promoting their views. That said, I think the recent flurry of press releases issued by universities about "tests of string theory" are every bit as dishonest as the press releases coming out of the Discovery Institute.

16. **Aaron Bergman**
February 7, 2007

I hope you would consider all the implications of what you are saying when you make comparisons with ID and ask whether such comparisons are necessary for you to make your arguments.

Reading a bit more on the history of the ID movement might help, too.

17. **Thomas Larsson**
February 7, 2007

to compare them to the intellectual dishonesty that is ID is something I'd hope you would think long and hard about before doing.

It seems much more fair to compare string theory to aether theory. The aether theorists were serious scientists – Lorentz won the Nobel prize and Poincare was one of his generation's best mathematicians, like Gross and Witten. They had good reasons to view aether theory skeptics to be crackpots – aether theory is more or less an inevitable consequence of Newtonian mechanics and a finite speed of light, and the latter was experimentally proven beyond reasonable doubt. And they kept ignoring experimental data contradicting aether theory (Michelson-Morley, photo-electric effect), just like string theorists ignore experiments (no SUSY or extra-dimensions, positive cc contradicts AdS/CFT). It is an interesting empirical fact that the physics establishment kept believing in aether theory for 20 years after Michelson-Morley, i.e. for some five years after the crackpot patent clerk's annus mirabilis.

18. **Thomas Larsson**
February 7, 2007

BTW, no LQGist can IMO can be compared to the top aether theorists.

19. **Peter Woit**
February 7, 2007

Aaron,

I'm well aware of the implications of what I am saying. I really wish string theorists would seriously consider the implications of issuing dishonest press releases and pursuing pseudo-scientific research programs. This is doing real damage to the credibility of science among the general public.

20. **Aaron Bergman**
February 7, 2007

I'm well aware of the implications of what I am saying.

I'm not sure you do. That's why I suggested reading up on the history of the ID movement.

21. **1uk3**
February 9, 2007

LOL Peter when you compare string theory and its advocates to ID and its advocates you are just as ridiculous as certain string theorists who say that skepticism about string theory is analogous to "skepticism" of "darwinism".

Here's what Lubos said once:

"I think that the analogy between evolution and string theory is a rather fair one. In neither case, we have a practical method that would indeed allow us to kill the whole framework by a single observation. In both cases, there are hundreds of details that must be answered by a more detailed work. In both cases, someone's emotional feelings that evolution is too cruel or extra dimensions are too religious are completely irrelevant for science's opinion."

22. **Peter Woit**
February 9, 2007

1uk3,

Yeah, sure, the idea that some string theorists behave like intellectually dishonest fanatics is just ridiculous….

23. **Aaron Bergman**
February 9, 2007

I see. Reductio ad Lubos.

24. **Peter Woit**
February 9, 2007

Aaron,

Lubos is often the best example, embodying many of the problems with the behavior or string theorists in a pure form, something one rarely sees in nature.

But, even among those string theorists with blogs, he's not the only example. At least he doesn't have Harvard issuing press releases…

25. **Aaron Bergman**
February 9, 2007

You know, I'm not particularly interested in playing this game. We're not talking about all the people you dislike or people who dislike you; we're talking about whether it is fair to compare string theorists to proponents of intelligent design. This relates to very specific questions about motivation, methods and intellectual honesty. If you think those comparisons are appropriate, I think you've gone beyond the pale. If you just want to talk about how the bad bad people are doing bad bad things, then I've got better things to do.

26. **Peter Woit**
February 9, 2007

Aaron,

I'm not making blanket accusations about "string theorists are as bad as IDers", and I'm not making any judgements about who is "bad, bad" or likable or dislikable. You and others assure me Distler can be a charming guy, I've heard the same from many people about Lubos, and from what I've seen of Susskind, he certainly has his charm too.

This doesn't mean I don't have serious problems with the scientific arguments that they make, and the tactics they sometimes employ in making them. There are well-understood norms of what an intellectually honest scientific argument is, and my claim is that at times these people have violated these norms, and all the evidence that I've seen is that they have done so for ideological reasons.

What's "beyond the pale" I think is not my views about this (which, by the way are shared by a sizable number of people in the physics community, not just Riordan, try asking around), but the kind of unprofessional behavior that some string theorists have decided to engage in. It's doing a lot of damage to physics and to the credibility of the field. I'm not going to apologize for or stop pointing this out.

27. **Amos Dettonville**
February 10, 2007

Aaron, in view of your rejection of any sort of comparison between string theory and Intelligent Design (ID), it's interesting to recall this from Smolin's book:

"In a recent interview, Susskind claims that the stakes are to accept the landscape and the dilution in the scientific method it implies or give up science altogether and accept intelligent design (ID) as the explanation for the choices of parameters of the standard model: 'If, for some unforeseen reason, the landscape turns out to be inconsistent … as things stand now we will be in a very awkward position. Without any explanation of nature's fine-tunings we will be hard pressed to answer the ID critics. One might argue that the hope that a mathematically unique solution will emerge is as faith-based as ID.' "

Granted, he phrases this in the ambiguous form "one might argue", but it seems clear that he is saying that, barring some kind of anthropic guide through the landscape, string theory is as faith-based as ID. Was Susskind "beyond the pale" in making that statement? Was Smolin beyond the pale for paraphrasing it as he did?

28. **Aaron Bergman**
February 10, 2007

I suggest you reread the passage. I don't agree with what Susskind says, but there is no way to go from the text you quoted to the paraphrase, "barring some kind of anthropic guide through the landscape, string theory is as faith-based as ID."

29. **Amos Dettonville**
February 10, 2007

Aaron, I'll conceed that my paraphrase may have been off the mark. Susskind said "if the landscape is inconsistent" whereas I said "barring some kind of [should have inserted "consistent"] anthropic guide through the landscape". Admittedly those are two different conditionals. On the other hand, I don't think they are as unrelated as you do. Susskind's "if the landscape is inconsistent" could be taken to mean different things, especially in view of his other statements, where he refers to faith in the emergence of a unique solution. From what would a unique solution emerge "if the landscape is inconsistent"? He also talks about having nothing to determine the constants of nature in that case… and it's well known that he thinks the anthropic principle is the key to selecting from among the landscape of possibilities. But if the landscape itself is inconsistent (whatever that means), we wouldn't need any kind of guide to select the right one. But anyway… disregard my paraphrase…. the point of my message wasn't to paraphrase him, but to note that he made a comparison between string theorists (admitedly in a hypothetical situation) and proponents of ID. (By the way, I'm a bit surprised you didn't also object to Smolin's paraphrase, which if anything was even more tendentious than mine.)

Forget the paraphrases. Just focus on what Susskind actually said. I see that you don't agree with him, but my question was whether Susskind went beyond the pale by even suggesting that those who believe string theory may somehow produce a unique solution are comparable to proponents of ID. Do you disagree that this is what he implied? I guess it all depends on what he meant by "if the landscape is inconsistent". It's a rather muddled conditional, because even if the landscape IS consistent, surely there could still be theorists who think a unique solution could somehow emerge. In fact, we might more easily believe this if the landscape IS consistent than if it is not.

Taken in its entirety, I admit that it's not easy for me to assign a self-consistent meaning to Susskind's remarks, but I do think it's clear that he was, in some way, comparing how some string theorists might behave in some circumstances to how the proponents of ID behave. I suppose you could argue that his comments don't apply, because his conditional (landscape inconsistency) is both counter-factual and inconceivable, but then what was the point of his comment? I think you have to admit that he was acknowledging that string theorists could end up seeming like ID proponents. Does this put him "beyond the pale"?

30. **Aaron Bergman**
February 10, 2007

Do you disagree that this is what he implied?

Of course. He didn't say anything close to that. What Susskind is saying (and he thinks he's being clever — sigh) is that the universe looks fine tuned for the existence of life. Either we have to accept that the universe was designed for us or we have to accept some sort of multiverse and anthropic explanations. This is an old, old argument. Regardless, Susskind is using ID in a nonstandard way, referring to the design of the universe rather than the usual critiques of evolution. It is the people propounding the latter that are subject here.

31. **Amos Dettonville**
February 10, 2007

Here's an exact quote:

Susskind: "One might argue that the hope that a mathematically unique solution will emerge is as faith-based as ID."

Then I asked Aaron if he thought "Susskind went beyond the pale by even suggesting that those who believe string theory may somehow produce a unique solution are comparable to proponents of ID. Do you disagree that this is what he implied?”

And now Aaron replies:

“Of course. He didn’t say anything close to that.”

This is fascinating, in a peculiar sort of way. We have two statements:

(1) “One might argue that the hope that a mathematically unique solution will emerge is as faith-based as ID.”

(2) Susskind suggested that those who believe string theory may somehow produce a unique solution are comparable to proponents of ID.

Now, I will conceed that (1) and (2) are not identical, but I find it hard to accept that they are *not even close*.

By the way, Susskind isn’t using ID in a non-standard way. The idea of intelligent design (of the universe) has been debated for thousands of years, going back at least to the ancient Greeks, and has been featured prominently in the thinking of many great scientists and philosophers. The adoptation of these arguments by anti-evolutionists is what is non-standard.

32. **Aaron Bergman**
February 11, 2007

Oh good. Now we can play definition games. Why don’t you google “Intelligent Design” and find me the first link that doesn’t deal with anti-evolutionism of some sort. (What you’re referring generally goes by ‘the argument from design” or the “teleological argument”. In modern usage, “intelligent design” almost invariable refers to the argument against evolution, and, more importantly, before we started playing Susskind-gotcha-games — isn’t it fun? — it was the subject of this thread.)

Regardless, Susskind is not making a comparison between string theorists and IDers in general. What he is saying is that he believes that the belief in a single vacuum of string theory is not currently supported by the preponderance of the evidence, so that belief is “faith-based”. He hides behind a “one might argue” because he’s not actually making the comparison; he just thinks its clever to juxtapose the hope of some that string theory may have a unique vacuum with the faith that IDers have that a designer exists.

LHC Prospects

February 3, 2007
Categories: Uncategorized

Just to show that New Scientist doesn't always get it wrong, there's an unusually good article in this week's issue by Davide Castelvecchi about prospects for new discoveries at the LHC. Besides the usual story, he concentrates on the question of how the data will be analyzed.

For one perspective on the problem, he gives an amusing quote from Ian Hinchliffe of Atlas who says:

People always ask me, "If you discover a new particle, how will you distinguish supersymmetry from extra dimensions?". I'll discover it first, I'll think about it on the way to Stockholm, and I'll tell you on the way back."

Nima Arkani-Hamed optimistically claims that "The most likely scenario is that we're going to have a ton of weird stuff to explain,' and Castelvecchi quotes him and others as promoting a new sort of "bottom-up" data analysis. Here the idea (various implementations exist under names like VISTA and SLEUTH) is that instead of looking "top-down" for some specific signature predicted by a model (e.g. the Higgs, superpartners, etc.), one should instead broadly look at the data for statistically significant deviations from the standard model. Castelvecchi mentions various people working on this, including Bruce Knuteson of MIT. Knuteson and a collaborator have recently promoted an even more ambitious concept called BARD, designed to automate things and cut some theorists out of a job. The idea of BARD is to take discrepancies from the standard model and match them with possible new terms in the effective Lagrangian. Arkani-Hamed is dubious: "Going from the data to a beautiful theory is something a computer will never do."

While the article focuses on the LHC, the role of such "bottom-up analyses" may soon be explored at the Tevatron, where they have a huge amount of data coming in, and have already put a lot of effort into the "top-down" approach (for the latest example, see Tommaso Dorigo's new posting on CDF results about limits on Higgs decays to two Ws.) For the next few years all eyes will be on the LHC, but it will be the Tevatron experiments that will have a lot of data and be far along in analyzing it. Maybe lurking in this data will be the new physics everyone is hoping for, and it will be of an unexpected kind that only a broad-based "bottom-up" analysis might find. Doing so may raise tricky questions about what is statistically significant and what isn't, and require a lot of manpower, at a time when these experiments will be losing lots of people to the LHC and elsewhere.

Comments

1. **AGeek**
   February 3, 2007

   "Beating a grand master in chess is something a computer will never do."

   Sorry, couldn't resist.

2. **luzo**
   February 3, 2007

   «"Beating a grand master in chess is something a computer will never do."

   Sorry, couldn't't resist.»
   ———–x——–

   Well, you should have!

   Chess has a very deterministic set of rules which the computer has to follow to reach an optimal well defined state (winning the game).

   Extracting Physics from raw data implies induction and not deduction from well defined rules and defining the optimal outcome may actually be part of the problem.

   This is why I think this analogy is flawed.

3. **Jonathan Vos Post**
   February 3, 2007

   Von Neumann and Morgenstern invented Game Theory. John Forbes Nash, Jr., took it deeper, using polytope theory in his famous (but rarely read) PhD dissertation.

   John H. Conway et al then produced a Theory of Everything for games, including the transfinite and non-standard, of which Chess is merely a single point on the landscape of all possible games.

   John Baez has explained by Category theory what ("^" means exponentiation) is the structure of Chess^Go and Go^Chess.

   In a tournament, you don't care what your opponent's metatheory of Chess is, or whether thery consider Checkers to be in the same Calabi-Yau space with Chess. You simply want to falsify their theory, by winning!

   The analogy is thus: in the World Tournament of Physics, who wins the interminably protracted String Theory versus Everyone Else International Grandmaster Championship.

4. **Tommaso Dorigo**
   February 4, 2007

   Well, Luzo… "the computer", one day (quite soon, some say) will have induction, too.
   The singularity is near…
   Cheers,
   T.

5. **luzo**
   February 4, 2007

   "Well, Luzo… "the computer", one day (quite soon, some say) will have induction, too.
   The singularity is near…"

————x————-

It has been near for some 20 years now without almost any concrete evidence that it's getting closer.

Kind of reminds me of a TOE that has also been very promising for about a litle over 20 years and has delivered very litle when one demands concrete substance or even something to back one's "faith" in it.

Sorry, now I was the one that couldn't resist 😉

Induction is not the problem, the biggest problem (in my opinion) is that knowing when you have an optimal outcome is not even evident.

Bottom up approaches work in order to indicate a possible theory and then work top bottom to verify it.

6. **Seth**
   February 4, 2007

   Going from data to a *beautiful* theory is something a computer will never do, sure. Going from data to an effective Lagrangian, though, seems a more possible—at that point, though, the theorists will still have to step in.

   I don't expect BARD to be useful so much as a tool for discovering new physics, as for pointing people in the right direction on what to look for via more traditional methods with the next round of data.

7. **AGeek**
   February 4, 2007

   Beauty is in the eye of the beholder. Writing down all terms of a QFT action consistent with Lorentz invariance and renormalizability can certainly be reduced to a perfectly mechanical task; fitting experimental data to them too. As noted by Seth, the result may not be "beautiful" to some – but then, so what?

   luzo: the term "Singularity" does not refer to old-style AI (though your claim that the latter has "delivered nothing" is wide off the mark), it refers to the extrapolation of long-term historical trends in a wide range of technological and economic areas, all pointing to the year 2050 or thereabout as the time when they go essentially vertical on the time scale of (contemporary) humans.

   If you are an optimist like Kurzweil, you take this to mean that we will then break through to a whole new regime (human minds transferred to immensely faster electronic substrate, or whatever technology Intel will be peddling by then). If you are a pessimist, you take it to mean that 2050 or so the latest possible time when our civilization becomes unsustainable (runs out of gas and other resources maybe, Peak Oil and all that). Me, I prefer to be an optimist, since I fully plan to be around well after 2050. 😉

8. **luzo**
   February 4, 2007

   AGeek, thanks for clarifying the singularity point. I was indeed referring to old style AI (since it's what is related with the post) but didn't actually say it delivered nothing. I intended to say initial prospects were FAR too optimistic. Go and ask some working in AI in say the early 1980's whether they ever thought that by 2007 human computer interaction would be taking place using such contrived tools as the ones we are using right now. Most if honest will say they probably though by 2007 things would be much more advanced. Some would even thing that my doubts regarding things like BARD would be as irrelevant by 2007 as doubting the earth isn't flat.

   From my life experience I have to say things look to be slowing down and I still haven't seen the often mention (and desired) "paradigm shift". This in almost every field from Physics, social structure, Biology, etc. Nothing really interesting and corroborated for decades now. Physics at leats had this in the early 20th century, other fields are still lacking.

   Regarding Physics, I'm not a pessimist and I do hope the time we are living now is analogous to say the time when Kelvin was very old. Neither do I think the things that need explanation currently will remain without one for much longer, neither do I hope that explanation can be made with the tools we currently have. I'm not a big fan of singularities in human behaviour.

   Regarding the LHC, I tremendously doubt automatic data analysis alone will give us any theory that predicts yet unobserved phenomena. I could be wrong though.

   What I am really hoping for is for some really unexpected event observed at the LHC. Without a good wake up call from mother nNature this stagnation will most likely persist.

   One criterion for beauty is efficiency and conciseness (for me at least):)

9. **Alexey Petrov**
   February 6, 2007

   Strange point. I thought that all the people who do "low" energy phenomenology (including myself): B or D-physics, Peskin-Takeuchi parameters stuff, flavor-changing neutral currents in quark and lepton sectors, do just that — advocate a bottom-up approach by providing new low-energy observables which should be used in a combined analyses with direct studies at the LHC… after all, that's how any particular model's parameter space is constrained…

10. **Tommaso Dorigo**
    February 6, 2007

    About NS getting things wrong, a friend (David Orban) pointed me to a short article on the Higgs boson in the latest edition of the New Scientist, also online, which quotes me…

    In it, my name is misspelled! 🙁

    T.

Odds and Ends

February 3, 2007
Categories: Uncategorized

John Baez has a new issue of This Week's Finds. He has a lot of interesting things to say about Euler characteristics and how you measure sizes in a category. Among many things I learned from Graeme Segal when he was here last semester was the idea of thinking of the Faddeev-Popov prescription in the path integral approach to gauge theory as reflecting the fact that one should think of gauge fields as a category. The category is the category whose objects are bundles with connection, and gauge transformations are the automorphisms of these objects. The general principle that when you count objects in a category you need to divide by the number of automorphisms provides a sort of motivation of the Faddeev-Popov calculation.

The US FY 2007 budget situation for math and science, which was looking very bad just recently, has taken a huge turn for the better as the House has voted to increase funding for the DOE Office of Science and the NSF. More information about this here, here, here, and here. Looks like Fermilab and RHIC will emerge from the budget process unscathed. Soon the president's FY 2008 budget proposal will be unveiled, and we'll see what the new Democratic majority will do about science funding.

This week's press release announcing a "test of string theory" is from the University of Wisconsin (also here, here, and undoubtedly elsewhere). It's no competition at all for last week's spectacular press releases about "string theory tests", but like the many other examples of the genre it is designed to make claims about string theory highly likely to mislead unsuspecting readers. I made some comments about this here. It's not really that hard to come up with these "tests of string theory", since "string theory" now has been invoked to justify studying a huge variety of different kinds of models, and is compatible with just about anything. All you have to do is find one, no matter how complicated, obscure and lacking any evidence or motivation, where you can choose the parameters so as to create effects not visible to current experiments, but perhaps visible to potential experiments, even ones many decades down the road. Without too much trouble you should be able to get a paper about this published, and at that time your university press office will surely be happy to put out a press release for you announcing that "Researcher(s) at University X have discovered a way to test string theory." This has been going on for years, and people seem to never tire of it.

Sean Carroll seems to find it amusing that many articles on the arXiv can now be thought of as a new form of performance art. John Horgan, who got a lot of grief years ago for accusing physicists of engaging in "ironic science", should really enjoy this.

Update: The Distler et. al. media juggernaut rolls on, informing the world that : The LHC, due to be finished by and running by the end of the year, may rule out the string theory, as well as the work by Distler and his colleagues offers something profound – a way to actually test string theory, and that if Distler's bounds are satisfied, it would provide a weak support for string theory. The last article quotes Distler to the effect that string theory is just an "effective theory", which I'm sure will clarify this for the public.

Update: The Shiu et. al. "test of string theory" press release has also led to lots of misleading stories. For an example check out Physicists devise test for string theory, where you'll learn that "the University of Wisconsin theorists predict that upcoming experiments on the European Space Agency's Planck satellite will have the sensitivity needed to prove the case for string theory." Somehow I suspect string theorists will not give up on string theory if the Planck data doesn't work out, and there won't be any press releases…

Comments

1. **Sean Carroll**
   February 3, 2007

   I do find it amusing, although (of course) it has nothing to do with "many," or "now," or irony, etc etc.

2. **Eli**
   February 3, 2007

   FaDDeev

3. **newcomer to QFT**
   February 3, 2007

   It would be great if you have a chance to report more on Segal's Eilenberg lectures.

4. **Jonathan Vos Post**
   February 3, 2007

   Sean Carroll actually wrote about arXiv "Poetry" as opposed to "many articles on the arXiv can now be thought of as a new form of performance art" as summarized.

   Here's the difference: the paper (whether on the page or electronically published) can be poetry. The presentation at a conference (and on digitized video) can be performance art. Some physicists write great papers but give boring, confusing lectures. Some write trivial papers but give exciting oral presentations. A handfull (again, I'm a protege of Feynman, and coauthored poetry with him) can do both outstandingly well.

   Over in the Math world (but he also did Physics) Sato won the Wolf prise, but was famously bad at presentations, so that his work was essentially ignored for many years, despite his time at the Institute for Advanced Study.

5. **Peter Orland**
   February 3, 2007

   Peter

   It is good that mathematicians are thinking about
   how to study gauge-orbit space, via stacks or
   category theory, or whatever they think is
   useful. Having said that, the best progress on
   this front (in the last ten years), has been made
   by physicists.

   There are ways to parametrize orbit space which are
   more effective than the old methods – Karabali and
   Nair deserve some credit for this, and I will claim some

for myself as well. It is now clear how to solve Gauss's law in axial gauge for a lattice gauge theory. So far these techniques physicists have developed have been applied only to 2+1-dimensional QCD, but we all thinking hard about 3+1.

It's always good to have new points of view, but mathematicians working on this problem might do well to familiarize themselves with the progress made by the small community of physicists who still work on non-perturbative methods.

6. **woit**
February 4, 2007

Eli,

Thanks, fixed.

Sean,

Sorry for any misrepresentation of your views. Maybe I'm just in a lousy mood today, but the kind of thing you are finding amusing here I find depressing.

7. **Ralf**
February 4, 2007

"Performance art" or "ironic science" are nothing but euphemisms for fraud. If one does not believe in the scientific merit of one's projects one is committing fraud whenever one applies for funding and whenever one delivers a report on these projects. That is not a question of personal opinion. Any judge is well aware of this.

Fundamental physics is not merely in a crisis, it has ceased to exist. At some point it will need to be completely rebuilt on an entirely new foundation. But can do that when the entire field has been taken over by frauds, conmen, Witten adulators and Einstein heir wanna-bes? Everything is suffocated by an atmosphere of dishonesty, fundamentally faked convictions and the need to keep silent about the most obvious facts that rule out the b—s— to avoid losing the funding. Today, fundamental physics is nothing but lies in order to preserve funding and employment. *It never occurred to me that one day I would have to be ashamed of being a theoretical physicist*. What honest physicist could let any Ph.D. candidate pass who cannot debunk 99.9% of the subject matter of today's "research?" And if someone spells out this truth, he finds himself publicly contradicted *by people of whom he knows perfectly well that, in private, they agree with him completely.*

8. **Richard**
February 4, 2007

If Sean had given no clue that this was in fact a real abstract, I would have assumed that it was either a joke or fake physics babble in a science fiction story. I wonder what would happen to a math paper submitted to arXiv with an abstract that read like this.

9. **John Baez**
February 4, 2007

Thanks for the plug! [Euler characteristic and homotopy cardinality] are really cool, and I love how Leinster has begun unifying them using the notion of the [Euler characteristic of a category].

I first ran into the idea of "dividing by the number of symmetries" when learning how to compute Feynman diagrams. At the time I thought it was really weird. Why should a more symmetrical thing count for less. Later I saw it made sense and was part of a [big story] involving groupoid cardinality and ultimately homotopy cardinality.

By the way: I don't think Sean was trying to list abstracts that qualify as "performance art" or "ironic science". The [first one], by Jackiw and Pi, looks like good solid condensed matter physics (at first glance anyway).

10. **Peter Woit**
February 4, 2007

John,
The counting for Feynman diagrams with symmetries is Segal's favorite example of the principle. I was less impressed by this than the Faddeev-Popov idea, since Feynman diagrams are pretty much completely understood, whereas the non-perturbative quantization of gauge theories still seems to me to be something we haven't gotten to the bottom of (as Peter Orland also notes).

It's also intriguing to me that there are these generalizations of the "counting in a category" idea that seem to apply to spaces and use volumes (not just counting). I first saw this idea in the long Atiyah-Bott paper on Yang-Mills on Riemann surfaces, where they note interesting relations to Tamagawa numbers. This has always intrigued me, never known quite what to make of it…

About Sean's posting: I just mentioned it because I was very much struck by how he was amused by and seems to think highly of something like studying brane cosmologies where the branes "zoom and twirl around like multi-dimensional figure skaters", whereas this seems to me a typical example of what's wrong with theoretical physics these days. Nothing against this paper in particular, but the fact that there's a huge subject of research out there so outlandishly speculative and divorced from standard notions of scientific testability is not funny.

11. **Jonathan Vos Post**
February 4, 2007

First, I loved John Baez's latest posting about Euler characteristic of a category. Coincidently, I had just supplied my wife with some material on Euler characteristics for a Physics course she was teaching to university students majoring in fashion design. I supplied pages from B. Datta and A. K. Upadhyay, "Degree regular triangulations of the double torus", Forum Mathematicum, 18(2006)6, pp.1011-1025. These are to be treated as clothing patterns to be cut from cloth and sewed with edges identified, and the genus of the 3-D finished assemblage observed; after first sewing patterns for Platonic solids, asked to fill out a table of numbers of vertices, edges, and faces, and being led to discover Euler's formula for convex polyhedra.

Second, "If one does not believe in the scientific merit of one's projects one is committing fraud whenever one applies for funding and whenever one delivers a report on these projects." Fraud is defined on nolo.com as "Intentionally deceiving another person and causing her to suffer a loss. Fraud includes lies and half-truths, such as selling a lemon and claiming 'she runs like a dream.'"

Bringing funding into the picture allows one to determine a specific dollar figure for damages. But who has "standing" to sue? Whose ox is gored? A friend of mine was several consecutive years denied funding for an astronautical engineering concept he'd presented at conferences, then on his web site, and finally as an award-winning refereed paper in an engineering journal. The next year, another person (PhD in Physics) won exactly the Federal grant in question, for substantially the same material, even using the keyword which my friend had in fact coined and first published. The grant-winner (as I witnessed) both admitted and denied having read my friends's earlier work, could not explain where he got the keyword for the title of his grant application, and has been extremely hostile my friend and me subsequently. The grant in question was $75,000. My friend hired an attorney, who cocluded that proving fraudielent intent was allmost impossible, that intellectual property rightd were diminshed by open online and journal publication, and that the matter was not worth pursuing in court. My conclusion: the well-publicized frauds in science are about faked research data. The less-publicized but more common are about "lies and half-truths" and theft of intellectual property, but that these are diffult to pursue in court.

Remember the Math teacher who sued McDonalds, disputing how many billions of burgers had been sold? The judge agreed with the arithmetical argument, but denied that the teacher had been injured through the lies or half-truths, and thus had no standing to sue or prevail.

For string Theory, to use the Talmudic formulation, "whose ox is gored?" How can a Physicist hope to prove in court that he or she has been actually damaged by being denied hiring, promotion, tenure, or grants?

12. **Ralf**
February 5, 2007

The damaged parties are the federal government as represented by the funding agencies like the NSF and the DoE. I don't see how it is much different from, say, welfare benefit fraud or tax fraud.

13. **relativist**
February 5, 2007

"The Distler et. al. media juggernaut rolls on, informing the world that : The LHC, due to be finished by and running by the end of the year, may rule out the string theory, … the work by Distler and his colleagues offers something profound – a way to actually test string theory".
So if this is true, a genuine test as advertised, then if it comes out negative, presumably Distler, Green, Greene, Motl, Johnson, et al. will all give up string theory and do something else.
Does anyone believe that??? Not likely!

14. **King Ray**
February 5, 2007

String theory would make a strategic retreat to higher energies…

When theories retreat to higher and higher energies when confronted with experiment, they are probably wrong. Or not even wrong.

15. **Michael**
February 5, 2007

Why are you in such a lousy mood, Peter? Did your research suffer a setback?

16. **woit**
February 5, 2007

Michael,

Nope, research is fine, but progress is slow. I'm spending a lot of time working on the graduate course in representation theory that I'm teaching. It's time well spent since it is giving me new ideas and deepening my understanding of the subject. Always a pleasure to hear from charming anonymous string theorists such as yourself…

17. **Amos Dettonville**
February 6, 2007

The Feb 5 issue of Time magazine includes a full-page article under the banner **"The Geometry of Music: A composer has taken equations from string theory to explain why Bach and Bebop aren't so different".** Tymoczko has gotten a lot of coverage in the press over the past few months (for reasons that aren't obvious to me), but I'm just now noticing how prominently the "string theory" angle is being played. According to Time, *"Borrowing some of the mathematics that string theorists invented to plumb the secrets of the physical universe, he has found a way to represent the universe of all possible musical chords in graphic form"*.

They note that Tymoczko, a composer from Princeton University, is the first music theorist to have a paper published in the journal *Science*. His idea, for those who have somehow not heard about it yet, is that the universe of chords consists of "weird multi-dimensional spaces known as orbifolds". The simplest chords, consisting of just two notes, reside in a space like a Mobius strip. More complex chords *"inhabit spaces that are as hard to visualize as the multi-dimensional universes of string theory"*.

Harvard Magazine reports that *"Tymoczko spends time with scientists and it was a physicist who suggested the orbifold upon hearing his description of the musical map's properties. Tymoczko notes that physicists are forever using music as a metaphor for their work; now, he says, music can reciprocate."* This article goes on to say Noam Elkies helped Tymoczko with the math.

It occurs to me that this might be bigger news than people have realized. For years, string theorists have lamented the fact that "we don't really know yet what string theory is about". Maybe now we know. It isn't a theory of physics at all… It's about music! Or more specifically, it's a way of encoding traditional musical styles and pleasing chord progressions. But seriously, to the extent that "orbifolds" (in the sense used by Tymoczko) were invented by string theorists, this seems consistent with my impression that the mathematical machinery of string theory is actually a giant curve-fitting framework of almost limitless flexibility that can be fit to almost any subject. Does this marvelous applicability of mathematical techniques to music theory imply that this is the true final theory of music? Or is it a case of "When you have a hammer, every looks like a nail"? Interestingly, though, Tymoczko acknowledges that his theory won't really help anyone write better music. It essentially is just an attempt to represent formally some of the knowledge that composers have always known intuitively. Oddly enough, all the articles talk about chords, but none of them talk about rhythm, timbre, or any of the other aspects of music.

18. **Jun Xian**
February 6, 2007

I am the writer of one of the last articles quoted and I have a few issues that I would like to see clarified.

Firstly, Distler's meaning is not correctly interpreted in this quotation. I quote from the article directly:
– "Distler said that a successful outcome in the experiment, however, should not be seen as anything more than a weak support for string theory. The results of the experiment can effectively rule out certain quantum field theories but not serve as verification."
The full quote speaks for itself.

Secondly, an "Effective Field Theory" is not simply a field theory that is 'effective'. The reason why the article specifically placed these words in quotations is because it is a specific term referring to an approximate theory describing physical phenomena. I would hope the authors do their research adequately before quoting in a manner meant to misconstrue others' opinion.

Thank you.

19. **Ralf**
February 6, 2007

Amos,

I stipulate that absolutely nothing of any denotative content about string theory (which is not a theory) has ever been or could be conveyed to anyone who is not a physicist or a mathematician (or graduate student therein). There is absolutely no shortcut around the shift in the conception of physical reality of 1926 (and the less drastical ones between then and 1974). The physics illiteracy of the general public is a necessary condition for the rise of propagators of patent nonsense to the echelons of academia. People not just don't know anything about it, they don't even know enough to be aware that they don't know anything. (That includes anyone who doesn't know about Lagrangian and Hamiltonian mechanics.) And this won't change until it is acknowledged.

20. **Ralf**
February 6, 2007

String theory is the tantrum that spoiled rotten brats throw because they had to face the reality that they are not the *Übermenschen* that their inferiority complexes compell them to see themselves as.

21. **Astro**
February 6, 2007

You have all heard of NURBS: nonuniform rational B-strings.

22. **woit**
February 6, 2007

Jun Xian,

Seeing WW scattering that satisfies unitarity, Lorentz invariance and analyticity would not in any sense provide weak support for string theory. It would say nothing at all about string theory one way or another, and Distler's claim otherwise is just dishonest and intentionally misleading.

I know what an "effective field theory" is. Your text contains several inaccuracies about the relation between string theory and quantum field theory. It is not true that "String theory is the most successful of various quantum field theories..", string theory is not a quantum field theory. It is also not an "effective field theory". It's not surprising that you're confused about the relation between QFT and string theory, given that Distler et. al. have been on a campaign to try and confuse the issues in this case (their results apply to QFT, have nothing to do with string theory).

Instead of repeating unskeptically misleading claims about the significance of his work by a scientist, it would have been a good idea in your reporting to consult some other particle theorists than the authors of this paper, in order to see see if the author's claims are supported by their colleagues in this field.

23. **Steven H. Cullinane**
February 6, 2007

Some further details on "dividing by the number of symmetries"… The "general principle" mentioned by Peter and John sounds a lot like old-fashioned Polya-Burnside enumeration. (See John's "Week 147.") The "big story" paper mentioned by John is "Categorified Algebra and Quantum Mechanics, by Jeffrey Morton, which cites two papers by Joyal dealing with the combinatorics of "structure types" (as does John's "Week 185"). For details of the connection between old-fashioned Polya-Burnside enumeration and Joyal's structure types, see a 1999 dissertation, "Graphical Enumeration: A Species-Theoretic Approach," by Leopold Travis. The Travis paper is pure mathematics rather than physics, and so may appeal to a wider audience than the "big story" paper.

24. **Jun Xian**
February 6, 2007

Well, if you understood what an effective field theory is, perhaps you should not have stated "The last article quotes Distler to the effect that string theory is just an "effective theory", which I'm sure will clarify this for the public.", which is a rather overt attempt of yours to mislead the public, in my opinion.

Not to mention that I clearly stated in my article that Distler's words were to the effect that it could ONLY serve as a refutation if the WW scattering did NOT satisfy the bounds. Looked at from a different angle, failure to disprove can be taken as an extremely weak support.

I admit to making some technical mistakes in the article, which have since been corrected. However, I do not appreciate the exploitation of my personal failure at understanding as a method to attack Distler's work.

I have nothing for or against either side of the issue. As such I have no quarrel with you concerning the truth of his theory or otherwise. I simply would not like my article to be misquoted and hence cause undue misrepresentation of Distler's work, no matter it's value.

Thank you.

25. **woit**
February 6, 2007

Jun Xian,

My quotes from your article were accurate, and included a link to the actual article so that anyone who wanted to could see them in context.

Now you've turned the "weak support" from your article into "very weak support'. Again, the accurate statement is that if these bounds are satisfied, this has nothing to do with string theory. It would not provide "weak support" or "very weak support", it would have nothing to say at all about the subject.

I don't blame you for technical mistakes. This is a difficult subject and non-experts are going to have trouble understanding it. The inaccurate statements in your article seem to me to be the direct result of Distler's misleading you about the significance of his work.

26. **Big Red**
February 6, 2007

Amos Dettonville,

Tymoczko's father was a sort of logician/philosopher of mathematics and his sister is an assistant prof in math at Michigan. This might be the simplest explanation for any affinity he might have for mathematical ideas.

27. **hooman**
February 6, 2007

I know this is a bit off the topic, but your title is Odds and Ends and I could not resist…
Is this what Lubos is driving these days?
http://www.toyota.com/vehicles/2007/matrix/m_theory.html
the add says " a theory you can't wait to put to test! "

Has anyone studies the impact of string theory on consumer products yet, or vice-versa?

28. **mclaren**
February 7, 2007

Hesitated to mention Tymoczko's paper because it leads to such an obvious swamp of pseudoscience. The ultimate end point is Keely's Sympathetic Vibratory Physics:
http://www.svpvril.com/musicuni.html#TOP%20musicuni

And of course Bruce Cathie's series of ufology books, including "The Harmonic Conquest Of Space" (1998):
http://www.amazon.ca/s?ie=UTF8&rh=n%3A952076&page=15

Tymoczko's twaddle is such obviously vacuous pseudoscience it requires little discussion. But the fact that Tymoczko saw fit to trumpet some alleged connection with string theory seems ominous. It suggests the thin membrane (or should I say "brane"?) which separates mathematically valid but entirely speculative science from "that Serbonian bog," as John Clerk Mawell remarked in his Rede Lecture of 1876, "which has swallowed whole armies of scientific music-makers and musical men of science."

I suppose we must draw a distinction twixt speculative untestable nonsense which is nonetheless based on known laws of physics and contains valid mathematical procedures (though never leading to a testable calculation) and the outright gibberish purveyed by the John Keelys and Hans Keysers and Bruce Cathies of the world. But frankly, if you can't test any of it, I don't care for such fine distinctions.

Incidentially, there's a veritable Himalayan mountain of musical pseudoscience dealing with harmonics and eigenfucntions and various and sundry crackpottery. Tymoczko is just the tip of the iceberg.

http://www.altered-states.net/barry/update95/index.htm
http://www.sacred-texts.com/eso/sta/sta19.htm
http://www.sacredscience.com/archive/Kayser.htm

And so on. A tidal-wave-sized sewage spill of superstition masquerading as a mathematico-musical "theory of harmonics." Classic neo-Platonic number mysticism, acoustical gematria pure and simple. Perhaps string theory could be renamed "cosmological gematria"…?

29. **Chris Oakley**
February 7, 2007

I suppose you need a compact vehicle to navigate the compact dimensions. And you would need pretty good cornering to handle the 10^-35 m (or thereabouts) radius. No doubt Toyota have thought of all of that.

30. **Alex Nichols**
February 7, 2007

King Ray Says:
February 5th, 2007 at 4:26 pm
"When theories retreat to higher and higher energies when confronted with experiment, they are probably wrong. Or not even wrong."

Strictly speaking, the alchemists were NOT WRONG, even if they never did find the Philosopher's Stone
– Lead CAN transmute to Gold.

Upon discovering thorium changing to radium, Rutherford said to his assistant.
"For Christ's sake, Soddy, don't call it transmutation. They'll have our heads off as alchemists."

About 60 years later, Gold was produced in reactors. Without a handy Supernova, you'll never make a living at it though.

31. **Thomas Larsson**
February 7, 2007

Has anyone studies the impact of string theory on consumer products yet, or vice-versa?

It is not yet as successful as cold fusion.

32. **Thomas Love**
February 7, 2007

I've been aware of the connections between music and mathematics for a long time. Back in 1999 I was walking through a university book store and saw a book on harmonic analysis in the music section. I already owned the book, so I put it in the mathematics section. The next day, it was back in the music section. I returned it to the math section. The next day, it was back in music at which point I gave up.

33. **Chris W.**
February 7, 2007

Thomas Love,

You should have affixed a Post-It Note (or something) that sarcastically suggested to the bookstore staff that they open the book and flip through a few pages before jumping to conclusions about the subject matter. Then again, it probably wouldn't have helped……

34. **Chris W.**
February 7, 2007

It seems that in the minds of many people, including many journalists (and even, I suspect, more than a few mathematicians) that theoretical physics and mathematics have become an undifferentiated mush.

An interesting question: How does one explain to somebody that applying an aspect of a physical theory's *formalism* to a problem in an otherwise unrelated field is not the same as applying the theory to said field, and that identifying and characterizing the abstract structures underlying such cross-applicable formalisms is what mathematics—as opposed to the natural sciences that employ mathematical formulations in their theories—is all about.

[By the way, Dmitri Tymoczko evidently has a sister who is a mathematician (Michigan).]

> But this long history of learning how not to fool ourselves—of having utter scientific integrity—is, I'm sorry to say, something that we haven't specifically included in any particular course that I know of. We just hope you've caught on by osmosis.
>
> The first principle is that you must not fool yourself—and you are the easiest person to fool. So you have to be very careful about that. After you've not fooled yourself, it's easy not to fool other scientists. You just have to be honest in a conventional way after that.
>
> I would like to add something that's not essential to the science, but something I kind of believe, which is that you should not fool the layman when you're talking as a scientist. I am not trying to tell you what to do about cheating on your wife, or fooling your girlfriend, or something like that, when you're not trying to be a scientist, but just trying to be an ordinary human being. We'll leave those problems up to you and your rabbi. I'm talking about a specific, extra type of integrity that is not lying, but bending over backwards to show how you are maybe wrong, that you ought to have when acting as a scientist. And this is our responsibility as scientists, certainly to other scientists, and I think to laymen. ***—Richard Feynman, "Cargo Cult Science"***

Alexey Petrov, a particle theorist at Wayne State University, has a blog worth following called Symmetry Factor. He has news about the 2008 budget request for HEP at the DOE, which according to him includes a 12.7% increase in the final 2007 number and a 3.7% increase for 2008 above that (not sure where his numbers come from). This would be a very healthy increase over these two years. Research in the physical sciences has become a big priority for the Bush administration for some reason, it's a major part of the "American Competitiveness Initiative". The NSF is also seeing a large increase in its FY2008 request: 8.7%. For various news stories about this, see here, here, here and here. Still unclear what will happen to this budget request in Congress where the Democratic majority will be in control. They have been sympathetic to science research spending in the past, but may or may not want to go along with the emphasis on the physical sciences embodied in this request. Then there's the small matter of the huge US government deficits to consider. Somebody, someday might decide to try and do something about them.

Maybe I've been a bit unfair in the past to the Templeton Foundation, which recently issued this statement.

The IAS held a workshop last month on Homological Mirror Symmetry, notes are available here. Next month there will be a part two, which will mainly concentrate on Geometric Langlands. The schedule is here.

Via Jonathan Shock, the news that particle physicist Nick Evans has written a particle physics murder mystery entitled The Newtonian Legacy, and is making it available on-line for free. I'll definitely be reading it soon.

Last evening I gave a talk here in New York downtown at the Cafe Scientifique. I think the talk went quite well: the place was packed, the audience attentive and asked quite a few good questions. Up next month is Glennys Farrar of NYU, who will be talking about dark matter. This event is pretty new, organized largely by Stefanie Glick who just got it started last fall. Also in New York are two other similar monthly science events: Secret Science Club, organized by Dorian Devins at Union Hall in Brooklyn (Janna Levin will be there tonight), and Columbia's Cafe Science, which features Columbia faculty members (my colleague John Morgan will be speaking with Sylvia Nasar next week).

   February 8, 2007

   Hi Peter,

   I don't think you have been so unfair to the Templeton foudation in the past. In my experience most seriously religious people may accept certain scientific facts on the surface, but have a very unscientific point of view at their core. I have even heard more compromising religous types talk about how God guides evolution, that the Big Bang was a conscious act of Creation, etc. I don't want to be nasty or contemptuous of people who want to experience religion in some
   way through science, but to start putting the Big Kahuna(s) in the middle of scientific facts is wrongheaded at best, dumb at worst. To an atheist like me (most scientists as well, I think), this seems to be lot of excess baggage.

   Now I'll probably get email threatening my death by cancer.

2. **Alexey Petrov**
   February 8, 2007

   Dear Peter,

   Thank you for referencing my blog! My numbers regarding the budget increase are from the Under Secretary Orbach's presentation of the 2008 budget request, see footnote on page 4. The pdf file of this presentation is here: http://www.science.doe.gov/Budget_and_Planning/Budget_Rollouts/DrOrbach-FY2008-SCBudgetRollout-Feb05-stakeholders.pdf

   Regards,

   –Alexey.

3. **QWERTY**
   February 8, 2007

   DEAR PROFESOR WOIT,

   PLEASE DO NOT ENDORSE SYLVIA NAZAR. SHE HAS SOILED THE REPUTATION OF THE ENTIRE MATHEMATICS WORLD WITH HER UPSIDE DOWN ARTICLES ABOUT SHING TUNG YAU.

   ALSO (ABOUT THE MIRROR SIMMETRY) I KNOW ABOUT THE SYZ CONJECTURES BECAUSE THEY ARE JUST ABOUT SPECIAL LAGRANGE MANIFOLDS, BUT WHERE SHOULD I LEARN ABOUT TRIANGLED AND DERIVED CATEGORIES TO LEARN HOMOLOGICAL MIRROR SIMMETRY? AND WHERE CAN I LEARN WHAT IS A STACK AND WHY I NEED IT IN GEOMETRICAL LANGLANDS PROGRAMS?

   AND HAS EDWARD WITTEN AND ANTONY KAPUSTIN AND SERGAY GUKOV ACTUALLY DONE NEW MATHEMATICS ABOUT GEOMETRIC LANGLANDS OR IS IT JUST TALKING ABOUT IT IN THE LANGUAGE OF STRING THEORY

4. **Peter Woit**
   February 8, 2007

   QWERTY,

   I'm not endorsing anyone, please don't engage here in pro or anti Yau diatribes, I want nothing to do with that and will delete any further comments of this kind.

   Derived categories are what you get when you generalize homological algebra to consider not just the homology groups of complexes, but complexes up to homotopy. For an introduction, see

   http://www.arxiv.org/abs/math.AG/0001045

Stacks are useful whenever you want to work with objects with symmetries. Instead of thinking about the points of the space, you think about the category whose objects are points, morphisms symmetries. There's a collaboration underway to write a new textbook on the subject, with preliminary versions of some chapters here
http://www.math.unizh.ch/index.php?pr_vo_det&key1=1287&key2=580&no_cache=1
You might try reading the introductory chapter.

I don't know geometric Langlands well enough to know whether the Witten/Kapustin/Gukov work provides mathematical insights that the mathematicians working on this were not already aware of. The recent work of Witten and Gukov does seem to correspond to topics that mathematicians in this area are actively working on. I hope to make it down to the IAS in March to learn more about this.

February 10, 2007

I've never been able to completely uncover the true underlying motivations of Templeton, but Paul Davies is a publicly professed atheist who was forced to accept the Templeton prize only because they fund research into strong interpretations of the anthropic principle, and somehow, I just don't see the Discovery Institute doing this. Davies and others are forced to take money from them because nobody else will fund research into the most apparent implications of the observed universe, so I'd imagine that he'd tell people to get their dogmatic anticentrist priorities straight, or get over it, because they're unfounded belief system is no better than the idists.

I know for a fact that "leading" IDists, including Bill Dembski, do not like, nor do they support the position of the Templeton Foundation, so Templton certainly does not fit the profile of your standard fanatical ID proponents who would abuse science in order to force religion into the high school curriculum. Other than that, this isn't high school, children, so if a person wearing a cross around their chest is also holding science in their hand, then you should get over it and listen to them, because your otherwise unfounded paranoia will destroy ya…

> The "leap of faith" needed to accept the existence of a multiverse is greater than that normally expected of scientists, which is to assume the unexplained existence of the laws of physics, although it is perhaps less than that required for belief in a cosmic designer who made a universe fit for life.
> -Paul Davies

Perhaps? … 😉

ILC Price Tag

February 8, 2007
Categories: Uncategorized

The “Reference Design Report” for the ILC was released today, and here’s a presentation about this from Barry Barish, the director of the ILC GDE (Global Design Effort). The most closely held numbers in the report have been the cost estimates (see here for a document about the status of cost estimates that warns “don’t post cost estimates on public web or wiki sites!”).

The cost estimate comes out to $4.87 billion for the technology components, $1.78 billion in site-specific costs, 13000 person-years of labor, and two detectors (no cost estimate for these). In round numbers, roughly $10 billion. The machine would consist of two 11km linacs end-to-end, with an interaction region in which two detectors could be moved in and out. The biggest part of the cost is the cost of the linacs, which would accelerate electrons and positrons to tunable energies with collisions at center of mass energy between 200 and 500 Gev. A possible future upgrade of the machine would take it to 1 Tev.

The plan for the future is to start working on a “Technical Design”, a much more detailed design that would show exactly how to build the machine. The hope is to make a decision on whether to build the ILC around 2010, based on what the LHC has found, and on how much progress CERN has made on the much more ambitious CLIC design. Construction would take 7 years, so the earliest such a machine could be in operation would be around 2017.

The full report is here.

Update: More at Science magazine and the New York Times.

Update: Joanne Hewett has an excellent detailed posting about this over at Cosmic Variance.

   February 8, 2007

   A small price to pay to test string theory and find our place in the multiverse!

2. **Tony Smith**
   February 8, 2007

   Peter said “… The “Reference Design Report” for the ILC … cost estimate comes out … [i]n round numbers, roughly $10 billion …”.

   A competing way to spend a comparable amount is on a new aircraft carrier ($8 billion in construction cost alone) .
   According to a navydata web page:
   “… The CVN 21 Program is the future aircraft carrier replacement program for USS Enterprise and CVN 68-Class aircraft carriers. …
   The total cost to build the lead ship … CVN 78 … is $8.1B in FY08$.
   The Navy expects to award the CVN 78 construction contract in FY08 with an expected delivery in FY15. …
   the total ownership cost for CVN 78 … over its 50 year service life … is expected to be $26.8B …”.

   In short, by foregoing a new navy aircraft carrier, the USA fund its share of the ILC and have around a couple of billion left over (maybe to fund high energy theory alternatives to superstring theory?).

   According to an 8 February 2007 Reuters article by Edmund Blair:
   “… Iran’s Revolutionary Guards test-fired missiles on Thursday …
   “These missiles, with a maximum range of 350 km (220 miles), can hit different kinds of big warships in all of the Persian Gulf, all of the Sea of Oman and the north of the Indian Ocean,” senior Revolutionary Guards naval commander Ali Fadavi said.
   Fadavi was also quoted by the state broadcaster’s Web site as saying that the 500-kg (1,100-lb) warhead of this missile had the capacity to sink “all kinds of big warships” …”.

   A military commentator, Gary Brecher, said back around December 2002:
   “… A few years ago, a US submarine commander said, “There are two kinds of ship in the US Navy: subs and targets.” …”.

   Why doesn’t the USA forgo building a new big target for enemy missiles,
   and
   use that money toward building the ILC ?

   The carrier construction cost alone is over 80% of the total ILC cost estimate, and should by itself more than cover the USA contribution toward the international ILC project.

   Tony Smith

   PS – Here is a bit more from the military analysis web page mentioned above:
   “.. The fact that big surface ships are dinosaurs is something that’s gotten clearer every decade since 1921. … the aircraft carrier is now: a big, proud, expensive…sitting duck. Aircraft carriers came out of WW II looking powerful, but that was before microchips. …
   what about Iran? … The Iranians are … smart, they’re dedicated, and they hate us like poison. … Give the Navy the benefit of the doubt and say they get 90% of the incoming missiles. You still end up with a dead carrier. …
   … if Iran gets involved, those carriers won’t last one day. … And the sickest part is that the admirals and the captains and the contractors all know it. …
   it won’t be the brass who die. It’ll be the poor trusting kids on those carriers who’ll die, the poor suckers who thought they’d get free training and a world tour, or even get the chance to “defend America.” They’ll die not even believing what’s happening to them as the whole giant hulk starts cracking up and sliding into the water. …”.

3. **Q**
   February 8, 2007

   ‘Construction would take 7 years, so the earliest such a machine could be in operation would be around 2017.’

   Who is predicting that the LHC won’t provide the evidence for the real electroweak symmetry breaking mechanism within 10 years?

Or is this new project really more concerned with searching for massive stringy bosonic superpartners?

4. **Peter Woit**
February 8, 2007

Q,

The LHC will actually reach higher energies than the ILC, but if it finds something interesting, it may be very difficult to study it due to the much more complicated nature of proton-proton vs. electron positron collisions.

Basically, if the LHC finds nothing new in its accessible energy range except the expected SM Higgs, it will be hard to make the case for the ILC. If, as people hope, something new shows up, depending on what it is, the ILC may be needed to study it. One popular example is supersymmetry. Some people expect the LHC to see all sorts of superpartners, and the ILC would be a much better machine for studying these (IF their masses are low enough) than the LHC. In general, if the LHC finds that there's something more interesting going on in electroweak symmetry breaking than a scalar Higgs, again the ILC may be the right machine to study the phenomenon. All depends on exactly what it is….

5. **Tony Smith**
February 8, 2007

Q asks "… is this new project [the ILC] really more concerned with searching for massive stringy bosonic superpartners? …".

No.
Although the ILC might see stringy stuff such as superpartners if they exist (my opinion is that they do not exist),
that is not why I think that a high-energy lepton collider such as the ILC should be built. Here is why a non-superstringer like me wants to build such a thing:

The ILC could do a lot more precision tests of the Standard Model than LHC can do, so the ILC could either:
1 – find more subtle new stuff than can be seen at the LHC
or
2 – verify the Standard Model to much greater precision.

Either result would be significant.

For example, the EPP2010 report said in part:
"… The ILC will probe the Standard Model with unprecedented precision … involving the masses, lifetimes, and reaction rates of W and Z particles, top quarks, possibly Higgs particles, and others. If the Standard Model survives these tests, physicists will gain a new level of confidence in its validity and scope.
…
Even such a basic property of the Higgs particle as its spin cannot be easily measured at the LHC. The Standard Model requires that the Higgs particle has no spin … If a Higgs particle is discovered, the spin can
be measured straightforwardly by determining the rate at which it is produced at different energies at the ILC. …".

Therefore, I disagree with Peter when he says "… if the LHC finds nothing new in its accessible energy range except the expected SM Higgs, it will be hard to make the case for the ILC …".

Tony Smith

6. **wab**
February 8, 2007

My colleagues also argue point 2) about high precision measurements of the standard model. That arguement may sell to high energy physicists but I think it will be a hard sell to the other parts of the APS, let alone the general public… so we'd better hope for positive discoveries from the LHC.

7. **graviton383**
February 8, 2007

The $6.7 billion number is in `European' accounting & does not include overhead, contingency or any money for detectors. In `US accounting' the total is closer to $15B…

8. **Robert Musil**
February 8, 2007

At this point it seems quite unlikely that the ILC will be funded unless it is adopted by one or more Asian economic power (most likely China, but maybe India and/or Japan) seeking to make an essentially nationalist political statement about having "arrived" in the advanced world. The problem is that even the Standard Model, with all of its vaunted (perhaps excessively vaunted) cleverness and accuracy of prediction, has not made much difference on any politically significant issue … still less to anything that a Western politician could point to as justification for spending over $10 Billion in tax money … or even a substantial portion of that inevitably-to-bloat figure. Once one moves to questions outside the Standard Model things get even flakier and harder to justify financially and politically. So what's the point from a political perspective? That's the main reason why the old Super Conducting Super Collider eventually came to be seen as mere "pork" in the US Congress. That "pork" perception led to its defunding, since there were other pork projects with far more influential constituencies than any that supported the SCSC. (The LHC builders were lucky that Europe loves this kind of pork, but even Europe's appetite for physi-pork seems sated by the LHC itself.) It's hard to imagine what question the ILC possibly could settle or illuminate that would justify its cost in the political theater. Unfortunately, it's all too easy for academic researchers to imagine just such a question that matters to them … which speaks mostly for the political, economic and historical detachment of the current crop of academic researchers. Undemocratic Asian nationalism appears to be the ILC's only hope, which is one reason why China is a better hope than democratic Japan or India. But that is slender hope indeed.

9. **heh**
February 8, 2007

And here I thought Robert Musil wrote *The Man Without Qualities*, not Comments Without Quality. The most likely location for the ILC at this point seems to be Fermilab. There has been no serious talk, as far as I am aware, of building it in China or Japan. The way to sell the US Congress is to point out that (a) the energy frontier will have been in Europe for some time, and (b) the US tradition of particle physics experiment will be practically dead if we do not build the ILC. Appeal to the fear that the US is slipping far behind in science and technology. Talk about the technological spin-offs that come from accelerator R&D.

10. **heh**
February 8, 2007

Sorry, I meant "no serious talk… of building it in China or India." Japan is a possibility but does not seem likely.

11. **David Heffernan**
February 9, 2007

In response to Robert Musil and heh, Japan is a very serious contender to host the ILC. The Japanese High Energy Physics Advisory Panel agreed that investing in R&D on the linear collider, and then hosting the machine, was the "highest priority" for HEP in this country. The government has already formed a committee to investigate funding and advise how to bring the machine here.

It goes without saying that the host nation will have to make a significant investment in the project, and as far as I am aware the Japanese government is the only one seriously prepared to pay for the privilege at the moment.

12. **Robert Musil**
February 9, 2007

David Hefferman:

I agree that Japan is certainly a possibility as an ILC host to the extent there is any such possibility. Japan has the money and the brainpower – and in some quarters of the electorate an unfulfilled desire to show the West that Japan has "arrived," perhaps by using ultra-expensive particle physics as a demonstration. But any such desire is uninformed atavism. Japan has nothing to prove – it "arrived" in technology and science a long, long time ago. It may be possible to politically exploit such atavism to support the ILC, but that's a slender reed indeed.

Forming a committee to investigate funding and advise how to bring the machine to Japan is very far indeed from actually spending a major piece of $10 to $15 Billion and (probably) way up. In my opinion it is very premature to suggest that the Japanese government is seriously prepared to pay for the privilege. The Japanese High Energy Physics Advisory Panel does not make the decision as to whether the government of Japan is going to spend that kind of money on the ILC or instead on, say, a suspension bridge to some fishermen's island that happens to lie in the district of some well connected national representative.

It would also be premature to count China out. The New York Times article to which Peter linked above points out:

"The location of today's announcement, at the Institute for High Energy Physics in Beijing, underscores the growing role and ambition of Asia, particularly Japan and China, to become major players in high-energy physics, a field that has been dominated by the United States and Europe in the last century."

The fact is that if China were willing to host and fund the project, there is a very good chance it would be built there. Moreover, Chinese government processes are almost completely non-transparent, so there is no way to know if senior government people might at some point latch onto the ILC as a nationalist vanity project. That would be quite consistent with many other things the Chinese government is now doing. Of course, the price tag for the ILC is pretty big compared to almost anything.

Europe, on the other hand, is extremely unlikely to host ILC with the LHC already up and running. Unlike China's non-transparent system, the absence of any serious voiced interest from Europe tells a lot about what the Europeans are likely willing to do. If there were serious interest, some sort of response along the lines of those of Japan described by Mr. Hefferman would be in view. Nothing is in view.

What about heh's argument that "The way to sell the US Congress is to point out that (a) the energy frontier will have been in Europe for some time, and (b) the US tradition of particle physics experiment will be practically dead if we do not build the ILC. Appeal to the fear that the US is slipping far behind in science and technology. Talk about the technological spin-offs that come from accelerator R&D." Well, it's hard to take this argument seriously given historical precedents. All of these arguments were made repeatedly in support of the Super Conducting Super Collider and they did not work. Nothing has changed since then for the positive.

The fact is that there are many forms of science and technology, and it is a very hard political sell to explain to the public and their elected representatives why it means much if the US "falls behind" in this particular technology – which means virtually nothing to the lives of the people writing the tax checks. Other forms of technology clearly matter to taxpayers. A few years ago the EU came together in the so-called "Lisbon Accord," which stipulated that Europe would become the world capital of intellectual property development. Silicon Valley laughed, and the Europeans don't talk too much about that silly accord and its ambitions now. Falling behind in that technology clearly means a lot to elected officials, as the existence of the Lisbon Accord demonstrated.

13. **Haelfix**
February 9, 2007

As much as I would love to see the ILC become a reality, and would gladly donate generously out of my pocket to achieve such, I do see the political baggage such a thing costs.

There really isn't a great justification for spending those sums of money, outside of the simple answer 'just to know more'. A lot of the claimed side effects of spawning new technology and so forth tend to be overblown. Nasa gives this line everytime they have a new plan to send people to Mars/moon/etc and after decades of this, the politicians have grown a little skeptical (justifiably so too).

You know the usual line we get at cocktail parties
'Exactly what use is your field, and how does it benefit me?'
I now simply state '99% chance that it leads to absolutely no pragmatic app in our lifetime, and perhaps never'

14. **Steve Myers**
February 9, 2007

HEP got spoiled after WWII because of the fear of the bomb & the Russians & so $$$ weren't hard to get. There's money for crazy stuff like Reagan-Bush-Bush Star Wars but not for basic research; and the Pentagon (Carriers, planes, etc.) always gets what it wants no matter how useless. Maybe getting across the idea that basic research is important for its own sake has to start in grade school?
But if ILC is built my guess is it will be in China. Also, a not irrelevant note: as of Nov 2006 major foreign holders of US Treasury securites (in billions): Japan 637.4, China 346.5, UK 223.5. So whatever funds the U.$. contributes will be borrowed from Japan & China.

15. **dark-matter**
February 10, 2007

Whether ILC proceeds or not depends on reality in the 2017 era. First, the technical case: no ILC-class machines will be built by anybody unless LHC discovers something absolutely astonishing (like the discovery of nuclear energy decades ago) that has the potential to disrupt human fundamentals, opening up a new direction, and points to major military implications.

Suppose such discovery occurs. Then the major powers will want to jump in and build the next machine to exploit it. What machine depends on what is discovered. The proposed ILC design is based on current theoritical knowledge and its projections. BUT these projections have largely been discredited in the eyes of the politicians and a sizable portion of the public. That's why everybody's looking for the real thing, LHC, for guidance and not theories. So if the next machine is to be built, it is very unlikely to be this ILC.

As for China, it certainly wants to participate in the next big machine but won't insist having it on its soils. China knows it just doesn't have the ability to build any of the sophisticated components and support systems, including computing facility. Those who can actually design and build it have the greatest say on location.

Unless there's a dramatic change in the reputation of USA in the next decade, an ILC type machine will not be built there. The mess with the Space Station construction have just about destroy the chance of any country, even friendly ones, wanting to do such an international project again. USA is looked upon with high suspecion – everything must have a military angle, there's the American way or the highway, unreliable funding from Congress even after treaties and contracts were signed, high-handed politics at every turn. So if US wants the next machine it on its soil, it must do it alone and take the lead on everything. But if Congress does see a justification for this huge investment, it will do it. Afterall, $20B is chump change if the politics is right. An game-changer discovery by the LHC, supported by theoritical work, will make the politics right. Otherwise, the money will continue to go to space-based instruments for fundamental physics.

16. **mclaren**
February 10, 2007

By way of comparison, America spends 5 billion a year on potted plants. We can easily afford it. The tragedy is that we'd rather build mythical "missile defense" systems that don't work (40 billion so far and counting, no end in sight) than create machines that explore the basic constituents of the universe.

Robert Musil remarked: "The problem is that even the Standard Model, with all of its vaunted (perhaps excessively vaunted) cleverness and accuracy of prediction, has not made much difference on any politically significant issue … still less to anything that a Western politician could point to as justification for spending over $10 Billion in tax money … or even a substantial portion of that inevitably-to-bloat figure. Once one moves to questions outside the Standard Model things get even flakier and harder to justify financially and politically."

And there's the irony. Neutrino mass is arguably outside the Standard Model. Although the SM can be fudged and fiddled to include neutrino mass, the SM never predicted it. And how was neutrino mass discovered? With a relatively dirt-cheap experiment. A big tank of cleaning fluid and some photomultipliers. No 10 billion dollar investment, no 20 mile long superconducting accelerator.

Maybe we're better off w/o the ILC. Maybe we need to follow Rutherford's example and experiment smarter, instead of experimenting bigger.

Many have said it before, but it bears repeating: the 3 biggest experimental results over the last 20 years didn't come from giant accelerators. They came from a tank of cleaning fluid in a mine shaft and a couple of relatively inexpensive satellites. Maybe the glory days of the giant accelerators are past.

17. **Tommaso Dorigo**
February 10, 2007

Dear mclaren,

the Standard Model could not "predict" the neutrino masses, any more than it allows the prediction of the mass of charged leptons or quarks. I personally think that the neutrino masses force an extension of the Standard Model more or less as revolutionary as a rearrangement of the furniture in the kids' room forced by the arrival of a new baby.

Mind you, I am not trying to derate the significance of a measurement that we had all been waiting for, a confirmation of tens of years of chlorine experiments and helioseismology – although I believe the discovery of the top quark, just as unsurprising, was not less important -and indeed a confirmation of the Standard Model.

Anyway, I concur – maybe we do not need the ILC. And I personally hold that it won't be built, despite the US ambitions to bring back HEP frontier experiments to their soil or Japanese or Chinese pride. That is because the LHC will, IMO, not discover anything else than a regular Higgs boson…

Cheers,
T.

18. **mclaren**
February 10, 2007

"This discovery shows that it is likely that the Standard Model, proposed in the 1970s to describe the fundamental forces and particles that make up all matter, is incomplete."

(..)

"Theoretically, neutrinos can change from one flavor to another only if they have mass. The Standard Model, however, assumes neutrinos are without mass."

Global Team of Scientists Upends Standard Model With Discovery of Neutrino Oscillation, Mass

——
I'd be delighted to be proven wrong, since in that case I would learn something.

So I'd ready and willing to believe that all of the above statements are incorrect and the SM does indeed predict a non-zero mass for neutrinos. All you have to do is prove it.

Please provide four (4) peer-reviewed journal articles showing that the SM predicted non-zero neutrino mass prior to the discovery of oscillating neutrinos. Please provide the volume number, issue number, page number, principal author and co-authors for each of the peer-reviewed HEP journal articles. Since I have cited 4 articles, you'll need to provide 16 counter citations.

I look forward to seeing them.

19. **Peter Woit**
February 11, 2007

mclaren,

While, before there was convincing evidence for neutrino masses, people often thought of the standard model as the model with zero neutrino masses, it was clear to everyone that adding in neutrino mass terms was a very simple extension of the model, one that experimental evidence might some day require. When this evidence appeared I don't remember anybody being especially surprised. It's kind of a game with language whether you want to emphasize the importance of neutrino masses (they show the standard model is wrong!), or denigrate their importance (they're a trivial extension of the standard model!).

20. **Tommaso Dorigo**
February 11, 2007

Ditto, better than I could have myself.

Cheers,
T.

21. **a**
February 11, 2007

I don't see how neutrino masses can be considered as part of the Standard Model, since we do not yet know what the theory of neutrino masses is.

More likely neutrino mass are of Majorana type, and give us a window at physics around 10^14 GeV. This physics might "just" be a few right-handed neutrinos: it would be less exciting than what nowadays theorists like to dream. But it is not a dream.

Otherwise, neutrino masses could be of Dirac type. While this possibility just needs a few more more Yukawa couplings, their extreme smallness and the lack of a Majorana masses makes this possibility the unlikely one: crazy new physics is needed to justify it.

22. **Aaron Bergman**
February 11, 2007

The standard model doesn't have any renormalizable operator that gives rise to a neutrino mass, but there's a dimension five (?) operator that does so. By the usual rules of effective field theory, this operator is suppressed by the mass-scale of the new physics whatever it may be.

23. **woit**
February 11, 2007

a,

Unless the LHC discovers something really new, I think the neutrino sector is by far the most promising place to look for new insights, but I think it confuses things to state this as "neutrino masses are not part of the standard model". These days the standard everday model of particle physics is the version with neutrino masses, and when people refer to the "Standard Model", that's often what they mean. I think a better way to describe the situation is to make the point that the neutrino sector is the part of the standard model that we understand least well. We don't know the mass matrix completely, there are lots of interesting questions about it, and answering these questions may give insights into degrees of freedom that really are completely separate from the standard model.

So, I think it's just a question of language, with my own preference being to think of neutrino masses as the most poorly understood aspect of the Standard Model. It's of course also accurate to insist on thinking of them as an extension of the Standard Model. Both choices of language refer to exactly the same physics and mathematics.

24. **a**
February 11, 2007

Peter and Aaron,

years ago QED was the theory, Fermi described radioactivity adding non-renormalizable operators suppressed by the weak scale, and this lead to the Standard Model. Today the Standard Model is the theory, we (likely) have to add non-renormalizable operators suppressed by a new scale, 10^14 GeV, and we don't know to which new "Standard Model" this could lead.

It is true that neutrino masses were theoretically expected, but it is also true that almost all theorists expected smaller neutrino masses (suppressed by the GUT scale) and with small mixing angles. Theorists suggested "build Kamiokande to discover proton decay", and Kamiokande discovered atmospheric neutrino oscillations with large mixing angle. This is the most recent triumph of theory.

25. **Tommaso Dorigo**
February 12, 2007

Dear a,

neutrino masses were not just theoretically expected. They were predicted from experimental measurements of neutrino capture rates that date far back in the past. Indeed, the first chlorine experiment results to claim a deficit in solar neutrinos was Homestake in 1968.

About the reason for building super-kamiokande: I would like to read it in SK's technical design report. I think that the discovery of neutrino oscillations was one strong motivation, no less than proton decay.

Cheers,
T.

26. **a**
February 12, 2007

dear Tommaso,

the name is enough: the "nde" in kamiokande stands for "nucleon decay experiment".

About the Chlorine anomaly: ironically it started to be accepted after that it was realized how small-mixing-angle oscillations could explained it; this explains the importance of 2002 experiments, that established that it was due to large-mixing-angle oscillations.

About the top: its non-discovery would have been very important, as it is one example of those crazy things incompatible with accepted theories (including string theory, as some people like to emphasize).

27. **Thomas Larsson**
February 13, 2007

Neutrino oscillations were certainly a mainstream idea many years before the discovery. At least it was so in the spring of 1981, when I gave an undergraduate seminar about the topic, in a course which nominally was about nuclear physics but was called CERN physics by the students (CERN-Physik statt Kernphysik).

28. **wolf**
February 13, 2007

Neutrino oscillations were first proposed by Bruno Pontecorvo in 1957, if I'm not wrong. They were not included in the SM at the time of its formulation simply because then there wasn't any experimental clue as to whether neutrinos really oscillate or not

29. **a**
February 13, 2007

Potentecorvo 1957 paper was wrong: nu nubar oscillations don't exist.

Anyhow there is a big difference between doing things and talking about doing things. Today we talk about supersymmetry, extra dimensions, etc:, but what would be really interesting is discovering them.

30. **wolf**
February 14, 2007

Well, Yang and Mill's 1954 paper was also wrong since isotopic gauge invariance does not exist. Isospin is just a global broken symmetry.

Wrong ideas often turn out to be the best ones. That's why string theory might well have a bright future.

31. **Eugene Stefanovich**
February 14, 2007

wolf:

Wrong ideas often turn out to be the best ones. That's why string theory might well have a bright future.

That's the best endorsement of string theory I've seen so far.

32. **mclaren**
February 14, 2007

Tommaso;
Thanks for pointing out that nuetrino masses were theoretically predicted by at least some members of the HEP community long before neutrino oscillation was discovered. I didn't know that. It's always great to learn something new.

You remarked: "It's kind of a game with language whether you want to emphasize the importance of neutrino masses (they show the standard model is wrong!), or denigrate their importance (they're a trivial extension of the standard model!)."

I have to disagree with that claim because a number of cosmologists have suggested neutrinos with non-zero mass as the mechanism behind dark matter. While I don't know the details on the theoretical status of this idea, and there has been a good deal of debate about the exact mechanism behind dark matter, it's safe to say that anything that might make up 80-plus percent of the mass of the universe is not just "a game with language." Let's put it another way: when the SM assumed zero neutrino mass, oscillating neutrinos were out as an explanation for dark matter. When the SM was extended to include neutrino mass, that became a possible source of the missing mass. That seems like a significant difference to me. (OF course the missing mass could still be superpartners or who-knows-what-all, but the big difference there is that we have hard experimental evidence for neutrinos with mass, while to date we have no hard experimental evidence at all for superpartners.)

BTW, it's also fair to say that whatever extensions are required to the SM to accomodate neutrino mass do seem to be minor. My point wasn't that the SM is significantly "broken" in any way by the discovery of neutrino mass. Rather, I was trying to point out that there are areas in which the SM can be tested and in which it has to be modified, leading to potentially fruitful new physics.

Common sense would suggest that spinning out mathematical computer models of imaginary multiverses which can never be experimentally tested fails to qualify as fruitful physics.

Just something which I happened to stumble upon tonight.

The Newtonian Legacy

February 10, 2007
Categories: Uncategorized

Instead of doing the work I had planned, I spent much of today having a very enjoyable time reading the mystery novel *The Newtonian Legacy* by particle theorist Nick Evans. A copy is available at his web-site here, and there's a FAQ about the book here (I pretty much agree with his LHC predictions).

The book is well-done, very entertaining, and a good read that keeps you wanting to know what will happen next. It includes lots of popular-level explanations about particle physics and the ideas particle theorists are studying these days, so it might be an excellent way to introduce someone to these ideas. It is set at a fictional theoretical physics research institute in England, and many of the characters are particle theorists of one stripe or another (string theorists, phenomenologists, lattice gauge theorists).

The novel includes quite a few amusing portrayals of characters embodying the current sociology of particle theory: a postdoc trying to decide whether to write into the Rumor Mill to tell them he is on a short list at a place he'd rather not go to in hopes of getting other places to offer him a job, a lattice gauge theorist who stalks out of a string theorist's talk in disgust, postdocs comparing the string theory landscape to religion, a self-satisfied American physicist from the West Coast convinced that string theory has the answers to the ultimate questions of science, and quite a few others.

The main character, Carl Vespers, is a particle theorist who, besides getting involved in the investigation of a mysterious death and having people trying to kill him, has to contend with more than one attractive woman throwing themselves at him, tempting him away from his long-distance girlfriend. All in all, a highly accurate portrayal of the life of a typical particle theorist. Highly recommended.

Comments

1. **Eric Baum**
   February 11, 2007

   Hi Peter,
   Rudy Rucker's Mathematicians in Love is an amusing sci-fi set around the academic world.

2. **s k san**
   February 11, 2007

   "has to contend with more than one attractive woman throwing themselves at him, tempting him away from his long-distance girlfriend. All in all, a highly accurate portrayal of the life of a typical particle theorist."

   I just love your sarcastic sense of humour

3. **Jonathan Vos Post**
   February 12, 2007

   I agree with the Rudy Rucker novel recommendation. His PhD, by the way, was in Mathematical Logic.

   Going through old emails, I found that I'd made a wry commentary on TV popularization of String Theory, and the human side of the academic world, as follows:

   BLACK HOLE BIRTHDAY
   ——————-
   by Jonathan Vos Post
   copyright (c) 2003 by Emerald City Publishing
   ——————-

   At midnight, you turned 50,
   alone, in your underwear,
   eating a bowl of Cheerios
   and wondering — where did all your friends go?

   What happened to that commune
   with the famous scientists
   who liked to keep you around
   to remind themselves how smart they all were?

   What if you had taken her up,
   that reactor engineer
   from the 747
   who propositioned you, mid-funeral?

   The years blurred past you, passing
   like the billboards high above
   Koreatown — ideograms
   you can't understand, don't remember.

   Palm trees blaze, torches roaring,
   dropping Kentucky Fried rats
   into the scummy hot tub,
   where you once played underwater Scrabble.

   All your extra dimensions
   are compactified, rolled up
   too tight to be detected.
   In String Theory, your strings are out of tune.

They all ran away from you,
galaxies of hangers-on,
accretion disks of neighbors.
What remained imploded to a black hole.

The light of your former world
drools down the gravity well
and, even if you got it,
you can’t escape the event horizon.

— — — — — — —
1200-1230
7 Nov 2003
— — — — — — —

That’s my complex emotional response
to the NOVA series on String Theory, combined with an interview of Art Garfunkel in Modern Maturity magazine. Poetry, and most art in general, attempts to reflect the complexity of the real world…

— Professor Jonathan Vos Post

4. **r hofmann**
February 12, 2007

Congratulations to Nick Evans. I had an enjoyable weekend reading his book. The book is manifestation of his talent to use very subtle terms and intelligently arranged combinations thereof to bring his convictions across. The entertainment frame is professional novel writing.

I like Dr Evan’s decision to make his brainchild freely available.

5. **Scott Aaronson**
February 13, 2007

Thanks, Peter — I read *Newtonian Legacy* over the weekend, and it was superb! But for the accurate discussions of electroweak symmetry breaking, one would think Evans turns out potboilers for a living. Unlike many academic novelists, he actually knows how to develop interesting characters and (especially) keep a plot moving. I hope the fact that the novel is free won’t deter people from reading it.

The similarities between the Phi and PI (Perimeter Institute) are a bit too striking to be dismissed as coincidental.

6. **Peter Woit**
February 13, 2007

Scott,

So the financial backer of PI and his wife are just like their analogs in the Evans book, and live next door to the Institute? Wow….

7. **anon.**
February 13, 2007

Peter is suddenly finding that vacation to Waterloo more appealing 😉

8. **Scott Aaronson**
February 14, 2007

So the financial backer of PI and his wife are just like their analogs in the Evans book, and live next door to the Institute? Wow….

Mike Lazaridis does live right here in Waterloo (his company shares a parking lot with the Institute for Quantum Computing), and comes to some of our events to give speeches about how amazing we are. Admittedly, I don’t think he’s involved with any “Historical Society,” and I’ve never met his wife.

9. **Cynthia**
February 14, 2007

Hi Peter!

Come to think of it, we, as avid consumers of pop-physics, oughta just throw out all those cheesy authors from the lesser sciences–including from the humanities, of course–that have this incredibly annoying tendency to write about physics with utter recklessness, not to mention with sheer listlessness.

After all, it’s becoming increasingly clear that physics is blessed with a whole host of brilliant writers which–believe it or not–just so happen to be active workers (including players, of course;)) in the field.

Needless to say, thanks for sharing this story written by a genuine fellow in the field. In fact, I’ve gotta confess, what Nick Evans has put together truly makes a most enjoyable read!

Thanks again!
Cynthia

The March issue of the Notices of the AMS is out. Excellent summaries of the mathematical work of the 2006 Fields medalists and interviews with three of them (everybody except Perelman). By the way, does anyone know if the 2006 or 2002 ICM proceedings are available on-line (the AMS is advertising the published books for the 2006 ICM, 3 volumes for $428)? There’s also an interesting article about Jim Simons and “Math for America”, the New York City based program designed to encourage people with a mathematics background to go into teaching. The program is partially funded by a yearly charity poker tournament attended by various people in the financial industry. I’d heard from one of them about this, but didn’t realize the scale on which they were operating. Last year’s tournament brought in $2 million.

This year’s Fields Medalist Terence Tao has an article submitted to the Bulletin of the AMS entitled What is Good Mathematics? See here for commentary from David Corfield.

Last month McGill University sponsored a large public symposium on the Anthropic principle that attracted overflow crowds, and featured Paul Davies, George Efstathiou, David Gross and Lenny Susskind. Gross and Susskind made more or less precisely the same points they have been making publicly about the string theory anthropic landscape for the last 4 years. You can watch the video for yourself here. Susskind seemed a bit less of an aggressive salesman of the anthropic point of view than in the past, acknowledging that the question of how you put a measure on the multiverse (this is needed if you want to make even statistical predictions) still has no solution. Gross made his usual points that accepting the landscape is premature, since we don’t know what string theory is, don’t understand the “emergent” notions of space and time it seems to lead to, and lack consistent time-dependent states describing something consistent with what we know about cosmology.

Besides the Becker-Becker-Schwarz and Dine fat textbooks on string theory that have just come out, another one is due out soon. It is by Elias Kiritsis and is called String Theory in a Nutshell (at nearly 600 pages, kind of a big nut). Princeton University Press is bringing it out in May. One of the leading physicists chosen to give a blurb is Harvard’s Lubos Motl, who also features on the Dine book. Evidently people who write string theory textbooks and their publishers feel his endorsement will do a lot to sell the books. Some of his recent postings refer to me as a “Communist” of a more “primitive and fanatical” sort than the ones he had to contend with during the Soviet era. I’d like to make clear that my political tendencies lean more toward some combination of anarcho-syndicalism and Clintonism than Soviet Communism. He also refers to the loyal readers of my blog as “human waste” (that’s you, folks…)

Comments

1. **John Stanton**
   February 12, 2007

   Dear Peter,

   keep your way!

   The agressions of a certain Harvard professor are typical of
   frustrated people that did not defend themselves in situations
   when it was necessary, and then, out of shame, pass
   on the received agression to others in situations where they
   are not appropriate.

   I guess it would do him a lot of good to have a wife and kids.

   Continue on your way!

   John

2. **Chris Oakley**
   February 12, 2007

   > He also refers to the loyal readers of my blog as “human waste” (that’s you, folks…)

   Funny that he should say, specifically, *human* waste.

   It does rather support the notion that he might be an extra-terrestrial.

3. **Peter Woit**
   February 12, 2007

   I forgot to add that, besides Princeton and Cambridge University Presses, the other media organization getting its material from Lubos is the Drudge Report. See http://www.drudgereport.com/flash.htm

4. **Clark Goble**
   February 12, 2007

   Thanks for the text book list. There are lots of people who were physics majors who’d love to be able to try and get up to speed on some of the latest in theoretical physics but are unsure how to proceed. I knew Weinberg had a series of QFT texts, the fourth of which dealt with string theory. However I’d gotten some negative comments on them.

   I wonder if there are any good ones on Loop Quantum Gravity?

5. **Oleg Tchernyshyov**
   February 12, 2007

   Greetings to all,

   I happen to be the one to whom Dr. Motl recommended this blog in those rather strong terms after I spent a week at his blog. The recommendation was apparently triggered by my comment in which I pointed out that calling your opponent a communist is unwise for a couple of reasons (e.g. communists can be good scientists, too, as exemplified by Lev Landau, who was a communist at heart). That comment was promptly made to disappear by the freedom-loving host.

Anyway, here I am looking forward to learning some things from your blog.

Oleg Tchernyshyov

7. **wolf**
February 12, 2007

Clark, Weinberg's book consists of three volumes with the third discussing supersymmetric field theory. I haven't read the third volume in any detail. The first two, however, are the best QFT texts I know of in terms of technical accuracy, depth, and conceptual insight. Personally, I don't like his choice of notation and conventions, but that's a minor issue to me.

8. **Clark**
February 12, 2007

I have his first volume although I confess I wasn't a huge fan of it. I think it's one of those texts that might have been better for folks already familiar with the topic rather than learning from it. (Just IMO – others disagree but I know a few people I've talked to came away with the same opinion) Sorry about getting that volume number wrong. I could have sworn there were four, not three.

Anyway, I just figured I'd drop a note of appreciation from the masses no longer in schooling but who maintain their physics interest. Textbook recommendations are always welcome.

9. **Lee Smolin**
February 12, 2007

The now standard textbook on loop quantum gravity is "Quantum Gravity" by Carlo Rovelli, Cambridge University Press. There are older books by Ashtekar and Gambini and Pullin and a book in press with a rigorous approach to LQG by Thomas Thiemann, also CUP.

10. **gunpowder&noodles**
February 12, 2007

I don't agree that the Susskind et al symposium was the same old same old. In particular, Susskind was *very* much more tentative, with no declarations that his stuff is just straightforward, *standard* QFT and cosmology, and no claims that there is absolutely no alternative. For him, this was a very subdued performance. And on the other hand, Gross was much more specific than usual, pointing out for example that LS's proposal for creating new universes probably doesn't work. I wouldn't be surprised to see LS start putting out papers to the effect that the landscape doesn't work and that this is the greatest crisis in history.

11. **Amos Dettonville**
February 13, 2007

In the McGill discussion, I found it interesting that Davies and Efstathiou both posed essentially the same question to their fellow panelists, and yet the answers they elicited were quite different. Prefacing his question, Davies pointed out that if we imagine the "pre-existence" (in some Platonic sense) of a large set of physical laws, one of which is operative in our particular universe, then this set of laws is being imposed by some system of meta-laws, by a process that is, by definition, outside of the physical laws of our particular universe. His alternative is some kind of co-emergence of the universe with its laws, rather than imagining them to be imposed from some unknown (and presumably unknowable) "outside". He then asked the other panelists to comment on this. Susskind at first demurred, and Gross basically just said the question was not (presently) within the realm of science. He likened it to the philosophical question "Why is there something rather than nothing?" Susskind concurred, saying that Davies's question was profound, but couldn't really be addressed scientifically…

But here's what I found interesting: The next question was from Efstathiou, who asked the other panelists what they thought the prospects were for being able to compute the prior probability of various sets of physical laws within the landscape. Now this was a question that Susskind grasped immediately, noting that he himself had included this very question on his list of important areas of study during his earlier remarks. He didn't seem overly confident of being able to solve it any time soon, but he definitely recognized it as a legitimate and important scientific question. But…

Am I wrong, or was Efstathiou's question really just a re-phrased version of Davies' question – the question that had just been declared unscientific? Surely to determine prior probabilities for all the alternative universes, what's needed is an understanding of the very meta-laws and outer machinery that Davies had asked about. The difference between the two questions was just that Davies expressed the idea verbally in terms of laws being imposed from outside, whereas Efstathiou expressed the idea in the form of an equation involving what he called the prior probabilities (corresponding to Davies' imposition of laws from the outside). I guess Susskind was just more used to thinking about it in the terms that Efstathiou used, and didn't recognize it in the terms that Davies used.

Gross gave a fairly consistent answer to both questions, i.e., he responded to both by saying they were not scientific – at least not at the present time. He didn't fall for the "delta function" trap, i.e., he wasn't phased when Efstathiou suggested that if we discount the possibility of a (non-trivial) prior *distribution* of possible laws, then we are basically arguing for a delta-function distribution, aligned perfectly with the needs of a universe that has the seemingly special properties of our universe. Gross seemed to recognize this as essentially a repeat of Davies' question, so his answer (again) was that we don't know enough about the whole realm of possible modes of existence (why something rather than nothing?) to even think about this in a scientific way.

I didn't sit through the all audience questions, but I was bugged by the first guy who attributed the "why something rather than nothing" question to Leibniz. It's been a long time, but I distinctly recall this question being famously bandied about by the Scholastics in the Middle Ages ("Why be there soe much something and not much more nothing?"), and it was an ancient question even then.

12. **human waste**
February 13, 2007

About Lubos, his behavior (blogging instead of working on strings) suggests that he agrees with Peter, but cannot accept that a macho like him is scientifically impotent. Maybe he could find the solution to his problem in some spam e-mail.

More seriously, my opinion about Weinberg books:

Volume 1 (QFT introduced in a non standard way) looks worse than the standard way.
Volume 2 of Weinberg (advanced QFT) is very good.

Volume 3 (supersymmetry): people who worked on supersymmetry wrote better books.

13. **island**
February 13, 2007

> I wouldn't be surprised to see LS start putting out papers to the effect that the landscape doesn't work and that this is the greatest crisis in history.

This being the case, and if he was true to his word, then he'd be obligated to join the Davies/Wheeler side of the "debate"… or maybe he'll take-up preaching… 😉

As things stand now, we will be hard pressed to answer the IDists if the landscape fails.
-Lenny

Surely it would make more sense for him to ask Lee Smolin what we have in common with black holes.

14. **stinking human waste**
February 13, 2007

As another sample of stinkin' human waste, of the worst kind – I have been a communist in my early days, although I have successfully recycled myself into a social-democrat- I should say that we all need to be wary of the anti-communism of such patriots as Lubos Motl, who comes -let's not forget it- from a ex-communist country, and was certainly the subject of brainwashing. Beware!

Cheers,
QDS

15. **Greg Biffle**
February 13, 2007

Hello Peter,

I was wondering if you and Smolin were planning on appearing on a panel with Gross, Davies, et al.

I think that it's time that the physics establishment starts inviting you guys to String Theory conferences.

Smolin has written several papers on string theory, and a bestselling book.

Do you have any reflections on how long it will take before you are invited to participate in conferences, and add you valuable insigts to the debate?

Indeed, I imagine that this blog is read far more often than the books of Davies, Gross, et al combined.

Either your book or Smolin's pointed out that the average age of the tenured professors is approaching sixty.

As creativity is the domain of the young, and arrogance the domain of the old who have failed to create when they were young, should not Lenny Sussking ste down?

16. **Peter Woit**
February 13, 2007

Greg,

I think it would be a good idea for talks at string theory conferences to include a more self-critical take on the subject and more serious discussion of the difficulties it faces, but I think this should be done by string theorists themselves, not by me. Lee Smolin often has pointed out that string theory conferences rarely include discussion of alternative approaches to quantum gravity, and that it would be a good thing for them to do so. I think he's right about that, and that this is starting to change.

As for things like the Toronto symposium, which feature more philosophical talks by elder statesmen of the field like Gross and Susskind, obviously I'm not remotely in their class. They have had long careers of tremendous accomplishments, and have earned the right to have a prominent role in such things and have people pay attention to what they have to say (and possibly disagree with it…).

Some people have invited me to speak in various contexts. I've already done some of this and there are several events planned for the future that I'll be involved in. I think I'm personally getting more than enough attention, and I'd prefer to see more public debate within the particle theory community about the problems of string theory, with other people doing this, not me.

I also don't think the problems with string theory are generational or have anything to do with age. The anthropic landscape is not something being promoted just by an older group of physicists; many if not most of its proponents are younger. If anything, the problem of string fanaticism is most pronounced in the generations of physicists who have gotten their Ph.Ds. since 1984 and sometimes don't know much about the parts of particle theory that have nothing to do with string theory. Older physicists often have seen ideas come and go, and have a more skeptical attitude about the claims made for string theory than do less-experienced youngsters.

17. **The Anti-Lubos**
February 13, 2007

This may not be appropriate here, and I hope that Peter will delete this comment if he feels that way, but I would like to advertise for a new blog that I've just created, Deleted by Lubos. I invite anyone who has posted a comment to Lubos's blog only to have him subsequently delete it to come to this new blog and post what they had to say.

18. **Chris Oakley**
February 13, 2007

> As creativity is the domain of the young, and arrogance the domain of the old who have failed to create when they were young, should not Lenny Susskind step down?

Whether Susskind is uncreative, superannuated and arrogant or not, I think that I speak for the majority of the human waste who post here in saying that if the Anthropic Landscape is the best you can come up with, then you should at least have the decency not to brag about it.

19. **Eugene Stefanovich**
February 13, 2007

human waste:

More seriously, my opinion about Weinberg books:

Volume 1 (QFT introduced in a non standard way) looks worse than the standard way.

I would like to defend Weinberg's Volume 1.

First, I should note that QFT is a tough subject. Much more difficult than QM. You can easily teach yourself to write Lagrangians, calculate Feynman diagrams, renormalize things, and still don't understand exactly **what** you are doing. I tried to learn QFT by myself. After 10 years, half-a-dozen textbooks, and countless journal articles I still couldn't grasp the big picture. This all changed after I read Weinberg's Volume 1: "the lightbulb" turned on in my head. The difference was made exactly by Weinberg's non-standard approach. He places particles first and fields second. He doesn't worship the gauge invariance principle, but uses it as a pragmatic tool. This makes everything logical and crystal clear.

Some Weinberg's papers written in the 1960's are very good as well, e.g.,

S. Weinberg, "The quantum theory of massless particles", in Lectures on particles and field theory, vol. 2 (Brandeis Summer Institute in Theoretical Physics, 1964).

Though, I would agree that Weinberg's Volume 1 should not be your first QFT textbooks. Sometimes, especially in the 2nd part of the book his writing becomes too abbreviated for a beginner to follow. For starters, I would recommend earlier books by Schweber and Bjorken & Drell.

20. **Greg Biffle**
February 13, 2007

Hello Peter,

I understand taht you have to be nice on your blog, but what have Gross and Susskind really achieved?

What is the Gross eqution and Sussking equation?

And too, even if they did achieve great things (in higher dimensions, as we can't see them here), does not their arrogance trump their acheivement?

For as Einstein and Socrates reminded us, are not a man's greater achievements contained in the way they humble themselves before the unknown?

A certain arrogance has reigned the culture, and they're all in it togther. Kaku praises Greene who praises Gross who praises Susskind, but eventually a Lubos shows up, and the bluff gets called.

You would think that Susskind would have the courage to denounce Lubos, but he doesn't–now whay is that?

21. **defense**
February 13, 2007

Greg: What on earth are you talking about? Gross has a nobel prize and I don't think anyone of sound mind could question that both Gross and Susskind have made major contributions. I have met both and find them each to be quite modest and friendly, not at all arrogant as you claim. Also, I can assure you that at the McGill symposium Gross most certainly did not excessively praise Susskind.

About Lubos: did it ever occur to you that maybe Gross just doesn't care about Lubos? Maybe he just prefers to spend his time doing something other than badmouthing his collegues.

22. **Peter Woit**
February 13, 2007

Greg,

Well, Gross has a well-deserved Nobel prize for co-discovering asymptotic freedom and thus QCD, for a start. His achievements are undeniable.

Susskind has nothing on that level, but still quite a lot to his credit. One example would be Kogut-Susskind fermions.

I don't think Susskind does not denounce Lubos out of a lack of courage. Is he in any position to denounce someone for being arrogant, not very concerned about the usual standards of what is science and what isn't, fanatically devoted to string theory, and prone to over-the-top statements in public? This is kind of many string theorist's problem with Lubos: as far as physics goes, he just takes many of their attitudes and beliefs to an extreme.

23. **Peter Woit**
February 13, 2007

defense,

I agree with you that it's likely that Gross's attitude towards Lubos is just that it's best to try and ignore him. Do you have any insight though into why at least some string theorists think so highly of Lubos that they put endorsements from him on the cover of their books?

24. **Peter Shor**
February 13, 2007

Do string theorists actually get to decide whose endorsements get put on the cover of their books? Or is this the publisher's prerogative?

25. **Peter Woit**
February 13, 2007

Peter Shor,

In my limited experience, publishers do allow authors to vet jacket copy, meaning that they send it to you and ask you if there is anything you strongly object to. In this case, there are two different publishers involved. I find it very difficult to believe that both publishers, besides having editors so clueless as to think that a Motl endorsement would be a good selling point, also did not let the authors know what endorsements were going on their books.

26. **anon.**

February 13, 2007

Blogdom has reached a new low when an an uninformed commenter can call Gross and Susskind arrogant and claim they haven't accomplished anything. Greg Biffle, you might want to reconsider your own arrogance: you clearly know nothing about the last four decades of particle physics and have no right to judge those who do. You might want to read up on the development of the Standard Model in the 70s and reconsider whether to take Gross and Susskind seriously.

27. **defense**
February 13, 2007

Peter,

I really can't speculate as to why some string theorists might want Lubos' endosement on their books. It may be, as you would argue, that they endorse some toned-down version of his position. It may also be that they simply don't follow his blog and aren't familiar with the kind of stuff he says there. Or maybe they respect him as a theorist and are simply willing to disentagle his published work from his blogging activities.

28. **LDM**
February 13, 2007

Evidently people who write string theory textbooks and their publishers feel his endorsement will do a lot to sell the books.

Well perhaps, but personally, I tend to ignore *anything* written by Lubos. Any endorsement by him I could never trust to be well reasoned or balanced, so I simply ignore it. I would also question the business acumen of any publisher that used him as an endorser, given the negative comments on his blog and elsewhere.

29. **woit**
February 13, 2007

One of the wonderful aspects of running a blog like this is that every so often someone decides to engage in a campaign of harassment by repeatedly posting racist or otherwise obnoxious comments. By using different names and anonymized internet addresses, they can keep this up for quite a while.

Someone from the University of Toronto at Scarborough has been doing this quite a bit today, and you may see their comments here every so often when I'm not logged in and able to delete them. The computer people at the University of Toronto tell me that they think they have identified the person doing this, so perhaps some action can be taken that will convince them to stop this harassment, if necessary through lodging a complaint with the police.

Ah, the joys of the internet….

30. **Chris W.**
February 13, 2007

Amos,

What you pointed out—the differing responses by Susskind, but not Gross, to Davies' and Efstathiou's distinct formulations of essentially the same question—is revealing of what seems to be a widespread syndrome. It can be described as a propensity to mask philosophical confusion behind what appears at first to be a well posed physical or mathematical question.

Consider the phrase "prospects .. for being able to compute the prior probability of various sets of physical laws within the landscape". The obvious question to ask here is, *compute with **what**, if not a prior set of physical laws (or, if you like, meta-laws)?*. If one admits this, then one would have to explain what point there is in talking about "sets of physical laws" within in the landscape, instead of talking about a single physical law (or single set of laws?) that gives rise to the landscape, with its implications—or lack thereof—for the observable universe.

This episode strikes me as indicative of the sheer dismissiveness and indifference that Susskind and many of colleagues seem to show towards any kind of serious critical philosophical reflection on what they're doing. This seems pretty darn close to what Einstein had in mind when he referred to a certain physicist as someone who could calculate, but couldn't think.

31. **Jeff Moreland**
February 14, 2007

Maybe the publishers of these stringy textbooks feel that Lubos is well known for controversy, and that his name will help sell the books, regardless of what people think of him.

32. **mclaren**
February 14, 2007

Doesn't anyone find it disturbing that idle speculations about the landscape can be described as a "theory"? Maybe there is a multiverse, maybe there isn't. Maybe we're only one of many universes floating in higher-dimension space, maybe we aren't. And maybe there are pink unicorns on some planet circling a star in the Andromeda galaxy and maybe there aren't. None of that baseless daydreaming qualifies as a "theory."

Show us how oi disconfirm the hypthesis. Then you've got a theory. If there's no way to experimentally disconfirm it, it's not a "theory," it's idle speculation, smoke and mirrors, all hot air with no substance.

The other thing I find objectionable is calling all those empty slots for physical constants "parameters." If we called 'em what they really are, "fudge factors," I bet people's opinions would change in a hurry.

VERSION 1: "By proper selection of parameters, one of the 10^500 possible universes can be made to match experimental observations."

VERSION 2: "By proper selection of fudge factos, one of the 10^500 fudge factor outputs can be made to match experiment observations."

Version 2 doesn't sound so good, does it?

33. **Pindare**
February 14, 2007

Most of the Proceedings of the 2002 ICM have been posted to the arxiv. Some for the 2006 one too, try
http://front.math.ucdavis.edu/search?a=&t=&q=icm&c=&n=40&s=Listings

Also note that Tao's "What is Good Mathematics?" will appear soon on the arxiv with feedback incorporated (at least he says so on his website, the version you're pointing to being dubbed 'old version').

34. **anon on the hudson**
February 14, 2007

Clintonism!!! God help us. Did you enjoy Clinton's bombing of the Serbian civilian population(and the chinese embassy which could have trigered WW3)

Back to Math/Physics. Okounkov claims he never participated in the high powered russian math olympiads I thought this was an interesting comment. I wonder what percentage of current elite mathematicians and physcisists participated in Math olympiads. Did Thurtston and Witten participate in math olympiads. If so how well did the do.

Supposedly, Stallings entered Princeton graduate school with an English degree. I was told he majored in English at arkansas. Maabe I got this story wrong. It t's been a while since I was told this by one of his Princeton classmates(a classmate who has since passed on)

35. **jeff**
February 14, 2007

In defense of lubos motl, his criticisms of lqg etc are interesting because they're always rather specific about the physics.

36. **poochie**
February 14, 2007

You realize, folks, that Lubos-related discussion accounts for at least a third of the traffic on this site. Peter, if you banned Lubos related discussions, your hit counts would probably drop like a rock.

Peter-vs-Lubos is the "Itchy & Scratchy Show" of the Quantum Gravity world.

37. **M**
February 14, 2007

jeff, not always. For example the answers by Smolin in the (undeleted!) comments to

http://motls.blogspot.com/2006/02/doubly-special-relativity-is-just.html

show that he missed the point. And maybe lqg experts stopped answering to Lubos when he later started putting too many insults.

38. **woit**
February 14, 2007

Jeff,

M is right, I think if you try and seriously read what Lubos has to say about LQG (as about most topics), it's a mishmash of some valid comments and some complete misunderstandings (with a heavy helping of insults thrown in). He does do a good job of acting like he knows what he's talking about, even when he doesn't, and has impressed many people this way.

poochie is right that the Lubos discussion is pretty absurd. The guy is incredibly entertaining though, and the phenomenon of string theorists putting endorsements from him on their books still strikes me as weird beyond belief.

39. **Greg Biffle**
February 14, 2007

Hello All,

I understand that the seventies were a great time for physics.

But it saddens me that that gives Gross & Susskind license to monoplize the future of physics too, when the truth is, they have stood idly by while the vast string theory juggernaut rolled itself up into a ball that has so much gravitation mass that it sucks the lion's share of NSF funding.

Do we really need more string theory books with blurbs from lubos?

Why is it that theoretical physicists–the supreme gate keepers of the Laws of Nature and Mind of God–have not the power to remove Lubos's comments?

Lubos is far more famous for his politcial, and sometimes racist, rantings, than he is for physics. He is far more famous for leaving Harvard than perfoming any physics while there.

And yet, in Lenny & David's ST world, his endorsement is worth being printed on the back of a book. . .

Jut what is going on here?

40. **Chris Oakley**
February 14, 2007

> He is far more famous for leaving Harvard than perfoming any physics while there.

I'd hate it if Harvard were to kick him out. It would make the job of anti-stringers *so* much harder.

41. **CapitalistImperialistPig**
February 14, 2007

Peter,

I bought Michael Dine's book, and, so far at least, like it quite a bit.

I have a theory as to why Lubos's blurbs wind up on such books. Suppose we stipulate that it's impossible to have a rational discussion with Lubos (except maybe for the elect) and that his views on a whole range of issues are bizaare, fanatical, wrong, and expressed in terms that would lead to a short life in less civilized neighborhoods. The fact remains that he is a very bright guy who is willing to read books very carefully and give the authors detailed and helpful advice.

If he likes your book, you get a nice blurb. His blurb on Dine's book told me exactly what I wanted to know about it. Sieberg and Arkani-Hamed wrote nice blurbs too, but their info was far less relevant to my decision to buy it.

42. **Q**
February 15, 2007

Lubos does have a sense of humor. He has the funny Antiworld physics song playing in the background on his blog:

He was sitting there,
floating in the air….
With a smile on his face …
we jumped into hyperspace. …
He was an anti-man.
He lived in an anti-world.
He had an anti-dog.

Full lyrics and download: see http://musiclub.web.cern.ch/musiclub/bands/cernettes/songs/antiworld.html

43. **Steven H. Cullinane**
February 15, 2007

Corfield, in the remarks Peter cites, says, "I've been pushing for philosophers of mathematics to address the problems of values other than truth." Such values lead naturally to… Hollywood!

44. **woman**
February 15, 2007

"but cannot accept that a macho like him is scientifically impotent."

scientifically? Why does he hates women?

45. **human waste**
February 15, 2007

"scientifically impotent": I mean that he likes hard-core science (where everything is either right or wrong), string theory started as a hard-core science, but it now looks not-even-wrong. Since getting hard-core results seems now unlikely, barking against the landscape and biting Woit and Smolin is a good alternative.

46. **Greg Biffle**
February 15, 2007

Questions to ponder are:

Would the advancement physics be helped or hurt if:

1) logic and reason were held superior to hype and speculation
2) lubos motl had to back up his words with facts
3) kaku/davies/susskind, now in their sixties, stepped down with their religious prophecies to make way for simple logic and reason
4) NSF funded proposals based on logic, reason, and elegance, instead of how many time the words "m-theory" or "String theory" appeared
5) Ed Witten/Kaku/Susskind/Gross/Davies/et al. took some responsibility for the crisis and provided some moral leadership, humbling themselves before physics and reality, and admitting, as Smolin and Woit point out, ST abject and complete failure to advance physics so far
6) Prestigious university presses stopped using Lubos Motl as a referee and blurb-generator until he published a single legible paper in physics, or even a blog post that advances physics
7) Physicists such as Woit and Smolin were given more weight in the realm of physics than journalists such as KC Cole et al, who freely attack the truth of their books, and still find employment at prestigious institutions of learning and publications.
8) Polanski, Greene, Witten, Kaku, Davies, Susskind, or any one of thousandn of string theorists or NSF agents who read this blog stepped forth to stand up for science, reason, and truth, and pass judgment on KC Cole, Lubos, and the decaying bureacracy that was just yesterday the tragic String Theory juggernaut.

We all know what will be best for science, and it brings to mind the words of Max Planck,

An important scientific innovation rarely makes its way by gradually
winning over and converting its opponents: What does happen is that the opponents gradually die out. -Max Planck

The true genius of the string theorists is that instead of making ST the domain of an indvidual, as the advancement of science has ever been, they wed it to groupthink and immortal government bureaucracies. Thus even when they are gone, thousands of snarky postcos, who don't even believe in ST, will yet defend it as a means to get a job.

The only prerequisite to become a string theorist is the iwllingness to sacrifice a life of truth and beauty and physics for power and prestige, and that is the trap lubos has fallen into.

For what happens when the false reality comes crumbling down?

They lash out at not those who are bringing it down, but those who are noticing that it is tumbling on down, such as Smolin and Woit.

There's a lot of nervousness out there, as King Sussking and Witten and Gross still wield so much bureaucratic power. Every young physicists is asking themselves,

"I know it's all BS, but if I want a job and a family–I've got to go with the flow, and echo the ST mantra–give us a year, or two, or thirty, or a thousand, and we will figure it out, because we are smarter than you."

Imagine the poor, tormented souls, but such is the price one pays for going into physics and then playing politics to get ahead. For "those who live by the sword shall die by the sword." Let's wish them all the best–let's hope that NSF stops breeding this malicious dependency on groupthink and snarky, mean-spirited mythology at conferences in Aspen and Prague.

And let's all look forward to tomorrow's renaissance in physics that shall go not to politicians, but to Smolin's "seers"–those who grappble with the big questions–those who walk right on by the meaningless, masturabatory math as Odysseus sailed on by the sirens, and start approaching physics as that which it is–physics–simple, elegant physical models underlying reality.

47. **Peter Woit**
February 15, 2007

Greg,

Please don't post rants like this here, it's really not helpful at all, since so much of what you write is highly exaggerated and caricatured. Besides getting some people's names wrong, you are completely misjudging many people's influence. For example, I don't think there are any physicists at all who care in the slightest what KC Cole thinks. This kind of thing just convinces people that critics of string theory are as far gone and fanatical as Lubos, just in the opposite direction, please don't do it here any more.

48. **Greg Biffle**
February 15, 2007

Thanks Peter.

Thanks for running this blog and your kind, even-handed, level-headed spirit.

You're doing a lot more for the advancemnt of physics than perhaps you even know.

Your spirit brings to mind a poem by Rudyard Kipling–"If."

If
A poem by Rudyard Kipling

If you can keep your head when all about you
Are losing theirs and blaming it on you;
If you can trust yourself when all men doubt you,
But make allowance for their doubting too;
If you can wait and not be tired by waiting,
Or, being lied about, don't deal in lies,
Or, being hated, don't give way to hating,
And yet don't look too good, nor talk too wise;
If you can dream – and not make dreams your master;
If you can think – and not make thoughts your aim;
If you can meet with triumph and disaster
And treat those two imposters just the same;
If you can bear to hear the truth you've spoken
Twisted by knaves to make a trap for fools,
Or watch the things you gave your life to broken,
And stoop and build 'em up with wornout tools;

If you can make one heap of all your winnings
And risk it on one turn of pitch-and-toss,
And lose, and start again at your beginnings
And never breath a word about your loss;
If you can force your heart and nerve and sinew
To serve your turn long after they are gone,
And so hold on when there is nothing in you
Except the Will which says to them: "Hold on";

If you can talk with crowds and keep your virtue,
Or walk with kings – nor lose the common touch;
If neither foes nor loving friends can hurt you;
If all men count with you, but none too much;
If you can fill the unforgiving minute
With sixty seconds' worth of distance run –
Yours is the Earth and everything that's in it,
And – which is more – you'll be a Man my son!

Best,

Greg

49. **Ari Heikkinen**
February 16, 2007

"He also refers to the loyal readers of my blog as "human waste" (that's you, folks…)"

I don't think anyone should take his rants too seriously, as he seems to consider anyone who disagrees with his conclusions on any matter (and I don't even mean string theory here) a crackpot or an idiot.

It's freedom of speech folks, ofcourse, but you don't have to take everything you read seriously.

Updates

February 15, 2007
Categories: Uncategorized

Terry Tao's article What is Good Mathematics?, written for the Bulletin of the AMS, is now available at the arXiv.

There's a new article also on the arXiv by Zvi Bern et al. explicitly constructing the 3-loop 4-point amplitude of N=8 supergravity. They find various extra cancellations beyond those expected from supersymmetry, and argue that this and other calculations "strongly suggest that N=8 supergravity may be finite." The innumerable claims made over the years at the beginning of pretty much every string theory book or popular article that you definitely can't quantize gravity just using QFT are now no longer operational. There is quite a lot of interest in this topic, with an array of possible computations that need to be done in order to sort this out. Just at the Mathematics Institute at Oxford the past few weeks there have been talks related to this by David Dunbar, Kellogg Stelle, Bo Feng, and Michael Green. The Resonaances blog has a report about a talk by Lance Dixon, one of the co-authors of the new paper. Also a nice report on a talk about supersymmetry by David Kaplan, who gives an excellent definition of fine-tuning of parameters: "a model is fine-tuned if a plot of the allowed parameter space makes you wanna puke" (accompanied by an illustrative plot of the situation in mSUGRA).

I'm waiting for the above news about supergravity finiteness to hit the media, perhaps some of the people working on this need to get to work on their press releases. There's yet more press about the Distler et. al. "test of string theory." The Daily Texan has an article called Test May Prove Far-out Theory, where Distler explains how the LHC seeing effects consistent with unitarity, analyticity and Lorentz invariance will provide "more evidence" for string theory. The reporter who wrote this called me up, and includes a garbled version of what I had to say. I was trying to be polite and stick to just pointing out that the paper at issue was not a string theory calculation and its title had been changed to remove reference to string theory, something I suggested the reporter might want to ask the paper's authors about. He seems to have not taken up my suggestion. I probably should have just used more straight-forward language, something along the lines of "dishonest bulls**t".

The US Congress finally finished dealing with the FY2007 budget, sending a bill to the president which he'll sign. It restores money to the NSF and DOE, avoiding a freeze at FY2006 levels that looked possible for a while and would have forced shutdowns at Fermilab and RHIC.

Finally, Capitalist Imperialist Pig informs us that Princeton is taking the occasion of shutting down its parapsychology lab to also close down its string theory program and redirect the funds to research on global warming. Somehow I suspect this may be a bit of an exaggeration, but they do seem to be making moves away from string theory and towards phenomenology, sponsoring workshops next month on Physics at LHC: From Experiment to Theory, and Monte Carlo Tools for Beyond the Standard Model Physics.

Update: Here's a link to the Kaplan talks on SUSY.

Comments

1. **Greg Biffle**
   February 15, 2007

   Lance Dixon was a TA of mine when I was an undergrad.

   I think he was a postdoc at the time, but he was better than the professor, and we always went to his sessions.

   I look forward to reading his paper! Thanks!

2. **kuos**
   February 15, 2007

   Question for discussion: how many of these attributes identified by Tao apply to string theory?

   • A field which becomes increasingly ornate and baroque, in which individual results are generalised and refined for their own sake, but the subject as a whole drifts aimlessly without any definite direction or sense of progress;
   • A field which becomes filled with many astounding conjectures, but with no hope of rigorous progress on any of them;
   • A field which now consists primarily of using ad hoc methods to solve a collection of unrelated problems, which have no unifying theme, connections, or purpose;
   • A field which has become overly dry and theoretical, continually recasting and unifying previous results in increasingly technical formal frameworks, but not generating any exciting new breakthroughs as a consequence; or
   • A field which reveres classical results, and continually presents shorter, simpler, and more elegant proofs of these results, but which does not generate any truly original and new results beyond the classical literature.

3. **John A**
   February 15, 2007

   At last, Princeton has the guts to shut down PEAR aka "if you stare hard enough at random numbers you'll see a pattern"

4. **Q**
   February 15, 2007

   "… Princeton is taking the occasion of shutting down its parapsychology lab to also close down its string theory program …"

   These are unifiable, at least according to the paper of Nobel Laureate Professor Brian Josephson of Cambridge University, http://arxiv.org/abs/physics/0312012 :

   "String Theory, Universal Mind, and the Paranormal … A model consistent with string theory is proposed for so-called paranormal phenomena such as extra-sensory perception (ESP). Our mathematical skills are assumed to derive from a special 'mental vacuum state', whose origin is explained on the basis of anthropic and biological arguments, taking into account the need for the informational processes associated with such a state to be of a life-supporting character. ESP is then explained in terms of shared 'thought bubbles' generated by the participants out of the mental vacuum state. The paper concludes with a critique of arguments sometimes made claiming to 'rule out' the possible existence of paranormal phenomena."

   I suspect that those who don't like string theory have formed a conspiracy to suppress research into paranormal extra dimensions, or ESP mental vacuum states, in case paranormal research come up with some evidence to support M-theory. Hopefully string theorists like Lubos Motl (who is deeply concerned about global warming issues) will take great comfort from the fact that the money being spent by Princeton on string will in future go to global warming.

5. **JustAnotherInfidel**
   February 15, 2007

   From what I recall, people tried to do model building with N=8 SUSY a long time ago because it automatically contained a graviton, and so was automatically N=8 SUGRA. There are 28 spin = 1 bosons in the multiplet, which look suspiciously like the adjoing of SO(8). But SO(8) doesn't contain SU(3) x SU(2) x U(1), and I don't know any more than this. I guess one could study, say, N=8 SUSY SO(10) or something, and have SUSY break at the planck scale to N=1 SUSY.

   I dont know—does anyone know about any phenomenology which has been studied along these lines?

6. **kramnik**
   February 15, 2007

   The point with this is not that N=8 might be the TOE that we want. Rather, if it is finite it's probably due to some as yet unknown deep symmetry which we don't know about. Determining whether it is finite, and if so why, will be a major clue to uniting gravity with the rest of physics.

7. **andy**
   February 15, 2007

   At first I was sure that it was a joke, but the phrase "mental vacuum state" does in fact appear in the abstract referenced by Q.

8. **CapitalistImperialistPig**
   February 15, 2007

   Peter,

   My remark about Princeton's getting out of the string theory business was unmitigated bullshit. I thought I had implied that pretty clearly in the post, and apologize to anyone who was thereby misled.

   Mea culpa!

9. **Jean-Paul**
   February 15, 2007

   The only reason to be excited about finitness of N=8 sugra is that it's an existence proof of a finite QFT with spin 2. From the particle physics point of view this is as irrelevant as the vanishing of c.c. in N=1 case.

10. **Gordon**
    February 15, 2007

    CapitalImperialistPig:
    No need to apologise–we all know your comments are always
    unmitigated bullshit.

11. **Thomas Larsson**
    February 16, 2007

    I don't see why one should be excited if N=8 sugra were finite. That theory certainly has as least as much problems with experiments as string theory. Besides, QFT infinities are not just a nuisance, but something which explain some experiments via anomalies, e.g. pion decay. Could really that effect be reproduced if the SM were embedded in some finite field theory?

12. **A String Theorist**
    February 16, 2007

    Hi Peter,

    In the abstract, at least, they were very careful to quantify the word "finite" with by saying "perturbatively finite." I don't know anyone who even would speculate that N=8 might actually be finite also NON-perturbatively. Presumably the non-perturbative completion of N=8 supergravity would be some string theory.

    Take N=4 Yang-Mills theory as an example. It is perturbatively finite, and its non-perturbative completion is a string theory (namely, type IIB string theory on AdS5 x S^5).

13. **CapitalistImperialistPig**
    February 16, 2007

    Ah Godon, coming from you, that means so much!

14. **Tim**
    February 16, 2007

    Peter,

    you write "on the arXiv by Zvi Bern et. al. explicitly" but "et" means "and" in latin and is not an abriviation thus needs no dot.

    Tim et al.

15. **woit**
    February 16, 2007

    A String Theorist,

    I've heard many claims about string theory providing an "ultraviolet completion" of a QFT, but you are the first person I've heard claim that it provides a "non-perturbative completion” of QFT. Actually, I think you just got this completely backwards: every string theorist I’ve heard say anything like this has said it in the other direction. No one knows what non-perturbative string theory is, but AdS/CFT can be interpreted as saying that the N=4 SYM QFT (which is believed to make sense non-perturbatively) provides a “non-perturbative completion” of string theory, where we only have a perturbative definition.

Thomas,

I think kramnik has it right. The point is not that N=8 supergravity is a viable TOE, it is that this result says there is some structure in it we don’t understand that is causing unexpected cancellations improving its ultraviolet behavior. The conventional wisdom that QFT’s involving gravity inherently have bad behavior in the ultraviolet looks like it is just wrong. This may be quite analogous to what happened with asymptotic freedom: up until 1973 the conventional wisdom was that QFTs in general had bad ultraviolet behavior, behavior that furthermore was inconsistent with observed high-energy scaling. That change in conventional wisdom killed off string theory once, it could happen again…

Tim,

Thanks, I always forget that. Fixed.

16. **Robert Musil**
February 16, 2007

According to the NY Times, various “legitimate” scientists visited PEAR’s and even gave them money from time to time. There is a unconfirmed rumor that Ed Witten was hard at work trying to move thought bubbles with his mind when the Princeton Dean rudely turned off the PEAR’s lights, plunging the special ‘mental vacuum state’ into darkness and making Ed stub his toe on the way out.

17. **A String Theorist**
February 16, 2007

Hi Peter,

Yes I realized right after submitting the post that I was being imprecise.

The essential problem, as you point out, is that we don’t have a non-perturbative definition for “N=8 supergravity”. I would bet that if someone someday finds such a definition, it will end up being a string theory.

18. **Hmm**
February 16, 2007

It is a stunning indication of americas descent into mediocrity that you are now being contacted by journalists to give views on *scientific* rather than sociology-of-science matters. Wow. Its enough to have a blog; you don’t need to have a record of research accomplishment or to even understand the technical claims being made. God help us all!

19. **A String Theorist**
February 16, 2007

Oops, I hit submit before I was finished.

About N=4 Yang-Mills, I never said that string theory provides the non-perturbative definition of YM.

I said that the non-perturbative completion of the theory (which you may take to be a Feynman path integral, or lattice I suppose) is a string theory (i.e., in a certain regime of parameter space, it describes relativistic strings).

20. **Scott Aaronson**
February 16, 2007

*The reporter who wrote this called me up, and includes a garbled version of what I had to say … I probably should have just used more straight-forward language, something along the lines of “dishonest bulls**t”.*

Peter, I’m having the same problem these days talking to journalists who want to bullshit up their quantum computing stories (“the world’s first commercial quantum computer has been unveiled, able to solve NP-complete problems in a heartbeat…”). I patiently explain to them why the story doesn’t mean anything like what they think it does, but I get the sinking feeling, even as I’m talking, that the article will have zero mutual information with anything I say. If you ever figure out how to dissuade a journalist from writing the misleading piece he or she wants to write, please let me know.

21. **woit**
February 16, 2007

A String Theorist,

Thanks for the clarification. I still think it’s kind of misleading to talk about a “non-perturbative” completion of N=4 SYM. By itself N=4 SYM is inherently a non-perturbative theory (even if we don’t completely rigorously understand it). One doesn’t talk about the “non-perturbative completion” of QCD, QCD is just inherently a non-perturbative theory, and going to a supersymmetric version doesn’t change this.

I haven’t thought much about this, but it’s not clear to me that you can’t just define N=8 supergravity non-perturbatively as the path integral, and try and make sense of this. If this works, you would have a purely conventional QFT for quantum gravity. Like many QFTs it might have some regime where a string theory approximation was useful, but I don’t think that would justify calling it a string theory since it is fundamentally defined in terms of quantum fields, not strings.

Hmm,

My, some of you string theory partisans are charming, especially the ones too cowardly to put their names to their ad hominem attacks. I’ll leave it to informed people to decide who was giving this reporter honest, accurate information, me or Jacques Distler.

Scott,

Similarly, if you figure how how to stop journalists from writing the “quantum computers solve NP-complete problems in a heartbeat” story, let me know and maybe it will help me figure out how to dissuade them from the “string theorists figure out how to prove string theory” stories which they are being continually led to write.

22. **Thomas Larsson**
February 16, 2007

My concern about combining anomalies, which are experimentally confirmed consequences of QFT infinities, with a finite theory are not original. I essentially took the argument from Roman Jackiw, hep-th/9911071, which ends with

"one very important lesson we should take from quantum field theory is not to banish all its infinities. Apparently the mathematical language with which we are describing Nature cannot account for all natural phenomena in a clear fashion. Recourse must be made to contradictory formulations involving infinities, which nevertheless lead to accurate descriptions of experimental facts in finite terms. It will be most interesting to see how string theory and its evolutions, which purportedly are completely finite and consistent, will handle this issue, which has been successfully, if paradoxically, resolved in quantum field theory."

23. **anon**
February 16, 2007

"I'll leave it to informed people to decide who was giving this reporter honest, accurate information, me or Jacques Distler."

Since you complain that the reporter misquoted you, are we to assume, in contrast, that he quoted Distler accurately?

24. **Peter Woit**
February 16, 2007

anon,

I don't think people need to or should base their decisions about this on what the reporter has either of us saying, since he for good reason had trouble understanding what is going on. In my case, you can judge from what I've written here on this topic as to its scientific accuracy. In Distler's you can read the press release the university issued for him, or consider the many other press stories quoting him on this topic. My scientific claim is simple, and it seems that a PRL referee agreed: Distler's paper isn't about string theory so can't claim to have a test of it. Distler seems to be quite clear in his claims to the press that he has a test of string theory that can be performed at the LHC.

Up to you to consider which of those two claims is more scientifically accurate.

25. **Robert Musil**
February 16, 2007

Peter,

"The reporter who wrote this called me up, and includes a garbled version of what I had to say … I probably should have just used more straight-forward language, something along the lines of "dishonest bulls**t"."

In general, those who deal frequently with the media come to understand that when a reporter calls asking to speak one has two choices: Speak, and be misquoted – or refuse to speak, and be misinterpreted.

I pray you have the widom to choose correctly.

26. **Chris W.**
February 16, 2007

Scott and Peter,

I'm afraid that the people you need to dissuade are the editors that have final say on what gets published. (Maybe it goes higher than that.) I suspect that in most cases a reporter who is conscientious in this sense would have trouble continuing to report on science-related stories; he or she would be told that they can play ball, take other assignments, or get fired.

Perhaps there is an editor out there who would like to take issue with this. If so, please post a comment, preferably with some helpful explanation. Try not to blame it on the great unwashed public, ie, your alleged readers.

27. **Tim**
February 16, 2007

Peter,

You write "My, some of you string theory partisans are charming, especially the ones too cowardly to put their names to their ad hominem attacks." and this is not the first time you bring up such a remark.

Did I miss the sign "If you post here, you are obliged to give your real name!"?

You chose this type of forum yourself and you know very well that posts can remain anonymous, so why complain? If you chose a different forum (refereed journal, arxiv, conference, etc) for letting the world know what you think, all responses would bear the real name of the respondent. However it is by your own free choice that you use a blog which implies by the very nature of this forum that responses can and will remain anonymous.

Your complaining is analogous to a writer who refuses the advice of his publisher to order high quality paper for a new book but later on complains that the books are worn out too quickly.

Tim

28. **Ari Heikkinen**
February 16, 2007

"close down its string theory program and redirect the funds to research on global warming"

Heh, that's funny, as I thought the biggest web-advocate of string theory thinks that global warming is utter nonsense (sorry, couldn't resist:).

29. **island**
February 16, 2007

Tim, Peter often knows or can find out who the anonymous posters are, yet he generally keeps their secret from the public, (unless he is being severely harassed), while calling them out for being too chicken to claim responsibility for their unsubstantiated bullshit.

Shut up.

30. **Peter Woit**
February 16, 2007

Tim,

I don't encourage people to post anonymously here; I think it would be best if people always used their real names. Personally I don't post comments on other blogs without using my real name, although I can imagine some unusual situations in which I might choose to do so. But my policy certainly is to allow anonymous comments, and I realize there are many legitimate reasons for people to choose not to use their names. If someone wants to engage in anonymous attacks on me, I'm allowing that. I also have every right to refer to people who decide to do this as "cowardly".

31. **Peter Woit**
February 16, 2007

island,

Thanks for the supportive comment, but do try and keep the hostility level down…

It is also true that it's often not too hard for me to figure out who anonymous commenters likely are. For instance, in the case of "Hmm", his comment was posted from a somewhat unusual and precisely identifiable location, making it not hard to, with a small amount of research, make a pretty good guess as to who he is.

32. **Rugs**
February 16, 2007

I have a friend that is an editor for a newspaper (I will leave his name, my name and his paper anonymous so we can remain friends) and when we had a mutual friend die in an accident I got to watch how he dealt with reporters. He wrote out every statement and read the statements to reporter's one word at a time making sure they wrote each word as he had intended. He was very concerned about how the circumstances of our friends' death were reported. He not only understands how sloppy note taking can lead to bad reporting he also knows that a sensational story can help a reporters career better than a boring one. Though he doesn't believe it is done intentionally (I feel a little differently) he does feel human nature will push a simple story in the wrong direction. I don't know if knowing how a newspaper editor deals with reporters is any help but I sure found it enlightening.

33. **Peter Woit**
February 16, 2007

Chris W.,

I should say that my experience over the last year or so with quite a few reporters is that they try hard to get things right. They're not experts in the science involved, and, faced with people making contradictory or hard to evaluate claims, they do the best they can. With one exceptional case of behavior that was worse than I would have guessed goes on, I've been pleasantly surprised by the competence and degree of professionalism of almost everyone I've dealt with.

The problem with the "physicists finally discover how to test string theory" stories mostly doesn't come from the people reporting these stories, it more often comes from the scientists involved.

34. **Michael**
February 16, 2007

Peter,

suppose N=8 sugra is finite and exists at the quantum level. In order for your conclusion that it is a theory of quantum gravity besides string theory to hold, you'd still have to show *that*, namely that it cannot be realized as a string theory. Absent such a proof you could make that claim already about N=4 SYM, which is a sugra theory on an AdS space written in funny variables.

Until someone does this for you (clearly you are not capable of it yourself), it is much more plausible to say that N=8 sugra resisted embedding into string theory so far simply because it doesn't exist beyond perturbation theory.

So even if I swallow all the ifs buts and maybes you interjected, your line of reasoning has more holes than swiss cheese. Your thinking is really very flaky.

35. **Eric**
February 16, 2007

Michael, the gravitational degrees of freedom in a SUGRA theory are pretty straightforward to isolate (in contrast to the surprising case of AdS/CFT). If N=8 SUGRA were shown to be finite and a sensible quantum theory, no convoluted rewriting of the theory in a dual string picture, or showing that you can get N=8 SUGRA in particular backgrounds ,will change the fact that you have found a non-string theory of quantum gravity.

36. **Michael**
February 16, 2007

Dear Eric,
How can you say that isolating the degrees of freedom is "pretty straightforward" if you cannot even show that the theory exists? There might just be another "surprise" in stock for you.

The smart money remains on the reverse logic: N=8 sugra cannot be embedded into string theory, because it doesn't exist beyond PTB.

37. **Peter Woit**
February 16, 2007

Michael,

You anonymous string theorists are all such polite folks, always a pleasure to try and have a discussion about scientific issues with you.

"N=4 SYM, which is a sugra theory on an AdS space written in funny variables"

That's just not true. Even if you believe everything conjectured about AdS/CFT, N=4 SYM is supposed to be exactly dual to a full, non-perturbative string theory, not to supergravity on AdS.

It's kind of hilarious to see string theorists claiming that N=4 SYM should be understood as a string theory, when they don't know how to define non-perturbative string theory, except as N=4 SYM.

I don't think the argument "OK, QFT can also give you finite terms in perturbation theory, just like string theory, but it may have problems non-perturbatively, unlike string theory (wait a minute, we don't know what string theory is non-perturbatively, other than through the QFT…)" is going to fly.

38. **Michael**
February 16, 2007

"such polite folks"

Stop whining and talk about the issue!

"That's just not true."

For large radius, my statement is perfectly accurate; the generalization is obvious. My point was well taken.

You have failed to address the hole in your logic, which I pointed out. Thanks for nothing!

39. **Eric**
February 16, 2007

Michael,

I'm not even anti-string theory, but you don't make sense, and your point is definitely not well taken. Since one of the things you do in SUGRA is quantize the metric, you've got a perturbative spin-two field staring you in the face, giving you gravitational interactions, just like the relevant closed string mode in string theory: this is very easy to isolate.

For the large radius limit of an AdS space, yes it is supposed to be well-described by a SUGRA, but this is just an approximation, there's nothing really to "generalize."

40. **Peter Woit**
February 16, 2007

Michael,

Despite your rudeness I'm trying to have a serious discussion with you. I have addressed the issues here, you haven't. The discussion is not about a limiting case of large radius. All you seem to be able to do here is talk about "the smart money". If you know of an argument showing that N=8 supergravity can't be defined outside of perturbation theory, but string theory can, let's hear it.

41. **Michael**
February 16, 2007

Peter,
I may have an opinion, but I do not know if N=8 sugra exists. I simply pointed out that under the assumptions you made your logic still had a gaping hole, and it remains so.

You are trying to sidestep the issue and claim `string theory isn't better`. Perhaps. Bananas. Whatever. It does not reduce the number of holes in your argument.

42. **CapitalistImperialistPig**
February 17, 2007

Ari – Yes, that was whatever point there was of my little "joke." Lubos had just deleted a global warming comment of mine when I wrote the post.

43. **CapitalistImperialistPig**
February 17, 2007

Michael said: "suppose N=8 sugra is finite and exists at the quantum level. In order for your conclusion that it is a theory of quantum gravity besides string theory to hold, you'd still have to show *that*, namely that it cannot be realized as a string theory. "

If this is the "hole" you keep talking about, you are pegging your argument on a pretty flimsy support. Whether some QFT can be realized (I think you really mean represented) as a string theory is irrelevant to the question of whether there is a QFT of gravity. Perhaps the second law of thermodynamics can be realized as a game of parchesi – if so, it would certainly be amusing, but it would hardly show that parchesi is essential to the description of the world.

44. **gunpowder&noodles**
February 17, 2007

Michael's comments are so funny — especially "My point was well taken" [Haha, I thought *other* people are supposed to say that!] that I suspect he is pulling Peter's leg. Unlike, sadly, "Hmm", whose determination not to have a sense of humor is known far and wide.

45. **Steven H. Cullinane**
February 17, 2007

Q: Regarding thought bubbles– Thanks for sharing.

46. **ObsessiveMathsFreak**
February 17, 2007

And for examples of What is Bad Mathematics, see Jean-Pierre Serre's How to Write Mathematics Badly.

47. **mathjunkie**

February 17, 2007

What is the importance of that N=8 supergravity exists? Does it mean that it can replace String theory?

48. **Alex Nichols**
February 18, 2007

There are now two papers:
1) http://www.arxiv.org/pdf/hep-th/0702112
-based on point particles

2) http://arxiv.org/abs/hep-th/0610299
-based on strings

Both claim to be u-v finite.

Question: At what sort of energy levels would it be possible to exclude either 1 or 2?

49. **Arun**
February 18, 2007

If I understand correctly, crucial to the Bern et. al. argument is the use of the KLT (Kawai, Lewellen, Tye) tree-level relations, orginal expressing tree-level closed-string scattering amplitudes in terms of pairs of open string ones, which in the low energy limit of compactifaction to four dimensions relate N=8 supergravity and N=4 super YM tree amplitudes.

Unless this step could be discovered independently, it would appear that a digression into string theory is essential to the (possible) discovery of viable QFT gravity theories.

🙂

50. **Peter Woit**
February 18, 2007

Alex,

This isn't an experimental question, it's a purely theoretical one about whether these higher order terms are finite or not. In principle it's a straightforward calculation, and one can just calculate. The problem is that the calculation is so difficult that people have to use indirect arguments and make some assumptions in order to get an answer at high orders.

51. **onymous**
February 18, 2007

Alex, from your comment it seems you think that the papers you link to are about two different theories, one stringy and one involving point particles. This is not the case. Both are about N=8 supergravity in four dimensions, they are just approaching it from different directions: you can get to this theory by compactifying 11D maximal supergravity.

In general the question of whether this is a "field theory of gravity" or a "string theory of gravity" is not well-defined. As with any interesting field theory, there are nonperturbative effects. In gravitational theories these contribute exp(-1/g) terms, which are understood in string theory to be associated with branes. So solitonic objects are inescapable in this theory, even if it is perturbatively finite. (The solitons are associated with the divergence of the *sum* of the perturbative theory, which will diverge even if the individual terms are finite.) N=8 supergravity is part of the same family of theories as M-theory (the UV completion of 11D sugra), which includes both theories with light strings and those without.

In any case, it certainly isn't a typical local QFT of spin-2 objects, the usual difficulties with constructing local observables in quantum gravity apply to N=8 supergravity even if it is finite.

52. **JustAnotherInfidel**
February 18, 2007

"The conventional wisdom that QFT's involving gravity inherently have bad behavior in the ultraviolet looks like it is just wrong. "

I don't think this is the conclusion that the authors are claiming—in the last paragraph they seem to imply that stringy effects are still needed to get all of the cancellations needed:

"The result presented here, in conjunction with the allloop-order evidence from unitarity [13] and string theory hints of additional cancellations [7, 8, 9], strongly suggests that N = 8 supergravity may be ultraviolet finite."

53. **woit**
February 18, 2007

JustAnotherInfidel,

The reference is to independent duality arguments of Green et al. that do have to do with string theory, but have implications for pure supergravity. What is being discussed here is not string theory, it is a QFT, N=8 supergravity, and the question is whether the terms in this perturbation series are finite. String theory methods may be useful for showing this (although the Bern et al. paper under discussion does not use string theory), but the claims are being made about a theory that does not involve strings, and is a conventional QFT. It is precisely this conventional QFT that people have in the past believed had bad high energy behavior, but now it appears this may not be true.

54. **Gordon Chalmers**
February 20, 2007

I havent checked the blog for a while, but I would like to point out that it is straightforward to obtain a nonperturbative formulation of N=8. Take the nonperturbative formulation of IIB string theory compactified on a six torus and decouple the massive modes. I believe the exact S-matrix of IIB string theory is known, and for that matter, after decoupling the massive modes so is the exact matrix of N=8 sugra. Of course the exactitude of the S-matrix relies on the belief of S-duality
so consider it a hypothetical exactness until duality is shown.

By the way in case you are interested there do seem to be some early articles on obtaining the standard model with some technicolor type of arguments but that is all. The theory seems to be nonviable unless the standard model gauge group changes, which is in fact possible if you read some more about string bits.

Also, just as a plug, I am in fact the first person to argue for finiteness in a concrete manner, and to this day my arguments are
repeated almost by everyone except for Bern et al, who use the
no-triangle hypothesis in a convincing manner.

55. **Vogelsang**
February 20, 2007

> Also, just as a plug, I am in fact the first person to argue for finiteness in a concrete manner, and to this day my arguments are repeated almost by everyone

Could you please provide some references?

56. **gordon chalmers**
February 20, 2007

Would yould you like that with at symbols or what?
I could give you the references, which you could look up, or I could give you the 200 papers that I have catalogued which are unpublished.

Which is which is what I know of.

Gordon

57. **gordon**
February 22, 2007

There are further cancellations at 3 loops and beyond which are not accounted for by the no-triangle hypothesis. These cancellations occur in two and three loops. They are not accounted for by any symmetry and the integral functions are absent and they are many. So the theory is probably secretly hiding a symmetry which noone has encountered before. The theory is probably finite, and if you dont like my comment why dont you ask me or Zvi Bern for details: but they are unproven.

Richter, MiniBooNE and an Eternal Feast

February 18, 2007
Categories: Uncategorized

At the big AAAS conference held in San Francisco the past few days there was a session on "A New Frontier in Particle Physics", about the LHC and the promise of physics at the TeV scale. Burton Richter's talk there on Charting the Course for Elementary Particle Physics is now available at the arXiv.

Richter uses the "It was the best of times; it was the worst of times" line from Dickens to characterize the current state of particle physics. He expects the LHC to begin operations at full energy in summer 2008, with physics results beginning to appear in 2009. As for the ILC, at the earliest it would be completed in 2019, and he sees no chance of it being built if the LHC doesn't find something new by 2012. He also sees a luminosity upgrade of the LHC being considered next year, one which would take place after the machine had been running for 5 years or so.

He also discusses the MiniBooNE experiment at Fermilab, a neutrino experiment that is late in reporting results. They are doing a "blind analysis", not "opening the box" and looking at the final answer from their data until the last moment. Richter is dubious about this, saying: "I never did like blind analyses", claiming that they prevent experimenters from seeing problems in the data, and he worries that the MiniBooNE result (which is trying to check results from the LSND experiment that disagree with the standard picture of neutrino physics) will be inconclusive.

We should know soon, I see that on March 1 there is a colloquium scheduled at Princeton by one of the MiniBooNE experimenters on "New Neutrino Oscillation Results from the MiniBooNE Experiment". For a recent talk about MiniBooNE given at Columbia, see here. This talk did also definitely mention the possibility of an inconclusive result, requiring a more sensitive experiment that might take place at the SNS (Spallation Neutron Source) in Oak Ridge.

Also at the AAAS meeting was yet another session on the wonders of the multiverse called "Multiverses, Dark Energy and Physics as an Environmental Science," featuring the usual Stanford team of Linde and Susskind, with Lawrence Krauss brought in to provide a little bit of reality. Stanford has put out a press release promoting Andrei Linde's talk at the meeting. Linde goes on about what he calls 10^{1000} vacua, and how they are "an unexpected gift from string theory… an eternal feast where all possible dishes are served." He seems to be positively gleeful about the "Alice's Restaurant" aspect of this pseudo-science, where "you can get anything you want…"

Update: For the YouTube generation, Stanford has a video here.

Update: Jon Bagger's talk at the AAAS is available here.

Update: Various reports on the AAAS multiverse session including here, here (Wired blog, couldn't get in the room, too full), and here (New Scientist blog, describes the session as "you might have mistaken the proceedings inside for a stand-up comedy act").

Comments

1. **Q**
   February 19, 2007

   Linde goes on about what he calls 10^1000 vacua, and how they are "an unexpected gift from string theory… an eternal feast where all possible dishes are served."

   A string miracle, hallelujah! Regarding the eternal feast, Christians should be impressed with this blessing, for it way exceeds the miracle of Jesus feeding the four thousand (Mark 8:1-9),

   In those days the multitude being very great … they did eat, and were filled … And they that had eaten were about four thousand: and he sent them away.'

2. **Steven H. Cullinane**
   February 19, 2007

   Christians, as a web search shows, use the phrase "eternal feast" to refer, not to an earthly repast, but to Heaven. Few of them are likely to find the Heaven of string theory more appealing.

3. **A**
   February 19, 2007

   Interesting reporting about MiniBoone. You may already know this but the co-spokesfolk for this experiment, Janet Conrad and Mike Shaevitz, are both at Columbia.

4. **Hans de Vries**
   February 19, 2007

   Christians should be impressed with this blessing, for it way exceeds the miracle of Jesus feeding the four thousand.

   Christians use the phrase "eternal feast" to refer, not to an earthly repast, but to Heaven

   Then the joy must be because the number of the beast, 10^666, has been finally beaten. This makes all the difference between a Universe expanding into the eternal Heavens or one collapsing back into Hell fire. :^)

   Regards, Hans

5. **Bee**
   February 19, 2007

   A string miracle, hallelujah! Well, you don't actually need to turn water into wine, you just have to convince everybody that it is wine.

6. **Arun**
   February 19, 2007

   "Well, you don't actually need to turn water into wine, you just have to convince everybody that it is wine."

   Does this have to do with the question – what is reality?

7. **Steven H. Cullinane**
February 19, 2007

Or “What is Kool-Aid”?

8. **Chris W.**
February 19, 2007

It sounds like Andrei Linde has irrevocably *jumped the shark*.

9. **Louise**
February 19, 2007

You would have enjoyed hearing Larry Krauss' intro to the AAAS session: “Why scientists have gone mad.” He said that supernova data “naively implied” that the universe was accelerating. Introducing Lenny Susskind, Krauss asked rhetorically if strings were a sinking ship. The room was very crowded!

10. **Bee**
February 20, 2007

“Well, you don't actually need to turn water into wine, you just have to convince everybody that it is wine.”

Does this have to do with the question – what is reality?

Well. Everything has to do with the questions what is reality, no? But in this case I was more thinking about ‘marketplace’ tactics. Like, you don't need to actually produce the best pizza, you just need to convince everybody it IS the best pizza (alternatively, you can make sure all competitors go broke, then you have the one-and-only best-and-worst pizza).

PS: I don't want to get spam-filtered, so I won't include a link, but check Lubos for a 2007 edition of the landscape, I had to laugh quite a lot.

PPS: And make sure to turn down the volume before you do.

11. **a quantum diaries survivor**
February 20, 2007

By 2012, the upgrade of the LHC (SLHC) will probably be almost completed. So we will have many years to delve in Standard Model boredom, undisturbed by new R&D for the suppressed ILC…

T.

12. **Vogelsang**
February 20, 2007

So we will have many years to delve in Standard Model boredom,

If the SM is boring to you, why not switching to some other area of physics? Astrophysics and nanophysics for example are currently very active, with lots of experimental/observational results to feed theory.

13. **Thomas Love**
February 20, 2007

I just read on a google group:

Lubos Motl (a Czech national) pressured to resign from Harvard's physics department
because of his vicious shotgun public polemical attacks on Woit, Smolin,
Penrose and even Susskind!

Is it true?

14. **Peter Woit**
February 20, 2007

Thomas,

That's from Jack Sarfatti, and I think he's about as reliable a source of information as Lubos, and in this case the origin of this claim is some comment from Lubos about resigning from Harvard. No idea whether he is leaving Harvard, in the last few years he has repeatedly talked about it.

As far as I've ever been able to tell, the theorists at Harvard are fine with Lubos's attacks on people who criticize string theory (or his much more mild criticism of Susskind). On the other hand, his spending all his time on a blog devoted mainly to global warming and other right-wing causes, while not doing much in the way of physics research, may make their decision about whether to keep reappointing him much more difficult.

Sarfatti also has been distributing a description of the AAAS talk, which evidently he and Sean Carroll both attended. He claims that Susskind called his talk “Rats Leaving the Sinking Ship”, in this case the sinking ship of the “reductionist” view of string theory, that it is based on simple mathematical principles and makes unique predictions.

15. **the+ed**
February 20, 2007

Newton delayed the publication of his gravity law for many years in order to get a quantitative confirmation. Other scientists who proposed religion-sensible theories similarly waited for scientific evidence.

Now, we have no evidence for the String Anthropic Eternal Fest, no tests, no ideas about how to devise a test, a few years of attempts resulted into interesting papers but no physics, all this could end up with a failure. But we have some guys who publicly promote this new religion.

This is more dangerous than the old-fashioned string hype, that only irritated people within the physics community. Suppose that LHC will find nothing new: this would support anthropic views, but are we going to tell “we are the new pope, give us 10Giga$ for new experiments”?

16. **Garbage**
February 20, 2007

“But in this case I was more thinking about ‘marketplace’ tactics. Like, you don’t need to actually produce the best pizza, you just need to convince everybody it IS the best pizza”

Wouldnt that make it the BEST pizza anyhow? 😉
There seems to be some degree of objectivness around these sentence which might not apply to the REAL world….

G

17. **Peter Orland**
February 20, 2007

I want to echo Vogelsang’s song. There is a lot of interesting physics to do. So why do so many people stay in string theory?

I think one reason is that string theory is a field in which it is relatively easy to come up with a tractable problem. Some of these problems have more intrinsic value than others, but in any case, writing papers, getting grants, etc. is much easier if you know exactly what to do. Some of the work done is very interesting and most of it isn’t.

It is also interesting that string theory appears to be a bigger field than it is. You can do almost anything formal and call yourself a string theorist. This isn’t a joke. I haven’t published anything string-theoretic in a while, but when I attended a lattice-gauge theory workshop at the KITP a few years ago, a postdoc there said, “but you aren’t a lattice-gauge theorist. You’re a string theorist”. My experience suggests that in some eyes , almost any high-energy theorist not doing phenomenolgy or numerics is a string theorist.

18. **Phil**
February 20, 2007

Dr. Woit,
Your book is good, but too technical for a mass audience and not technical enough for specialists. Maybe if you really want to do damage to string theory, you should write a more academic book. I did get a sense you were trying to do that with this book, but ran into too many referees.

19. **Peter Woit**
February 20, 2007

Phil,

The book as published is pretty much as originally written. Referee problems kept Cambridge University Press from publishing it, but commercial publishers agreed to publish it in the form I wrote it. It’s not for everyone, and was intended to be more the sort of thing an academic press would publish than something really commercial. Given that, I did try to make it as readable as possible, and have been pleasantly surprised at how many different kinds of people have told me they enjoyed it and got something out of it. I think there is a market out there for things that are more intellectually challenging than a lot of the standard popular science fare.

As for more technical discussions, the blog is aimed at a narrower audience and I’ve probably beaten to death here the question of what the technical problems of string theory are. Many of them are not anything abstruse: you don’t need to have a lot of technical knowledge to see what the problems are with the anthropic landscape, for instance. I certainly hope in the future to write some much more technical things, but they won’t be about string theory…

20. **Q**
February 22, 2007

Stanford’s video http://news-service.stanford.edu/news/2007/february21/videos/180_flash.html only has a few seconds of Andrei Linde talking, about three-quarters of the way through, about the failure of string to accommodate observed cosmology. The eternal feast is edited out.

21. **D R Lunsford**
February 22, 2007

th+ed,

I believe Newton delayed publication because he was just disgusted with Hooke and the environment he represented, and generally a sour and suspicious person, and basically quit and went home with his football. He already knew he was right.

-drl

22. **the+ed**
February 22, 2007

as far as I know, Newton wanted to check that the gravitational field that explains the orbit of the Moon is quantitatively the same that explains the fall of apples. So, Newton had to do a difficult integral over the volume of the Earth, and (without knowing the Gauss theorem) this computation needed years.

Anyhow “Hypotheses non fingo” is a better slogan than “Hooke is a jerk”.

23. **D R Lunsford**
February 24, 2007

the+ed – re this last comment..

This illustrates in stark terms the real problem with physics. A lot of (supposedly) smart people have taken over, with no knowledge of either history or, really, the real world.

Ah! now i get it. You rotated the real world by pi/2, and made it imaginary.

Alain Connes is now a blogger, contributing to the new Noncommutative Geometry blog. There will be a conference in his honor next month in Paris.

Today and tomorrow there's a HEPAP meeting going on in Washington, with some of the presentations available here. Excluding the SLAC linac, which is getting moved around in the budget, the DOE HEP FY208 budget request is for $782 million, a very healthy more than 16% increase over FY2006. There's also an HEP demography study being discussed, which somehow involves "tagging" and "tracking" HEP physicists, and they seem to be having trouble with the tagging. Not clear what sort of analysis will be performed on the data once all HEP physicist tracks have been reconstructed.

Next month on the 28th there will be a debate on the topic of

Does string theory merge general relativity and quantum mechanics to explain the origin of time, space, and the universe? Or is it extraordinarily complex mathematics that has nothing to do with physics, and so explains nothing?

between Lawrence Krauss and Brian Greene at the Smithsonian Natural History Museum in Washington. I recall attending a similar debate at the Museum of Natural History almost exactly six years ago here in New York, also featuring Krauss and Greene. Some things seem destined to never change…

Comments

1. **Jimbo**
   February 22, 2007

   Hopefully, the Krauss/Greene debate will be a more or less balanced affair. In the aftermath of David Gross's colloquium here at the U. of Oregon, it is clear that the stringers are on the defensive, big-time, & are sending out their heaviest artillery to ramrod their case to the general community of physicists & grad students.
   Gross' lecture was notable only for its ineloquence, non-technicality, and being conducted very much from a bully pulpit here, cutting off a faculty member in mid-sentence who asked a reasonable question. All else listened, intimidated into silence for the entire 90 mins.
   The chair (a former Princeton colleague) allowed him to run ~30 mins over the normal hour, effectively crushing opportunities for questions, and virtually all bolted after the obligatory applause for a nobelist. It was a sales pitch thruout, and not even colloquial.

2. **woit**
   February 22, 2007

   Jimbo,

   My first substantive post on this blog 3 years ago was about what sounds like pretty much the same talk from Gross. Things definitely haven't changed at all. That talk, here at CUNY, also went on for 90 minutes, but there was time for questions. I don't think that going over time is something Gross does to thwart questions about string theory. same with cutting someone off; my impression is that's the sort of thing he has always done, mainly because he's quite quick, not very patient, and at least thinks he knows what a questioner is talking about before they've finished stating their question.

3. **Thomas Love**
   February 23, 2007

   Since Lawrence Krauss and Brian Greene are repeating a debate they had 6 years ago, I have to conclude that there in good money in it for them.

   I heard David Gross speak at the March 13, 2005 conference on The Legacy of Einstein's Science. Totally unimpressive.

4. **Peter Woit**
   February 23, 2007

   Thomas,

   I doubt that either Krauss or Greene are doing this for the money. What's striking to me is how incredibly static this field has become, with string theorists like Gross just digging in their heels, refusing to admit that there's any problem that needs to be addressed. The attitude these days seems to be to just give up, sit on one's hands and talk about how the LHC will solve all problems by giving us wondrous insights into the nature of space and time, etc… I see very little hope of positive change over the next couple years, and predict that in 2009 the same debates will be going on and Gross will be giving the same talk. After that, maybe the LHC results will start changing things. All depends on what they are…

5. **Thomas Love**
   February 23, 2007

   The debate on the question:

   "Does string theory merge general relativity and quantum mechanics to explain the origin of time, space, and the universe? "

   should be interesting since it is impossible to "merge general relativity and quantum mechanics". The two theories are mutually incompatible. A new theory which includes some aspects of each is necessary.

6. **a quantum diaries survivor**
   February 23, 2007

   Things will change, Peter. Just give it time… As much as I wish them a long life, the two debaters will die one day. And old ideas die with those who support them…

   Cheers,
   T.

7. **Zathras**
   February 23, 2007

So what was the Krauss/Greene debate 6 years ago like?

8. **woit**
   February 23, 2007

   Tommaso,

   Unfortunately what I find scariest these days are the ideas supported by people who are likely to outlive me… The fact that in a few short years we may no longer have to listen to as much propaganda about "new dimensions of space and time are right around the corner" is definitely something to look forward to.

   Zathras,

   It also included Glashow and Jim Gates on opposite sides, with Lisa Randall there to espouse an in-between point of view. The discussion was polite, but very much the same as what one hears these days, minus the Landscape, which hadn't yet come on the scene. Krauss even quoted at one point from the writings of an unknown guy who had just posted a polemical article about string theory on the arXiv. As I said, not much has changed.

9. **Greg Biffle**
   February 23, 2007

   I see a lot of troubling passisivity which is in part to blame for the "trouble of physics."

   Many people are of the mind–oh–it will come to pass.

   Oh–it makes good entertainment, year in and year out.

   Oh–they are fine fellows, and nice, and provide good PR for NSF.

   Oh–let them be. Of course it makes no sense, but join the group and get a postdoc and trips to Aspen.

   I have been a bit shocked to see all too many SCIENTISTS sit idly by as science is redefined to suit the political aspirations of entertainers and showmen.

   Our major crisis is not that new ideas aren't being accepted (even though they aren't), but that false ideas are being institutionalized.

   I thought that Not Even Wrong and The Trouble With Physics would have had a greater impact, but now Greene is celebrating with Discover Magazine's contest to see who can come up with the best two minute summary of ST.

   I wonder how many entries trumpeting the wisdom and truth in NEW and TTWP will be considered.

10. **mclaren**
    February 25, 2007

    A conjecture: "In the limit as new experimental results approach zero, the state of HEP approaches Dianetics."

11. **D R Lunsford**
    February 25, 2007

    Biffle said

    Our major crisis is not that new ideas aren't being accepted (even though they aren't), but that false ideas are being institutionalized.

    Yes, that is the exact point.

    -drl

    Terence Tao has a sort of blog as well. Check out "whats new" under his hoempage.

The Dynamics of Cats on Yarn Theory

February 23, 2007
Categories: Uncategorized

Over at Dynamics of Cats, Steinn Sigurdsson has a posting on Yarn Theory, to some extent a review of Lee Smolin's *The Trouble With Physics*. Steinn is an astrophysicist, but started out life as a string theorist before getting disillusioned with the subject. His account of his early career is well worth reading, doing a good job of capturing the atmosphere around 1990 at Caltech, a major center of string theory research. He was working on orbifold heterotic string compactifications, discouraged by how many there were. Not much has changed…

His general point of view on string theory is that it has led to the discovery of a family of unified theories, but that it is missing some basic principle that would tell us which is the true theory and why. He is sympathetic to Smolin's criticisms of the dysfunctional way theoretical research is being pursued, focusing efforts on one very speculative idea and making it unlikely that people who chose to try and work on others will be able to make careers for themselves:

… a lot of people will not only not believe that this is a real problem, they will make sure nobody else believes you either. Someone out there quite likely is already on the right track to the true theory, but their odds of survival in the current academic system are not wonderful. We may just have to wait a generation or two for a good approach to be rediscovered, which is a shame, cause some of us want to know! Now!!

… points on groupthink, and the systematic bias which discourages innovation and risk taking by young researchers hit painfully home – it is all too true, and yet it self-perpetuates because the mechanisms which reinforce conservatism in science are there for reasons. The system is flawed, and possibly broken, but the fix is not as simple as Smolin suggests – funding agencies are terrified of funding bad science, since there is so much pretty good science it is safe to fund, and as a community scientists are very harsh when bad science is mistakenly given precious resources.

It is the same market flaw that gives us beautiful flawless large red apples in supermarkets – with no taste. To get the old intense flavour varieties that everyone loves when they taste, we would have to choose small bruised discoloured apples when we shop, and leave the flawless big red apples with no taste in the bins. But collectively we do not, and the market responds. All for the fear of being the one ~~department head~~ consumer to go home with an occasional rotten apple. The real shame is that the big red shiny tasteless apples are rotten just as often, they just look so good sitting there, waxed and sprayed, in the bin. 'Course if you only get to buy one apple every three years you learn to be very conservative in your choice; don't want a rotten or even tart apple this decade.

I think Steinn gets to the rotten core of the problem here. There are very good reasons for conservatism in deciding what kinds of research to encourage, but with the very difficult situation that particle physics now finds itself in, the standard mechanisms for making these decisions have led to a seriously problematic situation. There are various things one could imagine doing to help get out of this, but even getting started on a discussion of them first requires that the powers-that-be in the field acknowledge the existence of a problem, and that has yet to really happen.

On a completely different subject, there's a new preprint by Michael McGuigan which manages to cite both *Not Even Wrong* (the book), and a Lubos Motl blog entry. The citation of my book seems unnecessary, surely there are other sources critical of string-based unification that have priority. The article is about the "see-saw" mechanism for getting the right magnitude of the cosmological constant, and it is for this that Lubos's blog gets a citation. This does seem to be a more promising idea about the CC than many. I for one think it will be a wonderful development if the field of particle theory turns around, stops promoting pseudo-science justified by the Weinberg anthropic CC "prediction", and heads instead in a more promising direction, all based on an entry in Lubos's blog…

Comments

1. **D R Lunsford**
   February 23, 2007

   fear that is where string theory went. It discovered a family of theoretical approaches and solutions which clearly encompass an essential truth of quantum gravity and its union with the standard model and post-standard model physics, but we missed on the deep guiding principle which tells us how to select the true theory (such as it is) and where the exact theory came from and leads to.

   A comment like this is simply mysticism. You don't discover "essential truths" in physics. There are no "inessential truths". If something is right in context, then it is right. String theory has never been right in any context. In fact, to coin a phrase, it's not even wrong.

   The current blog is essentially unique. It is empty of both mysticism and shameless egotism. It is wonderful that we have at least one physics blog with these properties.

   February 24, 2007

   We're having a discussion relating to 'groupthink' over at the Café. I agree that its unacknowledged presence is at the root of the problem. You may enjoy the Thom quotation in this comment.

4. **mclaren**
   February 24, 2007

   Delightfully tongue-in-cheek take on string "theory":
   http://arxiv.org/abs/hep-th/0011065

5. **Ralf**
   February 24, 2007

   The citation of my book seems unnecessary, surely there are other sources critical of string-based unification that have priority.

This is an unwarranted condescension towards the author who probably knows best what has “priority” for him. Your “modesty asides” are becoming annoying. This is about the last thing one wants to hear from someone who put himself in the public sphere, after all. The fact that he cites you does not mean that he grants you the authority to tell him whom to cite. There are good reasons for prefering to cite you rather than those “other sources”, and I don’t think I have to spell them out. You’ve been overrating these sources all along.

6. **a quantum diaries survivor**
February 24, 2007

Ralf.

I think there is a good point in not putting oneself at the forefront – you are not the first one to fall if things turn awry, while in case you are running for the prize you can always make that extra step later.

I do not think that is the reason of Peter’s acknowledgement that others have been doing what his book does before him or more authoritatively. But it is a good reason nonetheless…

T.

7. **Peter Woit**
February 24, 2007

Ralf and Tommaso,

It just seems a bit peculiar for me to be getting credit for the fairly obvious idea that string theory based unification is an idea that hasn’t worked out. Many particle theorists have always thought this, and some have expressed themselves publicly on the topic over the years. I am happy to take some credit for successfully drawing a lot more attention to this issue, but that’s a bit different. If the LHC finds supersymmetry, with a pattern that identifies a particular compactification of string theory, producing real successful predictions, that will certainly make me look like a fool. I’m willing to take that chance…

8. **Chris Oakley**
February 24, 2007

Yes, but here is an example of string theory based unification that *has* worked out.

9. **srp**
February 24, 2007

One modest proposal to attack the groupthink problem, and the red apple problem, not just in physics but in the rest of the US scientific community: Establish a source of money (say a private foundation) that makes grants to research proposals that have been rejected by the NSF (or NIH) BUT have extreme variance in ratings from the panelists. The benefits of this idea are;

1) Breakthrough research (as well as plausible but wrong ideas) is likely to polarize expert opinion.

2) Disagreements about the prospects of a research proposal suggest that there might be high information content in the outcome of the research.

3) At least some qualified people consider the research interesting and feasible.

4) Nobody has to rewrite their proposals! Anything that gets scientists to spend more time doing science and less time writing proposals to do science makes me a happier citizen.

A colleague once said to me that if two academics have the same opinions, one of them is redundant. I wouldn’t go that far, but the spirit of the idea applies to this proposal. Maybe Templeton should shift some of its resources in this direction…

10. **Peter Orland**
February 24, 2007

The groupthink problem is inherently unsolvable. Any foundation or organization which is designed to encourage ideas outside the norm will have its own set of preferences (or prejudices). A foundation which rejects NSF proposals will have its own criteria, which will either quickly conform to groupthink or fade into obscurity.

The situation isn’t new. There is always resistance to new ideas. Organizations which attempt to change the situation disappear or merge into the mainstream in order to survive (the Nobel foundation is a good example. Nobel prizes were origninally supposed to encourage junior people who hadn’t yet made their most significant contributions).

The only way to deal with groupthink is make an effort to change what the group thinks. That is a realizable goal, but only after a lot of yelling and screaming.

11. **srp**
February 25, 2007

Peter: I’m sorry if my suggestion wasn’t presented clearly.

I’m not proposing a foundation to “reject NSF proposals.” I am proposing that someone fund NSF-rejected proposals that had high variance in the ratings they received from the NSF review panels.This agency wouldn’t have groupthink–they wouldn’t have to have any-think–because they would work off the scores already generated by the NSF evaluators. And since they would fund proposals where the reviewers for the NSF DISAGREED with one another, groupthink in evaluation would be ruled out from the start.

This idea may be impractical for a number of reasons, but I don’t think an ex cathedra statement that groupthink is inevitable, without showing specifically why this exact mechanism would fail, is very persuasive. And “changing what the group thinks” isn’t a big help if it just creates a new set of unsupported orthodoxies.

12. **Arun**

February 25, 2007

srp, it sounds like a good idea. Maybe bring it to the attention of the Bill and Melinda Gates foundation?

13. **Nathan Myers**
February 25, 2007

Arun: very funny. George Soros, perhaps?

14. **Nathan Myers**
February 25, 2007

How appropriate that someone would move from string theory to astrophysics. Astrophysics is in much the same state, today, except in lacking eloquent voices like Smolin's and Woit's to puncture it.

15. **mclaren**
February 25, 2007

I would disagree strongly that astrophysics experiences anything like the degeneration we observe in string "theory" (how can it be called a scientific theory when it fails to make any experimentally faslsifiable preidctions?).

Astrophysics remains vibrant and fertile because _new experimental data keep coming in_. This is the real Achilles' heel of HEP right now. The data at energy ranges and luminosities and cross sections required to disconfirm even low-range estimates on the superpartners, let alone the Higgs, has simply not been there. We reached the limits of current accelerators and hit a wall. You can only do so much, and then you have to build a whole new machine — which nowadays takes decades. Calibrating the detectors on these accelerators is a gigantic undertaking. The computer technology involved is simply staggering. You're talking about events so rare, and amounts of data so large, that it boggles the mind.

By contrast, with astrophysi9cs you just send up a new satellite. Or sometimes not even that — dump some cleaning fluid in a tank underground and set up photodetectors. That's cheap! It's quick. It's easy compared to building an ILC or LHC. So astrophysics has been awash in new experimental results, while HEP has been starved for 'em. That to me is the core of the problem in HEP right now.

16. **Q**
February 25, 2007

Nathan, I recall that Peter answered this point before. The small positive cosmological constant, or some alternative idea which does the same job, is required to fit GR to the observations of supernovae redshifts, explaining why gravity isn't slowing down the recession.

String theory by contrast provides speculative explanations for things which are not observed, such as unification at the Planck scale (inventing supersymmetry to explain that speculation), and inventing gravitons (inventing supergravity to explain gravitons). String theory thus 'explains' speculations, not observations.

The point Peter made before about cosmology is that at least it is being led by observations, unlike string theory.

Mainstream models for observations might turn out wrong, but that's better than being not even wrong. Approximations like flat earth theory, caloric, and phlogiston could later be disproved by evidence. Epicycles could provide an endlessly complex mathematical way of representing observed data, but were eventually replaced by Kepler's simpler laws for convenience, which in turn could be explained by a simple inverse square force law.

String theory doesn't even model or duplicate any existing observations, so it is worse than Ptolemy's epicycles: Feynman's criticism of string theory was largely that it doesn't address the parameters of the standard model. It's not even wrong because it doesn't even model anything known to exist.

17. **Peter Orland**
February 25, 2007

srp,

You took my misprint too seriously. I garbled the message earlier.
Yes, I know you didn't mean another round of rejections.

I also have no objection to your idea of some private foundation funding proposals rejected by the NSF (or DOE). The more funding, the better.

My point was that such measure would not cure the groupthink sickness, whatever their other virtues might be.

18. **Peter Orland**
February 25, 2007

Just to add. The reason I don't think groupthink would be cured
is because any such private funding would quickly succumb to
the same pressures the NSF and DOE have to deal with. Maybe not
in the first year or two, but before the funding could alter the
course of the field.

19. **Peter Orland**
February 25, 2007

Nathan,

To add my voice to those above…

Experimental cosmology is thriving. The theorists have not caught up
with the data yet. Explaining dark matter wil take more investigation
(maybe particle physics experiments), and nobody has a clue about
dark energy. This is a healthy field, even if theorists haven't satisfactorily
explained what is going on.

20. **Kyrie**

February 25, 2007

>This is a healthy field, even if theorists haven't satisfactorily
>explained what is going on.

I'd change "even if" to "because".

21. **Christine Dantas**
February 25, 2007

Hi,

John Baez has just released his Week246 writing about your book and Smolin's.

Christine

22. **srp**
February 25, 2007

Peter: Still not reading what I wrote. The proposed innovation isn't really a new funding SOURCE. It is a new funding RULE, a rule which explicitly prevents groupthink by funding ideas which draw high-variance, divergent responses from reviewers. If you have a theory as to how this RULE could be corrupted by groupthink, I would be interested.

I tossed out the idea that a private foundation might implement this rule only because I see significant political obstacles to its adoption by the standard funding agencies. The essence of the proposal is not the funding source, however.

23. **Amos Dettonville**
February 25, 2007

The idea of a rule that forces a group of people not to make decisions based on "groupthink" is sort of interesting… in a paradoxical sort of way. As described by "srp", it seems to rely on at least some pre-existing non-groupthinkers, because he says to award money to proposals that meet with very divergent responses. In a pure "groupthink" environment, there wouldn't BE any divergent responses (more or less by definition), so the scheme would only have a chance if we suppose there are some non-group thinkers in the system with votes that matter.

But this raises the interesting question of whether a scheme could be devised that would actually enable a *pure groupthink environment to free itself from its own groupthink. Suppose everyone agrees on what they should do… but they are worried that they might all be suffering from groupthink. How could they address this worry? I'm reminded of a Seinfeld episode in which George decided that, from now on, he was going to do the opposite of whatever he thought he should do in every situation.*

But seriously, I think the folks at google and other search engine designers have considered how groupthink can cause their search criteria to go unstable, because they feed back to themselves. (Give high ranks to pages that have lots of links, and those pages then tend to get even more links, which gives them even higher rankings…) If you notice, they sometimes "dither" their rankings, to "shake things up" a bit, and see if other pages would rise to the top after a re-shuffle. (Dithering is a technique carried over from control theory.) Maybe what the funding agencies need is a little dithering. (Off topic, but I suspect a healthy human mind must have some degree of "dithering" (not to be confused with blithering), or it would just become fixated on a small number of specific things.)

24. **Ralf**
February 26, 2007

Why is it that nobody is taking down string theory from its very inception and input? Why bother with any of its "content" in the first place?

Doesn't "supersymmetry" really mean not understanding the nature of fermions and bosons? Doesn't "GUT" really mean not understanding the nature of the observed gauge interactions? Isn't the idea that virtually any observed structure is due to some kind of spontaneous symmetry breaking (and the "anthropic principle") transparently the cynical nihilism of intellectual bankruptcy?

Up to now progress in the understanding of fundamental structures has always been marked by an increase in simplicity and efficiency and explanatory prowess.
The principles associated with string theory are not only "not even wrong", they are of fundamental stupidity and lack of sophistication. The undeserving heirs squandering the wealth the fathers worked so hard to gain. To truely believe in string theory one must have never understood any physics in the first place. It's so 19th century!

25. **Chris W.**
February 26, 2007

Amos,

Another way to describe that healthy tendency to dither might be a tendency to get bored and frustrated with whatever rut one has gotten into, due to social influences, financial inducements, or one's own overripe enthusiasm.

mclaren,

I think that allegedly tongue-in-cheek take on string "theory" (hep-th/0011065) was intended fairly seriously. What the hell—it beats someone's posting yet another goddawful braneworld scenario.

26. **srp**
February 26, 2007

Amos: My understanding, not based on systematic data but anecdote, is that in real life there are many grant proposals to the NSF and NIH that receive high-variance scores–some judges love them and some hate them. Supposedly, these usually get rejected with only the proposals that get high scores from all evaluators funded (and not always all of those, depending on budgets). So whether or not it can happen in theory, divergent evaluations appear to be an empirical phenomenon. Maybe a moderate psychological level of groupthink is institutionally amplified by the current rules of only funding proposals that everyone agrees on.

Dithering, simulated annealing, and other ideas for randomly jiggling things to get away from being trapped on local peaks may be good analogies for what I'm suggesting. One common approach to avoiding groupthink is to use dialectical processes, such as an adversary system, to surface as many points as possible for and against something. But that only works if the judges of the dispute aren't subject to groupthink. My proposed rule finesses that problem.

Another approach is to cultivate multiple funding sources drawn from sociologically separate communities. The military and ARPA used to function this way to a degree, but I'm not sure that still holds true for basic science. There are lots of people in Congress and the bureaucracy who argue for "rationalizing" the system by centralizing decision-making in a body like the NSF.

27. **Peter Orland**
February 26, 2007

srp,

I am still skeptical. How does one re-evaluate proposals with diverging scores to encourage diversity of ideas? One institution which does essentially such a re-evaluation is the Physical Review, as you probably know. I don't think their refereeing policy has specifically encouraged more directions of research (nor, do I think it was intended to).

Though re-evaluation proposals might not be a bad idea, I can't see it altering the dominant culture.

28. **Benni**

February 26, 2007

Peter O: Here's one way to do it: A scientist whose grant proposal got rejected at the NSF submits the same proposal to the hypothetical new funding source, along with the reports and scores of the NSF review panel that rejected him. The new funding agency sorts these proposals according to the within-panel variance in NSF ratings. It then funds the highest-variance proposals first and works its way down the list until it exhausts its budget (or the proposals start to look too gamy).

I am not aware of the Physical Review process (I'm not a natural scientist), so if they do something similar I would be interested to hear how it works (in both senses).

31. **Ralf**
February 26, 2007

How do you write a proposal if what you have is an idea that might lead to a breakthrough, but you can't possibly put the idea itself in the proposal because that would effectively mean giving it away? Doesn't the funding process virtually exclude anything that doesn't fall under "normal science"?

32. **srp**
February 26, 2007

Ralf: Wow! Are these panelists really that unethical that you can't report your ideas without them ripping you off? That would be a lot more serious problem than groupthink.

In any case, I'm not saying that my proposal would guarantee funding to all breakthrough ideas, merely that current proposals that have more breakthrough potential than average could be funded.

33. **Peter Orland**
February 26, 2007

srp,

Here is the Physical Review refereeing process (as far as I can tell from my experience submitting and refereeing papers). Most papers are sent to two referees. If there is one rejection and one acceptance it goes to a third referee. If that referee rejects it, it usually goes back to the author with a rejection from the editors.
The author can (and often does) challenge this assessment.
Sometimes the editors can make a clear judgement of rejection or acceptance – but if they can't, it goes to another referee. And so on.
If the author can get two acceptances, the paper is usually published.
So at some level, the process resembles your suggestion.

While in principle I like your idea, I am not sure it would work effectively if real money is involved. Financial considerations will eventually make the people running your system unwilling to take too many risks.

34. **lostsoul Ph. D.**
February 27, 2007

An insight into peer review, as practised in the UK, circa 1980, long before science became as venal as it is today. (And this is tawdry applied physics/engineering, in which the stakes are not that high, and one is thus less likely to compromise one's mortal soul.) A barely post-doctoral physicist puts together a paper, relating to a finer point of detail relating to laser operation, and submits it to a respectable journal. Nothing, beyond the usual politesse of receipt, is heard for several months; thereafter discreet enquiries elicit only the reassurance that due process is in hand. Some nine months on, the second referee's report arrives, which grudgingly accepts that the substance of the MS is sound, but would benefit from some experimental verification (contact with reality, hep-th dudes) which the referee would be happy to provide, in a joint publication. Honour amongst thieves or what? And if a trip to Stockholm was up for grabs? Oh dear.

35. **Chris Oakley**
February 27, 2007

Hi lostsoul,

The private sector is much better. If my own experience is anything to go by, then I cannot say that people behave any more honourably, but at least they are scrabbling for something more tangible than glory. It is also a thing that can be exchanged for goods or services.

36. **srp**
February 27, 2007

Peter O: You're right that any attempt to institutionalize behavior at a non-profit foundation is quite difficult. Random personnel turnover eventually leads to a critical mass in management and among trustees who want to circumvent or change the deceased founder's original vision. John MacArthur probably wouldn't be too thrilled with today's MacArthur Foundation, and I wouldn't even want to try to estimate the rpms in Henry Ford's grave over the antics of the Ford Foundation.

On the other hand, if a founder's mandate is fairly narrow and specific, it can only be overturned by the trustees going to court and proving that changing conditions have made that mandate non-practicable or absurd. That doesn't happen very often. So, for example, a foundation that was tasked to give out college scholarships to people residing in a given town would be hard to mess with unless the town became depopulated or colleges became obsolete and disappeared.

Anyway, I am off this thread. Thanks for the feedback.

37. **amused**
March 1, 2007

"There are very good reasons for conservatism in deciding what kinds of research to encourage, but with the very difficult situation that particle physics now finds itself in, the standard mechanisms for making these decisions have led to a seriously problematic situation."

Yep. As best I can tell, the main citerion for determining who gets jobs is: "Which influential senior physicists are you buddies with, and what have you done to help advance their research programs?" This might work fine when the way forward is clear, e.g. during the development of the Standard Model. After all, senior influential physicists usually get to be that way for a reason, and young people could do much worse than to follow their lead. But in a situation where, to paraphrase Polchinski, there is "remarkable convergence on an unproven idea" it might be good for physics if there was a possibilty for people to work on other things and still have the chance of a career. Btw, "other things" doesn't just mean the QG alternatives of Smolin&co but also the various topics in formal theory that Susskind refers to as "near-coast exploration". Physics advanced quite far by near-coast exploation in the past, so it might be a good idea to allow it to continue in the present rather than forcing everyone who wants a career to go off on some or other epic voyage.

Actually there is an easy way to fix this situation if people really want to: Take away the NSF/DOE funding which currently goes to individual faculty members or research groups to hire postdocs and use it to fund postdocs directly via an open competition. Schemes like this already exist, e.g. the EU's Marie Curie fellowships. A crucial feature of the scheme would be that the applications are assessed by a broad committee with representatives from all areas of theoretical physics. Then the string theory member of the committee will have to explain to colleages from condensed matter and atomic physics why string theory applicant X, who has never done anything on his own but whose famous advisor has declared him to be "brilliant", is more deserving of support than non-string applicant Y who has published single-author papers in PRL. Many, perhaps most, of the people supported under such a scheme will be the same ones who find support under the current system, but there will also be others following more independent paths who currently don't have a chance. For it to be worthwhile the scheme would have to be supplemented with a similar one at the junior faculty level, e.g. along the lines of the UK's PPARC Advanced Fellowships, but with assessments again being made by a broad committee with representatives from all areas. If the reps are all from particle theory it will just be buddies rubbing each others backs and the outcomes will be no different than under the current system.

Various…

The Princeton Physics department colloquium on "New Neutrino Oscillation Results from the MiniBooNE Experiment" scheduled for this Thursday has been canceled. I wonder what is going on with that. Have they not opened the box yet on their result, or did they do so and have a problem with what they found? Other talks about MiniBooNE results are still scheduled for March 14th in Manchester ~~and March 17th in Montreal (the abstract of this last one is ambiguous about whether there will be results "MiniBooNE's oscillation path and what may lie beyond, will be presented")~~ . The MiniBooNE colloquium has been replaced by a Nikita Nekrasov talk on "The Mathematics of String Theory". Not sure if I'll make a trip down to Princeton that day; Nekrasov's talks are usually worth hearing, but I'd prefer to hear a more technical talk about his recent work, which is quite interesting.

John Baez's latest "This Week's Finds" is largely about the controversy over string theory and my book and Lee Smolin's. As usual, John's take is quite level-headed. Faced with people who claim that string theory is "the only game in town", John advocates leaving town, striking out and looking for another place to live and work, maybe even starting a new one. Some comments about this at his blog.

On Friday at Fermilab Michael Chanowitz gave a talk on Precision Electroweak Data and the Direct Limit on the Higgs Mass. He updates previous work on these fits, including recent CDF and D0 values for the top and W masses. The new, presumably better, top quark mass values from CDF and D0 are lower than those of a couple years ago, with recent CDF results about 170 GeV. The main interest in these fits is that they give you a predicted value of the Higgs mass, although not a very accurate one. The lower top mass drives down the predicted Higgs mass, to the point where it is starting to get in trouble with the fact that LEP showed it had to be heavier than 114 GeV at 95% confidence level. The fits to all data give a most likely value for the Higgs mass of 85 GeV, with only an 18% probability of it being over 114 GeV.

Chanowitz devotes a lot of attention to the one measured value that deviates the most (3 standard deviations) from that predicted by the other data: the forward-backward asymmetry in b-quark production at the Z-pole. If you throw this out from the fit, on the grounds that it is less reliable than the other data since it doesn't match the SM as well, your Higgs mass really goes down, to a most likely value of 48 GeV, with only a 2% chance of it being above 114 GeV. Hard to know what to make of this, evidently it's hard to come up with a model that would explain the anomalous forward-backward asymmetry while not ruining the rest of the fit. Maybe this is a first indication that the SM is not the full story….

Update: This just in, from Michael Nielsen. Seems like this is the month for Fields Medalists to become bloggers. First Alain Connes, now it's Terry Tao. Will Grisha Perelman be next?

Update: Well, not Grisha Perelman, but today the latest mathematician blogger is David Goss. Goss is a specialist in the mathematics of function fields over finite fields, and his first post includes comments about how ideas have entered this very different field from physics, as well as remarks about the work of Bost and Connes that expresses zeta-functions in term of partition functions of statistical mechanical systems.

Update: A couple more. The talks at the recent AAAS session on A New Frontier in Particle Physics are available (~~some in a weird format I've never seen before which works on Internet Explorer, not Mozilla~~). Also some remarks by DOE's Raymond Orbach at the HEPAP meeting where he seems to be raising an important question: even if the ILC is built, it may not be ready until the mid-2020s or later, and the Tevatron and SLAC B-factory will be closing down relatively soon, so "I would like to re-engage HEPAP in discussion of the the future of particle physics. If the ILC were not to turn on until the middle or end of the 2020s, what are the right investment choices to ensure the vitality and continuity of the field during the next two to three decades and to maximize the potential for major discovery during that period?"

Update: Fermilab director Pier Oddone discusses the Orbach letter and the need for planning for the possibility of a long wait for the ILC in today's Director's Corner at Fermilab Today:

I am requesting a steering group composed of members of our laboratory and the community under the leadership of Deputy Director Kim to produce a detailed plan for positioning the field and Fermilab in the next two decades for a robust program of discovery based on accelerators. I am asking for such a plan by August 1st.

   February 26, 2007

   Perhaps you could mention Tommaso's excellent ongoing commentary on the Higgs.

   Maybe this is a first indication that the SM is not the full story…

   Well, hardly. Cosmology has been troubling for a while now.

2. **LDM**
   February 26, 2007

   For the last few decades, astrophysicists have been making amazing discoveries in fundamental physics: dark matter, dark energy, neutrino oscillations, maybe even cosmic inflation in the very early universe! — John Baez

   Baez should confine his commentary to math. Dark matter, dark energy, and cosmic inflation are still speculative ideas, not confirmed discoveries.
   What has happened to scientists? The need to publish and self-promote must never be allowed to overtake the scientist's responsibility to disseminate accurate information to the public.

3. **Marco**
   February 27, 2007

   If I read well, the MiniBooNE talk at McGill that you mention already took place in March 2006 (i.e. one year ago).
   By the way, I'd be a bit surprised if the collaboration announced results in an individual invited talk at some university. They might choose a more formal way, e.g. at Fermilab, so I am keeping an eye on the Fermilab events list.
   Please keep covering news&rumors on this topic, thanks!

4. **1uk3**
   February 27, 2007

   why not Grisha Perelman? It would be a nice way for him to spend some of his free time.

5. **Q**
February 27, 2007

The hyperlink to David Goss's first blog post in your second update doesn't work because "http://" is duplicated…

6. **Peter Woit**
February 27, 2007

Q,
Thanks, fixed.

7. **island**
February 27, 2007

Baez should confine his commentary to math. Dark matter, dark energy, and cosmic inflation are still speculative ideas, not confirmed discoveries.

My experience with the thinking of John Baez tells me that he's not making the kinds of assumptions about the true nature of our observations that many string theorists make when he says that. Which means that he'll now step-in to prove that I don't know what the heck he thinks… 😉

What has happened to scientists? The need to publish and self-promote must never be allowed to overtake the scientist's responsibility to disseminate accurate information to the public.

It has also been my observation that there is a rather large gap between the rigor that is expected for accepting conclusions made about Relativity, and those of QM.

It isn't pretty in the latter case… and "Katie bar the door"… beyond that.

8. **Ari Heikkinen**
February 27, 2007

It's kind of nice that experts begin to start blogs. That way the general public can ask questions from them and get expert answers on their time and for free.

9. **Coin**
February 27, 2007

The lower top mass drives down the predicted Higgs mass, to the point where it is starting to get in trouble with the fact that LEP showed it had to be heavier than 114 GeV at 95% confidence level. The fits to all data give a most likely value for the Higgs mass of 85 GeV, with only an 18% probability of it being over 114 GeV.

What kinds of bounds will the LHC be able to fix on the mass of the Higgs; and is the maximum mass it will be able to probe at enough that if the LHC *doesn't* find the Higgs, we can start asking questions like what if the Higgs as we think of it doesn't actually exist?

10. **srp**
February 27, 2007

Is there any significant effort in the physics community to develop new accelerator concepts that can get to higher energy without costing as much as a couple of aircraft carriers? I recall reading years ago about plasma-wave concepts, but haven't heard much since. A physicist (whose identity I can't remember) once told me that getting that idea to work would be as hard or harder than magnetic-confinement fusion, but I have no way of knowing if that opinion is general among accelerator physicists.

It seems to me that if there are any radical ideas out there, now is the time to break 'em out. The public is daunted by the prospect of building multi-kilometer, multi-billion dollar extravaganzas for such esoteric (to the public) purposes. (Personally, I'd rather build you guys a giant accelerator than pave over more of West Virginia for the glory of Robert Byrd, but my priorities are not shared in the broader political system.) Anything that mght make higher energy more affordable, even if it takes time to develop, strikes me as something the physics community should embrace.

11. **Martin Griffiths**
February 28, 2007

There has been some recent progress with plasma wakefield technology: see [here].

12. **Peter Woit**
February 28, 2007

srp,

I've written about this at least a couple times on this blog, see for instance:

http://www.math.columbia.edu/~woit/wordpress/?p=339

As far as I can tell, turning these exotic ideas into workable HEP accelerators is conceivable, but still a long way off (50 years?). The idea I've heard that sounds closest to something that might work is to use this kind of acceleration as an "afterburner": at the end of a long conventional linac like the ILC, double the beam energy using this kind of technology.

13. **Thomas Love**
February 28, 2007

Just found a jewel:

"It is very important that we do not all follow the same fashion… It's necessary to increase the amount of variety… and the only way to do this is to implore you few guys to take a risk with your lives that you will not be heard of again, and go off in the wild blue yonder to see if you can figure it out." Richard Feynman(1965), Nobel prize in physics award address.

Take a risk or string yourself up.

14. **A.J.**
February 28, 2007

SRP,

There's a lot of work being done on plasma wake acceleration being done right now. See for instance this expository piece in Nature, from Feb 15 2007.

http://www.nature.com/nature/journal/v445/n7129/full/445721a.html

Still a lot of problems to be solved, of course, but they're making progress. And I don't imagine that the energy losses would be any worse than in synchotrons.

15. **Neville**
February 28, 2007

Maybe I'm blind, but I couldn't find the *wild blue yonder* text in Feynman's terrific Nobel lecture. I discovered a slightly expanded version of the quotation elsewhere. It would be nice to have the complete original text.

16. **Neville**
February 28, 2007

For obvious reasons, I should have described Feynman's address as *mostly* terrific.

17. **srp**
February 28, 2007

Thanks for the references on plasma wakefield technology. Those articles were actually more encouraging than I thought. Problems, but the sort of thing that could actually be solved, and some signs of substantial progress.

So let me ask: Is this research at the point that it is primarily resource limited or idea limited? In other words, if more people and apparatus were directed to developing these technologies, would things get sped up significantly? Or is this still a matter of waiting for inspiration to strike on some currently unsolvable problems?

Because if these technologies could be brought on line much faster with more resources, I would definitely try an argument like, "Well, if you don't want to fund the ILC, will you at least give us (pick your percentage) of it to work on plasma wakefields and afterburners?" From an advocacy standpoint, it's a lot easier to sell research on cool new breakthrough technology than on expensive applications of old technology. It also has the advantage that it might be the smarter policy.

18. **JoAnne**
March 1, 2007

The box (MiniBooNe) is still closed. I heard they were on step 2 of a 6 step process to open the box. It will be another month or two…

The LEP results on the forward-backward asymmetry of the b-quark are puzzling. This measurement depends on the product of the electron's couplings to the Z boson and the b-quark couplings to the Z-boson, and is 3-sigma off from the expected Standard Model value. However, individual measurements of both the electron's (at both LEP and SLC) and the b-quark's (at SLC) couplings are bang on the Standard Model expectation.

19. **Peter Woit**
March 1, 2007

Joanne,

Thanks for the MiniBooNE news (or rumors…) and the comment on the anomalous forward-backward asymmetry result. It does sound like this anomaly can't be new physics, but then, where is the Higgs???

20. **anonymous**
March 10, 2007

see http://neutrino.pd.infn.it/conference2007/Talks/Shaevitz.ppt for the most recent MiniBooNE talk.

Symmetry Magazine

February 28, 2007
Categories: Uncategorized

There's a new issue of Symmetry magazine out. It is a bimonthly magazine about particle physics put out by SLAC and Fermilab, and often has interesting and informative articles. But, even though I generally read the whole thing when it comes out, I've always had a feeling that, somehow, there was something missing. This latest issue kind of explains why.

In a very well-done article about the BaBar experiment and B-physics, John Ellis is quoted, explaining the origin of the name "penguin diagram" as follows:

That summer, there was a student at CERN, Melissa Franklin, who is now an experimentalist at Harvard. One evening, she, I, and Serge went to a pub, and she and I started a game of darts. We made a bet that if I lost I had to put the word penguin into my next paper. She actually left the darts game before the end, and was replaced by Serge, who beat me. Nevertheless, I felt obligated to carry out the conditions of the bet.

For some time, it was not clear to me how to get the word into this b quark paper that we were writing at the time…. Later…I had a sudden flash that the famous diagrams look like penguins. So we put the name into our paper, and the rest, as they say, is history.

If you look up the original source of this, you find a bit more of an explanation of where that "sudden flash" came from. Here's the full second paragraph:

For some time, it was not clear to me how to get the word into this b quark paper that we were writing at the time. Then, one evening, after working at CERN, I stopped on my way back to my apartment to visit some friends living in Meyrin where I smoked some illegal substance. Later, when I got back to my apartment and continued working on our paper, I had a sudden flash that the famous diagrams look like penguins. So we put the name into our paper, and the rest, as they say, is history.

Lots of other articles worth reading in the magazine, including one by an undergraduate at Humboldt State in California about taking a science course that explained how physical reality is stranger than any fiction, ending with the anthropic principle and the theory of evolutionary cosmology. The course is called Cosmos, and you can check out its web-site. Maybe I'm wrong, but I get the impression that John Ellis is not the only physicist out there who may have at one time or other sampled the agricultural products of Humboldt County…

Comments

1. **island**
   February 28, 2007

   ending with the anthropic principle and the theory of evolutionary cosmology

   A true anthropic cosmological principle *necessarily* defines a Darwinian Universe… which indicates that physicists pursuing this idea should be looking for a mechanism that enables a universe with pre-existing volume to "leap/bang" to higher orders of the same basic configuration… now, pass the bong, "hippie"… 😉

2. **Steve Myers**
   February 28, 2007

   On Cosmos-type classes. Maybe it's possible to understand the physics without the math but I doubt it. I've found people who say that or "feel" that are just kidding themselves. If you can't do the problems, I don't think you understand the material. Would they say the same thing about their bank account?

3. **Chris Oakley**
   February 28, 2007

   I think that the likely explanation is that the game of darts was one of the things that Ellis hallucinated while smoking the illegal substances.

4. **Arun**
   February 28, 2007

   "Aspects of Symmetry", Selected Erice Lectures, Sidney Coleman
   The 1979 lecture, 1/N, on the large N limit of SU(N) theories:

   "For the baryons, things are not so good. Witten's theory is an analytical triumph but a phenomenological disaster".

   For some reason, I found it very funny.

5. **Jimbo**
   March 1, 2007

   Looks like High-Times at Humbolt High ! And we only thought that such libations were confined to UC Santa Cruz ! Without doubt, one of the best physics course advertisements I've ever seen, and I'll bet his enrollment saturates in the first week.
   And lets not forget, that Sagan & Glashow both were heads (am I leaving anybout out ?), so there must be somethin to it.
   Should be a lotta phun !

6. **Thomas Love**
   March 1, 2007

   The biggest difference between science and science fiction is that fiction has to make sense. The biggest difference between science and mathematics is that science has to match reality. Mathematics can be used to model fictional universes as well as the one we live it. That is the problem with the landscape: too many fictional universes and we are not sure that there is one which matches reality! My PhD is from UC Santa Cruz and I got high by thinking about higher dimensions, no agricultural substances necessary!

7. **island**
   March 1, 2007

   But it is *people* who carelessly abuse the counterintuitive aspects of some theories to rationalize their way round appearance of absurdity that appears with others, thereby enabling them to avoid the most natural extensions in order that they might dodge causality and first principles in order to use “selection effects” to choose from a hypothetical and mathematically derived woulda’ could’a shoulda’ “what-if” landscape, instead of doing real physics.

This goes WAY far back before ST became the only game in town though… That’s the kind of thing that Einstein used to bitch about… a LOT!

8. **Greg Biffle**
March 1, 2007

I spent the weekend reading original papers by Bohr, Einstein, and Heisenberg.

Oddly enough, there was no mention of drug use, nor cutesy-wootsie dart games, nor insider wink-wink-nudge-nudge let’s get some cash from NSF to meet again next year for more darts and drugs.

Physicists of yore seemed quite content to contemplate reality, and thus left us with lasting physics.

There seemed no peer-pressure back then to smoke up in those glorius original papers.

I hope that by and by we (and journals) can return to supporting physicists concentrating on advancing physics and contemplating the beauty and natural wonders of the world that surrounds us, rooting it all in humility, logic, reason, and a dedicated search forr the truth.

9. **Coin**
March 1, 2007

> I spent the weekend reading original papers by Bohr, Einstein, and Heisenberg.
>
> Oddly enough, there was no mention of drug use, nor cutesy-wootsie dart games, nor insider wink-wink-nudge-nudge let’s get some cash from NSF to meet again next year for more darts and drugs.

Clearly your mistake here was not including some Feynman in the mix.

March 1, 2007

Greg,

I’m deleting your latest comment. Please do not post rants and personal attacks on people here. You’re just adding heat and no light to the discussion. There’s too much of this already.

Short-term and Long-term

March 1, 2007
Categories: Uncategorized

There's an article in this week's Science magazine by Adrian Cho entitled Dreams Collide With Reality for International Experiment. It's about DOE Undersecretary Orbach's warning to HEPAP (mentioned here) that current plans were too optimistic about the time-scale for the ILC, leaving a potentially dangerously long period with few US HEP experiments in progress.

Some physicists who had proposals for experiments (BTeV and RSVP) that were canceled in favor of going ahead full steam with the ILC were not amused:

*Meanwhile, Orbach's call for a program of smaller projects evoked jeers from researchers whose experiments had been cut. "This is really stupid and very frustrating because we **had** a program," says Sheldon Stone, a physicist at Syracuse University in New York who worked on an experiment called BTeV that would have run at the Tevatron collider at Fermilab.*

While experimentalists are worrying about the short-term, string theorists seem to be taking the long view. In his talk on String Theory: Progress and Problems at the recent conference celebrating the centennial of Yukawa and Tomonaga, John Schwarz ends with the conclusion

Even if progress continues to be made at the current rapid pace, I do not expect the subject to be completely understood by the time of the Yukawa-Tomonaga bicentennial.

I don't find his claims about a current rapid pace of progress very convincing, and the idea of the entire next century of theoretical particle physics being dominated by the kind of unsuccessful more and more complicated string theory constructions we've seen for the last 25 years doesn't seem like something to look forward to.

Turning from the difficulties of the future, Howard Georgi gave a wonderful talk on The Future of Grand Unification at the same conference, which was actually mainly about the past, largely devoted to telling the story of how he and Glashow came up with the first GUT models. He emphasizes the kinds of manipulations of representations of Lie algebras that he and Glashow were masters of and used to construct many different kinds of models. There's also an advertisement for his wonderful book on the subject, the text for his course where I first many years ago encountered this subject. This semester I'm teaching my own course on the same material, from a rather different point of view, emphasizing geometry. It remains one of the most beautiful and central parts of modern mathematics as well as physics.

Comments

1. **Peter Orland**
   March 1, 2007

   Hi Peter,

   I am surprised you are waxing so poetically about GUTs. GUTs have no real successes, with the noteworthy exception that experiments to detect proton decay were built (and found something else). The GUT unification scale isn't really all that convincing as physics – it isn't even completely clear that there IS unification, since the matching of the Weinberg-Salam and QCD scales is so rough. I remember the vanishing total charge of each generation (for anomaly cancellation) was considered a success. But later it was pointed out that it has nothing to do with GUTs specifically.

   Something's there at higher energies, but why should it be a GUT?

2. **Peter Woit**
   March 1, 2007

   Peter,

   I thought Georgi's talk was fascinating to read through, but that doesn't mean I'm a huge fan of GUTs. One nice thing about the GUT story is that Georgi shows how particle theory is supposed to work: he and Glashow came up with a tolerably simple model which does offer some sort of explanation of some of the questions the standard model doesn't answer (I do think the way fermions fit into the spinor representation of SO(10) is intriguing). They then made real predictions based on it (proton decay), and when these didn't work out they gave up (Georgi points out that he stopped working on GUTs in the early 80s). What they didn't do was keep coming up with more and more complicated models trying to evade failure. Once that seemed to be what was happening, I think they changed their attitude to "this doesn't seem to be working. Maybe it's true, but making more complicated models is a waste of time", and went on to try other things.

   The main problem with the GUT idea is that it's not a very satisfactory sort of unification, since you've just moved many of your problems into a new Higgs sector. The electroweak Higgs sector is already the source of most trouble, adding a new Higgs sector with similar problems doesn't seem like a promising way to make progress.

   It is a wonderful mathematical exercise in Lie algebra technique, even if these higher rank groups don't end up having anything to do with physics.

3. **Benni**
   March 1, 2007

   As to the ILC thingy…
   I find it somekind strange that physicists want it.
   The ministry of research in germany recently stated that it is unlikely for germany to apply for becoming Hamburg an ILC site.

   Well, after some asking around why, it becomes clear, that there is research underway at various universities in germany to increase the energy of particle beams with many new techniques (some, in fact optical).

   It seems that the german ministry of research has decided to leave the ILC to US america and then, after 20 years or such, build a new linar collider of much higher energy!

   At this time then, you in the US will have a wonderful ILC without any value!

Whatever State wants to get the ILC site, I wonder what to do with this rather low energy collider, when not a single hint of supersymmetry can be found. Is it not likely, that this will be a machine, which will have almost nothing to measure?

> There's also an advertisement for his wonderful book on the subject [Lie Algebras in Particle Physics]

If you don't mind me asking, what would you say would be the level and nature of required background knowledge for this book?

5. **Benni**
March 1, 2007

As to peter, what he says about GUT: I think that is absolutely correct. Glashow and Georgy are very honest researchers of the good old school.
The behaviour of some theorists, everytime when an idea does not work (in Feynmans words) to come up with a "fix-up" and look what happens if you add a parallel-world, hyperspace or a new unobserved differend standard-modell as hidden sector is simply what would be considered as scientific misconduct in experimental science. Expecially when they overhype these theories in press releases and refuse to mention any of their problems. When one looks at the Susy and sting propaganda one simply gets scared, since they often do not mention even the obiousliest problems

This is the same behaviour as of an experimentalist, who measured something and before publication deletes all his data which might be problematic.
For example why after the appearance of
Phys. Rev. D 20, 403 – 408 (1979) http://prola.aps.org/abstract/PRD/v20/i2/p403_1 does anyone continue to write propaganda material like: http://arxiv.org/abs/hep-ph/0203114 where it is statet that there would exist "a consistent pictures of breaking susy" and let experimentalists in fact believe, that such a theory would exist?

6. **Peter Woit**
March 1, 2007

Coin,

It's a textbook for a graduate physics course, basically what a mathematician would call a physicist's take on Cartan-Weyl theory, with lots of examples worked out. I took the course near the end of my undergraduate years, but I was a ridiculously ambitious student and took lots of courses that were over my head (this one was only a bit over my head… and Georgi was a good teacher).

The background needed to go through the book is basically quantum mechanics and a good grasp of how angular momentum and spin works in that subject.

Benni,

I think most people agree that the case for the ILC depends on the LHC first finding evidence of some new physics that can be studied at ILC energies. One reason I suspect Orbach is saying the ILC may take a while is that it may take a while for the LHC results to arrive. New accelerators and detectors often take a while to get working properly.

If the LHC does find something new that the ILC would be the right tool to study, it would make sense to build it, and building it in the US will solve the problem of what's next for US HEP research. This is what people are preparing for, but it is a bit of a gamble. Things like laser acceleration technologies are a long ways off, I strongly doubt having an accelerator of that kind ready 20 years from now is feasible.

7. **Coin**
March 1, 2007

Thanks.

8. **JC**
March 1, 2007

Peter,

slightly offtopic

What specific courses did you take in undergrad that were "over your head"? (Besides the Georgi group theory course).

9. **Peter Woit**
March 1, 2007

JC,

By far the most ridiculous thing I did was take a quantum field theory course in my second year (taught by Roy Glauber). I did come in with advanced standing due to taking a lot of AP exams, so technically I was a junior, but still… That year I started out taking a classical mechanics course from Arthur Jaffe, and sitting in the QFT course to see what it was about. A few weeks into the semester I realized that the classical mechanics seemed boring and required doing lots and lots of hard problem sets that had to be handed in on time, whereas the graduate course just had a few problem sets due every so often. So I went to see my advisor (Shelly Glashow), who, when I asked him if I could drop one and enroll in the other, irresponsibly said "Sure, whatever you want, I don't want you to be unhappy…". He would sign pretty much anything, if you could find him.

This is definitely getting off-topic, enough about misspent youth.

10. **Domenic Denicola**
March 1, 2007

Re: Schwarz's attitude, I too was rather perturbed by it when I went to talk to him last term about frontiers in physics. He said he didn't think we would have a Theory of Everything before he died, which seems to me to be overly pessimistic. Maybe it's just the naivete of youth (I'm an undergraduate freshman), but it seems to me there are enough people poking around in the right directions that we should stumble upon something, and probably in the next 10–15 years. Maybe working on string theory for so long engenders pessimism, heh.

11. **JC**
March 1, 2007

Domenic Denicola,

I use to think exactly like you 20+ years ago, when I was younger and naively bought into string theory. It took me a long time to eventually figure out that string theory wasn't all that it was cracked up to be.

12. **Peter Woit**
March 1, 2007

Domenic,

I'm about 15 years younger than Schwarz, so probably have a bit longer than him. If you extrapolate from the last 25 years, both Schwarz and I will be long gone before there's serious progress towards a TOE.

But, unlike him, I'm more optimistic. What strikes me about the Standard Model is both how incredibly good it is and how much beautiful, deep mathematics it involves. Besides gravity, most of the problems it leaves unresolved have to do with electroweak symmetry breaking. If either the LHC tells us what is really going on there, or someone figures it out without experimental guidance, we may very well end up with a theory that deserves to be called a TOE.

13. **Zing**
March 2, 2007

Undersecretary Orbach's remarks is his 'politically correct' way of saying the ILC is dead. Kaput. So forget about it. There is simply no justification for such an expensive machine. It is the wrong machine for the wrong time. We can try again in 10 years' time.

14. **a**
March 2, 2007

Maybe LHC will tell that ILC has a strong physics motivation. Today we have a strong argument against ILC (high-energy physics needs moving to more advanced technologies) and a strong argument in favor of ILC (it would keep the US high-energy physics community alive). Small experiments have been killed to emphasize the last argument (without explicitly mentioning it), but maybe it is not the best strategy.

It seems unavoidable that high-energy physics will become (for both experimentalists and for theorists) a part-time job: one big experiment every 30 years and in the meantime progress on astrophysics, neutrino physics, and whatever lower energy physics that happens to be interesting. Trying to do this transition in a smooth way could be the way of exploring physics up to the maximal possible energy.

Theorists often don't like near-cost navigation, but being interested only in big projects (such as a Theory of Everything) can be suicidal.

15. **Thomas Love**
March 2, 2007

In "Lie Algebras and Quantum Mechanics" (1970), Robert Hermann wrote theoretical physicists

"…are like greyhounds all chasing the same rabbit, never really catching it, but periodically convincing themselves that it is not worthwhile chasing this particular one any longer, and going off after another." (p. x)

It looks like Schwarz has given up.

16. **Benni**
March 2, 2007

BTW: Peter, do you often speak with Glashow? Because in your book, where you write about symmetry principles and group representation theory, these chapters look, as if they could be written from Glashow himself (At least it looks like this, when one looks at what Glashow is trying now with group theory). It seems indeed as if your book belongs to somewaht that could be called a "Glashow-school". Is this correct?

17. **Peter Woit**
March 2, 2007

Benni,

I haven't talked to Glashow since I was a student, and am definitely not a member of a "Glashow school". I suspect that, other than agreeing with me about a lot of the problems of string theory, we see things very differently. In his book Georgi (who definitely is in the "Glashow school") warns very explicitly about the seductive danger of making too much of representation theory, treating it as more than a device for doing approximate calculations. From his point of view, I've definitely gone too far and been seduced, since I see representation theory as a fundamental principle of physics. In general Georgi and Glashow are both pretty suspicious of abstract mathematics (one reason they didn't become string theorists), quite the opposite of my belief that progress in particle theory will require more mathematics, not less.

18. **Benni**
March 2, 2007

Well now, Glashow does such things involving group theory:
http://arxiv.org/abs/hep-ph/0601236
(I for me, of course find this somewat misleading and wrong. But it is refreshing to see that some people try their own new ideas).

19. **JC**
March 2, 2007

Peter,

How common is it for particle theorists to be suspicious of abstract mathematics? (Excluding string theorists).

Some of my previous colleagues who did string phenomenology, were not really interested in the overly abstract math stuff. On the other hand, a few other string colleagues were heavily into the abstract math stuff (ie. stuff related to mirror symmetry, etc …).

20. **woit**
March 2, 2007

JC,

I think particle theorists are all over the map on this issue these days. Some are highly suspicious, some are quite enamored of abstract math. For something related, see my next posting….

21. **D R Lunsford**
March 3, 2007

Peter said

The main problem with the GUT idea is that it's not a very satisfactory sort of unification, since you've just moved many of your problems into a new Higgs sector. The electroweak Higgs sector is already the source of most trouble, adding a new Higgs sector with similar problems doesn't seem like a promising way to make progress.

This is exactly the point – embedding the gauge group is not the real problem, and that is why SU(5) seemed doomed to me from the beginning. In the "real" theory this embedding will be explained naturally and perhaps the heroic effort will be seen in a new light and will not simply be recorded as a failure. I think in some sense the failure of GUT, which was certainly unexpected, coming hard on the heels of the failure to find a UFT for light and gravity, demoralized the community of physicists, and so string theory had a fertile ground of disillusionment in which to take root.

-drl

Weinberg in Physics Today

March 2, 2007
Categories: Uncategorized

The March issue of Physics Today is now available. It contains a piece by Steven Weinberg based on a banquet talk he gave to a group of postdocs. He describes his own memories of his time as a postdoc, writing that "Many of us were worried about how difficult it seemed to make progress in the state that physics was in then." This was the heyday of S-matrix theory and he comments:

Some people thought that the path to understanding the strong interactions led through the study of the analytic structure of scattering amplitudes as functions of several kinematic variables. That approach really depressed me because I knew that I could never understand the theory of more than one complex variable. So I was pretty worried about how I could do research working in this mess.

He describes envying the previous generation of 10-15 years before his time, that of Feynman, Schwinger, Dyson, and Tomonaga, thinking that all they had had to do was sort out QED, and speculates that they in turn had envied the generation before them since quantum mechanics was even easier. I can see that he's trying to provide encouragement, ending with

So the moral of my tale is not to despair at the formidable difficulties that you face in getting started in today's research… You'll have a hard time, but you'll do OK.

Postdocs in high energy physics these days do need some encouragement, but I also think they need some recognition from their elders that they're facing a different situation than that faced by earlier generations. Coming into a field that has not seen significant progress in about 30 years is a different experience than what Weinberg or previous generations of particle physicists had to deal with. High energy physics is now facing some very serious problems, of a different nature than those of the past, and I think these deserve to be mentioned.

In the same issue, Weinberg makes another appearance, in an exchange of letters with Friedrich Hehl about the torsion tensor in GR. Hehl takes him to task for his comments in a previous letter that torsion is "just a tensor", pointing out that it can be thought of as a translation component of the curvature. Weinberg responds that he still doesn't see the point of this:

Sorry, I still don't get it. Is there any physical principle, such as a principle of invariance, that would require the Christoffel symbol to be accompanied by some specific additional tensor? Or that would forbid it? And if there is such a principle, does it have any other testable consequences?

Actually, Weinberg is rather well-known for taking the point of view that GR is just about tensors, and that their geometrical interpretation is pretty irrelevant, so it's not surprising that he doesn't see a point to Hehl's comment. In his well-known and influential book on GR, he explicitly tries to avoid using geometrical motivation, seeing this as historically important, but not fundamental. To him it is certain physical principles, like the principle of equivalence, that are fundamental, not geometry. There's a famous passage at the beginning of the book that goes:

However, I believe that the geometrical approach has driven a wedge between general relativity and the theory of elementary particles. As long as it could be hoped, as Einstein did hope, that matter would eventually be understood in geometrical terms, it made sense to give Riemannian geometry a primary role in describing the theory of gravitation. But now the passage of time has taught us not to expect that the strong, weak and electromagnetic interactions can be understood in geometrical terms, and too great and emphasis on geometry can only obscure the deep connections between gravitation and the rest of physics.

This was written in 1972, just a few years before geometry really became influential in particle physics, first through the geometry of gauge fields, later through geometry of extra dimensions and string theory. I recall seeing a Usenet discussion of whether Weinberg had ever "retracted" these statements about particle physics and geometry. Here's an extract from something written by Paul Ginsparg, who claims:

back to big steve w., when he wrote the gravitation book he was presumably just trying to get his own personal handle on it all by replacing any geometrical intuition with mechanial manipulation of tensor indices. but by the early 80's he had effectively renounced this viewpoint in his work on kaluza-klein theories (i was there, and discussed all the harmonic analysis with him, so this isn't conjecture…), one can look up his research papers from that period to see the change in viewpoint.

Comments

1. **Sean Carroll**
   March 2, 2007

   Weinberg's point that the torsion is "just a tensor" is an attempt to draw a distinction with the Christoffel part of the connection, which is *not* a tensor. You can't just stick a term like (connection)^2 into the action, but there's no trouble at all sticking in a term like (torsion)^2, or any of a million other terms. There aren't any symmetries that give you any information at all about what the dynamics of the torsion should be, or how it should couple to other fields. So you can write down whatever action you like. (In particular, there's no obstacle to giving the torsion a mass at the Planck scale.) Consequently, there is no conceivable way that you could detect some new field and say "aha, that must be the torsion."

2. **Peter Woit**
   March 2, 2007

   Sean,

   Isn't this just like the curvature then?

   Won't your particles couple to it in a very specific way, since you're not changing the Dirac equation, just allowing spin-connections that are not torsion-free? I assume that's the kind of physical prediction that Hehl is talking about.

3. **Tony Smith**
   March 2, 2007

   Peter said that Paul Ginsparg said "… by the early 80's … big steve w. [Weinberg] had effectively renounced this viewpoint [of]… replacing any geometrical intuition with mechanial manipulation of tensor indices …".

   I think that Paul Ginsparg is correct about that. At the 1984 APS DPF Santa Fe meeting, Weinberg gave a talk "Unification Through Higher Dimensions" in which he not only discussed "The Kaluza-Klein Idea" but also concluded by discussing "Research Directions" including "The SO(32), N+4=10 Green-Schwarz theory".

   At that same meeting John Schwarz gave a talk (on work with Shahram Hamidi) entitled "A Unique Unified Theory That Could Be Finite And Realistic", in which he

discussed “SO(32) and E8xE8 superstrings” with respect to finding “the correct low-energy (compared to the Planck mass) theory in four dimensions with which to make contact”.
Swarz went on to say that “In collaboration with J. Patera, we have classified all the chiral N=1 theories that satisfy the one-loop (and hence two-loop) finiteness conditions. The list includes theories based on E6, SO(10), SU(5), and SU(6) that can describe three or more families without mirror partners. However, if we also require the occurrence of elementary Higgs fields in representatins that can give realistic symmetry-breaking patterns, then one unique scheme is singled out. …
The unique model that is potentially finite and realistic is based on the gauge group SU(5). …
To be perfectly honest, we are not sure how seriously this should all be taken. The three-loop calculation could result in a dramatic failure and is therefore of utmost importance.
The connection between superstring compactification and finite four-dimensional theories is only a speculation … It need not be true in general.”.

IIRC, during the talk by Schwarz, Weinberg stook in the rear door of the lecture room. Many of the physicists at the meeting were on the edge in deciding whether or not superstring theory would be the new fashion for theoretical physics, and were looking to Weinberg for a sign about which way to go. At the end of the talk, Weinberg commented that he was favorably impressed, and in my opinion that comment had some influence in the establishment of superstring theory as the fashion and paradigm for the next 20+ years.

It is interesting that in his 1984 Santa Fe talk Schwarz presented, on grounds related to what I think of as “real physics”, a “unique unifed theory”
and
that Schwarz proposed a direct test of that “unique” theory by doing three-loop calculations
and
that even though the “unique” theory failed to be a realistic model, superstring theory advocates refused to acknowledge the failure,
and even now, over two decades later,
they continue to “work” on stuff that has
more and more complex structure (to avoid theoretical failure)
and
less and less contact with experimental observations (to avoid refutation by experiment).

Tony Smith

4. **Eugene Stefanovich**
March 2, 2007

Weinberg is also famous for his non-orthodox views on QFT. For example, he writes on page 200 of his “The quantum theory of fields” vol. 1:

Traditionally in quantum field theory one begins with such [Klein-Gordon] field equations, or with the Lagrangian from which they are derived, and then uses them to derive the expansion of the fields in terms of one-particle annihilation and creation operators. In the approach followed here, we start with the particles, and derive the fields according to the dictates of Lorentz invariance, with the field equations arising almost incidentally as a byproduct of this construction.

To me this suggests that Weinberg does not consider fields as being fundamental physical quantities. However in another place (http://www.arxiv.org/hep-th/9702027) he seems to be contradicting himself:

In its mature form, the idea of quantum field theory is that quantum fields are the basic ingredients of the universe, and particles are just bundles of energy and momentum of the fields.

It is also interesting to see the evolution of Weinberg’s views on the local gauge invariance principle. On page 990 of Phys. Rev. 138B (1965), 988 he writes (after short introduction to what he calls “extended gauge invariance”)

The only criticism I can offer to this textbook approach is that no one would ever have dreamed of extended gauge invariance if he did not already know Maxwell’s theory.

I read it as an admission that he doesn’t know how to justify the gauge invariance principle, except by the fact that it works. I find this attitude somewhat refreshing when compared to the modern textbook dogmatic approach. He continues:

In particular, extended gauge invariance has found no application to the strong or weak interactions, though attempts have not been lacking.

This was in 1965. Long before electroweak theory and QCD. Do we know better today **why** there should be local gauge invariance? Besides the fact that it works.

5. **JC**
March 2, 2007

Tony,

Has anyone done this particular three-loop calculation mentioned by Schwarz?

6. **Moshe**
March 2, 2007

The way I read the torsion issue is that it is an irreducible representation of the Lorentz group (= a tensor), so when coupling to gravity or anything else you just write the most general couplings consistent with symmetries, since there is no symmetry that will prevent them from being generated.
\
On the other hand, treating this tensor like “torsion” entails presumably very specific way of coupling to matter, in other words setting some of the possible couplings to zero.

7. **Sean Carroll**
March 2, 2007

No, particles don’t *have* to couple in any specific way. Ordinarily we decompose the covariant derivative into (d+G), where d is the partial derivative and G is the connection coefficients. And they have to come along with each other, since each alone is not a tensor. But with torsion this becomes (d+C+T), where C is the Christoffel part of the connection and T is the torsion. But there isn’t any reason they have to come together! (d+C) by itself is a perfectly good covariant derivative, and T is a perfectly good tensor. In a low-energy effective theory, we would expect T to couple to anything it was allowed by symmetries to couple to. And there aren’t really any symmetries to prevent it from being massive and coupling indiscriminately.

More here: http://arxiv.org/abs/gr-qc/9403058

Geometry is fun for inspiration, but physics plays by its own rules.

8. **gunpowder&noodles**
March 2, 2007

On the other hand, it is clear that the generic connection does have torsion. The restriction to zero torsion connections is a very strong one, so it should be justified. Setting something equal to zero is not the same as saying that it *has* to be zero for physical reasons.

Traditionally, students were told that torsion had to vanish because non-zero torsion, being a tensor, would violate the equivalence "principle". [Basically, anything about GR that one doesn't understand is referred to that so-called principle.] People apparently didn't notice that the same idea can be used to "prove" that the curvature tensor also has to be zero.

Hehl had a very influential paper about torsion in Rev Mod Phys in about 1977. People interested in the subject should read that. Torsion certainly would be observable, but it hasn't been: for some reason the torsion tensor of our Universe is zero. Nobody knows why.

9. **Tony Smith**
March 2, 2007

JC asked "… Has anyone done this particular three-loop calculation mentioned by Schwarz? …" [for his "unique" string theory SU(5) "unified theory"]

Yes. As might be expected, after Schwarz made his 1984 Santa Fe talk, a lot of work was done on that SU(5) structure.

For example,
in Physics Letters B, Volume 160, Issues 4-5 , 10 October 1985, Pages 267-270,
D. R. T. Jones and A. J. Parkes wrote a paper entitled "Search for a three-loop-finite chiral theory". Its abstract stated:

"Grand-unified theories have been constructed out of supersymmetric SU5 theories which are finite at one and two loops. We investigate the three-loop divergences in these models and find that they can never be three-loop finite. We present an example based on E6 of a three-loop-finite chiral theory."

The Jones-Parkes paper was received by Physics Letters on 19 June 1985, about 7 months after the Santa Fe meeting (which was from 31 October 1984 to 3 November 1984).

Tony Smith

10. **Joseph Smidt**
March 3, 2007

I tend to agree with Weinberg. When I took GR I thought geometry was front and center in importance. Now taking QFT, I am beginning to think that geometry distracts from particles and fields and other fundamental quantum ideas.

I also liked what Sean Carroll said in a comment on his blog. He said you should be careful wanting to axiomatize relativity. I've given this a lot of thought and it seems every time we axiomatize a theory we end up having to alter things here and there to fit nature. I'm beginning to think it is more important to have an evolving theory which evolves with experiment.

11. **Levi**
March 3, 2007

"That approach really depressed me because I knew that I could never understand the theory of more than one complex variable."

Sorry to isolate this bit of quotation from Weinberg, but it reminded me that I have never seen a good clear text on multi-variable complex analysis, Does anybody here know of one?

12. **Peter Woit**
March 3, 2007

Sean,

You can certainly, as a consistent low energy theory, write down all sorts of things. But, if your Lagrangian is supposed to be a fundamental one, and your only fields are spinors and the spin-connection (metric, but not necessarily torsion-free), then there's one simplest Dirac equation (standard covariant derivative, i.e. "minimal coupling"), and you can ask what the implications of assuming that are. I haven't really looked at Hehl's papers, but am just assuming that's what he does. Forgetting questions of aesthetics, philosophy or whatever, Hehl claims to have predictions (even if not practically testable), and Weinberg seems to be saying he doesn't see this (although his wording is unclear). Is Hehl right?

I agree that the problem with torsion is that you don't know what its dynamics is. If you start looking at all consistent possible couplings to all physical fields, maybe you can't predict much of anything. Presumably Hehl is making some sort of assumptions about this dynamics.

Joseph,

The problem with the "GR involves geometry, QFT" doesn't point of view is that the it turns out that the very particular QFT that governs the real world (the Standard Model) is very much a geometrical theory (gauge fields=connections, field strengths=curvature, matter fields=sections of associated vector bundles with connection).

The point of talking about "axioms" is just so you make explicit what your assumptions are, and being clear about that is generally a good idea.

13. **Moshe**
March 3, 2007

Peter, interjecting again…GR certainly is not a fundamental theory, as it is not renormalizable.It is an effective field theory at low energies, so you can only make sense out of it if you allow all possible couplings (they run with scale, so it is meaningless to just set them to zero, zero at what scale?). So, if you add to your theory that particular tensor, there is no way to ensure it couples precisely like a torsion. If I got it right, that is the issue discussed.

14. **Sean Carroll**
March 3, 2007

I think Moshe and I are in agreement. Things like "simplicity" and "aesthetics" and "geometry" might inspire you to think about theories with certain symmetries and certain degrees of freedom. But once you have that, you should write down all of the possible terms consistent with the symmetries; if they're not there in the fundamental Lagrangian (whatever that means), they'll be generated at low energies by radiative corrections.

There are many specific models with torsion, and each individual one may very well make predictions. But there is no possible observable that would allow you to conclude that a certain new degree of freedom was the torsion. It's just a tensor, as someone once said.

(In fact, classic "Riemann-Cartan theory" doesn't even give the torsion a kinetic term, for the very bad reason that it's not there in the Einstein-Hilbert action; since the Einstein-Hilbert action didn't have torsion at all, that's just silly. If you don't give it a kinetic term, it's just a Lagrange multiplier and you can integrate it out, leaving some non-renormalizable contact interactions.)

15. **Peter Orland**
March 3, 2007

Levi,

There are few readable texts on several complex variables. I assume you mean subjects like polydiscs, Hartog's theorem, envelopes of holomorphy, etc. The best known texts are by Bochner and Martin and by Vladimirov, but these are quite old and it isn't clear how useful they are nowadays.

A short book which is to the point is the paperback by Narsimhan. A more
sophisticated text by is by Krantz.

16. **Peter Orland**
March 3, 2007

Sorry that's Narasimhan.

17. **woit**
March 3, 2007

Moshe and Sean,

I understand the effective field theory philosophy that our Lagrangians are just effective low energy theories, so all you have is what you think you know about the symmetries of the theory to constrain terms in the Lagrangian, and non-renormalizable terms like the Einstein-Hilbert one occur with powers of the energy scale at which the effective field theory is no longer valid.

But I'm just not convinced by it. The fact that asymptotically free gauge theories make sense at all energy scales makes me suspect that they're not just effective field theories for something more fundamental. I think it continues to be a valid thing to do to try and make sense of QFTs not just as effective low energy theories, but as fundamental theories, valid at all energy scales. If you try and do this, there are three sources of problems:

1. Elementary scalars like the Higgs. They're bad news for lots of reasons, and quite possibly are just effective fields, not part of the fundamental theory (e.g. technicolor). Maybe the LHC will clear this up…

2. The U(1) gauge coupling. Maybe there are GUTs, and the U(1) unifies with a non-abelian group, is asymptotically free above a certain energy scale.

3. GR. Maybe the people claiming N=8 supergravity is finite are right. Maybe there are fundamental Lagrangians that give consistent dynamics at all energies, with an Einstein-Hilbert term, other terms having some specific structure. There seems to be something going on in supergravity that we don't understand, causing extra cancellations. Maybe the LQG people are right, and if you quantize your theory differently you'll get something that makes sense. Maybe part of this story is that, just like SU(2) and SU(3) connections are fundamental fields in the non-gravitational part of the theory, the spin connection is a fundamental field, not necessarily torsion free, and its torsion components may have some well-defined dyamics, with measurable consequences.

I'm still curious about Hehl's claims of a prediction, and what assumptions they make. Any comments about those?

18. **Sean Carroll**
March 3, 2007

I'm happy to admit that there is some fundamental high-energy Lagrangian, but what we actually observe at low energies is the low-energy effective field theory. For example, the gauge field-strength tensor doesn't involve the torsion at all, so there is no "fundamental" coupling between torsion and photons. But there is a coupling between torsion and fermions, and between fermions and photons, so voila — at low energies you get an effective coupling, suppressed by the Planck scale, between torsion and photons. And so on — there's nothing in the dynamics of "torsion" that protects it from being just another propagating tensor field at low energies.

I believe that Hehl is referring to classic Einstein-Cartan gravity, in which the torsion is non-propagating. You can integrate it out to leave a four-fermion interaction, suppressed by the Planck scale. Observable in principle, but not relevant to any conceivable experiment.

19. **Peter Woit**
March 3, 2007

Sean,

OK, I think it's clear now that you and I were just talking about two different things. I was discussing a conjecturally fundamental Lagrangian, you the effective low energy Lagrangian relevant to what we actually measure. In principle the low energy Lagrangian is derivable from a fundamental one, should it exist, but I certainly acknowledge there's no problem-free candidate for such a thing at the moment.

20. **D R Lunsford**
March 3, 2007

I am so happy that Weinberg is still Weinberg!

Yes, torsion in GR proper is a lost cause because of reducibility. But, you can make a theory where torsion is a sort of gauged electromagnetic duality, and there it is interesting. Since a charge-pole system has an intrinsic angular momentum independent of spin, and since asymmetry of the connection is associated with intrinsic angular momentum, torsion becomes very interesting. But I have other things to work on.

The Weinberg book on GR is far and away the best one to be had, even now. The approach is thoroughly geometrical, in spite of the author's own statements. See this thread on SPR.

-drl

21. **JC**

March 3, 2007

Peter,

Is there a possibility that there does not exist a “fundamental” Lagrangian?

Or maybe higher energy physics (ie. higher than the electroweak scale) cannot be quantitatively described in a Lagrangian/path integral framework?

22. **D R Lunsford**
March 3, 2007

Sean Carroll said

Consequently, there is no conceivable way that you could detect some new field and say “aha, that must be the torsion.”

You could if you could find a magnetic monopole.

-drl

23. **Peter Woit**
March 3, 2007

JC,

By “Lagrangian” I was referring to the standard QFT setup, in your favorite formalism: path-integral, Hamiltonian, or whatever. Sure, at scales we haven’t probed yet, QFT may no longer describe things. Maybe it will need to be thrown out in favor of string theory or something else. But there’s no evidence for this, and, to me, the fact that asymptotically-free QFTs give mathematicallly beautiful theories that are highly constrained and perfectly consistent at all energy scales seems very striking. Maybe nature has got a better idea, and these are just low energy approximations, but I haven’t seen a convincing better idea.

24. **D R Lunsford**
March 3, 2007

JC,

This is the approach of David Finkelstein as I understand it – if you are philosophically comfortable with that, then you should investigate his work.

-drl

25. **Chris W.**
March 3, 2007

Can anyone clearly state the presuppositions behind the assumption that a “fundamental” Lagrangian exists? Is there a way to know that one doesn’t exist, or must we settle for simply observing that we haven’t found one—ie, all the candidates have problems—and their are some general reasons to be skeptical that we will find one?

26. **Moshe**
March 3, 2007

One more comment, possibly redundant…The use of EFT does not commit you to the form of the fundamental theory. Even when you have a complete description, such as in QCD, it is still useful to use various EFT (such as chiral PT, soft collinear EFT, etc.) in different regimes. That is why I don’t like the expression “EFT philosophy”. It is not a philosophy, it is just a self-consistent approximation scheme.

27. **D R Lunsford**
March 3, 2007

Chris,

My own view is that the Lagrangian is the embodiment of the idea of a conservation law, and insofar as physics is the study of conservation laws, it involves a Lagrangian. Finkelstein believes instead that physics is about processes, and that conservation laws are derived ideas in the limit of many processes.

-drl

28. **Peter Woit**
March 3, 2007

Chris W. and DRL,

Sorry, but this discussion has moved far off-topic into a kind of discussion I don’t want to have to try and moderate here. Please stick to comments relevant to what Weinberg had to say in Physics Today.

29. **Levi**
March 3, 2007

Peter Orland,

Thanks! I’ll take a look at those books.

30. **Tony Smith**
March 3, 2007

Levi asked “… Does anybody here know of … a good clear text on multi-variable complex analysis … ? …”.

In addition to the references given by Peter Orland,
from my old (1960s) college days, a book entitled “Analytic Functions of Several Complex Variables (Prentice-Hall 1965) by Gunning and Rossi is an introduction that I like.

The Gunning-Rossi book is based on polydiscs, which are different from unit balls,
so you might also want to look at the book “Function Theory in the Unit Ball of C^n” (Springer-Verlag 1980) by Walter Rudin. As Rudin said in his preface:
“… Around 1970, an abrupt change occurred in the study of holomorphic functions of several complex variables. Sheaves vanished into the background, and attention was focussed on integral formulas and on the “hard analysis” problems that could be attacked with them … The ball is the prototype of two important classes of regions that have been studied in depth, namely the strictly pseudocomplex domains and the bounded symmetric ones. …”.

If you are interested in the bounded symmetric domains, a standard reference is the book “Harmonic Analysis of Functions of Several Complex Variables in the Classical Domains” (AMS Translations of Mathematical Monographs Volume 6 1963) by L. K. Hua (whose life story in China is very interesting but probably off-topic here).

Two recent books with a lot of interesting further details are:
Analysis on Symmetric Cones (Oxford 1994) by Jacques Faraut and Adam Koranyi; and
Analysis and Geometry on Complex Homogeneous Domains (Birkhauser 2000) by Jacques Faraut,Soji Kaneyuki, Adam Koranyi, Qi-keng Lu; and Guy Roos.

Of course, the above is far from an exhaustive list, and you can find a lot more fascinating stuff to read if you are interested.

Tony Smith

31. **Levi**
March 3, 2007

“The Gunning-Rossi book is based on polydiscs, which are different from unit balls”

Right, and for various reasons I am more interested in the unit ball. Unfortunately, the book by Rudin is hard to get ahold of these days. Thanks for the help, though, and I know I’m off topic so I will leave it at that.

32. **nontrad**
March 3, 2007

I have to agree with Peter on his point about asymptotically free theories. QCD, for example, from it’s number of parameters to its mathematics and experimental verification is a very very interesting theory. To speak loosely, I’ve always regarded QCD as a paradigm.

GR, on the other hand, (where I’ve spent more then a few idle moments) is, as much as everyone has ever wanted it to be anything other, a much much more difficult situation (including the work of….insert bigwig buzzword names here from A to Z).

And here on this blog and elsewhere, we all know this! Bottom line, GR is a stumbling block that is not simply the speed bumb that the success of SU(2)XU(1) or the success of SU(3) might suggest. Instead, GR is more like an Everest of some kind… and like Everest just waiting for the right person (who as far as I am concerned will arrive one of these days).

When I was first learning GR I read Weinberg’s book and considered his comments about geometry and, simply, I was confused. A primary source of my confusion was Chandra’s comments about how GR is ‘indistinguishable’ from a geometric view point. If the two are indistinguishable then why have a preference? Why not use the tool for the job that gets the job done? After all, who really cares? Afterall, this isn’t philosophy…this is physics borne out of a history that includes Bethe’s calculations… meaning always have a calculation!

Well, it’s probably obvious that I have a dog in this fight…. and I suppose I do.

33. **Thomas Larsson**
March 4, 2007

IIRC, Schrödinger was very excited about torsion in the 1940s, thinking that it was a means to reconcile gravity with QM. Einstein, having thought about and dismissed torsion 25 years earlier, made him change his mind. There was a paper about this on the arxiv a number (5-7) of years ago.

34. **Benni**
March 4, 2007

Lubos has now a discussion on Weinberg vs Hehl.
http://motls.blogspot.com/2007/03/steven-weinberg-vs-weird-physicists.html

He calls The editor of “Annalen der Physik” and former chief of the workgroup “gravitational physics” in germany a “weird physicist” because Hehl’s theories would not come close to experiment….

(german gravitational physics was rather good, because not completely devoted to fashions like strings. In Germany, traditionally many approaches are considered. I do not like it, when our (small) gravitational physics is malighed this way. Hehls theories are not more weird and disconnected from experiment than string theory is. People like Lubos would be called as ill-suited here because Lubos follows standard-fashion, not able to create own ideas.

I do not know, If someone should bring this to attention of the professional association of gravitational physics in germany:
http://www.zarm.uni-bremen.de/GR/organisation.htm
maybe someone has the time to send an email to the responsible persons:
http://www.zarm.uni-bremen.de/GR/kontakt.htm

35. **woit**
March 4, 2007

Benni,

I don’t think people should be contacting the (large number) of targets of Lubos’s unprofessional behavior. If people see a problem with it, and don’t want to do what is generally considered to be the sensible thing (ignore him), it would make more sense to contact those of his colleagues who have promoted him, and now appear to tolerate if not encourage his behavior.

36. **Benni**
March 4, 2007

Yes. But this must be done by german gravitational physicists. That is, one must first inform the GRE group of the German DPG about Lubos, so that Ehlers, Hehl, Kiefer, Nicolai and Fraundiener can take the appropriate actions.

The point is:
German theoretical physics suffers since the second world war when Hitler had forbidden jewish physics and relativity.
Due to the speculative nature and risky business of this research, government was and is very sceptical of it and would to this day not create any new professorships studying relativity. In Germany, there are (without the AEI) only around five relativity groups. And this groups are generally under the pressure of a majority of experimenters who think that they simply do not need this research which has no connections to any sort of experiments.

So, it is very bad, if the small theory group in germany is maligned from someone outside.

Since the only reason to install new theoretical professorships for german government would be the pressure, that germany will lose important competence to the US. (This is the reason why they agreed to fund some strin projects recently).

If a Harvard Professor calls a german gravitational physicist as "weird" it could have consequences for the small group in Germany.

37. **woit**
March 4, 2007

Benni,

I doubt that scientific policy decision-makers in the German government are reading Lubos's blog, so presumably would be unaware of his nonsense about Hehl, unless you bring it their attention.

If they are reading Lubos's blog and taking it seriously, German science has a lot worse problems to worry about….

38. **Benni**
March 4, 2007

Of course, policy makers are not reading Lubos blog.

But maybe experimentalists, who are curious about theoretical physics and want a good reason to set an experimentalist on the chair when Hehl becomes emeritus.

Or other members of the Harvard group can read this, who are then, after some look at the publications of Hehl, finding out, how strange Germans theoretical physics is (not string theoretic).

In fact, German policy makers often get their referees from foreign countries. In this situations, such entries of Lubos blog do not help when one wants to enlarge a research group.

39. **gunpowder&noodles**
March 4, 2007

Benni: don't worry, LM will soon be leaving Harvard, because he is being persecuted by left-wing academics on the grounds that he thinks that GR is nothing but perturbation theory around Minkowski space. He also thinks that topologically non-trivial spacetimes are possible but they, too, are perturbations around Minkowski space, and this too is anathema among leftist academics. In short, LM's 1920s style understanding of GR is politically unacceptable in Cambridge, so he has to leave and that will solve your problem.

40. **Benni**
March 5, 2007

Haha,
Well, I know at least one Gravitational physics group in germany (the one of Dehnen in Konstanz) which was destroid because Dehnens chair was after his retirement not taken again.
This chair was stopped because a majority of experimentalists (solid state physicists and optical physicists who thought that theoretical research on cosmology and general relativity is not worth doing.

Well, and this here might have been a reason too:
(I've wondered everytime who the referee of the Bogdanoff Hoax paper in class quant grav was. In his Math-Zentralblatt review of the Bogdanoff paper, it seems clearly that Heinz Dehnen did not get their joke:
http://zmath.impa.br/cgi-bin/zmen/ZMATH/en/quick.html?first=1&maxdocs=3&type=pdf&rv=Heinz+Dehnen&format=complete

41. **Benni**
March 5, 2007

An interesting thing to note might be, that Hehl, whom Lubos calls a weird physicist has much more publications in prestigious journals than Lubos and even very much more citations!

and well, it seems that Lubos fears consequences. He writes now on his blog (I wonder what this is about. In every case, the german GR association should be informed about Lubos):

Lubos wrote:
There's just far too much organized influence terrorizing people in science. Whenever your results or conclusions of your work disagree with a sufficiently large group of ignorants, they will attack you personally in the worst possible ways. They will present the fact that your results reject their preconceptions as your moral flaw.

I am looking forward to be away from the focus of these intellectual bottom-feeders who exist not only on Not Even Wrong and who enjoy a silent approval by many of the leftist officials in the Academia.

42. **Peter Woit**
March 5, 2007

Benni,

Please, enough about Lubos. People who want to read his rantings can go to his blog. He generates a vast amount of this kind of stuff, devoting attention to it would overwhelm any sort of intelligent discussion. Enough.

43. **King Ray**
March 6, 2007

Peter, et al, thanks for posting on this topic. I found many of the links and comments very interesting.

Semi-precise Predictions

March 4, 2007
Categories: Uncategorized

Many string theorists seem to have decided to react to the criticisms of string theory that have recently been getting a lot of attention by going to the press with claims to have experimental tests of string theory that can be performed in the very near future.

The latest of these claims has nothing at all to do with the aspect of string theory that has come under criticism, its failure as a unified theory of gravity and particle physics, but instead involves the conjectural use of string theory as an approximation method in QCD. The main problem with this idea so far is that it involves not QCD but a related theory (N=4 supersymmetric Yang-Mills), and it is very unclear exactly what the relation is between the calculation and the real world. For some earlier comments about this, see here. John Baez also has a summary, and the Backreaction blog of Sabine Hossenfelder and Stefan Scherer has a very extensive explanation here.

Last week the AIP Physics News site carried a story entitled String Theory Explains RHIC Jet Suppression, which dealt with recent work by Hong Liu, Krishna Rajagopal and Urs Wiedemann concerning the jet quenching parameter, which describes how charmed quarks move through a quark-gluon plasma. In the AIP story, Rajagopal claims that their calculation "agrees closely with the experimentally observed value", and that other related calculations "make a specific testable prediction using string theory." This story was picked up by Scientific American, which has a story by JR Minkel. According to Scientific American, "trying to fit the QCD-like theory to reality makes the results only semi-precise, Rajagopal says," alluding to the problem of doing the calculation in the wrong theory. Maldacena is quoted about this as follows:

It's like saying you are trying to study water, but instead you are studying alcohol… We certainly know it's not the correct theory, but maybe it behaves in the same way.

Theorist Ulrich Heinz is even more skeptical:

Even if any of the numbers worked out by accident, I don't think it would validate the approach… If they predict the color of an apple, and somebody looks at a pear and finds it has the same color, would you say that the prediction was correct?

Other recent claims by Shiu et al. and Distler et al. to be able to make predictions using the string theory approach to unifying physics are covered in the latest issue of Plus magazine, in a story entitled Stringent Tests. According to this story

It seems that string theory, so far the strongest contender for a physical "theory of everything", may soon be put to the test for the first time. Two separate teams of physicists have just published work describing how to compare the theory's predictions with reality….

Neither of the two new tests will be capable of verifying string theory once and for all. If the results concur with its predictions, then this is just some further evidence for its correctness, not absolute proof. But the tests' ability to falsify string theory, or at least certain aspects of it, means that a philosophical barrier has been overcome.

On a somewhat related note, I'll soon be traveling to Italy, giving talks in Rome and Pisa on the topic of "Is String Theory Testable?".

Comments

1. **Kea**
   March 4, 2007

   The only way to sort out this mess is to REALLY figure out QCD. Why don't we spend our time doing that instead of playing cowboys?

2. **kramnik**
   March 4, 2007

   Fancy new string-theory-inspired methods to calculate amplitudes in supersymmetric theories do have relevance to the real world. For one thing, purely gluonic QCD tree amplitudes actually coincide with the analogous ones in susy theories. At loop level, one can add appropriately chosen susy amplitudes in a clever way and end up with a qcd amplitude.

   (i'm not for a minute defending the ridiculous pseudo-predictions you've reported on recently, Peter)

3. **Peter Woit**
   March 4, 2007

   There's no denying that string theory has inspired a lot of important ideas, both in math and in physics. The field would be a lot healthier if people would just admit that trying to get a TOE out of string theory doesn't work, and if they really want to keep doing string theory, instead focus on trying to better understand those parts of the theory that might lead to something interesting. Trying to better understand QCD via AdS/CFT is a perfectly reasonable thing to be doing, although over-enthusiastic claims about where that project is don't help matters. And it would be nice if there were more encouragement for people trying to understand QCD or other non-perturbative QFTs using non-string theory methods.

4. **A String Theorist**
   March 4, 2007

   "The field would be a lot healthier if people would just admit that trying to get a TOE out of string theory doesn't work."

   It depends on your definition of "TOE".

   If by "everything" you mean something like "the Standard Model, along with whatever (if anything) supplements it at the next 10 orders of magnitude (or so) in energy", then I think that the vast majority of praciticing string theorists (it's hard to think of any exceptions) would happily admit this.

   However, many string theorists have a broader definition of "everything", roughly something along the lines of "the set of all possible consistent quantum theories of gravity".

5. **Peter Woit**
   March 4, 2007

   A String Theorist,

Interesting to hear that almost all string theorists have given up on getting particle physics out of string theory. Maybe you're right, most of the ones I talk to are certainly pretty pessimistic about it, although not necessarily willing to give up on the idea.

Besides the usual arguments about whether string theory has actually produced a "consistent quantum theory of gravity", I'm not sure I see the point of a research program devoted to generating "the set of all possible consistent quantum theories of gravity" based on the idea that they're all extremely complicated, ugly and untestable. This will certainly keep one busy for a long time, but why do it?

6. **Peter Orland**
   March 4, 2007

   Kea,

   There is a very tiny group of people who still try to figure out QCD. Unfortunately, it's a tough problem. The best we can do now is try to solve related models which we hope are relevant, much as the string theorists do. Whose models are better is in the eye of the beholder, and will
   continue to be so until QCD is finally understood.

7. **Thomas Larsson**
   March 5, 2007

   String theory is testable, even
   supertestable 🙂

8. **Q**
   March 5, 2007

   If a theory predicts something, that only validates the theory if there is evidence the theory is the only one possible. Ptolemy's epicycles-based mathematical model of the universe allowed predictions of where the planets would be at any time. As a spin-off, it also led to new mathematical methods. It's practitioners were extremely enthusiastic about it being the final theory of everything, so they tried to block all nonsense of alternative ideas without investigating them (one turned out to be more predictive!).

   Falsifiability isn't the key. Newton's theory failed to predict the precession of the perhelion of Mercury, but that didn't lead to dumping the theory. Today the Pioneer anomaly doesn't falsify general relativity. An error in prediction is just an anomaly. This would be true for string theory if it made a predictive error. The real problem for string theory is that it isn't based on an facts.

   Time and again the scientific method in physics has been to

   collect data
   summarise the data by empirical maths
   check the maths by predictive extrapolations
   come up with a theory for the maths that predicts more
   check it experimentally/observationally

   The basis of M-theory is religious belief in spin-2 gravitons, planck scale unification, and the 6/7 extra-dimensions which are required to make string explain these speculations. It's not factual physics.

9. **Thomas Love**
   March 5, 2007

   Peter: You mentioned your trip to Italy which reminded me of a famous Italian story about strings: Pinocchio! In the Disney version, Pinocchio sings: "I've got no strings to hold me down…"

10. **Eric Mayes**
    March 5, 2007

    The best way to test string theory is to construct a realistic MSSM model derived from string theory that can be tested by LHC. In this regard, please see our upcoming paper (Chen, Li, Mayes, Nanopoulos).

11. **thomas**
    March 5, 2007

    This post conflates a number of questions that are
    really quite distinct:

    1) Can string theory predictions for physics beyond the
    standard model be tested? (Do such predictions exist?)

    2) Can string dualities (like AdS/CFT) be tested?

    3) Are AdS/CFT results useful for QCD phenomenology?

    I would argue that the answers are:

    1) Maybe. A definitive test in the near future would
    certainly seem to require a lucky break.

    2) Absolutely.

    3) Yes. I agree with you that "semi-precise" in is an
    unfortunate choice of words. At present, this is clearly
    a qualitative rather than a quantitative exercise.

12. **A String Theorist**
    March 5, 2007

"I'm not sure I see the point of a research program devoted to generating "the set of all possible consistent quantum theories of gravity" based on the idea that they're all extremely complicated, ugly and untestable. This will certainly keep one busy for a long time, but why do it?"

They are not *all* extremely complicated, ugly and untestable. Some of them, such as for example topological string theories or maximally supersymmetric ones, can be quite simple and beautiful. For the same reasons, these are also the most well-studied ("under the lamppost").

As far as testability, there is absolutely no reason to expect any observational consequences of quantum gravity below 10^19 GeV. We might get luck, of course (large extra dimensions, braneworld, cosmological signatures, etc…)

13. **Peter Woit**
March 5, 2007

Thomas,

I think some of the people promoting this work to the press would actually like to see some of these issues conflated in the public mind…

You're also conflating different things, by using the term "test" in quite different contexts.

I'll agree with you about 2), duality conjectures like AdS/CFT coming from string theory can be tested. Whenever you manage to compute things that correspond on either side of the duality, whether they match is a test of the conjecture. But this is something completely different from an experimental test of a theory. You're testing the conjecture that two theories are related, not testing whether a theory has anything to do with the real world. If you go around telling people "string theory is testable", meaning that you have tests concerning whether a certain string theory is related to QCD, you are being misleading.

About 1), that's what I'm writing a talk about. I'd claim that the conventional understanding of the phrase "test a theory" means to use distinctive features of the theory to make falsifiable predictions about what you will see if you do a specific experiment, acknowledging the theory is wrong if you don't see what you predicted. By this definition, string theory is not testable. Attempts to use different definitions of "testable" again sometimes seem to be motivated by a desire to obscure this point.

As for 3), sure, this is an uncontrolled approximation, maybe it's qualitatively useful. That's fine and an interesting thing to work on, but people should avoid misleading the public about what is going on.

14. **A String Theorist**
March 5, 2007

Oops, I clicked submit again before I was finished:

We might get lucky, but this fact has been clear for decades — it's not as if there has been some massive conspiracy on the part of string theorists to cover up elementary dimensional analyisis.

"This will certainly keep one busy for a long time, but why do it?"

Different people will give you different answers, but fundamentally the reason people study string theory is that it interests them. Some people study the distribution of prime numbers, others study pre-Columbian musical rituals. Most people find both of those topics, as well as string theory, to be uninteresting wastes of time. But they don't start blogs, or write books, about their prejudices.

15. **A Non-Scientist Observer**
March 5, 2007

The March 5 observation by AST misses the point. Of course, many people study many things for their own sake. The difference is that they do not make extraordinary claims about what they are doing. No one studying prime numbers has asserted that they are on the verge of explaining huge swathes of the natural world, at least, not since Pythagoras. If string theorists said "Hey, this is just esoteric math stuff that is fun" there would be no real issue. In fact, it appears that many make profound claims, and other string theorists implicitly endorse those claims by not opposing them.

16. **Thomas Larsson**
March 5, 2007

However, many string theorists have a broader definition of "everything", roughly something along the lines of "the set of all possible consistent quantum theories of gravity".

Some days ago, I stumbled across the Wikipedia entry about [Paul Ehrenfest](). I learned a number of things, e.g. that Ehrenfest's suicide probably had something to do with his youngest son having Down's syndrome. What really caught my eye, however, was the title of his 1912 inaugural lecture: "About the crises of the light-ether hypothesis". My point is that in 1912, i.e.

* 25 years after the [Michelson-Morley]() experiment,

* 12 years after Planck's formula for blackbody radiation,

* 7 years after Einstein's explanation of the photo-electric effect and discovery of special relativity,

mainstream physicists realized that there was a crisis in ether theory.

How could an obviously wrong idea keep its hold for such a long time? Clearly because most physicists considered it as "the set of all possible consistent theories of light".

It seems to me that string theory is following the trail of ether theory, exactly one century behind.

17. **Bee**
March 5, 2007

Hi Peter,

thanks for the link.

Trying to better understand QCD via AdS/CFT is a perfectly reasonable thing to be doing, although over-enthusiastic claims about where that project is don't help matters.

I think the sentence you quoted: ‘make a specific testable prediction using string theory’ has been very carefully formulated. Krishna Rajagopal gave a colloquium here at PI some weeks ago about his calculations, and he has definitely not made any over-enthusiastic claims. For me it looks like this: there is a model that has turned out to agree with some observables. Now people are using it to make actual predictions to see how far its range of application extends. Whether or not one can justify *why* this is (or isn't) a useful approximation (in certain regions of the phase diagram) is a different question. For sure one would like to understand that better.

In case somebody is interested, there's video, audio and slides at the PI websites

[Probing the Properties of Quark-Gluon Plasma]

(I hope the link works, they keep moving the item IDs which drives me nuts. In case the link is broken, search the seminar series by speaker.)

What concerns me most about the AdS/QCD hype is that suddenly so many people jump on the topic. For one, even if it turns out to be the greatest model for heavy ion collisions ever, there will be only limited demand on people working on it. But what's worse is that it means all these people have previously worked on something so fascinating that they are willing to drop it from one day to the next.

Best,

B.

18. **Peter Woit**
March 5, 2007

Bee,

Thanks for the explanation and link to Rajagopal's talk.

A String Theorist,

The problem is that the non-ugly string theory backgrounds provably don't relate to the real world. If you want to amuse yourself by studying string theory backgrounds that you know can't ever be related to the real world, purely for your intellectual entertainment, that's fine, but you should be honest about it, and then compete for resources with lots of other people who have their own arcane intellectual interests. Somehow I've never seen this description of string theory research on a grant proposal or research statement from someone trying to get a job.

Some of these things (especially topological strings) do involve some wonderful mathematical structures, and they're under active research by many people in the mathematics community. If this is what you want to do, great. I do suggest though that you might want to try and get a job in a math department. You'd find there some very smart people who know a lot about what is already known about the relevant mathematical structures, and an active, healthy research field.

19. **Benni**
March 5, 2007

Your talk in Pisa is somewhat funny:
https://indico.pi.infn.it/categoryDisplay.py?categId=24

March:
29 Raphael Bousso (Berkeley), Predictions in the Landscape
20 Paolo Gambino TBA
19 – 21 Supersymmetry, Supergravity, Superstrings
15 Peter Woit Is String Theory Testable?

First you, and then, when the audience has learned something, comes Bousso!

It is important, that you traven to europe. Since some departments think of installing LARGE string departments.
It would be important that you say, string theory should be installed, but only with small groups, for investigation of QCD or purely mathematical physics and under all circumstances, not as the only game in town for fundamental particle physics.

Otherwise it is the danger, that Europe makes the same mistakes as theorists did in the US.

20. **grant**
March 5, 2007

“Somehow I've never seen this description of string theory research on a grant proposal or research statement from someone trying to get a job.”

How often do you think it happens that people who study pre-columbian music rituals or prime number distributions write grant applications reading “my reseach is completely esoteric and without practical applications, focusing on some details of a field which most people consider to be an uninteresting waste of time”?

21. **Peter Woit**
March 5, 2007

grant,

Obviously my comment was a bit sarcastic. In grant or job applications, people try and make the case for the widest possible significance of their work. But the honest ones don't write things that they privately acknowledge to be untrue. Claiming that what you are doing is going to lead to predictions about beyond the standard model physics when you know very well this is not possible is not honest.

Look, I know people who study prime number distributions, and have seen their grant and job applications. These documents make a case for studying prime number distributions for their intrinsic interest and give legitimate arguments about the significance of this kind of research for the rest of mathematics.

22. **puzzled**
March 5, 2007

Peter, this is hilarious! Are you seriously saying that you will give talks on a subject on which you've never ever worked in your entire life? Writing a blog about it is fine because one can blog just about anything but giving a talk at a university??? And you complain about the lack of professional attitudes on the part of certain string theorists?

23. **Peter Woit**
March 5, 2007

puzzled,

If you're unhappy with the concept of my giving these talks, take it up with the physicists who invited me to do so, I can assure you that the talks were not my idea. Quite a few physicists read this blog, and many of them seem to find what I have to say well-informed and worth listening to. Also, I hate to break this to you, but it's not the first time I've given a public talk about this at a university.

As a relevant example, I don't see why only people who have written papers on the landscape should be giving talks about it and the problems it raises. It might be a good idea to hear from people who have experience as Ph.Ds and postdocs in particle theory, have spent a lot of time learning about the issue and debating it with others, coming to the conclusion that "working" on the landscape by writing papers about it is not a good idea.

And, you know, it's really tiresome how many string theorists seem to be unwilling to put their name publicly to their critical comments here. That is something I find highly unprofessional.

24. **Peter Woit**
March 5, 2007

Eric,

Sorry your comment initially got caught in my spam filter for some unknown reason.

If the LHC sees super-partners, how can you tell they came from a string theory.?In particular, what values of the MSSM parameter space are predicted by string theory, or does string theory say nothing about this?

25. **A String Theorist**
March 6, 2007

A propos your suggestion that string theorists should look for jobs in math departments:

Of course as you know several string theorists have gone to math departments. I think this movement will pick up steam in the next few years. In fact, this year is the first year that (barely) more than half of the "string theory" jobs listed on the rumor page are actually in math departments.

26. **Gina**
March 7, 2007

It is very nice to see the overall moderate tone of the post and remarks. I was impressed by Peter's sentence "There's no denying that string theory has inspired a lot of important ideas, both in math and in physics". Recognizing this while playing a role of "devil's advocate" regarding string theory is perfectly fine.

Attempts to make predictions via string theory should be welcomed by everybody. As we often try to make predictions on humans based on mice, predicting the behavior of water based on alcohol and of apples based on pears is reasonable.

27. **JUAN R.**
March 7, 2007

A String Theorist Said:

> It depends on your definition of "TOE".
>
> If by "everything" you mean something like "the Standard Model, along with whatever (if anything) supplements it at the next 10 orders of magnitude (or so) in energy", then I think that the vast majority of praciticing string theorists (it's hard to think of any exceptions) would happily admit this.
>
> However, many string theorists have a broader definition of "everything", roughly something along the lines of "the set of all possible consistent quantum theories of gravity".

When String Theory was initially promoted as "the only serious candidate to TOE", string theorists defined "everything" like *everything* (not just extension of SM or a quantum gravity theory) in papers, lectures, and books.

String Theory was promoted in that way to general public also.

> For this reason string theory is sometimes described as possibly being the "theory of everything" (T.O.E.) or the "ultimate" or "final" theory. These grandiose descriptive terms are meant to signify the deepest possible theory of physics—a theory that underlies all others, one that does not require or even allow for a deeper explanatory base.

It is fine if you want change now the meaning of "everything" in basis to the recent String Theory *fiasco* as a sensible TOE. It is fine if now the superb String Theory is now to be promoted like just some kind of QCD recipe.

It is not fine you want change history.

28. **Jonathan Vos Post**
March 7, 2007

The prime number theorist might well include this in the grant application:

My theory, with a little more work, will solve important problems in Physics. See:

"Applications of Statistical Mechanics in Prime Number Theory"
Marek Wolf

http://secamlocal.ex.ac.uk/people/staff/mrwatkin/zeta/wolfgas.htm

Wolf begins by briefly referring to the general phenomenon of the 'number theory – physics crossover'. Two references to the application of prime number theory to quantum chaology in particular are given [1,2,3]. Two mathematical properties which are normally associated with physical systems have been detected in the distribution of prime numbers by Wolf himself, namely multifractality [4] and 1/f noise [5]. A paper which numerically calculates Lyapunov exponents (familiar to chaos theorists) for the distribution of primes is mentioned [6]. Finally an article is cited [7] wherein the authors apply the Wiener-Khintchine formula, which relates spectral densities and the autocorrelation function, to the problem of the distribution of pairs of primes {p,p+2}.

29. **A String Theorist**
March 8, 2007

Juan R:

Your quote about the "theory of everything" is precisely in accord with my original post.

String theory IS a theory of everything, including many things (such as topological strings, an example I gave above) which do not actually "exist" in our universe.

But even though it is the deepest possible theory of physics, it's not going to tell you what the next winning lottery number is (any more than it will tell you what the mass of the electron is).

30. **Q**
March 8, 2007

No, it's not a theory because it doesn't explain anything about real phenomena. It links gravitons nobody has ever seen to Planck scale unification nobody can see, using extra-dimensions that have to be explained away by a Calabi-Yau manifold which gives the string a massive landscape of 10^500 solutions of particle physics.

Explaining (by further speculation) a few speculations about gravitons and unification isn't a theory of everything. It's not even a 'theory' about speculations, it's just vague hype that isn't tied down to any known facts. The claim it's the "deepest possible theory of physics" suggests you have a disproof of LQG and every suggested alternative. Where are these disproofs?

Kap

March 5, 2007
Categories: Uncategorized

There's a short memoir out this evening on the arXiv by Peter Freund about the algebraist Irving Kaplansky, universally known as "Kap", who died last year at the age of 89. Freund worked with Kaplansky at Chicago during the mid-seventies on the classification of Lie superalgebras, and comments about the relations between math and physics at that time. He also claims that Kaplansky told him with assurance that Hopf algebras couldn't possibly be of relevance to physics, and that Andre Weil was the greatest living mathematician, since he called all the courses he taught "mathematics", and lived up to this title. Freund also tells a well-known story about a talk by Weil at Chicago that he heard about first-hand from Kaplansky.

Freund's piece is based on his talk at the recent memorial event held for Kaplansky in Berkeley at MSRI. His student Hyman Bass has a wonderful presentation describing Kaplansky's life and work.

I have my own personal recollections of Kap since he was director of MSRI the year that I was a postdoc there (1988-9), a year during which I unfortunately had only a few short conversations with him. The conversation with him I remember best was our first, which occurred on the phone. In early 1988 I was working part-time teaching Calculus at Tufts and had applied for several full-time mathematics jobs for the next year, not at all sure that there was any chance this would work out, since my Ph.D. and first postdoc had been in physics. When the call came from Kap offering me a job at MSRI for the next year I was elated, partly because Berkeley is one of my favorite places to live as well as being an excellent place to work in both mathematics and physics. During our conversation Kap told me a bit about his work on and continued interest in supersymmetry. I didn't really have the heart to tell him that because my own inclinations are so geometric, I'd always found supersymmetry and superalgebras a tantalizing but very frustrating subject.

John Horgan keeps moving his blogging activities to different locations, the latest one is here.

For a truly sad and distressing story about what has happened to Billy Cottrell (who was mentioned snarkily by me long ago here), see this LA Weekly article and a Clifford Johnson posting. The abuse of people going on in this country associated with labeling them "terrorists" is just appalling and deeply shameful.

More from Steinn Sigurdsson on Yarn Theory.

Cern Courier reports on the recent Axion workshop at Princeton and the 2006 Quark Matter conference in Shanghai.

Lee Smolin's book is out in the UK, here's a review from the Financial Times.

The latest London Mathematical Society newsletter has a review of Not Even Wrong.

David Ben-Zvi was here last week and gave a wonderful colloquium talk on Langlands duality, loop spaces and representations of real groups. Much of was somewhat general philosophy about a new way of thinking about these topics, and this was quite compelling, although I need to find a sizable chunk of time to sit down and really understand what he is doing. If I can do this, maybe I'll then take a stab at trying to explain this here. He did convince me that one needs to think not only about stacks, but derived stacks. There's a long foundational document about this by Jacob Lurie (see here), something more readable from Bertrand Toen.

This semester Edward Frenkel is running a seminar on Topics in the geometric Langlands program. The slides of a talk by Ben Webster that are there are wonderful. One problem with this field has always been how unreadable much of the material about is. People like Webster and Ben-Zvi are starting to do a great job of explaining what is going on in a form that others have some chance of following.

Later this month the IAS will have a conference related to this topic, next year a whole program.

I'll be travelling most of the next week and a half or so, so blogging will be light to non-existent. Behave.

   March 7, 2007

   It is simply heartbreaking to hear of someone being denied their physics (and other) books and writing materials, being denied access to the kind of work where their skills might best be put to use – Clifford
   What rubbish.
   You break the law. You go to jail. You loose freedoms. Anybody who can understand string theory can undoubtledly understand this.
   However, the terrorist charge, based on the "evidence" in the links, looks wrong…yes, therefore the sentence should be reduced accordingly.

2. **Choo**
   March 8, 2007

   Uh. Yes, you lose freedoms. But if you read the article, this is not what they are complaining about. They object to the mischaracterization and voodoo fear of Billy's science training, taking his papers away as a "fire hazard" and inconsistent treatment on account of his "terrorism" label. Now, I actually lean towards calling him at least some sort of an economic terrorist, but not if it encourages this kind of result.

3. **yeti**
   March 8, 2007

   The notion that Billy Cottrell should have gotten leniency because of his intellect and talent is offensive.

   The notion that someone should get 7-8 years in jail for what he did is also offensive.

   The notion expressed in the LAWeekly article that ELF does not exist is ridiculous. Maybe it has no clear organizational structure, but the folks are out there. Go to Oregon.

9. **relativist**
March 9, 2007

Seeing this section is labelled `quicklinks’, and given the broad interests of this blog, I think it is appropriate to point out new work by one of the best quantum theorists around, just placed on the arXiv, as follows:

quant-ph/0703060:
Title: A Topos Foundation for Theories of Physics: I. Formal Languages for Physics
Authors: A. Doering, C.J. Isham

This paper is the first in a series whose goal is to develop a fundamentally new way of constructing theories of physics. The
motivation comes from a desire to address certain deep issues that arise when contemplating quantum theories of space and time. Our basic contention is that constructing a theory of physics is equivalent to finding a representation in a topos of a certain formal language that is attached to the system. Classical physics arises when the topos is the category of sets. Other types of theory employ a different topos. In this paper we discuss two different types of language that can be attached to a system, S. The first is a propositional language, PL(S); the second is a higher-order, typed language L(S). Both languages provide deductive systems with an intuitionistic logic. The reason for introducing PL(S) is that, as shown in paper II of the series, it is the easiest way of understanding, and expanding on, the earlier work on topos theory and quantum physics. However, the main thrust of our programme utilises the more powerful language L(S) and its representation in an appropriate topos.

quant-ph/0703062
Title: A Topos Foundation for Theories of Physics: II. Daseinisation and the Liberation of Quantum Theory
Authors: A. Doering, C.J. Isham

This paper is the second in a series whose goal is to develop a fundamentally new way of constructing theories of physics. In this paper, we study in depth the topos representation of the propositional language, PL(S), for the case of quantum theory. In doing so, we make a direct link with, and clarify, the earlier work on applying topos theory to quantum physics. The key step is a process we term `daseinisation’ by which a projection operator is mapped to a sub-object of the spectral presheaf — the topos quantum analogue of a classical state space. In the second part of the paper we change gear with the introduction of the more sophisticated local language L(S). From this point forward, throughout the rest of the series of papers, our attention will be devoted almost entirely to this language. In the present paper, we use L(S) to study `truth objects’ in the topos. These are objects in the topos that play the role of states: a necessary development as the spectral presheaf has no global elements, and hence there are no microstates in the sense of classical physics. Truth objects therefore play a crucial role in our formalism.

quant-ph/0703064
Title: A Topos Foundation for Theories of Physics: III. The
Representation of Physical Quantities With Arrows
Authors: A. Doering, C.J. Isham

This paper is the third in a series whose goal is to develop a fundamentally new way of viewing theories of physics. In paper II, we studied the topos representations of the propositional language PL(S) for the case of quantum theory, and in the present paper we do the same thing for the, more extensive, local language L(S). One of the main achievements is to find a topos representation for self-adjoint operators. This involves showing that, for any physical quantity A, there is an arrow $\breve{\delta}^o(A):\Sig\map\SR$, where $\SR$ is the quantity-value object for this theory. The construction of $\breve{\delta}^o(A)$ is an extension of the daseinisation of projection operators that was discussed in paper II. The object $\SR$ is a monoid-object only in the topos, τ_ϕ, of the theory, and to enhance the applicability of the formalism, we apply to $\SR$ a topos analogue of the Grothendieck extension of a monoid to a group. The resulting object, $\kSR$, is an abelian group-object in τ_ϕ. We also discuss another candidate, $\PR{\mathR}$, for the quantity-value object. In this presheaf, both inner and outer daseinisation are used in a symmetric way. Finally, there is a brief discussion of the role of unitary operators in the quantum topos scheme.

quant-ph/0703066:
Title: A Topos Foundation for Theories of Physics: IV. Categories of
Systems
Authors: A. Doering, C.J. Isham

This paper is the fourth in a series whose goal is to develop a fundamentally new way of building theories of physics. The previous papers in this series are concerned with implementing this programme for a single system. In the present paper, we turn to considering a collection of systems: in particular, we are interested in the relation between the topos representation for a composite system, and the representations for its constituents. We also study this problem for the disjoint sum of two systems. Our approach to these matters is to construct a category of systems and to find a topos representation of the entire category.

10. **Vogelsang**
March 9, 2007

>new work by one of the best quantum theorists around,

Relativist, just out of curiosity, are you Doering or Isham?

11. **Peter Orland**
March 9, 2007

Fellow scientists,

Let’s maintain our sense of shame. No abstracts on Peter Woit’s
blog please! That’s what archive is for.

12. **Who**
March 10, 2007

The UK paperback edition of Peter's book is scheduled to come out 7 June 2007.
http://www.amazon.co.uk/Not-Even-Wrong-Continuing-Challenge/dp/0099488647/ref=pd_sbs_b_2/026-3303388-4063638

The publisher is Vintage. Evidently people are already advance ordering because the UK amazon sales rank (among all books) is currently #6,726.

The US paperback edition is scheduled to come out in September:
http://www.amazon.co.uk/Not-Even-Wrong-Failure-Physical/dp/0465092764/ref=ed_oe_p/026-3303388-4063638

Currently Smolin's book is #1 on the UK amazon physics bestseller list and Peter's book (hardcover) is #7
http://www.amazon.co.uk/gp/bestsellers/books/278409/ref=pd_ts_b_nav/026-8303087-5718006

Both are doing rather well, I'd say, judging by their sales ranking among all books. For example Smolin's book is currently #49
among all books that UK amazon sells, as can be seen here:
http://www.amazon.co.uk/Trouble-Physics-String-Theory-Science/dp/0713997990/ref=pd_ts_b_1/026-3303388-4063638?ie=UTF8&s=books
That is pretty astonishing for a physics book, because it is #49 in competition with popular genre—detective, cookbooks, selfhelp, humor, diet, fantasy, Harry Potter, and so forth.

13. **yagwara**
March 15, 2007

Off topic, but I just had to share this someplace:

http://www.tenthdimension.com/

What makes this so weird is that it is a crackpot site, but it presents no red flags (at least to me). It is a beautifully designed site (no CAPITAL LETTERS IN DIFFERENT COLOURS) and the animation is lovely. Moreover, it starts out completely sane in dimensions 1-4. Then it turns to complete garbage.

I've sometimes seen real physicists' websites that look like crackpottery at first glance, but this is the first time I've seen crackpottery that looks totally professional at first glance.

(Although in retrospect, the inclusion of a category for "songs" should have given me pause.)

14. **Ptolemy**
March 15, 2007

yagwara: he seems unaware that 10 dimensional superstrings are composed of a worldsheet of 1 time dimension and 1 spatial dimension, plus 8 other dimensions to include supersymmetric particle physics, 6 of which are accounted for the the Calabi-Yau manifold.

But if you examine anthropology objectively, you find the coincidence that we have 10 fingers (and also 10 toes) which is the same number as the number of superstring dimensions! Anthropic ideas are currently used (in default of anything else) in string theory to try to select the standard model from the landscape of 10^500 models string theory includes.

The anthropic principle implies that the reason for particle physics being the way it is, is due to the fact that we are around to see it. Anthropically, we have ten fingers and ten toes, and most commonly we use base ten. So, we have evolved with as many fingers/toes as there are supersymmetric dimensions. Coincidence?

Remember, as a great Harvard assistant professor once wrote, 'God wrote the world in the language of superstring theory'.

Thus, it's logical that God made the superstring from 10 dimensions, so that people can use their fingers to count them.

As for the eleven dimensional supergravity bulk in M-theory, can it be a coincidence that he square root of 137 is merely 6% higher than the number eleven?

But the anthropological fact we have 10 fingers is quite irrefutable. So it is pretty water-tight evidence for string theory being on the right track. In addition, because 2 of those fingers are really thumbs, we have 2 thumbs plus 8 other fingers. This is exactly like the 2 dimensional worldsheet, plus 8 added dimensions for conformal symmetry of particle physics. Don't try to tell me this is coincidence. It first suggests that the anthropic principle is valid (the world is the way it is because people exist!), plus it indicates that there are hidden clues in evolution which tell us about string theory.

15. **LDM**
March 15, 2007

yagwara,

Red flags are obvious, although it is a beautiful flash application.

In part 5, he mentions part five "waves of probability" from Quantum Physics.
There are no waves of probability in Quantum Physics.

16. **yagwara**
March 15, 2007

LDM,

Oh yes, certainly, if you get to section 5 you're already waist deep in crazy. I just meant there were no red flags at first glance.

Usually you can look at a website from across a room and tell in an instant if it is a crackpot site.

17. **Robert Musil**
March 16, 2007

According to the Economist magazine the LHC may lose out on the discovery of the Higgs (http://www.economist.com/science/displaystory.cfm?story_id=E1_RRTDJRR&login=Y – subscription required):

To find [the Higgs], scientists at the European particle-physics laboratory, CERN, in Geneva, are building what will, when it starts up later this year, be the world's most powerful particle smasher. This machine, known as the Large Hadron Collider, is designed especially to look for the Higgs boson. But the Europeans may be pipped at the post by rivals working at what is the highest-energy collider working today, the Tevatron, at the Fermi National Accelerator Laboratory (Fermilab) near Chicago.

18. **Anon**
March 16, 2007

On a totally unrelated note:

http://www.math.uchicago.edu/~arinkin/langlands/Illusie.wav

is an audio clip of Luc Illusie reminiscing about Alexander Grothendieck, his work, etc.

Just thought you'd like to know.

Is String Theory Testable?

March 17, 2007
Categories: Uncategorized

I've been traveling in Italy for the past ten days, and gave talks in Rome and Pisa, on the topic "Is String Theory Testable?". The slides from my talks are here (I'll fix a few minor things about them in a few days when I'm back in New York, including adding credits to where some of the graphics were stolen from). It seemed to me that the talks went well, with fairly large audiences and good questions. In Pisa string theorist Massimo Porrati was there and made some extensive and quite reasonable comments afterwards, and this led to a bit of a discussion with some others in the audience.

I don't think the points I was making in the talk were particularly controversial. It was an attempt to explain without too much editorializing the state of the effort to connect the idea of string-based unification of gravity and particle physics with the real world. This is something that has not worked out as people had hoped and I think it is important to acknowledge this and examine the reasons for it. In one part of the talk I go over a list of the many public claims made in recent years for some sort of "experimental tests" of string theory and explain what the problems with these are.

My conclusion, as you'd expect, is that string theory is not testable in any conventional scientific use of the term. The fundamental problem is that simple versions of the string theory unification idea, the ones often sold as "beautiful", disagree with experiment for some basic reasons. Getting around these problems requires working with much more complicated versions, which have become so complicated that the framework becomes untestable as it can be made to agree with virtually anything one is likely to experimentally measure. This is a classic failure mode of a speculative framework: the rigid initial version doesn't agree with experiment, making it less rigid to avoid this kills off its predictivity.

Some string theorists refuse to acknowledge that this is what has happened and that this has been a failure. Most I think just take the point of view that the structures uncovered are so rich that they are worth continuing to investigate despite this failure, especially given the lack of successful alternative ideas about unification of particle physics and gravity. Here we get into a very different kind of argument.

It was very interesting to talk to the particle physicists in Rome and Pisa. They are facing many of the same issues as elsewhere about what sort of research directions to support, with string theory often being pursued as an almost separate subject from the rest of particle theory, leading to conflict over resources and sometimes heated debates between them and the rest of the particle physics community. Many people were curious about how things were different in the US than in Europe, but I'm afraid I couldn't enlighten them a great deal, mainly because I just don't know as much about the European situation, although I've started to learn more about this on the trip. Several wondered if the phenomenon of theorists going to the press to make overhyped claims about string theory was an American phenomenon. I hadn't really noticed this, but it does seem to be true. While the hype starts in the US, it does travel to Europe, with the US very influential in this aspect of culture as in many others. In the latest issue of the main Italian magazine about science, there's an article explaining how certain US theorists have finally figured out how to test string theory with the new LHC…

   March 17, 2007

   "The fundamental problem is that simple versions of the string theory unification idea, the ones often sold as "beautiful", disagree with experiment for some basic reasons."

   This seems similar to the situation with Grand Unified Theories. I gather that SU(5) was the "beautiful" version, and when that version ran into problems much of the beauty went out of GUTs. It's interesting to contrast this with cosmic inflation, where Guth's original version didn't quite work, but Linde and others found forms of inflation which worked better, and WMAP data gives a reality check.

   I should mention that I'm not a physicist, just a casual reader, so if I'm misinformed I hope somebody will point it out.

   March 17, 2007

   It would be nice to know what Porrati said, if at all possible.

3. **Joseph Smidt**
   March 17, 2007

   Great Post. I thought your comments on US/Europe string culture were interesting. Thanks for the slides.

4. **Irish physicist**
   March 17, 2007

   Off-topic – but congratulations on 3 years of blogging and Happy St. Patricks day too!

5. **woit**
   March 17, 2007

   Irish Physicist,

   Thanks! I hadn't realized that the blog was started on a St. Patrick's day. Surely some sort of homage to the Irish was unconsciously intended.

   Arun,

   I can't recall exactly what Porrati's points were, except that he said that he had five of them, and none of them were things that I really had a substantive disagreement with. Some of them were (from memory, and in loose translation, surely he would express these differently)

   1. String theory shouldn't be thought of as a theory that leads to a unique, predictive model, but instead as a very general framework, like QFT, valuable for the different kinds of models it allows.

   2. He mentioned the "swampland" idea, that one could try and characterize those low energy theories that come from an ultraviolet completion like string theory.

   3. His main point I think was that as long as there was no alternative way to unify particle theory with quantum gravity, string theory would continue to be a main focus

for people to pursue. Kind of the “only game in town argument”.

4. He may also have mentioned the use of string theory in heavy-ion physics, in regimes where lattice gauge theory has trouble providing results.

I guess I’m missing at least one…

6. **anon.**
March 17, 2007

Porrati’s 1st point is with all due respect exactly the argument that defended the use of epicycles by both Ptolemy and Copernicus: it seemed to be a very useful framework of ideas. (Ptolemy used epicycles in the earth-centred universe, c. 150AD. In 1543, Copernicus used epicycles in his final model of the solar system.)

As a ‘general framework of ideas’, the false theory of epicycles was invaluable to Ptolemy, Copernicus and generations of physicists. But that useful approximate framework was really false, as Kepler eventually discovered. So in the end both the earth-centred universe and its general framework of ideas were discredited. Will the string theory framework of ideas similarly mislead generations?

What is so interesting is that it seems to be disconnected from reality not just with regard to its failure to make testable predictions, but also at the input end. Instead of having solid input, everything which has been put into string theory is completely speculative. It is less testable than either of the epicycle theories, and has less solid evidence.

People now laugh at the idea that a theory was once constructed in which the stars and planets were carried around the earth while imbedded in closed crystalline shells. At least that false model was an attempt to interpret data. Perhaps people will cry with pity in the future, reading how physicists defended 10/11 dimensional M-theory in the 21st century, without providing any evidence at all.

7. **Chris W.**
March 17, 2007

The pre-Copernican astronomers could be excused on the basis of epistemological naivete; their successors largely *invented* the understanding of science that is now being invoked in discussions of string theory.

String theorists can’t be so excused. They should have known better, and should know better now. Certainly ‘general frameworks of ideas’ are important; they set the context for *formulating problems*. This is why metaphysics is important in science, even though most metaphysics ultimately proves worthless.

The questions that must be asked now with respect to quantum gravity and unification concern the problem formulation. (Shiing-Shen Chern, who discussed the matter with Einstein in the 1940s, recognized this as the essential work of the physicist.) The alternatives to string theory in quantum gravity challenge the received wisdom in this regard, and for this reason alone are important. In this context Porrati’s main point (as stated by Peter, and echoed by many of Porrati’s colleagues) strikes me as a complete crock. The string theorists who adopt this attitude are the least likely to arrive at the crucial insights into the problem. One can hope they’ll at least have the good sense and simple honesty to recognize those insights when they appear, although I’m less and less optimistic about that.

8. **Vijay Shankar**
March 17, 2007

There seems to be many differences in opinions unfortunately based on nationality. What people would want Physicists to come up with is a theory that holds in all frames or an experimental method that would help us test all the theories. Until then, we can’t stop someone crying foul whenever there is a news about ‘revolutionary’ theories.

9. **tomj**
March 17, 2007

My question is: what is the difference between no theory and one which cannot be tested?

I cannot figure out why string theory is a theory. It barely ranks as a hypothesis, and a poor one, very close to what my teenager would come up with. It is 100% mental.

A theory, at minimum, should cover all the facts known, but as Einstein once said (something like): a theory should be as simple as possible, _but_ no simpler. The implication is that there has to be a careful balance, and the theory _must_ track data. How else could the complexity of theory be measured? Yes, you can predict new facts, but first you have to account for known facts. We have to start with the abilities of the observer. And the first ability is that of objectivity, and objectivity begins with the repudiation of belief.

If a theory cannot be any simpler than necessary, how … really … how can a theory be more complex than necessary? If over simplification is a sin, complexity is beyond sin. A ‘theory’ (or set of words and math) which can ‘explain’ everything ‘after the fact’ is useless. Can someone please explain to me this: do physicists really believe that it is possible to formulate a complete description of the universe which will be testable? Because one possible reality is that we are incapable of this. We have thousands of years of data to suggest this conclusion, and only wishful thinking to suggest otherwise.

I like the name of the book, it is important to echo prior thinking. But it might have been even more valid to call it ‘Beyond Reason’. Everyone seems to think that they have reason, that they think logically. And as long as we can avoid testing our reason and logic, we can continue to ‘think’ and ‘believe’ whatever we want. And if we become dogmatic in these untested beliefs, what is this? Science is not belief. Science is experiment. And experiment is based upon question, the antithesis of belief. Science is not an answer, science is a method.

10. **Ptolemy**
March 18, 2007

‘I cannot figure out why string theory is a theory.’ – tomj

Gerard ‘t Hooft:

‘Actually, I would not even be prepared to call string theory a “theory” – rather a model or not even that: just a hunch. After all, a theory should come together with instructions on how to deal with it to identify the things one wishes to describe, in our case the elementary particles, and one should, at least in principle, be able to formulate the rules for calculating the properties of these particles, and how to make new predictions for them. Imagine that I give you a chair, while explaining that the legs are still missing, and that the seat, back and armrest will perhaps be delivered soon; whatever I did give you, can I still call it a chair?’

– http://www.math.columbia.edu/~woit/wordpress/?p=258#comment-5030

Peter Woit’s argument of why a non-predictive framework is not science can be found on p211 of Not Even Wrong (UK ed.):

‘An explanation that allows one to predict successfully in detail what will happen when one goes out and performs a feasible experiment that has never been done before is the sort of explanation that most clearly can be labelled 'scientific'. Explanations that are grounded in … systems of belief and which cannot be used to predict what will happen are the sort of thing that clearly does not deserve this label. This is also true of … wishful thinking or ideology, where the source of belief … is something other than rational thought.'

11. **r hofmann**
March 18, 2007

`Several wondered if the phenomenon of theorists going to the press to make overhyped claims about string theory was an American phenomenon. I hadn't really noticed this, but it does seem to be true. While the hype starts in the US, it does travel to Europe, with the US very influential in this aspect of culture as in many others.´

There are many examples of theoretical physicists
working in the US (foreigners and US citizens) who do extraordinarily good work but on the short run are screened by those that produce overhyped newspaper headlines. My general impression is that the US culture supports the go for extremes in generating scientific opinion, publicizing of `results´, and network formation. This may be helpful in projects where a focus of resources is needed (Cobe, WMAP,…). On the theoretical side, however, it may at times just produce entropy, a lack of well-fermented orginality, and thus no gain in robust knowledge.

12. **Stacy**
March 18, 2007

A note on inflation, inspired by Levi's comment:
Actually, the situation with Inflation is quite analogous to that with string theory. The original idea was beautiful, and made a simple prediction (the universe should be flat) which solved the coincidence problem (to do with the evolution of the density of the universe). These together were compelling and propelled the theory to the dominance it enjoys today. But it did suffer problems (like a graceful exit from inflating) which have not entirely been solved. Worse, the compelling aspect of the flatness prediction – confirmed by the WMAP satellite – was that the density parameter should be unity – all in mass – in order to solve the coincidence problem. But it isn't all in mass – we have now to invoke dark energy. This makes the coincidence problem worse.

In other words, the compelling part of Inflation that led us all to believe it not only doesn't work, but has made worse the problem it originally seemed to solve. I can't help wondering if future generations of sociologists will debate whether speculative theories like string theory and Inflation were ever distinguishable from some sort of mathematically motivated religion.

13. **matteoeo**
March 18, 2007

I agree with Stacy, I think cosmology suffers just the same problems as string theory. Cosmologists can produce potentials that would suit to any possible dynamics of inflation and produce the desired spectrum of cosmic background radiation, without actually deriving them from the properties of the known QFT particles. The worse, cosmology at the moment is a melting pot of the most un-scientifical theories and hypothesis in town: dark energy, cosmological costant, strings and GUTs (early universe), inflation, higgs boson, quintessence, supersimmetry. In cosmology it seems one could just say whatever he wants without too much care about scientific estabilished facts. I was impressed once reading some articles that showed that accelerated expansion of the universe could be explained without any reference to cosmological costant and dark energy, but just owing to some very peculiar relativistic effect (I can give references if any of you is interested). The point is: before inventing theories about the universe, shouldn't we study general relativity a lot better? And, before unifying gravity and the quantum, shouldn't we try to understand the basis of QFT and the geometrical structure of QM, and the very profound implications of GR itself?

14. **woit**
March 18, 2007

Please, cosmology is off-topic. I'm not a cosmologist and don't want to moderate discussions about cosmology.

15. **Alex Nichols**
March 19, 2007

I don't think the epicycles analogy is correct.
That's an example of an incorrect theory that was disproved by subsequent observation, rather like to the ether theory.

The suggestion being made is that string theory is incapable of falsification because it can't be tested.
Possibly true, but there are compelling reasons for believing that extended entities that fluctuate are the only possible basis for observable space-time.
This could include strings, loop quantum gravity, spin foams, spin networks etc…

Were it found that the higgs boson is a fundamental particle by the the LHC, all of these would be disproved.
But aren't the problems of falisfiability at high energy (planck or horizon size) equally true for all the other theories?

Perhaps all the effort shouldn't be going into one avenue of research. When it comes to funding though, governments may simply decide that we need more effort in applied physics, such as energy production.

16. **Alex Nichols**
March 19, 2007

BTW, could this finding have any heterotic implications? :-

http://web.mit.edu/newsoffice/2007/e8.html

17. **CapitalistImperialistPig**
March 19, 2007

The problem with particle physics, if it is a problem, is that we don't have any new particles, and the very good theory we have for those particles looks pretty much like a kludge – all those undefined parameters hovering there like epicycles – which were very highly predictive, by the way.

String theory is a heroic attempt to go beyond the SM, but so far hasn't proven predictive in a confirmable sense. My guess is that we might be stuck without more input from the Universe, which is why everybody is pinning their hopes on the LHC.

Maybe it will provide some clue that makes it possible to turn ST into a predictive theory, maybe it will make it more unlikely that ST has any reality, and maybe it will be mute on ST and other subjects.

Only the last would be a bad outcome.

18. **off topic**
March 19, 2007

sorry to be off-topic, but let me point out that simplest inflation predicts Omega_total = 1: it is what we measure, and the fact that the total involves some components we don't understand has nothing to do with inflation. Simplest inflation models also naturally produce a spectrum of scalar adiabatic Gaussian cosmological perturbations with spectral index ns = 1 +- 1/60. Each word has a precise meaning, and it agrees with data. (The deviation of ns from 1 is not yet safely seen).

People tried and try to invent alternative to inflation, but it is not easy because inflation turned out to be good succesful physics. For example alternative models based on "simple string cosmologies" suggested wrong kinds of perturbations (isoentropic, ns not close to 1, etc), and a significant amount of additional complications seems needed to get what inflation naturally does.

19. **matteoeo**
March 19, 2007

I'm sorry I went off topic and I will retain from writing again, but nevertheless I think it's interesting to see how the scientific method has been mistreated and pseudo-scientific claims are made in almost any field of natural sciences and humanistic "sciences".
Or do you think that this bad string theory story is just an occasional mistake soon to be recovered?
My question was: do we know enough of the physics of the 20th century before adventuring in the physics of the 21st? I don't think this question is off-topic.

20. **Peter Woit**
March 19, 2007

matteoeo,

There are all sorts of problematic claims made in different sciences. I just don't want this blog turned into a discussion forum about all of them, but want to keep it focused on things I know about and am willing to moderate discussions of. The question of the evidence for inflation is an interesting one, and "off-topic" makes to-the-point comments, but I'm not an expert on this, and there are good blogs out there run by people who are, so that's where the discussion should really take place.

My point of view is certainly that the Standard Model QFT remains poorly understood in many ways, and that problem deserves more attention. There are lots of other issues in physics that aren't well-understood, but again, I don't want to moderate discussions of issues I don't know much about.

21. **Robert**
March 19, 2007

If your words were as reasonable as your slides congratulations for this nice presentation. For the philosophy of science section of the German Physics Societey I had indended to give a talk with a very similar subject (but of course slightly different conclusions). Unfortunately for personal reasons I could not attend the conference.

Just a minor point of nitpicking (and we have discussed this before): When you say there is no clear cut experimental prediction I would qualify that with "to be performed with currently available experimental technology". Otherwise I strongly believe your claim is wrong, at least if a weakly coupled description exisists (that is there is — possibly after a duality — a stringy description with g

22. **Robert**
March 19, 2007

Sorry for the sudden end of the previous comment. I wanted to say g less then less than (i.e. \ll in TeX) 1 but typing that froze my firefox (probably the script that does the preview. Luckily, I did not lose the post as after a few minutes it popped up a box asking me if I wanted to cancel a script. So I could still press the submit button. But there seems to be a bug either in the script or in firefox…

23. **Robert Musil**
March 19, 2007

Peter,

Please correct me if I mistake your views, but I believe you have several times made clear that while you harbor skepticism over many aspects of string theory as physics, you believe that much extraordinary and important mathematics has resulted from string theory. The "Mirror Conjecture" is one such example. Admiration for string theory mathematics spin-offs is widely shared by many of the worlds leading mathematicians.

But there are some very troubling aspects to even this, very real, admiration for string theory inspired mathematics – at least to my eye. It's trivial to formulate the Mirror Conjecture: Just flip the Hodge array on the diagonal and ask for a variety. But nobody bothered to ask the question before M-theory was posited. Moreover, the first few examples of the Mirror Conjecture are not hard to prove (although the entire conjecture is), yet nobody bothered to investigate them before M-Theory was posited. One main (or at least common) example that supposedly demonstrates the mathematical importance of the Mirror Conjecture – finding those curves – was being pursued (apparently) by exactly two Norwegians on a computer before the Mirror Conjecture came up. Yet the Mirror Conjecture is supposed to be ultra-important mathematics. There is something very strange here.

Perhaps what is strange here is reflected (oops! and unintentional pun) in the constant references to physics in all mathematical programs regarding the Mirror Conjecture (or at least the ones with which I am familiar). "Golly," the mathematicians seem to say, "What I'm noodling over has relevance to the real world! It must be important mathematics!" But if it turns out that string theory is not important physics, I believe it would be a first if the associated mathematics were really all that important – regardless of the level of enthusiasm it has inspired. After all, string theory inspired quite a lot of ill-considered, unchallenged enthusiasm as physics for quite a while.

In other words, I can't shake the sense that the enthusiasm over the Mirror Conjecture (for example) has itself a hall-of-mirrors aspect: Mathematicians (even very good ones) love it supposedly because it is "intrinsically" wonderful mathematics. But it's a strange kind of intrinsically wonderful mathematics that nobody gave a dam about before the physics came along in the form of string theory – even though it's wonderful mathematics whose formulation is trivial and whose first few examples are easy and whose supposedly important applications nobody cared about enough to work on but two Norwegians (not that I have anything against Norwegians, mind you).

Of course, on the other side of the hall of mirrors we find the string theorists reassuring themselves that their theory must be important (or even correct) because the mathematics is so wonderful. Bing, bing, bing goes the wonderful image across the hall – each time a little more distorted as it recedes.

Personally, I find this hall of mirrors aspect of things disturbing, perhaps because I associate halls of mirrors with lower-budget hotel lobbies trying to look bigger than they are. Somehow I get a similar feeling from the mathematical spin-offs of string theory.

Do you have anything to say on this?

24. **r hofmann**
March 19, 2007

Dear Robert Musil,

although I have no idea about the Mirror Conjecture what you say about it and its embedding into the modern relationship between physics and mathematics strikes me as an intelligent observation. Thanks for the info.

25. **David B.**
March 19, 2007

Dear Robert:

Mirror symmetry is not just about "flipping the Hodge diamond".

When you say
"But it's a strange kind of intrinsically wonderful mathematics that nobody gave a dam about before the physics came along in the form of string theory."

You are trivializing the contribution from physicists and mathematicians. The truth is that mathematicians had not suspected that the problem of counting curves in Calabi-Yau manifolds (a typical problem of enumerative geometry) could be related to the theory of deformations of the complex structure on the mirror geometry.

You are also trivializing the problem by making statements like "even though it's wonderful mathematics whose formulation is trivial and whose first few examples are easy".

The formulation is not trivial at all, and it took quite a while before someone produced a complete mathematical proof of the first few examples.

I don't like these misinformed statements about the relationship between research in string theory and mathematics. They seem to be crafted for purposefully misleading the public at large.

Many profesionals use simple statements like "flipping the hodge diamond" when giving presentations in order to explain the simplest aspects of mirror symmetry to an uninformed audience, and to try to give them something they might relate to. In this way they can share the excitement of the subject. Don't mistake those statements for the research that is done in the subject.

26. **Peter Woit**
March 19, 2007

Robert (non-Musil),

The slides pretty accurately reflect what I said. In this talk I wanted to just as clearly as possible state the facts of the matter and avoid any editorializing.

One thing that I should have put in the slides was a comment about the issue you raise, the claim that the testability problem for string theory only arises at low energy, that if we could do Planck scale experiments, it would be testable. I think we've probably discussed this before, but I would claim that the string theory framework continues to be not testable even at that scale. As you acknowledge, even a qualitative prediction of the kind I assume you have in mind (standard distinctive aspects of perturbative string spectra or scattering amplitudes) rely on the string coupling being small enough for the perturbation approximation to be good. Such a prediction is not falsifiable, since it could be evaded simply by saying "well, maybe the string coupling really is not small enough".

In practice, it is true that if we could do experiments at arbitrarily high scales, we'd presumably see what the structure of quantum gravitational effects is, and would see whether this looked at all like anything that had ever shown up in studies of string theory.

Robert (Musil)

David B. is right. The "Mirror Conjecture" and the associated mathematics it has generated go far, far beyond what you mention and are much deeper than "flipping the Hodge diamond". As an example of this, next week at the IAS they'll be an important mathematics workshop on "Homological Mirror Symmetry", focusing on relations to the geometric Langlands program. This is a very active and important area in matthematics. It has pretty much nothing to do with attempts to unify physics via string theory, but it's great mathematics, and maybe someday it will turn around and inspire some physics.

27. **Robert Musil**
March 19, 2007

Peter,

Thank you for your as-always thoughtful response. David B. seems a very intelligent and knowledgeable (if somewhat excitable) fellow, but he is certainly not right in mischaracterizing me as asserting that the Mirror Conjecture ends with the Hodge Diamond formulations. Indeed, I'm not aware of any comprehensive formulation of the Mirror Conjecture. Manifolds with mirror-symmetric Hodge tables are called geometrical mirrors. My point in this regard is (and was) that the Hodge Diamond formulation is trivial to state and notice and that nobody had bothered to do either prior to the positing of M Theory. Yet now that very formulation is deemed to be inherently wonderful mathematics. Of course, this is not an argument for dismissing or downgrading the significance of any version of the Mirror Conjecture. But to start the discussion it does help to get the question right.

Nor is David B.'s assertion that there are no easy examples of Mirror Symmetry right. Indeed, it is not that hard to find references to this fact in papers by central practitioners in the field. Of course, some of the known examples were by no means easy.

As for the geometric Langlands program, I'm not knowledgable in the area of mathematics. I realize that geometric Langlands is an active area of research considered promising by many very smart people. But promise and "rich" structure alone didn't make string theory great – or even important – physics. I'm not sure if I see why one can already conclude that Geometric Langlands is great mathematics – and evaluating the importance of Mirror Conjecture relationships to GL is another step after that.

28. **Peter Shor**
March 19, 2007

If somebody comes up tomorrow with a beautiful new theory which unifies gravity and QM and is much simpler than string theory, and if the LHC produces results that agree with its predictions, I assume that nearly all the string theorists will drop their current research and jump on the bandwagon.

The real question is (a) without any hints of an alternative, are any of them going to abandon string theory research, no matter how unpromising it looks and (b) whether a hint of a promising alternative is enough, or whether it takes a fully formed theory. For instance, if the LHC produces a Higgs mass close to that predicted by Connes, are any of the string theorists going to take this as a hint that maybe they're on the wrong track, and Connes on the right one?

Any wagers on this?

29. **Kea**
March 19, 2007

Any wagers on this?

What are we betting on? How long it will take the String theorists to figure out what's going on? Actual experimental outcomes at the LHC? Oooohhh, this is fun.

30. **A.J.**
March 19, 2007

Several comments for Robert Musil:

1) The relationship between Hodge diamonds predates M-theory by several years. It's part of the story physicists like to tell about M-theory and a simple example of a mirror phenomenon, but I don't think it's of deep importance. More of a decorative note.

2) I've never heard anyone claim that the existence of manifolds with mirror hodge diamonds was the important or deep part of the story. Complaining that others are calling it "inherently wonderful mathematics" seems like a bit of a straw man. Who exactly has said this?

3) What is important, as David B. more or less pointed out, is that we can relate moduli spaces of complex structures to moduli spaces of symplectic structures. This is incredibly non-trivial, and potentially very useful.

4) While I agree that "This shows up in string theory" isn't necessarily a good rationale for a mathematical research problem, I think it's a poor reason to dislike good mathematical ideas. And the notion that there's a topological field theory which carries information about the space of curves and maps to a fixed target has proven to be a fertile source of algebro-geometric ideas.

31. **A.J.**
March 19, 2007

Peter (Shor):

If the Connes et al prediction comes out right, I imagine that some people will take the hint and start working on it. On the other hand, I've also seen some stringy speculation around the fact that the noncommutative space in Connes, Marcolli, & Chamseddine has KO dimension 6.

32. **Robert Musil**
March 19, 2007

A.J.,

You are quite right in that current interest in mirror manifolds is due to the idea is that along with the equality h1,1(X) = h2,1(Y) of moduli numbers of Kahler structures on X and of complex structures on Y, the whole symplectic topology on X is equivalent to complex geometry on Y, and vice versa. In that sense perhaps I should have been more explicit about the means of establishing the Hodge equivalences. But the first examples of this equivalence are not hard, nobody was looking at them, etc.

I'm not sure what you mean by "The relationship between Hodge diamonds predates M-theory by several years," unless you are referring to the earlier computer results. I'm not aware of any general Hodge diamond conjecture that predated the positing of M Theory.

All that being said, I don't see why my points don't still stand. For example, while I don't mean to be snide or obtuse, neither do I see why the assertion that something is "a fertile source of algebro-geometric ideas" is a very good basis for concluding that those ideas or their source are important. The argument seems to completely assume its conclusion. Am I missing part of your point?

There is clearly great and broad enthusiasm for some mathematics derived from (or spun off from) string theory – much of it among very smart and accomplished people. But there was (and is) just such enthusiasm for string theory itself – an enthusiasm only recently seriously challenged. That challenge has been made from one redoubt: In physics one at least has the check on the products of such enthusiasms that at some point or other those products must be EXPERIMENTALLY TESTABLE (although, as this blog cogently points out, some string theory practitioners are struggling mightily to avoid even that check). There is no such check in mathematics. So how do we know that the mathematics spun off from string theory are not just empty enthusiasms? It's just silly to deny that a lot (as Peter points out, perhaps not all) of the enthusiasm is derived directly or indirectly from string theory itself. To make matters worse, some of the best mathematicians speaking to the public about mathematics spun off from string theory often make claims for its importance that are absurdly over the top (Michael Atiyah, for example). Certainly just asserting that one thing or another is "great mathematics" or the like doesn't advance matters, does it? What does?

33. **A.J.**
March 20, 2007

Robert:

OK first, most of the ideas of mirror symmetry predate M-theory by several years. The former is part of the body of evidence for the latter. If you want more direct evidence: Kontsevich's homological mirror symmetry lecture is from the summer of 94; Witten's M-theory announcement from the fall of 1995.

Second, why are we still talking about Hodge equivalences? This is a hint that there's something interesting going on, not the end goal of any major research efforts.

I don't understand what your metric for "importance" is. But it seems to me that algebraic geometers have judged Gromov-Witten theory to be important and interesting because of the ideas it's brought into their field, not because it's connected in some way to a much larger program in a different field. So, yes, by this standard, it's important. If you mean important in some other sense, I really don't have anything to say to you.

My point basically is this: You have a reasonable abstract point about a potential relationship between relative levels of enthusiasm about physics and mathematics, and a cute metaphor about hotel mirrors to go with it. But I think you're quite wrong to single out mirror symmetry as an example of the phenomenon you're talking about.

And I suspect you will have a hard time finding actual examples. It's true that some mathematicians like to talk and daydream about important physics connections, but I think you'll find that the physics-derived ideas which mathematicians have really taken the time to develop intensely have been those which are useful and interesting as *as mathematics*.

34. **Robert Musil**
March 20, 2007

A.J.,

You mention "I don't understand what your metric for "importance" is." Well, let's take that seriously. Terry Tao advanced a set of criteria for "bad mathematics" that I believe were discussed in this blog a while back:

• A field which becomes increasingly ornate and baroque, in which individual results are generalised and refined for their own sake, but the subject as a whole drifts aimlessly without any definite direction or sense of progress; or

• A field which becomes filled with many astounding conjectures, but with no hope of rigorous progress on any of them; or

• A field which now consists primarily of using ad hoc methods to solve a collection of unrelated problems, which have no unifying theme, connections, or purpose; or

• A field which has become overly dry and theoretical, continually recasting and unifying previous results in increasingly technical formal frameworks, but not generating any exciting new breakthroughs as a consequence; or

• A field which reveres classical results, and continually presents shorter, simpler, and more elegant proofs of these results, but which does not generate any truly original and new results beyond the classical literature.

Is it clear that the mathematics spun off from string theory has avoided each of these? It seems at least arguable that one, perhaps more, of these criteria fit uncomfortably well. Not that an answer to this would end the discussion, of course.

35. **Robert Musil**
March 20, 2007

A.J.,

I first want to be very clear that I appreciate your thoughtfulness and intelligent comments. I also want to apologize in advance for popping in this second post before you have a chance to respond to or digest the first.

With respect to Kontsevich's seminal address at ICM, Zurich 1994, it is worth keeping in mind that Kontsevich's himself characterized what he was doing as follows (I quote from his address):

"Mirror Symmetry was discovered several years ago in string theory as a duality between families of 3-dimensional Calabi-Yau manifolds (more precisely, complex algebraic manifolds possessing holomorphic volume elements without zeroes). The name comes from the symmetry among Hodge numbers. For dual Calabi-Yau manifolds V, W of dimension n (not necessarily equal to 3) one has
dim Hp(V,q) = dim Hn−p(W,
q). ….

"We describe here a not yet completely constructed theory which has potentially wider domain of applications than mirror symmetry. It is based on pioneering ideas of M. Gromov on the role of ∂-equations in symplectic geometry, and certain physical intuition proposed by E. Witten."

The relevant references to Witten's "intuitions" are to two papers: Topological sigma models, Commun. Math. Phys. 118 (1988), 411-449 and Two-dimensional gravity and intersection theory on moduli space, Surveys in Di□. Geom. 1 (1991), 243–310.

I believe these quotes address several questions and concerns expressed in your posts above (why we are talking about Hodge numbers, for example). I also believe these passages support my points.

36. **A.J.**
March 20, 2007

Robert:

Tao didn't give that list as criteria for bad mathematics. It's just a list of dangers (somewhat exaggerated as Tao admits) which *might* have detrimental effects on the development of a field. I think it's misleading to treat it as checklist for identifying "bad mathematics".

That said, the only danger I see being remotely applicable is is the 2nd one. But I don't think it's a particularly great danger. For one thing, judicious borrowing of physical intuition has a pretty good track record. (Donaldson theory, Chern-Simons, knot polynomials, mirror symmetry, Seiberg-Witten theory, and so on.) And for another, mathematicians have a habit of concentrating on problems they think are solvable. No one is butting heads with 4d Yang-Mills theory right now, because it's probably out of reach. But there's lots of motion in the Gromov-Witten theory of orbifolds right now; people are getting things done.

37. **A.J.**
March 20, 2007

Robert:

I don't see how the Kontsevich quotes support your points. Perhaps you'd care to explain? You'll probably have to take some care to spell out carefully what you mean, since we seem to be talking at angles.

Some of the confusion may stem from the term mirror symmetry. The symmetry gets its name from the duality of the hodge diamonds, but it's just a name. The actual set of ideas involved is considerably richer than the name implies. Most of it has been developed in the years since Kontsevich's lecture.

38. **David Williams**
March 20, 2007

Hello
Please have mercy on an old scocial science Phd.

I have had, basically, only a pragmatic and professional education except for a couple of biology courses and a stint as a biology teaching assistant (where I first encountered the scientific method) but I have indulged my interest in popularized science writing. I use this information in debating the champions of religion.

In debate the basic successful argument is that Science is not based on belief but on questioning and testing. Recently, String theory has become widely accepted in physics. I love the idea in the sense that it tells us that the universe is a symphony. HOWEVER, String theory appears to arrive at the position of a Unified Field Theory only by relying upon
a. mathematical solutions b. solutions that require positing multiple universes.

May I ask you these questions.

In your opinion are mathematical solutions the equivalent of an empirical test? Although I'm told (and I simply have to accept or not – at the level of my math and science skills) that M theory will offer an opportunity to empirically test String Theory. I cannot, to my satisfaction, imagine an empirical test for multiple universes.

And, If empirical tests are not available by the very nature of String Theory is this idea no better than religious belief?

I am inclined, therefore, to simply leave String theory to it's own devises and conclude that it lacks scientific credibility and that we are stuck with the contradictions between General Relativity and Quantum Dynamics. We would otherwise be as lacking in evidence as the religious. Why have physicists so departed from scientific standards?

Hope you will be able to spare the time answer this query.

David,

I have similar concerns. String theory is hyped or hoped beyond belief. This is serious, because if a scientist is supposed to be exact and careful about their theory, their work, etc., why doesn't this carry over into their public descriptions?

I somehow stumbled across this site a few weeks ago. But for several years I have firmly believed that there was something not right about the 'theory of everything' crowd.

At that point I was trying to track down some more concrete details about these theories. But nothing concrete ever appeared. Instead, I ran across some made up cafeteria dialog between a string theorist and (I guess) a LQG theorist. I think the point of the dialog was to highlight the lack of evidence for either theory, but more important for me was another principle: science is about the unknown, not the known or the unknowable.

If science is expanded to cover the unknowable, you forfeit the ability to apply Occam's razor. Occam's razor isn't a theory, it isn't a law of nature, it is a check on logic: it requires experiment. If a theory has no experimental results, how can you compare it to one that does? If a theory predicts unknowables like multiple universes, how can this win out over a theory that predicts only the one we experience?

My problem with the proponents of string theory is that their ideas fall into the category of 'known' or 'unknowable'. That is, their statements lead me to believe that they know something (strings are the basic building blocks of everything) or their theory covers stuff we can't know (multiple universes, etc.). In the first case, they are lying, or using language in a very sloppy way. If they are sloppy with English, why should I think that they are not sloppy in their math or logic?

What I don't understand is that if a scientist makes wild statements that they 'know' something or that their theory implies 'unknowable' realities, why shouldn't I remember their unscientific approach? Either put up, or shut up.

Known = technology
Unknown = science
Unknowable = fantasy

March 21, 2007

A.J.,

it's of undeniable educational value to follow the debate between Robert Musil and yourself.

`No one is butting heads with 4d Yang-Mills theory right now, because it's probably out of reach.'

This statement is, however, outright false and confirms
pretty much the relevance of Terry Tao's above quoted criteria.

Best, RH

41. **Ralf**
March 21, 2007

David and tomj,

String theory/M-theory is a speculative research program which therefore would not be covered at all in the popularized science press if the latter were responsible. Officially, string theory is "accepted" exactly as that. In practice this doesn't stand in the way of string theorists taking over high energy physics, in part because the field has been short of new ideas for three decades. In such cases the subjective criteria for what can be regarded "reasonable" ideas become rather flexible. The "scientific method" exists only in the imagination of philosophers of science. "Occam's razor" cannot be "applied" like a theoretical analog of a lab test.

People can be honestly deluded about things that are crucial to their identity, like their love life, their social life or their professional world. In addition, string theorists view themselves as intellectually superior to everybody else, which automatically degrades any objections brought up by those.

Finally, in reality there is simply nothing about string theory that can be related to laypeople. Anybody who writes about it is only heaping nonsense on a foundation of nonsense which again rests on a foundation of nonsense. It is utter intellectual dishonesty to pretend otherwise. Supersymmetry, by itself, cannot possibly be assessed by a non-physicist. Every account makes it appear much more reasonable than it is. Grand Unification sounds almost like a no-brainer if one doesn't know the details. The technical details on which string theory is built—and which are never even mentioned in the popular press—render it, in my opinion, deranged and demented. And it is exactly this wide gap between actual physics and string theory that—perversely—facilitates the public's susceptibility for it. The public never registered anything from the Schrödinger equation onward because they don't like the absence of visualizability.
That is why they prefer the faux visualizability of General Relativity—and of string theory, of course. Physics is not the Riemannian geometry of the 19th century. It was Einstein, after all, who commented that one should explain everything as simply as possible—but not simpler.

42. **a**
March 21, 2007

dear David,

let me try to give an answer to your “Why have physicists so departed from scientific standards?”. It is oversimplified and caricatural, but I think it captures a relevant aspect of the question. Do you believe that an average rational human being would choose option A or B?

Option A is what is happening now.

Option B is “I spent my life working on strings, but, contrarily to what press said, initial hopes mostly disappeared. Maybe I could start doing some other physics, but I only have expertise in strings, that is a highly specialized topic: so I resign from my academic job”

43. **A.J.**
March 21, 2007

R. Hofmann:

Sorry about that. I was not expressing myself clearly. (Why can’t you people just read my mind?!) A precise formulation: “Few if any mathematicians are attempting to construct 4d Yang-Mills theory in the sense required by the Clay Millenium prizes.” Obviously plenty of people are thinking about 4d Yang-Mills in a non-rigorous fashion, or trying to work out various facts about its topological analogues. But no one’s managed to do anything interesting as far as construction & mass gap goes.

44. **r hofmann**
March 21, 2007

A.J.,

I see … That problem was formulated by E. Witten and a famous Harvard mathematical physicist, right?

Best, RH

45. **A.J.**
March 22, 2007

Yes,

I don’t know anything about how the Clay Foundation works, but at the least the problem description was written by Edward Witten and Arthur Jaffe.

46. **Ari Heikkinen**
March 22, 2007

Peter,

Just a couple of questions, when you say:

‘The fundamental problem is that simple versions of the string theory unification idea, the ones often sold as “beautiful”, disagree with experiment for some basic reasons.’

Do you mean by this that what’s in Greene’s book (that “beautiful idea”) of particles being tiny vibrating strings of which amplitude and wavelength corresponds to different masses and force charges of them and that those “extra” dimension are curled up in Calabi-Yau shapes are what disagree with experiment?

‘Getting around these problems requires working with much more complicated versions, which have become so complicated that the framework becomes untestable as it can be made to agree with virtually anything one is likely to experimentally measure.’

And by this something that Greene’s book don’t mention?

47. **Peter Woit**
March 22, 2007

Ari,

One of the main problems is that you have to do something to fix the size and shape of the Calabi-Yaus, and the only ways people have found to do this involve introducing a lot of complex, ad hoc structure. This is the “moduli problem”, and I don’t remember what Brian says about it in his book. His book was written now quite a few years ago, before people had any solution at all to the problem. Back then I suspect there was a lot more optimism that a simple solution could be found.

E8 Media Blitz

March 20, 2007
Categories: Uncategorized

Last Friday night when I was in Rome I received e-mails in quick succession from two science journalists asking what I thought about a new mathematical result, the "mapping of E8" that was going to be announced at a press conference on Monday. Information sent to journalists was embargoed until Sunday night at 11pm, but the first journalist sent me a copy of the brief press release and told me that there was a longer one available. Reading the press release left me still baffled about what this could be about: what was the "century old problem" that this group of 18 mathematicians had solved? The obvious interpretation of "mapping of E8", mapping it as a geometrical object, didn't make sense since that's a well-understood problem. The group E8 is a 248 dimensional space, but its local geometry is the same everywhere and completely understood in terms of its Lie algebra. The global topology is interesting, but also well understood.

I wrote back to both journalists that the best person I knew to comment on this and its possible relation to physics would be John Baez, and asked to see the longer press release. It wasn't much more enlightening, but it did have a link to a web-site with details. After spending a little time reading this I understood that "mapping of E8" was a calculation of the structure of representations of the split real form of E8, and decided that I was on vacation and not about to try and quickly write a blog posting about this.

Well, here are the press releases from MIT and AIM, and David Vogan did give a public talk about this yesterday at MIT. The media blitz was quite effective, getting the story into not just the usual suspects (there's a good version of the story by JR Minkel at Scientific American), but also achieving a wide distribution in much less usual places such as today's New York Times, the BBC, le Monde, and many, many others. I think this may be getting about as much attention as the proofs of Fermat's Last Theorem and the Poincare Conjecture. There are also a huge number of blog postings, and I'm very pleased with myself to note that by far the best is the one by John Baez (crucially supplemented by the first comment there, from David Ben-Zvi), so I at least sent the journalists to the right place.

For mathematical details, John's posting and the comments there are the best place to go besides the technical papers linked to from the AIM site.

While the calculation is a computational *tour de force*, and the computational methods may be useful elsewhere, the level of hype in the press releases, especially about the possible relations to physics, is somewhat disturbing. The AIM page on E8 and Physics contains statements such as

…once one adopts the basic principles of string theory, it can be argued that we live in the universe we live in because it is the only one that is possible.

as well as making the highly misleading claim that the new calculation has something to do with heterotic string theory.

What initially confused me about the press release is that, with the standard interpretation of what one means by "E8", the "E8" that appears in heterotic string theory, there is no open problem to be solved. The group is well-understood, and so is its representation theory. As a compact Lie group, the representation theory of E8 is part of the standard Cartan-Weyl highest weight theory, and was worked out long ago. To read about this, there's an excellent book by Frank Adams about the representation theory of E8 and other exceptional Lie groups, called Lectures on Exceptional Lie Groups. It is this representation theory that appears in the heterotic string story. For more about E8, and one of the stranger things I've seen in a math paper, you might want to look up a 1980 paper by Frank Adams called "Finite H-spaces and Lie Groups", in the Journal of Pure and Applied Algebra.

What the new result is about is something quite different, the "split real form" of E8. The classification of compact Lie groups proceeds by classifying their Lie algebras, giving a well-known list, with E8 the largest of the exceptional cases. In doing this, one complexifies (works over the complex numbers), studying the complex semi-simple Lie algebras, which are the Lie algebras of the complexifications of the compact Lie groups. In the simplest example, one studies SU(2) by complexifying its 3d Lie algebra (R^3 with vector product), i.e. studying the Lie algebra of SL(2,C) instead. Finite dimensional unitary representations of SU(2) correspond to holomorphic representations of SL(2,C), and the same correspondence works in general between finite dimensional unitary reps of compact Lie groups and holomorphic representations of their complexifications.

Given the complexified group, one can ask if it has other "real forms", i.e. subgroups other than the compact one which would have the same complexification. In the case of SL(2,C), there is another real form: SL(2,R). The representation theory of SL(2,R) is a vastly more complicated subject than the case of SU(2). One reason is that the group is non-compact. Geometrical constructions of representations like the Borel-Weil construction give infinite-dimensional irreducible unitary representations. The case of SL(2,R) is difficult enough (and a central topic in number theory), but the case of representations of general real forms of semi-simple Lie groups is extremely difficult and complicated. Representations are infinite-dimensional and labeled by "Langlands parameters" instead of highest weights. This theory has been pretty well worked out over the last 30-40 years or so, with the case of E8 one where it was known how to do calculations in principle, but they had so far been computationally intractable. Dealing with this is the new advance.

What actually is calculated are things called "Kazhdan-Lusztig" polynomials; for an explanation, see John's blog. These tell one how to build arbitrary irreducible representations out of something simpler which one does understand, certain induced representations called "standard" representations. The numbers involved here also have a beautiful geometrical and topological interpretation. This is a generalization of what happens in the compact case, where the cell decomposition of the flag variety governs how irreducibles are built out of Verma modules.

So, this is a result about the structure of the irreducible representations of one of the real forms of E8 called the "split" real form. As far as I know it has nothing to do with heterotic string theory. The only thing I can think of that physicists have worked on that might make contact with this result is the work of people like Hermann Nicolai and Peter West trying to get physics out of Kac-Moody algebras like E10 and E11. I have no idea whether they have run into the split real form of E8 subalgebras and the representation theory of these in their work. In Pisa I had the pleasure of meeting blogger Paul Cook, a student of Peter West's who is now a postdoc in Pisa and has worked on this kind of thing. Perhaps he would know about this.

Update: I hear from Jeffrey Adams that he has put together a web-page about this, aimed at mathematicians, and designed to explain the nature and significance of this result. It's quite clear and does a good job of this, accessible if you have a bit of background in representation theory. If not, you may at least enjoy his comment on the media attention:

This leaves the question of why this story took off in the press. For us, that is harder to understand than the Kazhdan-Lusztig-Vogan Polynomials for E8.

Comments

1. **Matti Pitkanen**
   March 20, 2007

   Dear Peter,

   I think that AIM link is to an older posting of John Baez which is not
   about the recent calculation but about compact form of E_8.

2. **Peter Woit**
   March 20, 2007

Matti,

Not sure which link you mean. The "E8 and Physics" link is on the main page announcing the new result. It does just refer to the compact case and links to an old Baez piece about this. I think it would be better if they made clear that this is rather different than the case they're issuing a press release about.

The analogy in SL(2,C) would be trying to promote a new result about SL(2,R) representation theory by claiming that it had do with the physics of spin (SU(2)). They're two very different things….

3. **Aaron Bergman**
March 20, 2007

The split real form of E8 shows up when you compactify 11D SUGRA on an 8-torus. In particular, all the fields organize them into representations of the group (except for the scalars which organize themselves into a sigma model into the homogeneous space E8/K where K is the maximal compact subgroup). This is the inspiration for the ideas of Nicolai, West, Ganor and others about exceptional symmetries in M-theory.

4. **Cody**
March 20, 2007

Is it common for mathematical results to be announced via press release? What kind of coverage could anything less than a result like FLT hope to get?

5. **Peter Woit**
March 20, 2007

Thanks Aaron,

Very interesting. Do you know if there's any possible application of this calculation to that story?

Cody,

No, it's not common to announce math results this way. I'm rather surprised at how successful it was in getting attention. Lots of universities and other organizations issue press releases about the work of their people, but normally these are mostly ignored by the general media. Sounds like AIM has a really, really good person handling this.

6. **John Baez**
March 20, 2007

Thanks for the plug!

One of the people on the Atlas team, Jeffrey Adams, just let me post an email explaining more about what they calculated.

7. **Matti Pitkanen**
March 20, 2007

Peter,

Yes,I meant "E8 and physics". By the way, the flag manifold discussed in the page of John Baez is similar to that appearing in the construction of modular representations in Langlands program.

8. **J**
March 21, 2007

I just tried to read that about 5 times and now I want to hit my head on my desk because I am lost after about the first 8 words. 🙁

9. **Turkey Royale**
March 21, 2007

The tone of your post is unfortunately negative. You have allowed your antipathy to all things stringy to mislead you into misreading what has been done and what has been claimed to have been done. Look at the Atlas webpage and you will find nothing about string theory, only a coherent project to describe representations of real reductive groups. The split real form of E8 being the largest exceptional simple real Lie group, the calculation of things like its character table is impressive both theoretically and computationally. The goal of representation theory is not to know in the abstract how to find representations, rather to know the representations and how to decompose their tensor products. When G has many, and their structure is complicated, it is at first bewildering how one might even organize a map (a page in an atlas) of the representations of G. This is what the Atlas project is after.

There is a certain tendency to wish to find the exceptional simple real Lie groups in nature, but this tendency has really very little to do with a mathematician's interest in these groups.

10. **Dug**
March 21, 2007

To assist readers in better understanding the E8 relation to the Leech Lattice, the Monster and [string] physics, consider:

1 – The Terry Gannon arXiv paper 'Monstrous Moonshine: the first 25 years' [33 pages with 124 references].
http://www.arxiv.org/PS_cache/math/pdf/0402/0402345.pdf

2 – This appears to form the framework of the Gannon book, 'Moonshine Beyond the Monster' [477 pages, 575 references].

Lieven le Bruyn refers to [1] as a survey paper at 'Never Ending Books'.
http://www.neverendingbooks.org/?p=133

11. **Robert Musil**
March 21, 2007

Peter,

This is a worthy but quite modest result. But the hype surrounding it that has been confected by the people involved is just embarrassing. That the media have fallen so badly for that hype is just one more testament to how intellectially impoverished reporters and media outlets have become.

The classification of irreducible unitary representations of reductive Lie groups has been a central focus of David Vogan's work for over 30 years. But no general picture has emerged, not even a conjectural one. For the last few years he has been making a computational assault. But for this kind of question a computational approach all but concedes defeat. The original goal was a computer program that would tell you whether or not a parametrically inputted potentially unitary representation is actually unitary. Hypothetically, if there were a conceptual description of the irreducible unitary representations for all representations other than the split real form of E8 (rather than computational description), the omission would be of much concern to no one. Conversely for a computational approach, a general answer would not add all that much to an answer for all cases other than E8.

The matrix that relates the irreducible (unitary or not) representation to the so-called standard representations is called the "Kazhdan-Lusztig matrix." This effort computes the Kazhdan-Lusztig matrix for E8, as well as the inverse of that matrix. The algorithm to do this in all cases is well known. The only problem was that some of the matrix entries are very large integers, so computation for E8 required too much computer memory. Someone I will not name – someone who has not even been credited publicly in all this hype — suggested to the Adams-Vogan group that they perform the E8 computation modulo several large (but not too large) primes. That reduces the amount of memory enormously and the actual answer can then be reconstructed. This is exactly what the Adams-Vogan group now has done. The program can run on a laptop for groups other than E8. The hype (although not the result) is risible because just knowing the Kazhdan-Lustig matrix is parsecs from solving the unitarity problem.

12. **Michael**
March 22, 2007

Peter, if I needed an opinion about a scientific breakthrough, you'd be my first choice as well. I'll keep you on speed dial…

13. **Peter Woit**
March 22, 2007

Turkey Royale,

To the extent my comments were negative, they referred not to the Atlas project or its web-pages, just to the AIM web-pages and press release. I think the material there about relations to physics is seriously misleading, and one of the main things I wanted to do in the posting was to clearly explain what the issues are, something I don't see getting explained anywhere else on the web or in the media.

As for the significance of this as pure mathematics, sure, it's an impressive piece of work, especially as a computational achievement. The fact that the AIM people managed to get it so much attention is quite a phenomenon. In one sense it's great: if every mathematical advance of this magnitude was widely covered in the press, that would be wonderful, and there would be a lot more press stories about math. But, given how traditionally only the most dramatic millennium-prize sort of advances normally get covered, I do think it's a good idea to offer some perspective on this one.

14. **Robert Musil**
March 22, 2007

I particularly enjoyed digesting this hi-calorie forkfull of hyperblather (http://news.yahoo.com/s/afp/ussciencemathematicsfrancegermany):

"Today string theorists search for a theory of the universe by looking at E8 X E8. The scientists said the magnitude of the E8 calculation invited comparison with the Human Genome Project. While the human genome, which contains all the genetic information of a cell, is less than a gigabyte in size, the result of the E8 calculation, which contains all the information about E8, is 60 gigabytes in size, they said."

But this implied claim that the mathematicians who "have successfully mapped E8" have accomplished something about 60 times as difficult and important as the biologists "mapping" the human genome raises a difficult issue: How is it that the marketing geniuses who developed and sold string theory failed to call it "Strand Theory" instead? After all, if it were called Strand Theory the facile equation of (1) the importance of this branch of physics without a testable hypothesis or prediction and (2) the ultra-important and practical structure of DNA (which comes in the most famous double strands of all!) could have been enormously facilitated in the mind of the public. As it is, the Adams-Vogan group (or at least their publicists) have to labor mightily to insinuate that their result is as epoch making as the mapping of the human genome at the same time they are laboring to imply that E8 contains – through a completely preposterous and non-existent string theory connection – something like the "genetic code" of particle physics.

Gosh, they must be tired. And all of that extra labor could have been eased so much by just one simple change in nomenclature!

It just makes you wonder where their heads were at when they were poking them into all those extra dimensions.

15. **turkey royale**
March 24, 2007

Peter,

My post did not intend to defend the hype-seekers and fame-mongerers, just to say that the culpability for the allusion to string theory did not appear to belong to the representation theorists in the Atlas Project. That is not to say that their efforts merit or do not merit press coverage; the folks actively seeking press coverage are the same folks all the time scheming to dominate this or that aspect of academia, and they are very tiresome for the rest of us who just want to modestly understand a few modest things within our comprehension.

In this sense, I think you are basically right to criticize the publicity seeking efforts of AIM. Overstating one's case undermines one's credibility in the eyes of those who know something.

I think the unnamed suggestor mentioned in Musil's post was Noam Elkies.

16. **Jeffrey Adams**
March 25, 2007

Now that the dust has settled I would like to make a comment about the attention this story has gotten in the press.

The goal of the Atlas of Lie Groups and Representations is to classify the unitary dual of a real Lie group G by computer. A step in this direction is to compute the admissible representations of G, including their Kazhdan-Lusztig-Vogan polynomials. The computation for E8 was an important test of the technology. While an impressive achievement, it is but a small step on the way towards the unitary dual, and not remotely as important as the original work of Kazhdan, Lusztig, Vogan, Beilinson, Bernstein et. al.

Nevertheless, because of the nature of the result, the Atlas team
and the American Institute of Mathematics decided this would
be an excellent opportunity to educate the public about research in pure mathematics. The intended audience of this campaign was the general public, and it was

undertaken for the benefit of mathematics awareness as a whole, and not for the Atlas project itself. We are happy to have been successful in raising awareness of mathematics research worldwide.

For more information see some details about the Atlas project.

String Theory Debates

March 22, 2007
Categories: Uncategorized

This seems to be the month for string theory debates, with two a couple weeks ago in the UK involving Lee Smolin, and another featuring Lawrence Krauss and Brian Greene scheduled for next week in Washington D.C. The Washington Times has an article about this.

Smolin's book has just appeared in the UK, and there have been lots of (very positive) reviews. See here, here, here, here, and here.

Besides talks (for a report on the one at Cambridge by a skeptical American physics student in England, see here), there were two debates. One featured Smolin, Philp Candelas, Simon Saunders and Frank Close and was held at Oxford; for a report, see here. It appears to have been a respectful and reasonable public airing of a few of the issues where string theorists and some of their critics disagree.

A couple days earlier though, a debate in London between Smolin and Mike Duff (also involving philospher Nancy Cartwright) had a very different nature. According to the report from one attendee, after Smolin started things out by arguing his case:

Smolin sat down. Duff stood up. It got nasty.

The trouble with physics, Duff began, is with people like Smolin…

Duff is described as "string theorist and man for whom, one imagines, the words 'self' and 'doubt' do not often rub shoulders", and seemed to think it was a good idea to answer criticisms of string theory with vociferous ad hominem attacks. Lubos Motl and Clifford Johnson both found Duff's behavior an excellent example for all string theorists, inspiring Clifford to write part VII of his extended attack on me, Smolin and our two books. He admitted somewhere around part V or VI that he actually hadn't looked at the books and had no intention of doing so, and he's pretty steadfast in that attitude. It never ceases to surprise me that people like Clifford don't realize that, much as they may enjoy engaging in or listening to personal attacks on me and Smolin, this just doesn't do a lot for the credibility of their field. String theorists often complain that Smolin portrays them as arrogantly dismissing any criticism, but they should realize that behavior like Duff's doesn't help them at all on this issue, quite the opposite.

Duff pretty obviously has a double standard for popular books about string theory. He's quite capable of being polite, writing a very respectful review of Susskind's The Cosmic Landscape for Physics World. His review of Smolin's book in Nature Physics is something very different, much more like his performance at the debate. The review begins by misquoting Smolin, based upon something that was in the proof copy of the book he had (which the author hasn't had a chance to look at), but was different in the published version. After the review, he had been informed about this, but still seemed to think it was a good idea to use this as ammunition in his personal attack on Smolin during the debate.

One of his main points was that it is ridiculous to claim that string theory has not made any progress since the 80s. Obviously there are some areas in which there has been progress in better understanding the theory, but, as far as the central issue, that of getting any predictions out of the idea of using strings to unify physics, it's interesting to follow the link that someone with a waggish sense of humor at Nature put at the bottom of the page of Duff's review. It's a story from 1986 entitled Where Now With Superstrings?, and it reports on the views of string theorists at the time, roughly one year after the early developments that caused so much enthusiasm for string theory as a unified theory. The problem of too many vacua was something people were starting to worry about, but the feeling was that:

… another problem of non-uniqueness in superstring theory, the variety (thousands) of possible four-dimensional worlds it allows, is showing some signs of resolution.

The "progress" on this more than twenty years later is that instead of "thousands", the number has moved up to the exponent, and we've now got the "Landscape" of 10^{1000} or so possible four-dimensional worlds. Any "signs of resolution" of this are long vanished. Just as physicists are now waiting for the LHC next year, those of 1986 were waiting for the Tevatron to start up the next year, with Weinberg claiming that the mass range to be explored by the Tevatron was "a very plausible mass for them to have". The reporter wrote that:

If the Tevatron sees no superparticles, supersymmetry will lose its value in the hierarchy problem, and hence half its motivation.

So, I guess Duff is right that it's inaccurate to say that things haven't changed with the prospects for string theory since 1986, since the situation now is a lot worse than it was then.

If you want to listen to the debate, audio is available on-line here, with a transcript to appear shortly. For another kind of audio showing what this is all about, see this posting from Sabine Hossenfelder.

Comments

1. **Bee**
   March 22, 2007

   Hi Peter,

   thanks for the link. You know what I really don't understand is why some string theorists apparently deliberately try to make the situation worse for themselves. In my opinion, the smart thing to do is definitely no to argue with their interpretation of the author's intentions or psychological problems. For the public opinion – what many pretend to be oh-so concerned about – they could just have turned it into a reasonable discussion about funding in theoretical physics, instead of getting upset about a would-be here or there.

   Best,

   B.

2. **Peter Woit**
   March 22, 2007

   Bee,

   I agree. One of the weirder aspects of being involved in these arguments is sometimes watching people on the other side engage in self-destructive behavior. I think both Lee and I have often had the experience of feeling that we could do a better job of defending string theory research than many string theorists seem capable of.

   Especially in private, most string theorists I know have no trouble admitting that the situation is pretty discouraging for string theory right now. Those who feel this way aren't likely to agree to review the books or get into a debate on the subject in public, since it's kind of a no-win situation. String theorists who do take on these assignments are often the most fanatical true believers around, and this is all too obvious. It would be very much in the interest of more sensible string theorists to speak up for themselves, and not let their least convincing colleagues be the ones to publicly represent their field.

3. **Joseph Smidt**
   March 22, 2007

   Great post. Thanks for the heads up about the debate.

4. **JC**
   March 22, 2007

   Sometimes folks will just hang themselves with their own rope, with very little to no encouragement from others. This is very common in politics and religion, than in science.

5. **Erik**
   March 22, 2007

   I'm an undergraduate—I've only been reading this blogs for about 6 months or so. It is generally quite informative and enjoyable, and I appreciate your updates (although the overly technical discussions obviously go over my head for the most part, which I expect). I occasionally read most of the blogs that you link to, so I'm familiar with many of the harsher posts, but this latest round following Dr. Smolin's and Dr. Duff's debate seems a bit worse than usual—particularly nasty and biting. I guess I'm just wondering to what extent this type of behavior is… "normal?" Is this most common in this particular branch of physics? I guess the claims being made are pretty weighty and the stakes are certainly pretty high in this branch. And finally, for all the little flurries of posts and responses that these things set off in the "blogosphere," do you think the theoretical physics community at large experiences something similar?

6. **Peter Woit**
   March 22, 2007

   Erik,

   I think you'll find that academics in general are no better or worse behaved than the population at large. String theory is a bit of a special case: a huge amount of effort has gone into it and a lot of people have a lot invested in it, while it hasn't worked out as they had hoped. Under the circumstances, lots of people in the field are unhappy with the current situation, but mostly quietly, and behaving reasonably in a difficult situation. Unfortunately, some are reacting with less than reasonable behavior. The blogosphere kind of encourages some of this, but it's not just a blogosphere phenomenon.

7. **DB**
   March 22, 2007

   It's interesting, resurrecting that 1986 story. It shows how some (by no means all) string theory practitioners have transformed a once promising speculative path into a quasi-religious quest. I think Einstein, with his fruitless 30 year quest for a unified field theory, ignoring the wonderful empirical successes of quantum theory along the way, is at least partly responsible for the emergence of this attitude. I think it is no coincidence that Princeton, where Einstein conducted this quest, is today the locus of string theory research. Today's practitioners of this doomed tradition could do with some of his humour and humility.
   I can't just blame Einstein though, and I often wonder why it is that other great physicists, Newton, Weinberg, Schrodinger – have shown a willingness to become side-tracked into the realms of metaphysics in their later years, albeit to very different degrees in each case. An age-related onset of rigidity of thinking, allied to a diminution of creative powers perhaps?

8. **Peter Woit**
   March 22, 2007

   DB,

   The problems with string theory unfortunately can't be blamed on people getting old. That's a well-known problem in the sciences, and biology has an effective way of dealing with it. Many of those most fanatically devoted to the string theory ideology are quite young, with new converts coming up through the ranks all the time.

9. **Bee**
   March 22, 2007

   Peter Woit said: Especially in private, most string theorists I know have no trouble admitting that the situation is pretty discouraging for string theory right now. Those who feel this way aren't likely to agree to review the books or get into a debate on the subject in public, since it's kind of a no-win situation. String theorists who do take on these assignments are often the most fanatical true believers around, and this is all too obvious. It would be very much in the interest of more sensible string theorists to speak up for themselves, and not let their least convincing colleagues be the ones to publicly represent their field.

   This is also my perception, and I hope some of the 'more sensible string theorists' take your advice.

   (Though I suspect that in some cases the stage for a debate is set such that controversy is expected or even hoped for. In a certain sense, it must be boring for the public to hear that in most cases theoretical physicists get along with each other pretty well.)

10. **Aaron Bergman**
    March 22, 2007

    The problem, I think, is that there are at least three different debates going on simultaneously. The first is a discussion of the merits of string theory. At least speaking for myself, I think this is a perfectly legitimate debate to have. There's a lot of misinformation out there, but these are generally scientific questions and can be discussed scientifically. I don't believe I've ever personally attacked anyone for raising a criticism of string theory.

    Secondly, there is the debate about how to best encourage risk-taking and new ideas in the field of theoretical physics. This is a much more difficult debate to have because I don't think there are any easy answers.

    The real problem, however, is the third "debate" which is really a series of attacks on string theorists and the string theory community. This is a personal debate and has often led to personal responses. I can't imagine anyone finds it surprising that people often respons as such when their reputations as scientists are attacked.

    I don't see any real hope of disentangling these debates.

11. **Aaron Bergman**
    March 22, 2007

BTW — let me take this opportunity to give a short version of the response I'd like to give on the issue of the cc over at Asymptotia — I have someone visiting so I don't have the time to do an extended version. The short story is that you can look at contributions to the cc in SUGRA and nonSUGRA situations:

SUGRA:

1) Bare cc — related to superpotential
2) vacuum corrections — related to susy breaking scale
3) symmetry breaking
4) condensates

nonSUGRA
1) bare cc — free parameter
2) vacuum corrections — divergent, presumably cutoff by Planck scale
3) symmetry breaking
4) condensates

(and probably stuff I'm forgetting)

Now, given these charts which I hope you agree with, I don't see how the statement that the cc-problem is worse in susy situations is supportable.

12. **Ari Heikkinen**
March 22, 2007

There's also the question wether string theory is physics or philosophy based on mathematical reasoning.

My observation is that even suggesting the latter seems to be taken as an insult by atleast some string theorists.

13. **Peter Woit**
March 22, 2007

Aaron,

I don't really disagree with your charts. The point I keep trying to get across is that, as you note in your chart, in the SUGRA case the scale that appears is the SUSY breaking scale, and that is something well-defined enough for us to actually measure it. We have an experimental bound of around 100 GeV, and if low-energy SUSY exists, maybe the LHC will give us not just a bound, but a number. Problem then is that this number is at least 10^60 times too big, and this is what pretty much everyone describes as the "CC problem".

In nonSUGRA the situation is just different, there is no such thing as a SUSY breaking scale, so you don't have this problem. You do have the problem that vacuum corrections are divergent and so the CC is ill-defined, but that's a different problem than in the SUGRA case. It's somewhat a matter of taste which is the worse problem, but I think it's a sustainable point of view that having a theory in which a question is well-posed, but the answer is completely wrong, is worse than having a theory in which the question is ill-posed. Being wrong is a worse thing to happen to a theory than being not even wrong, since at least you can hope that further understanding will move you from not even wrong to maybe right, but wrong is just wrong.

14. **Aaron Bergman**
March 22, 2007

I don't see how you can distinguish the divergent computation in nonsusy situations from susy situations; it's the exact same calculation. You can even send the susy breaking scale to the planck scale and interpolate between the models.

15. **Peter Woit**
March 22, 2007

Aaron,

About the "third debate". I think most string theorists are careful not to engage in personal attacks, and in particular I think that you're not someone who has done this, other than at times expressing exasperation with Lee, which isn't especially unreasonable. But I think it's highly unfair of you to characterize either Lee or me as being responsible for this situation because we started personally attacking string theorists. I don't think there's anything at all in either of our books that could be characterized that way. In his other public statements (as well as in all private discussions I've ever had with him), I know of no case where Lee has personally attacked anyone. I've by now written thousands of pages about string theory and string theorists on my blog and others, and undoubtedly have, in a small number of cases, out of exasperation, made comments about people that I regret. Recently, I have made very specific accusations about the personal behavior of some people, and those I don't regret.

Sure, both Lee and I think there is a wide-spread problem with how string theory research has all too often been conducted. He gives examples of what he sees as problematic in his book, I do so in my blog and in my book. These aren't "personal attacks" on people, they're specific complaints about specific behavior and decisions, which we see as coming out of, not personal failings of specific people, but an organization of research that is not working.

This is very different than the wholesale personal abuse both Lee and I have been subjected to. You know very well that I can give you large numbers of examples of this (Lubos Motl and his supporters at Harvard, Susskind, Duff, Peet, Srednicki and the other jeering bozos at the George Johnson talk at the KITP, Jacques, Clifford, "Hmm", "Michael", and others). The problem with this "third debate" is real, but it's not of our making.

16. **Chris W.**
March 22, 2007

Ari:
There's also the question wether string theory is physics or philosophy based on mathematical reasoning.

My observation is that even suggesting the latter seems to be taken as an insult by at least some string theorists.

That's because they have such a dismissive (and not particularly well-informed) attitude towards philosophy. Not surprisingly, string theory is not particularly coherent or well-considered as philosophy.

In contrast, Einstein's thinking was a thoughtful, careful, and original philosophical thinker, largely because he saw philosophical thinking as playing an essential role in physics. In particular he saw it as an antidote to ill-considered and uncritical reliance on mathematical formalism in physics. He paid a certain price for this; in 1921 the Nobel Committee looked askance at the philosophical cast of Einstein's writing on special and general relativity.

17. **Mike C.**
March 22, 2007

I'm a little confused about the big problem with the landscape. The Standard Model appears to have a huge landscape of physically distinct compactified 2+1-dimensional vacua, many with a radius around 10 microns. A tiny intelligent creature living in one of those vacua would be forced to deal with vacuum selection. We would laugh if such a creature tried to explain the mass of his electrons based on some fundamental necessary principle. And since the existence of these 2+1-dimensional vacua depend only on low-energy physics, any theory that contains the Standard Model at low energies would also have to contain this landscape of 2+1 dimensional vacua.

So why is it a surprise that a theory with extra dimensions should have a landscape of vacua? If it must contain a landscape of 2+1-dimensional vacua, why is it a surprise that it should have a landscape of 3+1-dimensional vacua? And if the Standard Model has a landscape, why are we so upset to see other theories with a landscape, especially since any theory that contains the Standard Model will already have to contain its landscape?

I guess I just don't see the big deal here, but perhaps I'm mistaken!

18. **Chris W.**
March 22, 2007

Mike C.,

1) Please be a bit more specific about the Standard Model's physically distinct compactified 2+1-dimensional vacua.

2) If we were the tiny intelligent creatures in question then we would eventually conclude that the theory is worthless, because our observers and theorists could play this game (until 'O' gets fed up):

> **O**: I have some observations I would like to account for within your theory.
>
> **T**: Given a choice of vacuum X, I can show your observations are fully consistent with my theory.
>
> **O**: Oops, wait a minute, I made a mistake. The data I just gave you was wrong. Here is the corrected data. Can you account for it?
>
> **T**: Sure, no problem. Give me a minute and I'll find another vacuum that will do the trick. (I've got lots of 'em.) ….. Okay, here you go. Vacuum Y will do it.
>
> **O**: What the hell is up? I made up all this data! Can you tell me what you *couldn't* account for? Describe some results that I should *not* observe under specified circumstances—circumstances that I can independently verify! I need predictions from you with minimal wiggle room—none of this vacuum selection crap.
>
> **T**: [Yawn…] Sorry, but that's not the way the game is played these days. There are some older ideas (limiting cases of my theory, in a certain sense) that you might find more agreeable, but I don't find them particularly interesting; they've already been tested. The goal is to achieve agreement with observations, and that's what I'm giving you. If you don't like it then maybe you should consider another line of research.
>
> **O**: You really don't get it, dude. I'll grant you this; you know a lot more mathematics than the average astrologer. A lot of good it does you…

19. **Mike C.**
March 22, 2007

Chris,

I understand that you don't like the landscape. But my point was that the Standard Model has one, whether you like it or not. (Check out a recent paper on the archive for this. Distler also discussed it in his blog recently.) This is the vanilla Standard Model, with its tiny cosmological constant and small (but nonzero) neutrino masses. No SUSY, nothing funny. And this landscape contains a near-continuum of 20 micron-sized 2+1-dimensional vacua. And a tiny intelligent creature living in one of these vacua would never be able to find a theory that predicted the values of the couplings and masses he saw, because we know full well that he's living in just one of many vacua, all of which have different laws of physics.

But since the existence of these vacua is independent of any UV completion of the Standard Model, any other theory that extends the Standard Model at high energies will have to contain this landscape of 2+1-dimensional vacua, and thus, in particular, contain a landscape, whether we like it or not. The only question is whether a UV completion of the Standard Model must contain a landscape of 3+1 dimensional vacua, or if there is a unique 3+1 dimensional vacuum. But that's a pretty strong assertion! (And would be of little consolation to our tiny 1 micron sized friends.)

20. **woit**
March 22, 2007

Mike,

The big deal about the landscape is that it's a framework in which you can't make any experimentally testable predictions, so it's not science. Not being science is a big deal. If you want to do science, you have to come up with predictions that can be tested to see if your theory is right. In the landscape framework, you inherently can't do that.

The Standard Model is a 4d flat space QFT that makes an infinite number of predictions, many of which have been tested to very high accuracy. This is completely different than the landscape, and claiming that it's all the same is just sophistry. We've already had this discussion here, I think a couple times. I haven't looked closely at the Arkani-Hamed et. al. paper about this that recently came out. Maybe there's something interesting there. But if the claim is that it shows that there's no difference between the Standard Model, which is highly predictive and testable, and the landscape, which is completely non-predictive, that is obviously nonsense.

21. **Mike C.**
March 22, 2007

Peter,

So sorry to keep bothering you about all this, but it came up in the comments, and I thought it would be an interesting discussion!

You should check out their paper. It doesn't say that the 3+1 dimensional vacuum of the Standard Model isn't unique. It is, as far as the Standard Model is concerned. The Standard Model predicts a unique 3+1 dimensional vacuum. But the paper does shows that there exists a landscape of physically distinct compactified 2+1 dimensional vacua in the Standard Model, many with physics almost the same as in our 3+1 vacuum for objects that are small enough, and intelligent creatures could conceivably live in them, if they were small enough (~ 1 micron).

So what are these creatures supposed to do? They live in a landscape! Are they supposed to say that landscapes are bad and hence spend eternity looking for a reason why their electrons have the precise mass they do? We large creatures would laugh at them!

But the other is that any theory that contains the Standard Model would have to contain this landscape of 2+1 dimensional vacua, since the existence of this landscape depends only on low-energy physics. So there's no question about theories having a landscape. The only question is whether they have a landscape of 3+1 dimensional vacua. Let's hope there are no 4+1 dimensional creatures laughing at us!

22. **woit**
March 22, 2007

Aaron,

About SUSY/non-SUSY. Sure, you can put in broken supersymmetry as a regulator of the vacuum energy in a non-SUSY theory, then take it to infinity. But in one case it's a regulator, in the other it's a physical, measurable scale. Having a theory with a divergence that you don't know how to regularize without introducing trouble is bad. Having a theory that makes a robust prediction that is off by a factor of 10^60 is also bad, in a different way. Again, personally I think making a flat-out wrong prediction is worse than not being able to make a prediction. If you feel the other way, fine. Hard to argue about it though, they're two completely different things. It just seems a bit ridiculous to me when I hear people saying it is an advantage of supersymmetry that you can calculate the vacuum energy in it, when the result comes out absurdly wrong.

23. **Aaron Bergman**
March 22, 2007

It's really not true when people say that you can't calculate the vacuum energy in non-susy theories. It's a free parameter. The cosmological constant is superrenormalizable, and the divergence can be dealt with in the usual manner. Thus, the cc problem is a fine tuning problem, not a problem of an incorrect prediction. In SUSY theories, the only difference is that the renormalization is finite and the bare term is constrained to be related to the superpotential. From the point of view of effective field theory (which is the only way I understand QFT), it all seems the same to me.

Putting things another way, would you agree that SUSY at any scale below the Planck scale helps the fine tuning problem for the Higgs mass?

24. **Chris W.**
March 22, 2007

The paper Mike mentioned is evidently the following:

Quantum Horizons of the Standard Model Landscape
(hep-th/0703067 — Authors: Nima Arkani-Hamed, Sergei Dubovsky, Alberto Nicolis, Giovanni Villadoro)

25. **woit**
March 22, 2007

Mike,

Sorry, but I still don't see why I'm supposed to be interested in these 2+1 d compactifications. They have nothing to do with the real world, and I don't buy the analogy with the string theory landscape. Sure, maybe we're some random point in some landscape of some 4+1d QFT, or some 10 d string theory or whatever. Could be. But if you want to claim that going on about this is doing science, you have to come up with a way of testing what you are doing. If what you are doing inherently can't lead to a testable prediction, I don't know what you want to call what you are doing, but it isn't science. Does the Arkani-Hamed et. al. paper suggest any way to test landscape ideas? If it does, let's hear it. If it doesn't, any claims it makes about the landscape are not science.

26. **woit**
March 22, 2007

Aaron,

I don't see the relevance of the philosophical argument about fine-tuning. I've repeated endlessly what I see as the difference here. One case involves a physically measurable number (that is wrong), the other doesn't. If that's not an important difference to you, fine, just say so. But then we're operating with different value systems, and aren't ever going to agree on what is "better" or "worse".

27. **Mike C.**
March 22, 2007

These 2+1 dimensional vacua appear to exist, in our real world. And any theory that contains the Standard Model should contain this landscape of 2+1 dimensional vacua. That's a prediction. The Standard Model predicts their existence. So I'm a bit confused about why you're not interested in them. The upshot is that any theory that contains the Standard Model contains a landscape. Do you disagree?

28. **Aaron Bergman**
March 22, 2007

No.

In both cases, there is not an incorrect prediction. One can tune the cosmological constant by balancing the quantum corrections against the bare term in both the supersymmetric and non-supersymmetric theory. (Or, more properly, in the sugra and nonsugra theory.) The cosmological constant problem is always a fine tuning problem. It's just whether you are fine tuning a formally divergent quantity (such as with the Higgs mass) or a finite quantity (such as the Higgs mass in supersymmetric theories.)

29. **Chris W.**
March 22, 2007

Mike, the fundamental issue remains:

> **O**: … Can you tell me what you couldn't account for? Describe some results that I should not observe under specified circumstances—circumstances that I can independently verify! I need predictions from you with minimal wiggle room—none of this vacuum selection crap.

In the presence of the string theory landscape *what is excluded*, and more to the point, what is excluded that isn't already excluded by the Standard Model? If the answer to the latter question is "nothing" then we have an untestable pseudo-answer to the questions left open by the Standard Model. Some people may find this pseudo-answer appealing, but if it had been known 20+ years ago that this is where we were going to end up, few people would have bothered to continue down this path.

(And for those who take general relativity as a theory of spacetime structure seriously, and understand how deeply this viewpoint on the theory challenges the foundations of quantum theory, string theory and its offshoots have very little to offer—unless some major new insights are achieved into string theory's bearing on this question. If so I doubt we'll still be calling it string theory.)

30. **woit**
March 22, 2007

Mike,

No, these 2+1 dimensional vacua do not exist in our real world. Our real world has 4 large dimensions. You're talking about some other worlds which have nothing to do with ours. Again, tell me how I am going to learn anything at all about the real world by thinking about these things. If there's a proposal for this, it might be interesting. If there's not, I just don't see any reason to pay attention to this.

31. **Mike C.**
March 22, 2007

These other vacua can be connected to ours by interpolating geometries. They have to be very far away, though, because their opening angles are small. But if the universe is large enough, then they really must be out there. That's a prediction. Though, obviously hard to test.

32. **Chris W.**
March 22, 2007

These 2+1 dimensional vacua appear to exist, in our real world.

Really? And how would you verify their existence? Let's assume the "Standard Model predicts their existence," as documented (allegedly) in hep-th/0703067. How would this prediction be checked? Bear in mind that most predictions of existence are inherently problematic; a failure of attempted verification can always be dismissed on the basis that one didn't look hard enough. (Question begged: How hard is hard enough?)

33. **woit**
March 22, 2007

Aaron,

Talking about it as a fine-tuning problem, as you say, in one case you are "fine tuning a formally divergent quantity" which isn't a well-defined thing to do, and you can't characterize the size of the fine-tuning. In the other you are fine-tuning something you can experimentally measure, and the size of the fine-tuning required is known and huge. If you think this is an acceptable thing to do, fine, do it and there's no CC problem.

If you think there is a CC problem, then in the second case it has a well-defined size (huge), in the first it doesn't. I just don't buy the argument that it's better to have a huge problem than an ill-defined one.

34. **woit**
March 22, 2007

Mike,

You're not telling me how to experimentally see these other vacua. Do Arkani-Hamed et.al claim that they have new, in principle observable, predictions based on the standard model? If so, that would be much more interesting than empty analogies about landscapes. Where in their paper do they make these predictions?

35. **Aaron Bergman**
March 22, 2007

Talking about it as a fine-tuning problem, as you say, in one case you are "fine tuning a formally divergent quantity" which isn't a well-defined thing to do, and you can't characterize the size of the fine-tuning.

Of course it is well-defined. How does this situation differ from the Higgs mass? The Higgs mass is quadratically divergent. The hierarchy problem is that the measured Higgs mass is much less than the cutoff scale. The cosmological constant problem is that the measured cosmological constant is much less than the cutoff scale. I don't see how you're distinguishing the two cases.

36. **Arun**
March 22, 2007

Mike C.

http://www.math.columbia.edu/~woit/wordpress/?p=412#comment-23310

37. **woit**
March 22, 2007

Aaron,

The difference between the two cases is, as I keep repeating again and again, that in one case you are talking about an experimentally measureable number, in the other case there is no such number (you don't know what the "cutoff scale" is).

In the case of the hierarchy problem, trying to use supersymmetry to resolve it makes sense since the electroweak symmetry breaking scale may not be too different than the SSYM breaking scale (although experiment is on the way to ruling this out). In the case of the CC, it doesn't work at all, in a spectacular way.

This has become a complete waste of time. In one case the problem is characterized by an experimentally measured number that we know to be completely of the wrong magnitude, and in the other, no such number exists. Sorry, but this is a difference. Again, If you don't think it's relevant, fine. I think it is, but there is no way to "prove" that it is or isn't.

This all goes back to your complaints that what I wrote in my book about supersymmetry was not accurate. I don't agree at all. The book gives an accurate characterization of the reasons why supersymmetry breaking is a problem. I'm not going to repeat these here, except to say that getting the completely wrong scale for the CC is one of those problems. This is not some weird idea I came up with, but conventional wisdom in the field.

38. **Mike C.**
March 23, 2007

I'm a little confused. If you have a well-tested theory (and no theory known to humankind is better tested than the Standard Model), and the theory, without modifying it in any way, predicts something that is difficult to observe (in this case, a landscape of 2+1 dimensional vacua, which would appear to us observers as cosmic black strings and other black objects if we found one), are we supposed to reject such phenomena? If the universe is big enough, these things will exist, at least if the Standard Model—with the presently observed c.c. and our best estimates for the neutrino masses—is in fact the correct low-energy description of the universe. Are we supposed to insist otherwise? Unless you modify the Standard Model in some way, then it predicts these phenomena. The Standard Model, as it now stands, predicts the existence of a landscape of vacua.

So, there are two questions here:
1) If the Standard Model predicts the existence of certain phenomena, though they may never be experimentally observed, why insist that they don't exist and that we shouldn't think about them? There may be intelligent life out there in the universe that we will never ever observe, but does that mean that they can't exist? The universe is probably much bigger than the part we will ever be able to see, but does that mean that if a given well-tested theory predicts that it's bigger, do we just reject that prediction?
2) Why do we live in this noncompact 3+1-dimensional vacuum, when there are a huge number of other vacua predicted by the Standard Model with the same physics all the way up to 20 times the Planck scale, at least for objects that are smaller than 10 microns, other than because of the anthropic principle?
3) If the Standard Model predicts the existence of a landscape of other vacua, which can be interpolated smoothly into our own over large spatial distances, and the existence of these vacua depend only on low-energy physics (as is the case), then doesn't any high-energy extension of the Standard Model have to contain a landscape as well, at least a landscape of 2+1 dimensional vacua? So why criticize a theory that has a landscape?
4) If any such extension must have a landscape at least of 2+1 vacua, why is it so hard to imagine that there is a landscape of 3+1 dimensional vacua as well? Doesn't the onus now turn to people to prove that it doesn't happen? Just because it hurts predictivity somewhat, does that mean nature doesn't work that way? I wish I could predict all the species of animals on the earth today, but I can't. It's a bunch of historical accidents. Nonetheless, zoology and paleontonlogy are still a sciences, because we can make predictions about a limited class of phenomena.

39. **Mike C.**
March 23, 2007

By "two questions" I meant four. I can't count—so sue me!

40. **C. G.**
March 23, 2007

Mike,

I think you're getting confused between theory and experiment. The thing is, the standard model is a hugely successful phenomenological theory of particle-particle interactions, but, at the end of the day, it is still just a model. To believe that anything you can derive from it is absolute truth implies an implicit faith in the idea that the model is completely and absolutely correct. This I believe is a mistake, because to render reality to a theoretical artifact is not really the way physics should be done; physics should be based on real experimental observations.

41. **Mike C.**
March 23, 2007

C.G.

You make a lot of demands. Quantum mechanics predicts a lot of stuff that has been experimentally tested and verified. So does GR. But they both also predict a lot of strange stuff—well within in the physical regimes (energy regimes, length scales, etc.) in which they are known to be valid—but that we may never be able to see, and that at least we are not guaranteed to be able to rule out. Are we simply to insist that any such predictions that they make simply don't exist? Do things only exist if they can defintely be observed, even if an astoundingly accurate model predicts that they should exist and they might but not definitely be observable some day? It's like a fortune teller who predicts everything perfectly, but also starts telling you about things that you can't be guaranteed to check with your own eyes.

I'm reminded of what Feynman used to say about all this. He asked why nature should care what we human beings liked. The behavior of nature simply isn't up to any of us human beings. All we can do is try to figure it out and not be too prejudiced.

42. **M**
March 23, 2007

dear Mike C.,
I tried to have a look at the first pages of the paper you suggest, and it seems that what they find is just that the SM compatified to 2d can have one or a few vacua plus a quasi-flat direction i.e. some light scalar. That vacuum arises because neutrino masses are comparable to the cosmological constant, and likely this is an accident that has nothing to do with the string landscape. I don't understand why they choose the name "landscape" for this simple situation. Probably their little 2d animals would have some fun in understanding what goes on, but I fail to see why we 3d animals should get interested in it.

43. **Mike C.**
March 23, 2007

So is this whole debate really about the demand that no prediction of a theory be believed—not matter how well-tested the theory—unless that prediction is guaranteed to be experimentally checkable? I suppose that's a demand you can put on science, but it seems rather restrictive. Who are we to demand that nature must behave that way?

44. **Mike C.**
March 23, 2007

I guess the reason I disagree with that argument is that any theory of nature that addresses really, really high-energy questions is going to make lots of predictions that we cannot be assured of being able to experimentally verify, hopefully along with many predictions that we can be guaranteed to be able to verify so that we can decide if the model is good. But the ratio of the first kind of prediction to the second kind is inevitably going to get bigger and bigger as we approach greater and greater physical extremes. That seems unavoidable. And so should we always pretend that the first kind of prediction—those that may be testable but that are not guaranteed to be testable—just don't exist?

An example. Suppose just for the sake of argument that string theory is correct. Suppose that it suddenly makes a huge number of extremely nontrivial predictions that we know we can test, and we test them and they turn out correct. But suppose that there's idea how to do an experiment that would literally let us see these strings floating around. (It might be possible, but it's not assured that such an experiment is possible, say.) Do we then insist in this case that there are really no strings?

45. **Mike C.**

March 23, 2007

Correction: missing “no”
But suppose that there’s *no* idea how to do an experiment that would literally let us see these strings floating around. (It might be possible, but it’s not assured that such an experiment is possible, say.) Do we then insist in this case that there are really no strings?

46. **Aaron Bergman**
March 23, 2007

I don’t see how we have an experimentally determined quantity anywhere here except for the actual value of the cc (or, analogously, the Higgs mass). The SUSY breaking scale gives us a cutoff with respect to which we can express the fine tuning of the cc. We don’t know what the SUSY breaking scale is. It could be at the TeV scale (which would be nice), but it could be elsewhere. It could be at the Planck scale. And, if there were no SUSY at all, we’d still have a cutoff at the Planck scale. Are you claiming that these two cutoffs should be thought of differently? They’re both experimentally measurable, either through the detection of supersymmetric partners, or quantum gravitational effects.

Are you saying that because we don’t know the physics beyond the QG cutoff, there could be some mechanism that natural accomplishes the needed fine tuning? If so, I don’t see why you couldn’t make a similar argument for the SUSY-cutoff cc. If we don’t know, we don’t know, susy or not. But from the point of view of effective field theory, I don’t think it matters.

47. **woit**
March 23, 2007

Mike C.

You are claiming that Arkani-Hamed et. al. have discovered that the Standard Model implies the existence of “cosmic black strings and other black objects”. What exactly are their properties, and how could we produce them? Where in their paper do they make this claim? I have trouble believing this. The SM is not a quantum gravitational theory and it appears to me that you need to calculate topology-changing transition amplitudes, but lack a theory where such a calculation makes sense.

If string theory make a lot of testable predictions, and they’re correct, the theory is verified, and this has nothing to do with whether you can “see strings”. The problem with string theory has nothing to do with conceptual difficulties about whether or not you can “see strings”. Fine if the strings are not observable themselves. But a theory has to make predictions of some kind, and string theory just doesn’t.

Aaron,

SM + GR tells you nothing at all about how this “Planck scale” cutoff is supposed to work and you have no hope of doing experiments to see what happens. SUGRA gives a very precise understanding of what happens at the SUSY breaking scale, and people are spending billions of dollars to go out and measure this. These are just different situations. Again, for the N’th time, having a theory in which the question is well-posed is different than having one where it isn’t.

48. **Arun**
March 23, 2007

The best analogy I can think of is that in the Standard Model 3+1 large flat dimensions is an experimental input/theoretical assumption/whatever – asking why 3+1 dim in the context of the SM is ill-posed (and maybe even with SM + GR).

It is in string theory that the question of the number of experimentally observable dimensions comes up, and in a nasty way, because the theoretical answer is different.

—
Mike C., the physicists in the 2+1 dimensions in the (SM+GR) world don’t have these interesting theological debates, because in their world, (2+1) quantum gravity is tractable, and so the biggest single motivation for string theory (that it retrodicts gravity) is simply not there.

49. **andrea**
March 23, 2007

Hi all,

assume tomorrow someone comes up with a Rube Golberg compactification of string theory, with a lifetime say about 10^10Gyrs, which fits everything we know about particle physics and cosmology: how’s that different from Newton’s “hypotheses non fingo” about the 1/r^2 dependence of the gravitational forces? It works, and this is all that matters… i’m not saying it’s likely (as a matter of fact, it don’t think it is), i’m just saying i see no reason to get worked up on the landscape issue.

On the other hand, it is very likely that string theory compactifications cannot yield all conceivable quantum field theories at low energies, but only a “small” subset of them (e.g. if something like the “gravity as the weakest force” conjecture holds). Should one prove a rigorous theorem about this and find this subset experimentally ruled out, string theory would be falsified.

To sum up: string theory is undoubtedly way overhyped and has probably slowed down the progress of more down-to-earth theoretical physics by attracting many smart guys, but i don’t find compelling reasons for saying it is not still worth a shot, expecially given the fact that the nonzero CC makes the landscape picture a lot less unreasonable.

50. **Peter Woit**
March 23, 2007

Andrea,

The problem with the Rube Goldberg compactifications is that they are insufficiently rigid to be predictive. It’s not just a matter of finding one that fits what we already know, you have to find one that does that and is rigid enough to make falsifiable predictions. If the failure of every “prediction” can be fixed by going to a slightly different compactification, all you’re doing is coming up with a really ugly way of parametrizing experimental results.

As for the “Swampland”, the problem is two-fold. All the things that people are looking at as supposedly not able to come out of string theory already don’t look like the real world, so you can’t use this to falsify string theory. In addition, swampland proponents have this problem that sometimes when they announce that something can’t come from string theory, experts write into their blog explaining to them how to do it. “You can’t get X from string theory compactifications” often just means that no one has tried hard enough to do so. Yet another addition to the Rube Goldberg chain may do the trick. As long as you don’t know what non-perturbative string theory is, your arguments that “you can’t get that from string theory” are going to be dubious.

51. **M**
March 23, 2007

dear Andrea,

have you read “The Library of Babel” by Borges?

String theory seems to be a similar story. If tomorrow you scan 10^200 string vacua, you can probably find one vacuum that fits all the physics we know, and you get a Nobel prize. If on sunday you finish the work scanning the 10^500 remaining vacua, you can find 10^300 more vacua that fit everything, and you get an igNobel prize.

52. **Mike C.**
March 23, 2007

Arun,

You are not correct. These vacua only look like they’re 2+1 dimensional to large creatures like us. Tiny creatures, however (~1 micron), would see 3+1 dimensions, with one dimension wrapping around if they move along it far enough. Their physics—including gravity—is 3+1 dimensional and looks almost exactly the same as ours, all the way up to energies 20 times the Planck scale (when you start making black holes bigger than 20 microns) except for variations of all their coupling constants and masses. Read the paper to see why. So gravity is no more tractable for them than it is for us, and they still would have no explanation for the values of those coupling constants.

53. **Mike C.**
March 23, 2007

I must say that I’m a little bit disappointed with many of the commenters here. It seems like a lot of people here are making assertions and demands without having done their reading. People read the first two pages of a paper, for example, essentially just to find things that support their argument, and then start spouting things that aren’t true. A lot of the comments indicate that people don’t understand or haven’t read the relevant material. I’m feeling a lot of prejudice here. Can’t we all be a little more open minded?

54. **woit**
March 23, 2007

Mike,

You’ve come here, posted 13 comments, full of sophistry about the landscape which you base on a 44 page paper, which you refuse to answer my questions about. You seem to expect me and others to drop what we are doing and go read this 44 page paper. Sorry, everything I heard about it indicates to me that my time would be better spent reading other papers. It’s not even the topic of this posting at all. This isn’t a general discussion forum where you can just appear, start going on about what interests you, and expect others to go out and spend their time thinking about what you want them to think about, unless you’ve got a lot more compelling argument.

55. **Brett**
March 23, 2007

I don’t think it’s especially interesting that there is a “landscape of vacua” in theories in which some of the space-time directions are compactified. I say “landscape of vacua”–in quotes–because at the quantum field theory level, the different compactifications correspond to different theories; the underlying space-time is an element of the definition of the field theory. In a quantum gravity theory, maybe these are different states of the same underlying theory, but the standard model is not a quantum theory of gravity.

It’s no real surprise that by choosing different compactifications, one can get significantly different physics, because the compactifications themselves are ingredients in defining the theory. The parameter space of the theory includes the space of compactification manifolds. In order for these theories to be interesting physically, some additional conditions must be met; otherwise, we’re just adding extra free parameters. If there were any experimental indications that some of the dimensions of our universe were compact (either one of the four we see, compactified on a large scale or additional ones on small scales), this would be a very interesting subject. Or if having compact dimensions allowed a natural solution to some kind of hierarchy problem. Of course, there are various proposed “solutions” of such hierarchy problems using extra dimensions, but they are not natural. If we clean up a known hierarchy by introducing unnaturally sized extra dimensions, we haven’t solved anything, just moved the fine tuning into a new set of free parameters we’ve introduced just for that purpose.

If we want to allow for the possibility that one of the four dimensions we see is actually compact, and that somewhere far away in the universe, the corresponding compactification scale is quite small, that’s fine. This introduces a new generalization of the standard model, and maybe it’s what the universe really looks like. But it’s very much like introducing a new sector of particles near the Planck scale, with new free parameters, but hardly any new predictions for feasible experiments.

56. **M**
March 23, 2007

Mike C., I don’t see what these tiny creatures can teach us. In the case of strings, 10^500 vacua come out because you start with fields with a few 10d Lorentz indices and compactify many dimensions. These ‘features’ are not present when you compactify the SM to 2+1 dimensions.

Anyway I agree that theories with compactified dimensions tend to have many vacua, as discussed e.g. in the book by Smolin.

The true problem is: can we get good physics from the big string landscape? If the best we can do is debating about tiny creatures, then better to move to biology.

57. **dan**
March 23, 2007

Hi Peter,

you wrote “As long as you don’t know what non-perturbative string theory is, your arguments that “you can’t get that from string theory” are going to be dubious.”

How do you feel about physicists pursuing a non-perturbative string theory as a frontier of HEP?

thanks

58. **Peter Woit**
March 23, 2007

dan,

Finding a useful non-perturbative string theory is the big problem in string theory, and many people have worked on this over the last few decades and continue to do so. It would be great if there were progress on this, I just don’t see much recently.

59. **andrea**
March 23, 2007

brett,

the paper on standard model landscape is actually on standard model + general relativity landscape, so spacetime geometry is genuinely dynamical… that said, it goes neither here nor there as far as physics is concerned.

peter,

i don't get the rigidity argument: a single unit switch on one of the handles of the Rube Goldberg machine will generically lead to very large changes of the low energy physics (different number of flavours, or different gauge groups or planckian change in the CC). Nearby vacua don't give nearby physics.
If at least one vacuum is found which matches the physics we know, then one can make all sort of predictions: if they are verified we keep it and make other predictions, if not one is free to look for another one (typically very far away). No need to say that there may exist no vacuum with the right properties, but if Nature actually worked that way i'd be somehow disappointed, but i would not be shocked.

I've been following this debate for a while, and some string theorists have way passed the line of a civil exchange of ideas, but aside from that, the string community rightfully shows off its achievements (overhyping is unavoidable in the free market of ideas) and attracts smart guys because it is a very fashionable subject. The only way to put an end to this fashion before it eventually dies out is to take a swim in the swampland and falsify it. Sort of a catch22…

60. **Peter Woit**
March 23, 2007

Andrea,

For the reasons I mentioned, I just don't think the "swampland" has anything to do with actually falsifying string theory. If it did, maybe I would work on it… The string theory backgrounds people have most closely investigated are the ones that look most like the standard model, there are all sorts of these and absolutely no argument I am aware of that suggests the possibility of ruling out the standard model as a low energy effective theory for some string theory.

I just don't believe that we're going to find a single specific background that matches the standard model (which would then predict other things). There are solid arguments that it is inherently impossible to even identify those backgrounds with the right CC, much less the right CC and everything else. If one figures out how to overcome this, it would have to be by being able to precisely figure out the implications of large classes of vacua at once. If one can do that, I don't see why one won't end up with a large number of vacua with the SM properties, not just one or a small number.

In any case, given the current state of the theory, this kind of discussion is pretty much a theological one. I just don't think one can deny that what is happening is a classic example of failure: simple models disagree with experiment, so you are forced to more complicated ones. These are designed to be so complicated that you can't analyze them and confront them with experiment. Once this happens you are supposed to give up, not conduct philosophical arguments trying to justify continuing.

61. **Anon**
March 23, 2007

"You seem to expect me and others to drop what we are doing and go read this 44 page paper. Sorry, everything I heard about it indicates to me that my time would be better spent reading other papers."

And you complain that Clifford Johnson won't read your book?

"It's not even the topic of this posting at all."

But you've devoted space in previous blog postings to trashing this paper that you haven't read.

62. **Peter Woit**
March 23, 2007

anon,

Actually, I haven't mentioned the Arkani-Hamed et.al. paper in any of my postings. You're quite right that if I was writing a posting about it and not reading it, that would be reprehensible.

What I have done is responded to various commenters here who have written in claiming that "Arkani-Hamed et. al. show that the SM has the same landscape problem as string theory" by telling them that, while I don't know what is in the paper, that statement is obvious nonsense, and explained why. I've also asked them to back up what they were saying, telling me what the evidence for this claim was from the paper, but haven't gotten an answer. Presumably this is because the paper doesn't really make that claim.

Again, there are lots of interesting things I don't have time to learn about, so the properties of the SM compactified on very non-physical backgrounds just isn't very high on the list.

People write in here everyday with all sorts of claims based upon all sorts of misunderstandings, quoting lots of different papers. I'm not about to read them all, but will continue to point it out when people are spouting nonsense.

63. **Anon**
March 23, 2007

"while I don't know what is in the paper, that statement is obvious nonsense, and explained why."

It seems to me that MikeC has both read and understood the paper.

Aren't you on pretty thin ice calling his account of what's in it "sophistry" ? Especially, since it mirrors what previous commenters have said and which you have previously called "nonsense."

64. **Tim**
March 23, 2007

Peter,

You quot a reporter from the event:

"The trouble with physics, Duff began, is with people like Smolin…"

This posting of yours demonstrates very well that you are no different than the bad journalists and popular science reporters that you often complain about. This whole blog is full of misquotations and misinterpretation like the one above just as there are loads of misquotation and misinterpretation in bad populer science papers. I hope this will convince you and the audience here that what you are doing is not science but bad popular scientific journalism.

If you would have cared to check your facts — indeed a minimal requirement for any journalist — you would have found that what Michael Duff has said is the following:

"The trouble with physics, ladies and gentlemen, is that there is not one Lee Smolin but two."

Michael Duff went on explaining that the speaker before him — Lee Smolin — presented arguments which are perfectly fine and one can only agree with them. On the other hand his book is not of this nature but has rather many inaccuracies and went on explaining what he disliked in the book. Hence his opening sentence "there is not one Lee Smolin but two", which in the light of true facts becomes something completely different than what you quoted in your posting. The mp3 audio from the event is available to everyone including good and bad popular science writers but of course only the good ones will take the initiative to actually check it.

Here it is: http://www.rsa.org.uk/audio/lecture050307.mp3 and it was avaiable at the time of your posting.

Now I'm sure you will be ready to explain us all that your blog consists of hundreds of postings and so few have misquotations and misinterpretations such as the one above so everything is okay. Just the same argument any journalist or popular science magazine would pull when confronted with lies and distortion in their magazines "oooh, we have been publishing thousands of articles in the last 20 years and it's actually a proof of our high standards that only a couple of articles are completely false" and of course they would not be discomfortable with pulling the same argument over and over again and no matter how many times they are caught they would still continue to publish their magazine because that is what they live on.

The same behaviour that one can observe in the attitude of corrupt politicians. Although they might know they are not telling the truth and they know that they will continue to be distorting events but they have no other choice because that is what they live on and they are not couregous to say "okay, I've been caught too many times, it's time to stop and actually look for a real job".

Best regards,
Tim

65. **Tim**
March 23, 2007

Oh, and I forgot the always winning argument "some of my opponents were telling bigger lies than me so why should I resign?"

Best,
Tim

66. **Chris Oakley**
March 23, 2007

> "The trouble with physics, ladies and gentlemen, is that there is not one Lee Smolin but two."

Or there could be just one Lee Smolin, the illusion of two being a result of lensing by galactic-scale superstrings.

67. **Peter Woit**
March 23, 2007

Tim,

What I put in quotes is not a misquotation. It is an explicit quote from the report by someone who was there that I linked to. It does not purport to be a direct quote of what Duff said. It is a direct quote of how that person chose to characterize what Duff said. It reflects precisely how that person interpreted what he was hearing Duff say.

If you can point to a legitimate misquotation, even one, anywhere in the thousands of pages I've written here, please do so. Otherwise you should not make the kinds of accusations you are making. The one you mention was completely accurate, and included reference to the source it came from, so people could determine for themselves its reliability. Sure, they can also listen to the audio file, which I also linked to, and judge for themselves whether that report was accurate.

68. **Peter Woit**
March 23, 2007

Anon,

For about the 10th time, what I called sophistry is the claim that "the SM has the same landscape problem as string theory". I explained repeatedly here and elsewhere why that claim is sophistry and nonsense.

69. **Tim**
March 23, 2007

Peter,

I think we are getting into a problem in linguistics. The statement "your posting contains a misquotation and is hence misleading" holds. I did not say that you quote someone inaccurately, indeed, you quote the bad reporter accurately. The bad reporter on the other hand does misquote Michael Duff and hence your posting does contain a misquotation.

A good journalist certainly does not want to quote people saying misleading statements without clarifying that the person just quoted was indeed saying something misleading because if he did so he would himself be misleading his audience.

This is just what has happen in your case, you uncritically have taken over a quotation from someone that is very misleading and even insulting to a third person. You did not research the subject of your post although you have known full well that the quotation you quote will put a third person into an embarrassing light.

It is indeed the duty of every good journalist to give an impartial view, give the chance to anyone attacked by any of his quoted respondents to defend him/herself and check whether his sources are accurate or not. Failure to do so due to the fact that the respondents and other sources of his article are supportive of his preconception results in poor, biased, partial and activism oriented journalism something that is very far from a professional stand point.

In simple terms: repeating a lie (although accurately giving the source) without actually checking it and commenting on its untruefulness is called: propagating lies.

Best,
Tim

70. **Anon**
March 23, 2007

"For about the 10th time, what I called sophistry is…"

You accused MikeC of engaging in "sophistry" when all he has done is (accurately) recount what is in Arkani-Hamed et al's paper.

That's pretty much the same thing as accusing Arkani-Hamed et al of engaging in "sophistry."

But you'd never do that … because you haven't read their paper. Right?

71. **Q**
March 23, 2007

'In simple terms: repeating a lie (although accurately giving the source) without actually checking it and commenting on its untruefulness is called: propagating lies.' – Tim,

Tim, you've just contradicted yourself. You earlier stated that you want Peter's quote to be corrected to Duff's lying claim to the effect there are two Lee Smolins!

If you want quotes to not include lies, then it would be impossible to quote much said by some defenders of string theory.

For example, is the following quote a lie, because string theory predicts unobserved gravitons (instead of really predicting real gravity):

'String theory has the remarkable property of predicting gravity.' – Dr Edward Witten, M-theory originator, Physics Today, April 1996.

Should I 'correct' Witten's remark when I quote it, so I'm not propagating lies myself. Say to something like:

'String theory has the stupid property of predicting unseen gravitons and nothing checkable about gravity.' – Dr Edward Witten, M-theory originator, Physics Today, April 1996.

Would that make things nice and accurate in your view? 😉

72. **Tim**
March 23, 2007

Q,

Thank you for taking time to respond. No, that would not be accurate. The following would, if I suppose that you think that the quote from Witten is wrong:

" 'String theory has the remarkable property of predicting gravity.' – the above quote is from Dr Edward Witten, M-theory originator and has appeared in Physics Today, April 1996. I don't agree with Dr Witten's opinion for this and this reason."

In order for everyone to understand, the professional way for Peter to write his posting would have been this:

""""
According to the report from one attendee, after Smolin started things out by arguing his case:

Smolin sat down. Duff stood up. It got nasty.

The trouble with physics, Duff began, is with people like Smolin…

Now it turns out that I have checked what Duff said and the reported quoted is above is in fact lying, because Duff said

"The trouble with physics, ladies and gentlemen, is that there is not one Lee Smolin but two."

My opinion is however that Duff is wrong in saying the above because of this and this reason.
""""

Is it clear now?

If not let me give another example. I'm living in Germany so let's imagine I hang posters all over Berlin with the following content "Jews are killing Christian babies – see: Protocols of the Elders of Zion". Am I quoting accurately? Sure I am. Can people check the facts? Sure they can and they will find exactly what I am stating, namely that if they look up the Protocols of the Elders of Zion, they will find the quote I chose to post. Am I propagating lies? Sure I am. Is it impossible to quote from the Protocols of the Elders of Zion? Sure it isn't, all I need to do is make clear that it is a forgery something along the lines: "Jews are killing Christian babies – as can be read in the well known forgery Protocols of the Elders of Zion which nobody takes seriously in a civilized country"

I'm going to so much detail because I still believe that people like Peter can be convinced to change track and do somthing useful for the physics community instead of propagating lies and becoming irrelavant laughing stocks.

Best,
Tim

73. **Peter Woit**
March 23, 2007

Anon (and why is it that all you guys are anonymous, anyway?)

For about the 11th time, the claim that "the SM has the same landscape problem as string theory" is sophistry, see earlier iterations for the explanation why. It's sophistry whoever is making it, but the ones I know about are the ones writing in anonymously to my blog.

Tim,

In the quote I repeated, Duff's words are not in quotes and it is pretty clear that the person who wrote it is not giving a transcription of what Duff actually said, but the impression it left him with. He makes clear that is what he is reporting, and he explains why. Listening to what actually happened I think one can understand why this person had that impression of Duff's remarks.

I'm extremely careful in what I quote here. If something is in italics or quotation marks, it is an accurate quote from a source that has been indicated, and I have taken trouble to make sure that it is accurate and not taken out of context. In this case, what I wrote starts with "According to..", and explicitly gives the source. Everything I wrote is completely accurate.

On the other hand, you choose to make the accusation "This whole blog is full of misquotations and misinterpretation" and are not able to give any evidence of this. I think you have no evidence for this, and for you to make that kind of accusation is dishonest.

74. **The man**
March 23, 2007

Peter,

You often mention that *most* string theorists are reasonable and the type of string theory partisans that (often anonymously) post here are a strong minority.

After seeing the sampling of anonymous posts here, and at Clifford's, I'm beginning to doubt that. Where's the evidence the most string theorists don't behave like this?

75. **Anon**
March 23, 2007

"For about the 11th time, the claim that 'the SM has the same landscape problem as string theory' is sophistry,…"

Nowhere in his comments here does MikeC use the phrase "landscape problem." Nor does the phrase appear anywhere in Arkani Hamed et al's paper.

And yet you accused MikeC of engaging in sophistry.

As far as I can tell, he has given an accurate rendition of what's in the paper. So, if anything, you are accusing Arkani Hamed et al of sophistry.

Which might be OK if you had read their paper.

76. **Aaron Bergman**
March 23, 2007

At the risk of being annoyingly socratic, let's say that there was susy at 100 TeV. Would you say that this ameliorates the fine tuning in the Higgs mass?

77. **Mike C.**
March 23, 2007

I'm a little disappointed. I visited this blog, and saw that there was a mention of the landscape in the original blog posting. I was curious if the folks here had seen the recent work showing that the Standard Model has a landscape of a very similar form to that found in string theory, consisting of a continuum of lower-dimensional vacua. I pointed out a recent paper on the subject, which demonstrated the existence of these physically inequivalent vacua, and showed that they are perfectly acceptable solutions to the Standard Model + gravity with interpolations to our 3+1 dimensional vacuum. The paper also had the upshot of showing that any theory that contains the Standard Model must contain this landscape of 2+1 dimensional vacua, since their existence depends only on low-energy physics, and in particular, any theory containing the Standard Model has a landscape, by definition of what the word landscape means.

Instead Peter has repeatedly called me a "sophist" and people have told me that they can't be bothered even to look at the paper and clearly aren't even reading my posts. Well, fine. Perhaps I'm a sophist. But Peter, you're a dick.

I've got better things to do with my time too. Perhaps one day you guys will stop just for a moment and question your assumptions and prejudices. More likely, you're too confident in your ideology. I feel sorry for you.

Cheers,
Mike

78. **Jean-Paul**
March 23, 2007

I looked at the paper on 2+1 landscape. It deals with another nonsense extension of SM. Nonsense in, nonsense out.

79. **woit**
March 23, 2007

Aaron,

Maybe it's just late at night, but I can't even tell what point you are trying to make, or how what you are asking is responsive to my last comment here (is it?). I think it has been quite a few iterations since any substantive new point was made by either of us.

Mike,

I spent a lot of time trying to have a discussion with you, involving 13 comments here by you on my blog. You completely refused to address the points I made in response to you or answer the questions I asked you about the argument you were making, instead just endlessly repeating yourself and insulting me.

The Man,

On days like this, I must say that it becomes hard to maintain the point of view that most string theorists are reasonable. I still choose to believe that there's a silent majority out there, and the anonymous commenters don't reflect the behavior of most string theorists. My experience dealing personally with string theorists is very different. Only on very rare occasions have I run into unreasonable behavior in personal interaction. Anonymous blog comments unfortunately I think encourage this. You can behave like a complete jerk at no personal cost to yourself or your reputation by hiding behind anonymity. That's why people generally choose to do this.

80. **Aaron Bergman**
March 24, 2007

I'm just trying to understand how your philosophy applies to the case of another fine-tuned parameter.

81. **a**
March 24, 2007

dear Mike C., I read the section about "The SM landscape" and I confirm that the landscape exists only in the title: what they find is one 2+1d vacuum with one light scalar. A honest landscape is much bigger.

82. **Peter Woit**
March 24, 2007

Aaron,

It seems to me you keep ignoring the point I'm making (you don't have to agree with it, you just have to acknowledge that it's there), and trying to discuss something else.

As for the hierarchy problem, it's different, but the existence of a physically measureable 100 Gev or so SSYM breaking scale is also relevant. In the hierarchy case it's a feature (you're trying to use supersymmetry to explain why the Higgs is around 100 GeV), in the CC case it's a bug because it's the wrong scale.

All Sorts of Links

The LHC is the cover story on this week's issue of Science magazine, with three articles on the topic here, here and here.

Also in this week's Science is an article about the "spin puzzle", the fact that accelerator experiments with polarized particles give results for protons that are different than what one would expect from a naive quark model. The general assumption seems to be that this is a QCD effect, one that is tricky to calculate. I've always wondered if there is any chance that there is some sort of spin-dependent behavior of quarks different than that predicted by QCD. I don't know of any work by people trying to come up with such models, but maybe it's out there. I'd love to hear from some expert on this about whether the experimental results really do point to a serious possibility of something going on other than standard QCD.

A new book of interviews of scientists has recently appeared, Candid Science VI by Istvan and Magdolna Hargittai. It contains interviews with David Gross and Frank Wilczek. The authors ask both of them about their interactions with Wigner, and what they think of various other famous Hungarian scientists. Wilczek explains why he has made various moves over his career, that he was quite influenced by Peter Freund as an undergraduate, why he thinks it took so long to get the Nobel prize, and that his motivation for working on the beta-function calculation was to know if the electroweak model had the same Landau pole problem as QED.

Gross talks about his background and relation to Judaism, and also about his Nobel prize work. He remains enthusiastic about string theory, and characterizes opposition to string theory in many physics departments as due to people not wanting to learn it because it is hard work, as well as fear that if they hire string theorists, all the good graduate students will go work with them. There may be something to what he says, but I think it's out of date, and times are changing.

I hear from David Derbes, who put together Dyson's 1951 Lectures on Advanced Quantum Mechanics that were mentioned here earlier, that World Scientific is publishing them as a book this month. Profits will go to the New Orleans Public Library, where David grew up.

The two new Fields medalist bloggers each have fascinating blog entries on Millenium problems. Terry Tao writes a long explanation of Why Global Regularity for Navier-Stokes is Hard. He also comments about the recent New York Times piece about him and about math education issues. The comment sections of his postings have some very interesting discussions going on.

Alain Connes has a wonderful posting about Le reve mathematique, especially his mathematical dream of proving the Riemann hypothesis using non-commutative geometry. He notes that the first goal is to come up with a non-commutative geometry version of a proof for the function field case. More about this in a recent posting on the same blog by David Goss.

Comments

1. **Thomas Love**
   March 23, 2007

   I was delighted to hear that David Derbes, who put Dyson's 1951 Lectures on Advanced Quantum Mechanics into LaTex was contributing the proceeds to the New Orleans Library. I met David when I taught at Tulane University. He wrote his PhD under the direction of Higgs. He was teaching at the high school in N.O. from which he graduated, as a form of service. I was quite impressed by his knowledge and his discription of particles as broken symmetries help me in my work.

2. **Uncle Enzo**
   March 23, 2007

   description, not discription.

3. **wolfgang**
   March 23, 2007

   Peter,

   I am certainly not an expert on this, but I know that the so called "proton spin crisis" has been discussed for many years (at least since the 90s) and there are tons of papers and various proposals about it. You find them e.g. by searching for "proton spin crisis" on the arxiv or at Google scholar. I was always surprised that this "crisis" did not get much attention outside of the lattice-QCD and related communities, because (as you already wrote) it might very well indicate that something is wrong with QCD as we know it.

4. **Peter Woit**
   March 23, 2007

   wolfgang,

   I've also noticed papers on this over the years, periodically tried to read more about it to see if there was any chance there was something wrong with QCD. Never got far with this, so I was hoping to find a real expert who had some feel for the situation. I agree that it's surprising this problem has not attracted more attention in the particle theory community. Even if it's not evidence that will upend the standard model, it seems to be one of the least understood corners of particle physics, with experimental anomalies to guide one to better understanding, and new data coming in.

5. **Kris Krogh**
   March 23, 2007

   Peter,

   Quote from a web page on the standard model of particle physics:

   "So far every experiment test of the standard model has confirmed the predictions of the theory."

   I think I've seen similar statements on this blog. In light of what was initially called the proton "spin crisis," which has not gone away, how can this be said?

6. **Brett**
   March 23, 2007

A first principles calculation of how the spin of the proton is distributed among its constituents would be extremely difficult. So there is no really good prediction coming just from QCD to compare things to. Assuming that almost all the spin is on the valence quarks (or rather, appropriately dressed "constituent quarks") turns out to give quite good predictions for such things as the neutron/proton magnetic moment ratio. But if you look at the scattering off the quark spin, this model gives wildly wrong answers. So this very simple-minded model is wrong. What are needed (and what people have worked on developing) are calculationally tractable models that capture more of the essential features of QCD and explain why very simple models can give accurate results for specific quantities.

7. **Kris Krogh**
March 24, 2007

It seems when a simple-minded calculation agrees with standard model, that's taken as a vindication. If not, no crisis, we just need to do more work. Heads I win, tails we flip the coin again.

8. **lostsoul Ph. D.**
March 24, 2007

Ther is currently a paper that purports to disprove the RH, posted on the arXiv at

http://arxiv.org/abs/math.NT/0703367

This has not received the media attention that the cataloguing of E8 has (though there has been a rustle in the hedgerow of the blogosphere); is this because it may be wrong (I am not qualified to judge, though the approach looks pretty much 'old school' to me) or perhaps down to the author's lack of a good PR unit?

9. **modestproposal**
March 24, 2007

great blog but may I suggest that you put a description and some few key words in your html so that when searching on google you get an idea of what the blog is about – like lubos's "The best theoretical physics blog that the search engine can offer you".

10. **Chris Oakley**
March 24, 2007

Kris,

Yes, but since we do not really know how to do bound states for QFT in general and the Standard Model in particular the proton spin crisis is only a crisis for ad hoc, string-and-sealing-wax models used to plug this gap in our understanding.

11. **woit**
March 24, 2007

lostsoul,

That paper on the RH has all of the hallmarks of a wrong paper: dramatic claims to do something no one else has been able to do in over a hundred years, no evidence of a new idea that other people haven't looked at, a long technical argument, full of opportunities to go wrong. Remember, papers on the arXiv are not refereed, and even when they contain errors, the authors do not always acknowledge this and retract them. I have no idea if an expert has tried to go through that paper and the kind of problem most would expect to exist.

12. **Kris Krogh**
March 24, 2007

Hi Chris,

Your comment reminds me of an item from the Feynman biography by Gleick:

When a historian of science pressed him on the question of unification in his Caltech office, he resisted. "Your career spans the period of the construction of the standard model," the interviewer said.

" 'The standard model,' " Feynman repeated dubiously. . . .

The interviewer was having trouble getting his question onto the table. "What do you call SU(3) X SU(2) X U(1)?"

"Three theories," Feynman said. "Strong interactions, weak interactions, and the electromagnetic. . . . The theories are linked because they seem to have similar characteristics. . . . Where does it go together? Only if you add some stuff we don't know. There isn't any theory today that has SU(3) X SU(2) X U(1) — whatever the hell it is — that we know is right, that has any experimental check. . . . "

13. **Peter Orland**
March 24, 2007

The spin puzzle is neither a verification or a disproof of QCD. In the simple quark model, the quark masses in a nucleon are consituent masses. These are much greater than the current masses, which are actual masses. Most of the constituent mass is glue and virtual quarks – which should have an effect on any experiment measuring spin or magnetic moments. Nobody has calculated how this works, I believe.

14. **Doug Natelson**
March 28, 2007

Peter – Frank Wilczek gave a talk yesterday at Rice, and I asked him about the QCD spin situation. I have a new blog posting discussing this. In short, he says there is no problem with the QCD calculations or measurements; both say that the proton ends up as spin-1/2. Rather, the problem is that people's intuitions don't like that the calculations say that much of that spin comes from the gluon field.

15. **Peter Woit**
March 28, 2007

Thanks Doug!

(His posting is at http://nanoscale.blogspot.com/2007/03/frank-wilczek-talk-part-two.html)

16. **Jennifer Kovinski**
April 18, 2007

Navier Stokes Equations and Euler's Equations.
It's very brave of Penny Smith who persists in working on one of the hardest and still fruitless areas of mathematics–namely the Navier-Stokes and Euler's. From what I know, there are now only a handful of mathematicians who are still working on it: Peter Constantin is the most stubborn one among them. If you look at Clay Math's official problem description, you will notice that there are virtually no significant results. Humans have only moved a few steps in a thousand miles of the journey, yet, the problem seems to be that, the road doesn't exist, and one has to find a road to move forward. Sadly, all those leading experts in this field now become inactive simply because of the difficulty posted by the problems. I admire Dr. Smith's persistence. Her works are certainly good contributions to the field. I read about her papgers and preprints, left alone the mistakes, it doesnt seem to me that even the mistakes were abscent, each of the claims (correct or incorrect) still need to be proved, which is an extremely essential process. I, as well as my colleagues in Europe, don't believe that the claims have any usefulness in resolving the Navier-Stokes Equations. But nevertheless, good efforts. It's inspiring–hope more mathematicians would try it…

Is String Theory Testable? (Part II)

March 24, 2007
Categories: Uncategorized

I recently noticed that, around the same time I was preparing my slides for a talk about [Is String Theory Testable?](), Michael Douglas was doing something similar, preparing a talk on [Are There Testable Predictions of String Theory?]() There's a certain amount of overlap in our presentations, and people might find it interesting to compare them.

Douglas goes over much the same story I do, but reaches different conclusions. For him, string theory does "make predictions", just lots and lots of incompatible ones, so the problem is that:

none of the ideas which have been suggested so far are guaranteed signatures of string theory. We would be happier with one prediction, which could lead to a decisive answer either way.

This is the sort of thing I would call a prediction, so I guess we agree that they don't exist. Douglas ends by noting that the one way he can think of to get such a prediction is through a statistical argument based on counting vacua and the dynamics of eternal inflation. He doesn't mention the argument given in my talk that this is already falsified (by the lifetime of the proton), or that such arguments inherently lead to calculations that are inherently intractable and can never be done (this argument is due to him and Denef, it is surprising that he doesn't mention it).

Along the way, Douglas does make a couple claims about things that he thinks the statistical anthropic landscape arguments disfavor, especially varying constants and large distance modifications to gravity. Seeing these would falsify our current theory, but would not falsify string theory, since it can accomodate them, although perhaps not within Douglas's statistical framework.

One of the more surprising responses I've seen to my recent claims that string theory has failed as an idea about unification because it's inherently untestable comes from [Mark Srednicki](), who writes (in the context of mentioning an MSNBC interview with Brian Greene):

We see that the big issue for Brian, and for just about all scientists (though with the apparent exceptions of Lee Smolin and Peter Woit), is what is TRUE. Not what corresponds to some philosophy of what science is or is not. Lee writes that the landscape must be rejected because "it would mean the end of our field" (page 165). It should be obvious that this is not the basis that is traditionally used for accepting or rejecting a theory! Peter's (essentially the same) argument that string theory must be rejected because (at the moment) it does not appear to be sufficiently predictive (for Peter) is also irrelevant to the question of whether or not string theory is TRUE.

If the landscape is right, we may never get anything more than circumstantial evidence that it's right. But that's often the case in science. We've been spoiled in particle physics by having extremely precise data and highly predictive and quantitative theories for the past few decades. Most of the rest of science has not been so lucky. Perhaps we will not be so lucky going forward. The only way to find out is to do more work and see where it leads.

Srednicki's reaction to the lack of testability of string theory seems to be that testability is not what matters. What matters is what is TRUE, and it's perfectly logically consistent for string theory to be of such a nature that we can never test it. The problem with this point of view is that science is not so much about what is true as about how one knows what is true about the world. Religious believers are also interested in what is true and think they know what this is, but science is different since it provides a means for deciding what is true. Scientific ideas about the universe are true when they make predictions that can be checked in a convincing way. Ideas that can't be experimentally checked in some way, directly or indirectly, may or may not be true, but they're not scientific ideas, rather something of a different nature.

Comments

1. **Tim**
   March 24, 2007

   Peter,

   "….. the one way ….. to get such a prediction is through …….. this is already falsified (by the lifetime of the proton)"

   Ooooops, did you just say that string theory has been falsified? Consider changing the title of the blog to "Wrong".

   Best,
   Tim

2. **hack**
   March 24, 2007

   Srednicki is really making a fool of himself. History has not looked kindly on people who were sure they knew what was TRUE and didn't see the need to prove it.

3. **Robert Musil**
   March 24, 2007

   Lee Smilin has posted a fairly extensive rebuttal to Srednicki, including to Srednicki's (mis)use of the quote from Smolin's book and Srednicki's suggestion that scientific "TRUTH" can be divorced from falsifiable predictions – with most scientists favoring the divorce. Here:

   http://asymptotia.com/2007/03/13/more-scenes-from-the-storm-in-a-teacup-vii/#comment-34765

   Some excerpts:

   "Dear Mark,

   "Your selective quotation of me badly misstates my position. Not only do I acknowledge that the landscape is a possibility, I invented the idea, named it and was the first to explore its consequences, in papers from 1992 on. My issue, since then has been how we can continue to make falsifiable predictions if the landscape is true. …. I hope my point of view is clear: the landscape may or may not be a real feature of string theory-evidence is that I was right and it is. But if it is we are not relieved of our obligation to test the theory by making falsifiable predictions for doable experiments. There is at least one scenario that stands both as an existence proof that this can be done and as a challenge to observers to falsify. Any newer proposal for doing physics on the landscape then has to do at least this well.

   "Thanks,

“Lee”

4. **tomj**
March 24, 2007

I thought I had included this quote on the previous thread on this subject, but it isn’t there. Probably too long?

Anyway, from pg 22 of Albert Einstein’s _Relativity_:

“We thus require a definition of simultaneity such that this
definition supplies us with the method by means of which, in the present case, he can decide by experiment whether or not both the lightning strokes occurred simultaneously. As long as this requirement is not satisfied, I allow myself to be deceived as a physicist (and of course the same applies if I am not a physicist), when I imagine that I am able to attach a meaning to the statement of simultaneity. (I would ask the reader not to proceed farther until he is fully convinced on this point.)”

My question is that in the case of String Theory, if there are definitions being used, do they satisfy the above requirement? Can String Theorists point to any concept they use, and words they use whose definition includes a method of deciding something significant?

5. **John Armstrong**
March 24, 2007

I agree completely that the debate isn’t about what is true so much as how physics is done. You emphasize the epistemological nature of science as a method of coming to knowledge about the world.

There’s a parallel, altogether dirtier line, though: the debate is about what physics we will choose to fund. The danger isn’t that physics will wander in the Landscape with no guiding stars, it’s that we will spend all of our time (and money!) wandering while we could have spent it on other possible lines of research.

6. **Chris W.**
March 24, 2007

..and of course the assertion of the Landscape’s existence must be TRUE, because its existence follows from principles that we know to be TRUE, right? Just as a reminder, what are those principles again? And how, again, are we to be *assured* of their truth, and *know their proper application and interpretation*?

7. **Chris Oakley**
March 25, 2007

In abandoning Occam’s Razor in favour of brand loyalty to a particular speculative idea Srednicki drives another nail into the coffin of Scientific Method. To take the most optimistic analogy, supposing that Newton had proposed Lorentz Contraction and Time Dilation in 1700. This would be “true”, or at least more true than the dynamics he actually did propose, but with what justification could anyone living then abandon commonsense notions of space and time if they are not presented with a compelling reason to do so?

8. **Peter Shor**
March 25, 2007

When Marc Sredinski writes

> If the landscape is right, we may never get anything more than circumstantial evidence that it’s right. But that’s often the case in science.

what kind of science is he talking about? I wouldn’t think it could be any other kind of physics, chemistry, or biology – the fields commonly referred to as the hard sciences.

9. **Thomas Larsson**
March 25, 2007

I learned something new today from [this comment] of Mark Srednicki’s:

“For example, the string picture of black hole evaporation requires huge violations of macroscopic causality;”

Note the comment by “Elliot” a few lines below:

“If string theory predicts violations of causality, I am not sure this is type of assertion that would lead many “string agnostics” (of which I count myself as a member) to readily adopt the faith. Of all the scientific principles, causality is in my mind one of the fundamental cornerstones. “

10. **Peter Shor**
March 25, 2007

Is there actually a string picture of evaporation of black holes? I have not found any discussion of string theory and the black hole information paradox which looked more concrete than unfounded speculation.

11. **Peter Orland**
March 25, 2007

I think people are getting off track here and criticizing Mark
Snrednicki for something he didn’t say. He never said that the
landscape or even string theory is true. He said that it is
important to get at what is actually true. If you substitute
the synonym adjective “factual” for the word “true” in his
statement, perhaps, what he says seems less controversial.

There are other issues raised by Mark’s remarks, such as making
assertions about other Peter and Lee (which I disagree with), and
how one gets to the facts or TRUTH (which is where issues of falsifiablity are important). He’s absolutely right, however, in that science is about understanding reality, not the scientific method.
The method is only a method, not the goal – it is the proverbial
finger pointing to the moon. There are no rules in science beyond finding out what is.

12. **TCO**
March 25, 2007

Why don't the physicists figure out how to make a room temperature superconductor? And why (if they are so smart, and these problems so trivial) was High Tc found experimentally, rather than with theory or modeling?

13. **Peter Orland**
March 25, 2007

Sorry, misspelled Mark's name above – Srednicki.

Petre Drolan

14. **woit**
March 25, 2007

I don't think I'm criticizing Srednicki unfairly. I reproduced here his argument pretty much completely, and in later comments on the same thread he says that he strongly disagrees with the statement that string theory needs to make falsifiable predictions.

It's kind of absurd that Srednicki is criticizing Smolin for having too rigid a view of science, since, if you read Smolin's book, you'll see that he sees himself in some degree as a follower of the philosopher of science Paul Feyerabend, famous for his "anarchistic" philosophy of science, that there is no fixed "scientific method". Like Smolin I've also read Feyerabend and found myself in sympathy with this sort of idea. Sure, there is no fixed way to get to scientific truths, and all sorts of things should be tried. Personally, I'm partial to a semi-mystical belief that deep ideas about physics and about mathematics go together, so one should try and see if one can make progress in physics by concentrating on the deepest mathematical structures that seem to connect to physics. Other people have reasonable arguments about why this is a dumb idea that can't work.

In the end though, however one gets to it, the crucial thing about scientific truth is not that it is truth, but that the rules of logic together with experimental observation provide convincing evidence that it is truth, evidence that cannot be denied without violating logic or the evidence of one's senses. The current situation, with people like Srednicki promoting the idea that the landscape doesn't need to make predictions in order to become accepted as our dominant scientific theory of the physical world, is really dangerous to science, both internally and externally.

The attitude of Srednicki and too many string theorists these days seems to be that it is all right if the theory turns out to be non-predictive, that what is important is that it "has won out in the marketplace of ideas", i.e. achieved dominance in terms of things like NSF grants and faculty positions. The current situation is that he and others feel comfortable publicly jeering at those, like Smolin, who challenge this notion as "crackpots" (he has admitted to doing this).

I don't think this is about the landscape so much as it is about whether the conventional standard we insist on for recognizing a scientific truth will be upheld, or fall by the wayside because it requires some people to acknowledge failure. I disagree with Smolin about the landscape, but we agree about the crucial point: it has to make convincing, conventional scientific predictions, otherwise it's not science.

15. **matteoeo**
March 25, 2007

Peter Orland,

also bad science has no rules, beyond finding out what isn't. So, how can you distinguish them? I guess you can't or you know somebody upthere that tells you what TRUE is.

16. **Peter Orland**
March 25, 2007

Matteoeo,

I think you misread my message. I said nothing of the sort you
impugn to me (no prophet or messiah I!). In particular, I don't
think I was defending what you regard as bad science, which I
assume is the landscape (I also think the landscape is bad science).
Your question as to how to distinguish good and bad science is an important one, but seems more like a peccadillo directed towards me than a serious remark. But go ahead and metaphorically scream at me some more, if you like. I'm not proud.

Peter,

As you know, I also don't like the prevailing attitudes of string
theorists. I was not agreeing with the purpose of any attack on
you or Lee Smolin. I was just pointing out that one of Mark
Srednicki's points, which he was being criticized for here, was
a valid one. I don't think of scientific facts as TRUE in capital
letters, nor do I think the term has much meaning these days.
It has been abused by religionists beyond repair. In this I think Feyerabend (from whom I took a class at Berkeley) is absolutely right. Nor do I think ideas are scientific if they can't be either verified or falsified.

17. **matteoeo**
March 25, 2007

Peter (Orland),

believe me I'm not screaming at you. Maybe I'm mistaken, but then I don't really understand sentences like "There are no rules in science beyond finding out what is." What is what?

I think just the opposite, that science (from latin cognosco = I know) is the colletion of facts you know because their existence respects a few rules that were formulated long before Feyerabend was born, and that in a way belong to the logic of smart people without necessarily being taught of, al least until they stick up with an obsessive idea and direspect their own logic (but this is normal, since it's very hard to mantain a critical thinking just about anything. That's why phylosophers needed to formulate the Scientific Method as a painful rule). Scientific facts are a representation and a modelling of "what is" but they're not it – unless we embrace Pitagoreans' idea that the world is numbers.

I think it’s very important to distinguish “what is” from “what is knowable”. This is a problem that mathematicians were facing after Goedel’s theorem, and I think QG might encounter similar questions, indipendently of the approach – the AP in the Landscape is an example of that, of a strange and maybe circular overlap of thinking and meta-thinking. But that’s just a silly idea. Anyway something unknown (and unknowable, define it God or whatever) will always resist the attacks of scientists. Would you call that science?

As to Feyerabend, he was a great “dadist” thinker, but I think that his ideas on imaginative and inductive thinking had such great resonance because for half a century almost any field in science improved in a seemingly very fanciful fashion (owing to the technology mostly, which did very quickly “selective pressure”, to use biological comparison *à la* Smolin).

But now I think that String Theory failure is the demonstration that Feyerabend’s ideas are flawed. I almost regard him as (partly) responsible of all this. I know Popper isn’t as appealing, but he might end to be the only guy who really said something correct (besides the no-democracy-suicide statement).

Hope to have convinced you I wasn’t just yelling.

18. **Peter Orland**
March 25, 2007

Matteoeo,

Now that you have stated your position in more detail, I see you have something interesting to say. Maybe you are right that today’s trends indicate that Paul Feyerabend’s ideas are flawed. I’ll have to think about it…

19. **Q**
March 25, 2007

Chris, Newton’s motto, “hypotheses non fingo” (feign no hypotheses), kept him safe. Newton worked *from* data to formulate checkable laws, something that’s fast becoming a heretical approach today, and is the opposite to string theory.

20. **Who**
March 25, 2007

Matteo:
But now I think that String Theory failure is the demonstration that Feyerabend’s ideas are flawed. I almost regard him as (partly) responsible of all this. I know Popper isn’t as appealing, but he might end to be the only guy who really said something correct (besides the no-democracy-suicide statement).

What is the no-democracy statement. I did a search and came up with this quote of Popper:

“Dictatorship is morally wrong because it condemns the citizens of the state—against their better judgement and against their moral convictions—to collaborate with evil if only through their silence… It transforms any attempt to assume one’s human responsibility into an attempted suicide.

March 25, 2007

“I think people are getting off track here and criticizing Mark Snrednicki for something he didn’t say. He never said that the landscape or even string theory is true. He said that it is important to get at what is actually true.”

Well, even that much is wildly off-base. Science does not lead us to truth. At best, science allows us to generate models that, to a greater or lesser extent, are consistent with observation and experiment and allow extrapolation to observations and experiments yet unmade.

I wonder if Snrednicki has ever bothered to think with any seriousness at all about how one might define “truth.”

22. **matteoeo**
March 25, 2007

who,

I think this is a little off-topic here. Anyway I coined the epression no-democracy-suicide to make it short. Popper wrote that in a democracy people cannot vote the end of the democratic regime itself, and for example the beginning of a dictatorship – it might sound obvious but it’s not, it’s based on a logic argument and it would be an interesting task to read modern Constitutions and actually see if there’s some explicit article about this (I know italian has). Very boring reading from Popper, but foundamental, *The Open Society and its Enemies*.

As to QG and strings, I’d like to know if anyone has ever had the feeling I expressed, that there might be some foundamental inconsistency in unified theories, such as in mathematics Goedel’s theorem (and Chaitin’s reformulation), or if you think that there must be a theory, at all costs.

23. **A String Theorist**
March 25, 2007

Well we really have wandered off onto an epistemological tangent, haven’t we?

One of the marvelous things about scientific progress is that our understanding of which questions admit scientific answers evolves over time.

To use a somewhat tired, but very appropriate example: a long time ago there was interest in trying to derive the orbital radii of the planets from some fundamental principle.

Happily we now understand that this particular question is one which science does not, and CANNOT answer. This is NOT a failure of science! In fact, it represents a great triumph of science—Newton’s UNIVERSAL law of gravitation. By giving up the hope for scientific answers to a few of the “old questions” about the particulars of our solar system, we gain in exchange the answer to infinitely many “new questions”—namely the dynamics of any gravitating system anywhere in the universe.

Similarly, and this is the essence of Srednicki’s point: it is a logical possibility that, perhaps, there will NEVER be ANY scientific explanation for “why” the unbroken gauge group of the Standard model is what it is, or why the Yukawa couplings are what they are.

You are still welcome to work on those problems—and if you find a solution, no doubt fame and fortune will certainly be yours! But, again, you must accept the *logical possibility* that no explanation exists.

String theory finds itself in the awkward stage half way between realizing that the “old questions” that people used to be interested in, such as calculating the electron mass from first principle, are in fact unanswerable, and not yet being at the stage where we understand what the correct “new questions” are.

Historically some of the most exciting and productive times in physics have occurred as similar “boundaries” between old and new understanding were crossed.

24. **matteoeo**
March 25, 2007

who,

I’ve read my own post once again and I found that my bad english induced me to an error – I meant “including the no-democracy-suicide statement”, and not “besides”. Sorry for that.

25. **Peter Orland**
March 25, 2007

CD318,

I have a feeling this is getting off-topic, so I won’t blame Peter W. for deleting my comments. I just can’t resist to responding to what you have said about “truth”. As I said above, the term has lost its meaning, but maybe we should try to restore that meaning.

Outside of what anyone said, including Srednicki, Smolin or Woit, you have to be careful when you say science does not lead us to the truth.

If “truth” is something absolute, then it’s a rotten useless string of letters. If instead by “truth”, you mean facts (which are not immutable, but can change) then there is no problem with the term. A model which works well in predicting data is true, even if it doesn’t give us the whole truth.

Even a famous theorem could be untrue if the assumptions are found inconsistent, but I am willing to accept a theorem whose assumptions I accept and whose proof I understand as true. Most of us often use the word “true” in this sense (perhaps even you). Abuse of the term by religious types and even some scientists has led to our reluctance to use it. Perhaps we should try and reclaim the word from the abusers.

No good scientist or mathematician is willing to take for granted that no ideas are right. Newtonian dynamics is right – so why can’t we say it’s true, under certain circumstances.

I think scientists should not feel uncomfortable with refering to scientific facts as true. Otherwise they play into the hands of those who equate science with religion or a only a cultural phenomenon.

Anyway, I won’t say any more about this.

26. **Peter Woit**
March 25, 2007

A String Theorist,

The problem with the string theory landscape is not that it can’t predict the electron mass, it’s that it can’t predict anything at all. Nothing. If it made even one convincing standard sort of scientific prediction (for instance, allowing calculation of some experimentally measurable number to better than 1%, a number not calculable in the standard model), then it would be science. But the evidence is pretty strong now that it can’t do that. What I find remarkable is the way many string theorists and string theory partisans are reacting to this rather conventional sort of failure (it’s not really unusual to find that one’s speculative idea doesn’t work because it doesn’t predict anything). Instead of admitting failure, they’re trying to change the rules of what science is. It’s pretty amazing to see Srednicki and others arguing that a theory that can’t be experimentally tested is a viable scientific theory.

Sure, maybe Yukawa couplings are environmental and we’ll never be able to calculate them. But if you want to claim to be doing science, you have to come up with not just excuses, but some kind of predictions. What is going on now is that string theorists are turning Feynman’s criticism of them: “string theorists don’t make predictions, they make excuses” into a new philosophy of how to do science.

27. **matteoeo**

March 25, 2007

sorry Peters, I can't resist being nasty:

"Even a famous theorem could be untrue if the
assumptions are found inconsistent"

If the assumptions of a theorem are inconsistent (and thus the hypothesis is false), then the theorem is true (Ex Falso Quodlibet). The conclusion might eventually be wrong.

Anyway you can't just renormalize the meaning of words so as to be always in agreement with others. "Truth" as is meant by Srednicki is not "Facts", otherwise we would be talking about SM (as does the string theorist) instead of strings. Scientific facts cannot change with time, their interpretation might.

28. **Peter Woit**
March 25, 2007

Peter,

I didn't say that science doesn't lead us to truth. It certainly does, if there's any meaning at all to the notion of a truth about the physical world (and I think there is). My point is just that what distinguishes science from other human activities is not that it makes claims about what is true, but that it provides a method to reliably discover truths. I find it amazing to see supposedly serious scientists suggesting abandoning this in the case of the string theory landscape.

Religion also claims to lead to truths about the universe, and provides its own methods for getting there: consult the Bible, pay attention to what the pope says when he's speaking ex cathedra, etc. I think it will be very sad if physicists abandon conventional ideas about the scientific method in order to prop up a failed research program.

29. **anon.**
March 25, 2007

'I think scientists should not feel uncomfortable with refering to scientific facts as true. Otherwise they play into the hands of those who equate science with religion or a only a cultural phenomenon.' – Peter Orland

But happens when there is a radical overhauling of a scientific theory? Examples:

'Fifteenth century Europeans "knew" that the sky was made of closed concentric crystal spheres, rotating around a central earth and carrying the stars and planets. That "knowledge" structured everything they did and thought, because it told them the truth. Then Galileo's telescope changed the truth.'

– James Burke, 'The day the universe changed', Little, Brown and Company, Boston, 1986, p.9.

Other examples of 'false truth' abound: vortex atoms were the truth to Kelvin, mechanical aether was the truth to Maxwell, phlogiston, caloric, cold fusion, UFOs, alien abduction, etc., are all truth to cult believers.

The problem is that 'true' has always been emotional and hence poorly defined for science, yet well suited to religion. Critics of such 'truth' sound unreasonably, or immoral:

'What is truth?' – Pontius Pilate (Mark 15:2)

Popularising string theorists make a vague appeal to being the truth without having to actually make any checkable prediction.

30. **Peter Orland**
March 25, 2007

Well I was sort of finished with this topic, but a lot of people are
still respondingto my last comment, implying that I am defending
or attacking things that I am not, respectively, defending or attacking. It's very exasperating. I never said tentative theories (string theory or vortex theory included) should be considered true. I was just answering CD318's comments above about the word "truth".

My last point was just this: are we forbidden from saying
something is true? It all depends on what you mean by
"true". In common usage, the word just means factual.
Most of us say it every day. Are any of you prepared never
to use the word again in day-to-day life? If not, why can't
we use it as scientists? Just because some
people (and not everybody) attach a lot of extra meaning to
it doesn't mean we should. In particular, I think the word
needs to be rescued from those (perhaps some of the people
writing here) who take it too seriously.

Before responding to what you think I am saying, please
read twice.

31. **Peter Orland**
March 25, 2007

By the way Peter, I never implied that you said science does not lead to
the truth.

32. **dark-matter**
March 25, 2007

Come on guys. 21th century and here we are debating about 'truth'. 'Truth' can be defined any way. There are hundreds of truths on any one thing. Science is about being 'correct' A theory confirmed by experiments is correct, yielding correct predictions, the basis of reliable knowledge that have built our modern society. They give Nobel prizes for a theory being correct, not being 'true'. Leave the 'truth' stuffs to philosophers, theologians, etc.

33. **Chris W.**

March 25, 2007

The first sentence of a blog post by graduate student Jo Guldi:

> You might understand or not, but I write farce because I'm not convinced I have a handle, let alone a monopoly, on the truth.

Somehow this seems apposite.

34. **Chris W.**
March 25, 2007

(PS: Note the name of this particular blog.)

35. **Peter Orland**
March 25, 2007

Dark-Matter, isn't the conventional meaning of "true" in everyday usage is the same as "correct"? So why is one word better than the other? That is really all I am trying to say here.

36. **Arun**
March 25, 2007

Physics, then and now

A quote from C.N.Yang, seen by chance, to contrast with the quote from Srednicki.

37. **Jean-Paul**
March 25, 2007

String Theorist — Your argument about planetary orbits is yet another propaganda trick pulled by AP desperados, that appears in the introduction part of all Arkani-Hamed talks (at least of those that I attended). Yes, we do not understand initial conditions for many motions in the Universe, and its not a big deal that we do not understand them for the solar system which is in our nearest proximity. However, you cannot compare this ignorance to our lack of understanding of say electron's mass which is relevant not only in our proximity, but everywhere that we know in the Universe. If you want to consider the solar system at the same footing as the Universe, then you must subscribe to the multiverse faith which puts the solar system and the observed Universe at the same footing, as minuscule parts of a "bigger" story. Blah blah blah…

38. **Changcho**
March 26, 2007

Peter W. wrote: "The attitude of Srednicki and too many string theorists these days seems to be that it is all right if the theory turns out to be non-predictive, that what is important is that it "has won out in the marketplace of ideas", i.e. achieved dominance in terms of things like NSF grants and faculty positions. The current situation is that he and others feel comfortable publicly jeering at those, like Smolin, who challenge this notion as "crackpots" (he has admitted to doing this)."

This is also the viewpoint of people like LuMo. I agree that such a philosophy (if it can be called that) is a danger to science.

39. **King Ray**
March 27, 2007

String theory is no longer a science but a religion.

40. **mclaren**
March 28, 2007

Precisely. Once someone claims that what matters is not whether a claim is testable but whether it is true, we have passed out of science and into the realm of religion.

Did Jesus rise from the dead after he was crucified?

We can't test that hypothesis — but what matters is not whether it's testable, but whether it's TRUE.

Is Mohammed the one true Prophet of God, the only God, praise be to his Name?

We can't test that hypothesis — but after all what matters is not whether it's testable, but whether it's TRUE.

Is the Buddha the one Englihgtened one?

We can't test that hypothesis — but what counts is not whether it's testable, but whether it's TRUE.

This is the kind of self-deluded attitude that led people commandeer a pair of 757s and steer them into the twin towers. Thank you, but I've had quite enough of that kind of mindset.

If a claim is true, provide evidence for it. Otherwise, shut up.

41. **dan**
March 28, 2007

Hey Peter,
Since Lubos deletes your comments, have you considered debating it out over at http://www.physicsforums.com?

http://physicsforums.com/showthread.php?t=162163&page=2

"On the other hand, people like smolin and woit – especially woit – lost their battle in the arena of science long ago and are now trying to win it in the court of public opinion. Their books and comments are clearly meant for lay people who can be easily convinced of anything so that even if they prevail here – and it really doesn`t matter for research in quantum gravity either way – the victory would be a Pyrrhic one at best. Since they`re both no doubt already aware of this, one must wonder why they pour so much of their energy into this campaign of manipulation and misinformation."

42. **tomj**
March 28, 2007

"Precisely. Once someone claims that what matters is not whether a claim is testable but whether it is true, we have passed out of science and into the realm of religion."

This is a common theme, very understandable. But an interesting thing is that the religions that I am familiar with make lots of statements (similar to scientific principles) which can be applied to actual situations. The results can be judged, and the principle can be upheld or diminished. This process is not entirely personal, and therefore has some potential to be scientific. But religions have many facts which can never be verified. Maybe because they are singular events which occurred long ago.

From what I understand, in string theory there are no verifiable facts, at all.

Religion is already about something, maybe wrong, maybe mixed with unverifiable facts, but in general there is some useful advice, verifiable without the need to believe something you cannot test.

But equating string theory as it is being describe with religion, is quite the compliment for string theory.

43. **Peter Woit**
March 28, 2007

dan,

There's a limit to how much time I want to spend debating these topics. That's one reason I wrote the book, to get the case I wanted to make written down in one place. People can read it and judge for themselves.
While lots of string theory partisans are announcing they refuse to read it, quite a few physicists and mathematicians have, and I've been pleased with the response. String theorists were going on a lot at one point about how there was no longer an argument, since their theory had triumphed in the "marketplace of ideas". Now that it's not doing so well there, you hear this argument a lot less….

44. **dan**
March 29, 2007

Well thanks Peter,

Have you considered publishing technical articles in HEP/ARXIV critiquing string theory results such as string theory's derivation of BH entropy?

Peace.

45. **Peter Woit**
March 29, 2007

dan,

Lee Smolin has already done precisely what you suggest. As far as I can tell, his paper doing this (hep-th/0303185) has pretty much been ignored, especially by string theorists. I'm not so interested in quantum gravity, but have thought of writing up the arguments in my lectures in Italy in a more formal way to post on the arXiv. I suspect they would be ignored just as much in that form as in any other, which is an argument for spending my time writing up not that, but other things.

46. **Aaron Bergman**
March 29, 2007

Ignored? Say, rather, disagreed with, for reasons I'm sure you don't want to hear yet again.

47. **Thomas Larsson**
March 29, 2007

math-ph/0603024 more or less disproves string theory. Therein I make the simple observation that the Laurent or Fourier polynomial version of an algebra of gauge transformations is incompatible with nonzero charge unless there is an anomaly. Since nonzero charge evidently exists, and the relevant gauge anomalies in 4D do not exist in string theory, the latter is wrong.

E.g., for conformal symmetry the argument is simply this. If the charge L_0 != 0, then all L_m != 0, because
[L_m, L_-m] = 2m L_0.
Hence nonzero charge implies that there is no "local" part of the gauge algebra which is represented trivially, and unitarity then requires an anomaly. But this argument applies equally well to other gauge symmetries, provided that we consider the Laurent polynomial version of the gauge algebra.

AFAIK, this argument has never been disagreed with, only ignored.

48. **John**
April 1, 2007

"If it made even one convincing standard sort of scientific prediction (for instance, allowing calculation of some experimentally measurable number to better than 1%, a number not calculable in the standard model), then it would be science."

String Theory is Mathematics. Are u saying Mathematics isnt a science?Truth in science HAS to be mathematically consistent. String Theory maybe viewed as some mathematical religion but at least it satifies the law: Thou shall be mathematically consistent. (Unlike pretty much all the other theories proposed).

49. **anon.**
April 2, 2007

"Truth in science HAS to be mathematically consistent." – John

You're not even wrong! See http://www.cgoakley.demon.co.uk/qft/

"The shell game that we play … is technically called 'renormalization'. But no matter how clever the word, it is still what I would call a dippy process! Having to resort to such hocus-pocus has prevented us from proving that the theory of quantum electrodynamics is mathematically self-consistent. It's surprising that the theory still hasn't been proved self-consistent one way or the other by now; I suspect that renormalization is not mathematically legitimate."

– Richard Feynman, Nobel laureate 1965 (quote from Feynman's book, QED).

"[Renormalization is] just a stop-gap procedure. There must be some fundamental change in our ideas, probably a change just as fundamental as the passage from Bohr's orbit theory to quantum mechanics. When you get a number turning out to be infinite which ought to be finite, you should admit that there is something wrong with your equations, and not hope that you can get a good theory just by doctoring up that number."

– Paul Dirac, Nobel laureate 1933

Mathematics is used in science as a tool and language for patterns and quantities.

If a mathematical model for physical phenomena were completely scientific and consistent, it would be the end of scientific research!

50. **Peter Woit**
April 2, 2007

John,

"String theory" (interpreting those words to mean the version of the theory that tries to unify physics) is not mathematically consistent. It has no non-perturbative definition that works, the perturbative definition is based on a divergent series. There's a conjecture that a mathematically consistent definition exists for which the perturbative definition is an asymptotic series, but no one knows whether this conjecture is true.

51. **dan**
April 8, 2007

Peter Woit Says:

March 29th, 2007 at 12:19 pm
dan,

Lee Smolin has already done precisely what you suggest. As far as I can tell, his paper doing this (hep-th/0303185) has pretty much been ignored, especially by string theorists. I'm not so interested in quantum gravity, but have thought of writing up the arguments in my lectures in Italy in a more formal way to post on the arXiv. I suspect they would be ignored just as much in that form as in any other, which is an argument for spending my time writing up not that, but other things.

Peter,
Thanks for sharing this with me, I've looked at it. I infer from reading it that in string theory, spacetime is nondyanmical as it is in GR. Perhaps particle physics can be explained in terms of some for of quantum gravity. Have you had a chance to look at Wen's papers attemping to demonstrate that particle physics and arise as emergent states analogous to the phonon in condense matter physics? i.e http://arxiv.org/abs/cond-mat/0508020 implies that some form of quantum gravity gives rise to particle physics.

Censored Comments From Asymptotia

March 26, 2007
Categories: Uncategorized

Warning: There's not much science in this posting, just mostly people behaving badly. You would be well advised to skip this one, unless you find this kind of thing entertaining…

Long ago, as a public service, I set up a posting to hold comments censored by Lubos Motl, since his preferred way of dealing with people who make comments he finds hard to answer is to delete them. It appears that now a place for inconvenient comments censored by Clifford Johnson at his blog Asymptotia is also needed. If you have a copy of a substantive comment deleted from there or want to discuss one of these, you can use the comment section here.

Since the first thing censored was one of my comments, I'll provide a little background, then reproduce the censored material I have access to.

This exchange began with this comment from Clifford, which seemed to me to be little more than an out-of-control personal attack and rant, so my only response to it was:

Clifford,

As time goes on and the failure of string theory becomes more apparent, you are starting to rant in a manner which is converging with that of your junior colleague at Harvard. You should get a grip.

Not very long after I wrote this comment, the following comment appeared from Lubos Motl:

Dear Mr Woit,

your answer to Prof Mark Srednicki is absurd. The quark theory that Mark was writing about talks about physics at essentially the same energy scale as the effective theories with hundreds of hadrons from the first part of his story, namely hundreds of MeV. Also, the quark theory would be hard to test using the normal experiments at the QCD scale – which is essentially a low-energy scale – because one would have to calculate very complicated properties about bound states of quarks, and there are many of them etc. QCD is only easily testable at higher energies where it becomes weakly coupled.

Mark's gedanken experiment was designed to be isomorphic to the situation of string theory and if there is a difference, then the difference is that the natural scale of string theory is way above the observable scale so that the gap in string theory is greater than in the nuclear story, not in the other way around as you incorrectly wrote. Every physicist who has read Mark's comment knows it and understands it. The only reason why you argue that there is a significant difference between the two examples is that you don't understand how these theories actually work.

The fact that you find quantum gravity uninteresting is not surprising for me at all. At any rate, the key arguments – the mathematical robust ones – about questions such as the information loss came from string theory and everyone who was interested in these things – such as Stephen Hawking – knows this, too. Hawking admitted that the information is preserved primarily because of the AdS/CFT correspondence.

Concerning the anthropic principle, every scientist who has a sufficient talent and who has looked into it understands that there have emerged all kinds of reasons – not just pure string theory research – to think that the anthropic picture could be correct which is why this possibility must be seriously investigated, together with other possibilities. The people who are completely ignorant about everything could of course share your simple-minded and radical opinions but I think it would be a very bad idea if the people who are ignorant were deciding about the direction of the research done by the people who are not ignorant. You are effectively confessing that your goal is to manipulate people who can be easily manipulated – because they know nothing about the current state of knowledge in high-energy physics – and use them as a political force. I think it is deeply immoral and unscientific.

Dear Clifford, your value has increased in my eyes after the individual above compared you to me!

All the best
Lubos

This was followed by a similar comment attacking Smolin for what he had written about the black hole information paradox, and Smolin responded with a short and polite answer (I don't have copies of these).

Clifford has edited my original comment, removing "in a manner which is converging with that of your junior colleague at Harvard", and replacing it with "…snip … – personal reference deleted -cvj". He has also removed the comments from Lubos and the response by Smolin, replacing them with this comment. Here he claims to have deleted these comments without reading them, since, for undisclosed reasons, he has a policy of deleting all comments from Lubos. Whatever the reason for this policy, he does want to make clear to everyone that he has a high opinion of Lubos as a scientist, and for his work at the Reference Frame "widening the discussion" about physics:

Since I have a great deal of respect for his ability as a physicist, however, if he was making a physics point in his comments, perhaps he might make it on his blog and link to this discussion via trackback. I thank him for his physics contributions and widening the discussion.

Comments

1. **Chuckles**
   March 26, 2007

   You are quite correct of course; as demonstrating things to be true, or deduction from axioms and postulates is the province of mathematics and hardly that of science – even less of the wildly speculative endeavor in physics known as string theory. Perhaps Johnson misunderstood your point. Though how he could have is beyond me – since you pointed out so generously that logically consistency is hardly the defining feature of good science.

2. **Ari Heikkinen**
   March 26, 2007

   "I thank him for his physics contributions and widening the discussion."

   Heh, I thought his main contributions have been to denounce most of his colleagues (other than string theorists) as crackpots, idiots or otherwise incompetent people (kind of strong claims considering when you walk in say any city and look around there isn't anything that would have anything "string theory" in it).

3. **Chris Oakley**

March 26, 2007

I am posting this comment in the hope that it will be deleted, along with the other comments, and remainder of the post. Sorry, Peter, but I am sure that you have got better things to do.

4. **Hmmm**
March 26, 2007

I question any self respecting scientist whose policy it is to leave up a Lubos comment…..regardless of what is says.

5. **Nigel**
March 26, 2007

The following sentence among others 'snipped for brevity' from my comment http://asymptotia.com/2007/03/23/questions-and-answers-about-theories-of-everything/#comment-34707

'What's completely unique about string theory is that it has managed to acquire public respect and credulity *in advance* of any experimental confirmation.'

I'm not upset about this. It should have been written differently:

'String theory is completely unique in science because

(1) it's based entirely on unobservables (unobserved spin-2 gravitons, unobserved supersymmetric partners for all observed particles for unobserved unification near Planck scale, unobserved extra dimensions, unobserved branes),

(2) it fails to predict anything checkable after decades of research,

(3) it is hyped and celebrated *in advance* of success.'

6. **Peter Woit**
March 26, 2007

Chuckles,

Yes, that was my point. One can have rigorous theorems telling one about the properties of the mathematical formalism one is using to model the real world, but you can't have a "theorem" about the real world. You have to do experiments to test whether your formalism accurately models the real world.

7. **tomj**
March 26, 2007

It seems to me that the problem is exactly in widening the discussion. Maybe the tipoff should have been wide terms like 'theory of everything.' There is no method to distinguish what is in or out, that very idea seems to be the only thing not accounted for in the 'theory of everything'. Maybe string theory is 'wide science', much better than exact science.

8. **Peter Woit**
March 26, 2007

Nigel,

I don't want to encourage you or others to write repetitive critical comments about string theory either on Clifford's blog or elsewhere. If you do this on my blog I'm likely (depending on how busy I am…) to delete it, so I certainly don't criticize Clifford for deleting this kind of thing from his.

9. **Theo**
March 26, 2007

Surely the "great deal of respect for his ability as a physicist" comment referred to Smolin, who was the most recent antecedent?

10. **relativist**
March 26, 2007

"… he has a policy of deleting all comments from Lubos". Seems eminently sensible to me. Greatly improves the tone of the discussion.

11. **DB**
March 26, 2007

Theo,
I think Clifford's comment refers to Lubos, not Lee Smolin, as it goes on to mention "his blog". AFAIK, Smolin does not have a blog.

12. **Carl Brannen**
March 26, 2007

What I've been surprised by him in the recent tempest has been his willingness to criticize books that he's never read based on his reading of comments made by people who also refused to read it. I'm amazed that Clifford puts up with me as much as he does. Maybe it's because I'm a big Clifford algebra fan.

I might as well ask for you to add LaTex in comments like Clifford has. (Makes whining sound.)

13. **Peter Woit**
March 26, 2007

Theo,

It's quite clear he is referring to Lubos, not Smolin, partly because of the reference to the blog (Lubos has one, Smolin doesn't).

Despite repeated attempts, I never was able to get Clifford to criticize in any way Lubos's behavior as a string theory defender of the faith. It seems he approves of that, just can't tolerate what he sees as Lubos's racism and sexism. Many string theorists seem to find Lubos very sound when it comes to physics, a crackpot on other topics.

Personally I find him rather consistent.

Carl,

There is LaTeX in the comments (if not in the preview), but I'm a much less tolerant guy than Clifford when it comes to off-topic comments, even if they are about one of my favorite topics, Clifford algebras.

14. **LDM**
March 26, 2007

I tend to agree with Chris Oakley …

HOWEVER, Blogs are a new phenomena…and as many people put stock in what they read in blogs (not just physics blogs for that matter), there could be some real value in a site that tracks deleted comments to Asymptotia otherwise you can get this mechanism:

1) Somebody (a journalist?) searchs Google , finds Blog A
2) He finds some statement on Blog A that answers his query
3) Accept this answer as fact because he found it on the internet (sad, but this happens)

…but, now add:
4) Peter's proposed site would presumably show up in a Google search and thus be a partial remedy to 3)

Granted, this may not be Peter's original motivation, but such a site would be useful.

15. **John Baez**
March 26, 2007

I find it a bit tendentious to use the term "censorship" to describe what people are doing when they delete unwanted comments on their blogs. Maybe it's true according to some definitions of this term. But, at least in the United States, "censorship" has a connotation of "violation of the First Amendment right to free speech". This right is not violated when Prof. X deletes Prof. Y's comments on Prof. X's blog — just as it's not violated when a newspaper refuses to publish a given letter to the editor.

Of course, it's somehow more annoying to put a comment on a blog and then have it deleted, than it is to submit a letter or article for publication and not have it accepted. It's there — *and then it's gone! Censorship!!!*

This annoyance is part of the price we pay for a quick exchange of comments. The older, slower system of moderated newsgroups was closer to newspapers, where articles must be accepted for publication before anyone sees them.

But even in the old days, when I was moderating sci.physics.research and I'd refuse to accept an article, I'd sometimes get accused of "censorship". I found that a bit tiresome. Hence this mini-rant.

Go ahead — censor me. 🙂

16. **Peter Woit**
March 26, 2007

Hi John,

The "censorship" thing here is a bit tongue-in-cheek, maybe I should put smileys in there or something. Like you I've had all too much experience trying to moderate on-line discussions, have done plenty of "censoring" in my time, and think a certain degree of it is healthy and necessary.

This posting isn't really about "censorship", but just a little documentation of Clifford Johnson's behavior, which a few people fanatical enough to follow the details of some of these obscure battles in the string wars might want to know about (didn't you read the "Warning" at the top?)

Personally I thought it was pretty funny late last night, when, after responding to Clifford's Lubosian rant ("Do you actually teach any young people physics? Or any science? I dearly hope not.") by pointing out that it was, well, Lubosian, Lubos immediately wrote in with more of the same and a message of support for Clifford. Clifford's reaction to this, deleting my comment, claiming not to have read Lubos's, and praising him for his talents as a physicist and for "widening the discussion", was, as he says, priceless. I couldn't help myself, I had to share.

I keep telling people my next book is going to be a comic novel, cut and pasted from various blog entries and e-mails. I really need to keep this material somewhere….

17. **roy**
March 26, 2007

I really do think that you're making a fuss out of nothing here. Clifford is perfectly correct in removing personal attacks. If he does not do that consistently you could accuse him of hypocrisy though. Otherwise I think these string discussions are becoming more and more like pointless rants; someone–all of you– need to drag it back squarely to physics. It is not nice to see scientists wallow in this sort of personal attack laden filth. And Lubos should be kept away from all discussions– he is simply incapable of writing anything without insulting someone, and it seems, people like to write equally silly things about him.(Including probably this comment!) That said, I don't see why he should not be respected as a physicist. His papers are all right.

Please, please, all of you, get back to physics and mathematics and stay there. Much nicer that way.

18. **Peter Woit**
March 26, 2007

Roy,

Clifford is not "removing personal attacks", he is making them ("Do you actually teach any young people physics? Or any science? I dearly hope not."). You could ask him, but I'm pretty sure the reason he removed Lubos's comments (which were similar in tone to his own) had nothing to do with them being "personal attacks", but because he feels that Lubos is a racist and sexist (and it's pretty embarassing to have someone like that appear on one's blog, behaving in much the same way as oneself…).

19. **Roy**
March 26, 2007

I agree Peter, Clifford should have removed that bit as well. It was nasty and personal. I think in general it would be a good idea if people could simply control their tempers. I'm not taking any sides here– too many people are looking at this thing as something of a trench warfare.

On Lubos, even if Lubos weren't sexist or racist, he should be prevented from spewing his juvenile rants on anything. He has an uncanny ability to reduce a discussion to a brawl. That alone merits removal of his comments. One should perhaps give Clifford a benefit of doubt on the Lubos point.

All I am trying to say is that people should be a bit more respectful when in a scientific discussion– after all this is not, and should never be, personal.

20. **Peter Woit**
March 26, 2007

Roy,

I do agree with you that personal attacks don't belong in scientific discussions. When people start making them, it's often a sign that they're on the weak side of the scientific argument. I'm sure I've too often responded intemperately to a lot of the attacks that have come my way, I wish I had the much more even-tempered demeanor of Lee Smolin, who manages to respond politely no matter what sort of abuse he is subjected to.

But I really do wish people would read my warning, and only those who enjoy this nonsense would bother to pay attention to this posting.

21. **Chris Oakley**
March 27, 2007

Peter,

Since the post is still here, let me expand on what I was saying earlier, probably supported by LDM above. The battle (deflating ST hype) is won … when journalists write something about String Theory now, they generally call you or Lee Smolin up for the "sceptical" view. They did not do that before. The only purpose served by getting into pissing contests with String Theorists in the blogosphere is in getting them to reveal themselves as more crazy than those who criticise them. With Lubos that battle also is won. With the others I really do not think it is not worth the extra stress. Far better just to keep us updated on what is happening in the world of physics, plus your own efforts to use representation theory to solve QFT problems. I personally am sceptical of the latter, so prove me wrong!

22. **woit**
March 27, 2007

Oh no. If you don't find this entertaining Chris, it looks like I've lost what I thought of as my hard-core audience.

OK, no more. Off to Princeton to learn about the latest developments on the representation theory and QFT front….

23. **Chris Oakley**
March 27, 2007

For a blog to be good it has to be entertaining, informative, or both, and Not Even Wrong normally scores highly on both. I still savour the discussion about galactic-scale superstrings. The background noise here – which was considerable – mostly only enhanced the entertainment.

24. **tomj**
March 27, 2007

The Clifford post had this statement: "No-go theorems (and things in that spirit) are often the starting point for wonderful discoveries in science."

I've been wasting my time reading Einstein's _Relativity_, which says something of the antithesis of this. I'll quote in a second, but I just want to also ask if Peter believes that physicists don't have theorems, or if theorems are the same as theories? My concept is that we start with observation. This leads to speculation and maybe curiosity and prediction and more focused observation. Maybe a theory falls out. This is a process known as the scientific method. String theory, as described here and everywhere is stuck somewhere in this loop, but has never completed even one cycle, there is no feedback as of yet. So we have to have a theory to advance beyond where we are, but how to advance? Shouldn't we start with data which doesn't fit our current theory, or some principle which is easy to verbalize or quantify which could be applied to current theory. For instance, the anthropic principle doesn't fall into this category because there is no unexplained data, and it isn't clear how to apply it to current theory.

The quote from _Relativity_ (pg 66):

"No fairer destiny could be allotted to any physical theory, than that it should of itself point out the way to the introduction of a more comprehensive theory, in which it lives on as a limiting case."

The link between current theory and a future theory must be done via the clear statement of some principle. It is speculation if the principle is useful. But the starting point should be the immediate recovery of the current situation. It should explain why we are deluded to think our current theory is incomplete. There must be some benefit, maybe even some beauty.

I'm not sure why anyone has to understand string theory to ask for the principle upon which it is speculated to rest. It is like being given a map but not knowing where you are on the map.

25. **amused**
March 28, 2007

Peter, don't worry, some of your audience finds this stuff most entertaining. We want more! 😉
If stringers sling mud at you it is perfectly natural and appropriate to sling some back…

One thing I find striking in these "discussions" is the contrast between the knee-jerk reactions and simplistic views/arguments of the younger hard-core stringers (Aaron Bergman is an exception)
and the more reasonable, balanced and intelligent responses of senior stringers such as Polchinski and Harvey. Anyone have a theory for why that might be?

26. **Peter Woit**
March 28, 2007

amused,

Glad to hear someone else is amused by the spectacle. That people who consider themselves among the smartest in the world would behave this way and make these kinds of arguments seems to me quite a fascinating part of the human comedy.

People behave very differently in the face of legitimate criticism, a lot of this is just differences in character and emotional makeup. But string theory fanaticism does seem to be at its worst among the young. Lubos, Clifford and Jacques have spent their entire professional lives during the period of string theory dominance, trained in the subject at the heights of enthusiasm for the theory. I think they have a real problem even conceptualizing the idea that some of the core beliefs they were inculcated with could be wrong. To them, anyone claiming that must clearly just be ignorant, or not have learned the subject as well as they have.

Older people trained during the height of enthusiasm for gauge theory may often have more of a perspective on all this. Another factor sometimes at work is that, at least for some people, as they get older they get a bit wiser, and less often act like jackasses.

27. **Leonard Ornstein**
March 28, 2007

A scientist ideologically may be a 'Platonist': one who believes reality can be modeled by an ideal, yet-to-be-discovered set of absolutely TRUE, mathematical 'laws', which will exactly describe what can be observed;

or a pragmatist: one who looks at models as provisional guesses, that ALWAYS must depend upon realty checks.

Cliff Johnson and Mark Srednicki construct arguments that make it appear that they're Platonists…but not all of the time. If they were, it would be easy to see the source of their chagrin with critics of ST, and there wouldn't be much point in arguing the matter further.

I tried this out on them, on Questions and Answers on the Theory of Everything-Asymptotia #36. I wasn't censored…but drew no response!

(I was "trained (even before) the height of enthusiasm for gauge theory.")

28. **King Ray**
March 28, 2007

There is no doubt that string theorists are very intelligent, however they lack physical intuition, an aesthetic sense of beauty and simplicity, and are not independent thinkers (how could so many independent thinkers all think the same way?).

Einstein always felt that his greatest assets were his nose (physical intuition), his sense of beauty and simplicity, and his ability to think independently.

You could be the greatest machete brush clearing person in the world, but if you always go off in the wrong direction in the jungle, that is not going to help you. Your ability will just allow you to get further off track more quickly.

29. **JC**
March 28, 2007

Peter,

Do you remember any prominent bootstrap analytic S-Matrix old timers, being really vocal about string theory after 1984? (I can't think of any offhand). Folks like Geoff Chew seemed to be relatively silent on the subject of string theory.

30. **Nigel**
March 28, 2007

'I don't want to encourage you or others to write repetitive critical comments about string theory either on Clifford's blog or elsewhere.' – Peter Woit

My point is how *unique* string theory is in being the world's only grossly celebrated failed theory! Clifford earlier made the repetitive statement that string theory is *not unique,* so the controversy over it *could equally apply broadly in academic science to funding problems facing any non-mainstream projects*.

This is false since every other known mainstream theory in science has some kind of evidence behind it!

Therefore, it is a new point – not a repetitive criticism – that string theory is the *only* known example of a mainstream theory both unfounded on experimental fact and unable to produce checkable predictions, *existing anywhere in science*. Even the mainstream model of cosmology, the Lambda-CDM, is an ad hoc a fit of general relativity to the observed data, which is checkable to a certain extent by extrapolation and new data coming in. String theory is not even an ad hoc way to explain the standard model of particles, gravity or the small cosmological constant. It's a religion.

Has anybody ever emphasized before how *unique* the mainstream string theory crisis is? If string theorists do succeed in changing the definition of 'science' to mean uncheckable mainstream speculations about 'truth', this might infect science widely, supporting the merger of religion and mainstream science.

31. **Peter Woit**
March 29, 2007

JC,

By 1984 it was 20 years after the heyday of the bootstrap, and the kind of string theory and mathematics being used was completely different than the analyticity techniques of the bootstrap, so the two things had little to do with each other.

On the other hand, the younger people who during the late 60s and early 70s worked on dual models and early versions of string theory were quite enthusiastic about the rebirth of string theory after 1984 (Veneziano, Susskind, Mandelstam, Kaku, etc., etc….).

32. **adam**
April 2, 2007

I notice that Motl's wikipedia page is again up for deletion. Also that it appears that a mention of Motl can get comments deleted elsewhere or, at least it seemed that way to me when I made a reference to him in a CV comment that seemed to get deleted. But maybe I am just senile and forgot to submit it, or there was something else in my post that was so offensive that it Could Not Stand. Given the 'he who must not be mentioned' type of references in comments in, say, Chad Orzel's April Fool's blog entry, I guess that I just missed some collective attempt to starve Motl of the 'oxygen of publicity'.

I agree with John Baez that deleting blog comments isn't the Crime of the Century; it is, after all, that blogowner's own sandpit. I am not sure what is achieved by deleting all of Motl's comments, however; he might be considered to be unpleasant by many but his manner is not generally as offensive as his ideas (some will feel that that's damning with faint praise), although he is rude.

I personally find Motl's attitude to people that question string theory irritating: he appears like a 'You puny humans, YOU CANNOT UNDERSTAND!' movie villian. His social and political opinions, which I generally don't share, he is generally prepared to debate openly and in a more considered fashion, it seems to me. Clifford may have his objections the wrong way around, if it really is for Motl's beliefs that he's deleting the comments, rather than for the way that he expresses them. I don't know what Clifford's thinking, however. I certainly have no idea what Motl's thinking.

33. **Peter Woit**
April 2, 2007

adam,

Deleting comments, not just by Lubos, but by anyone who mentions his existence, I think is a tactic designed mainly to deal with the fact that he is a huge embarassment to string theorists, an embarassment that they would like to hide and eliminate any reference to. There is a case to be made for automatically deleting Lubos's comments because of his behavior, but I don't see the case for deleting comments that refer to this. The guy is a major figure in the string theory community, with many people in it having a high opinion of him, and not seeming to have a problem with his behavior. Two out of three of the very recent string theory textbooks carry Lubos's endorsement on their covers, a fact which speaks for itself.

Clifford Johnson makes it pretty clear that it's not Lubos's tactics in arguing for string theory that he has a problem with (he allows personal attacks in his comment section, often anonymous ones, engages in them himself, and writes approvingly of others). He goes so far as to praise Lubos as a physicist and thank him for "widening the discussion".

34. **adam**
April 2, 2007

Peter: It's a damn good thing that William Shockley never had access to blogs. He'd probably feature pretty high up anyone's* 'evil winners of the Nobel Prize in Physics' list.

If Motl really does get comments deleted because his other opinions are embarassing to people in his field, that's pretty silly. There have always been nasty or otherwise unloveable people in physics and every other area of human endeavour. One thing that is genuinely interesting to me about the string theory debate in which you are engaged is that the phony politeness (at least in the public eye) of the academic physics community is evaporating somewhat as the debate heats up. I know that there have been hot debates before, but this is the first one where I've met some of the combatants (rather briefly, in most cases, and not including yourself or Motl).

*Anyone except Motl, perhaps.

35. **Peter Woit**
April 2, 2007

adam,

The nature of the debate certainly has been an eye-opener about human nature. Especially seeing someone mild-mannered like Clifford Johnson descend into irrationality, Lubosian attacks and ranting as his view of the world is threatened has been something amazing to watch.

The number of people involved is still a small fraction of the string theory community, and the attitudes of most of the string theorists I know (adjusting for how likely they are to be polite in what they say to me) seem to be pretty different. While they're not happy about my activities, and annoyed especially at some of the unfair public criticism that has come their way because of this, they're well aware that string theory has serious problems and is not doing well (some are willing to characterize the field as "in crisis"). I've not run into any string theorist who, in private conversation, has told me that he thinks string theory research is doing fine.

Princeton Workshops

March 26, 2007
Categories: Uncategorized

Last week Princeton hosted a workshop on [Physics at LHC: From Experiment to Theory](). Many of the slides of the talks are available [here.]() The talks covered a wide range of ground, from theory not obviously relevant to the LHC to reports on the status of experiments. The talk by Michael Tuts of ATLAS reports that they may be roughly 5 weeks behind schedule, with nominal schedule setting the start of beam commissioning at 450 GeV late in November. 7 TeV beams won't be available until summer 2008, with first physics run perhaps in July, and about 10-100 pb^{-1} during 2008, giving similar statistics to what the Tevatron has today for some processes. It looks like it may be the 2009 run that will most likely produce data that will go beyond the Tevatron results, although if the Higgs mass is about 150 GeV, there may be evidence in the 2008 data. Plans for a luminosity upgrade in 2015 are already proceeding.

There was also a plan for a meeting of the String Vacuum Project at the workshop, with a discussion paper available [here]() (via their Wiki).

This week, also down in Princeton, but at the IAS, there will be a [Workshop on Homological Mirror Symmetry and Applications](), mainly devoted to recent work on geometric Langlands and its relation to mirror symmetry. Since I had to teach I couldn't make it down there today, so unfortunately missed the first talks by Kapustin and Witten, as well as that of Edward Frenkel, but I'm looking forward to going down tomorrow and maybe later in the week to hear some of the talks.

Comments

1. **Robert Musil**
   March 28, 2007

   So, what happened?

2. **Peter Woit**
   March 28, 2007

   Nothing too exciting to report I fear. I attended the talks by Witten, Kapustin and Gukov, which were just about the Witten-Kapustin and Witten-Gukov papers, not something newer. The Witten and Gukov talks were exceptionally clear. In both the Kapustin and Gukov talks, Witten was in the audience and often ended up being the one to respond to questions from other audience members.

   Witten was mainly talking about 't Hooft loop operators. He tried to jazz things up a bit by telling the mathematicians that studying moduli spaces of bundles in 2d using a 4d QFT was a way of dealing with a problem that they knew, that you have to think about not just the space of bundles on a Riemann surface, but the stack (geometric Hecke operators need to be defined using the stack). He also referred to the construction of the 't Hooft loops as a "categorification".

   I noticed few physicists there; the physicists in Princeton don't seem too interested in following Witten into this area. IAS math will have a whole program next year which will include more activity in this area.

   As always, lunch at the IAS was excellent, and many interesting people there to talk to.

3. **Robert Musil**
   March 28, 2007

   Peter,

   I'll be very interested to hear what comes of all this by the end of the week. As I mentioned previously, I'm no expert in Geometric Langlands, but I'm not aware of any spectacular results that have come out of this project to date. Of course, there are lots of indications (even to a non-specialist such as myself) that the project has lots of promise and talented researchers.

   But my impression is that the GL project was mostly interesting for its intriguing promise, not its existing results. More specifically, here's an outline of my understanding:

   Many attempts have been made towards a proof (or good understanding) of original Langlands conjecture, which of course applies to number fields. Those attempts have for the most part met with very limited success (one might say, that they've mostly "hit the wall"). My impression is that most of the researchers focusing on the original Langlands conjecture have come to believe that we're laking some essential geometric idea. So far, some new geometric ideas have emerged from the Geometric Langlands project – but these are ideas that pertain with some success to the function field case. However, I am not aware of a real, complete proof even in that case. Nevertheless, the ideas seem real, new and potentilly powerful, which is what I have understood to have generated high expectations for Geometric Langlands – expectations which may or may not be fully warranted.

   All that being said, I am not aware of any significant role played by Homological Mirror Symmetry in any of these new and promising geometric ideas – at least the ones that I have heard about.

   Am I wrong about the existing state of GL? Is some exciting new idea in Geometric Langlands predicated on Homological Mirror Symmetry expected to be revealed in this workshop?

4. **Robert Musil**
   March 28, 2007

   Just to be clear:

   My comments above contemplate Gaitsgory's fine work as well as the suggestive papers of Kapustin and Witten (Electric-Magnetic Duality and the Geometric Langlands Program) and Hausel and Thaddeus (Mirror symmetry, Langlands duality, and the Hitchin system). Thanks.

5. **Aaron Bergman**
   March 28, 2007

   I can talk a little bit about the role of homological mirror symmetry in geometric Langlands (although I'd probably be better off letting DBZ do it :)). In the physics formulation of the conjecture, one ends up with a mirror symmetry between the A- and B-models on certain Hitchin moduli spaces. This is in contrast with the mathematical conjecture which is an equivalence between categories of sheaves on the contangent bundle to Bun_G and D-modulies on Bun_Gdual (or something like that). To get that, Witten and Kapustin give some physics arguments that the A-model on a contangent bundle gives rise to D-modules on the base. I think this is a new idea (obviously, it is presaged somewhat by the work of Hausel and Thaddeus). Along the same lines, I don't think people had been aware that geometric Langlands has the structure of a 4D TQFT. On the math side, the connection between A-branes and D-modules has been proved in certain cases by Getzler and Nalder and Nadler. In the general situation, however, I think there's a lot more to be said, however, especially in regards to worldsheet instantons.

6. **David Ben-Zvi**
   March 28, 2007

   Robert,
   There are many things to say about your question, but I think it's
   quite fair to say

   1. the original Langlands program is doing spectacularly well, and is far from stuck at a wall.
   2. there are spectacular applications to representation theory as well as to the classical Langlands program that have come from geometric Langlands ideas.
   3. there are strong connections between geometric Langlands and
   homological mirror symmetry, at least the hyperkahler version thereof.

   I don't feel qualified to say much about 1, other than
   to mention Richard Taylor, Michael Harris and many others working in that area and proving fundamental conjectures in the area since
   Wiles' breakthrough – a recent meeting in Luminy on
   Langlands program left the uninformed spectators (eg me) in complete awe at the astonishing rate of progress in the area.

   For 2 I would focus for example on the work of Bezrukavnikov and collaborators, and that of Ngo and Laumon. Roman B. (together with Mirkovic, Rumynin, Ginzburg, Arkhipov, Finkelberg etc)
   has been proving a host of conjectures in "classical" representation theory, or what you might call Lusztig-world, in particular
   Lusztig's conjectures tying modular representaitons with
   representations of quantum groups or affine algebras. Also there's a profound understanding of (affine) braid group actions on various categories coming from this work of Roman that relates to many geometric problems, and work of Bridgeland and others.

   One of the most exciting things is the work of Ngo. Ngo was able to look at one of the fundamental geometric aspects of geometric Langlands, the Hitchin fibration, in a brand new way and use it with Laumon to prove the fundamental lemma for unitary groups (and maybe soon for other groups) — this being one of the central problems in the CLASSICAL Langlands program.
   There are a bunch of other concrete consequences of geometric
   Langlands ideas outside of its internal problems, but that's maybe enough for now.

   Finally for 3 I would point (besides the papers you mention)
   to the work of Donagi-Pantev, in which geometric Langlands
   is proved (in a certain degenerate limit, on an open subset)
   using T-duality (Fourier-Mukai transforms). I would also point
   out the work of Nadler and Nadler-Zaslow connecting Fukaya
   categories on cotangents to constructible sheaves,
   a key step in bridging the homological mirror symmetry
   picture of Kapustin-Witten to geometric Langlands.

7. **Aaron Bergman**
   March 28, 2007

   (Damn — why do I always confuse Getzler and Zaslow? Apologies.)

8. **A.J.**
   March 28, 2007

   Aaron,

   What do you have in mind about the worldsheet instantons? I thought they were supposed to be trivial?

   While we're on the subject of vague geometric Langlands speculations, I've always wondered what's supposed to happen to twisted N=4 at large N. Is there any sort of AdS dual theory?

9. **Robert Musil**
   March 28, 2007

   David –

   Many thanks for your very able and enlightening thoughts. That's a lot to think about, which I will try to do. Thanks again.

10. **Robert Musil**
    March 28, 2007

    Aaron –

    I also appreciate your thoughtful and reasonable response, which I am also going to try to think about.

11. **Aaron Bergman**
    March 29, 2007

    Hi AJ —

    I'm not sure I'm remembering this correctly, but I think the issue is the composition of cc – cc – A strings. There are no instanton contributions to the cc -cc strings or to the cc – A strings, but there might be to the composition law.

12. **Peter Woit**
    March 29, 2007

    Thanks David!

From many conversations with my colleagues here at Columbia, I can vouch for the fact that experts think that there have been big advances in the classical Langlands area during the last year or two, especially Taylor-Harris on Sato-Tate, and Ngo-Laumon on the fundamental lemma.

It also seems to me that there has been an increase in the interest of the rest of the math community in geometric Langlands ideas, and this is not just due to Witten's work and the relation to mirror symmetry. The connections to other subjects that David mentions have been part of this, as well as efforts by him, Ed Frenkel and others to make these ideas more accessible. A few years ago the widespread perception was that you had to speak Russian and hang out in Hyde Park to have any hope of understanding anything about geometric Langlands, but that has definitely started to change.

13. **Robert Musil**
March 29, 2007

Peter, Aaron and David –

A first, partial thought:

I don't mean to be harsh or dismissive, but my impression of the work concerning the relationship of mirror symmetry to geometric Langlands is that these papers strongly resemble the physics literature in this area: Written as fast as possible and largely motivated to stake a claim. Lots of claims to have "thrown up bridges" and the like, without too much in the way of bridge engineering detail. Of course, it is entirely possible that some of these ideas will yield real progress, but (for me, at least) it's far too soon to tell at this point in time.

I'm still thinking about your responses.

14. **Peter Woit**
March 29, 2007

RM,

My colleague Michael Thaddeus (with Tamas Hausel) was investigating this example of mirror symmetry several years ago, motivated I think partly by the hope that the Strominger-Yau-Zaslow picture could be worked out in this case, partly by the connection to geometric Langlands. That work was pretty standard mathematics, no connection to physics.

The more recent Kapustin-Witten and Gukov-Witten papers really are written from a physics point of view, and I think it's up to mathematicians to ultimately figure out how much insight they provide into the mathematics. This is not easy, given the very different point of view, grounded in difficult aspects of QFT. There have been amazing mathematical successes coming from this kind of activity in the past (Seiberg-Witten, knot invariants, counting curves on threefolds, etc.), we'll see what this leads to. I agree that it's still unclear…

15. **David Ben-Zvi**
March 29, 2007

I don't think there's anything tentative at this point
on the relation between geometric Langlands and T-duality.
Not being a physicist I can't vouch for the relation of this particular
T-duality with mirror symmetry, but Kapustin-Witten explain
it is precisely a hyperkahler instance of mirror symmetry.
From the math point of view if we take homological mirror
symmetry as our reference point, then geometric
Langlands is very close to fulfilling that requirement:
it relates B-branes on one space to D-modules on the dual.
Now you have to decide how close D-modules are to A-branes,
and that's a big part of the argument in K-W, and on
the math side is the topic of Nadler&Zaslow's work.
Unfortunately we don't yet actually have a definition of the category of A-branes outside of the Lagrangian objects (Fukaya category)
so it's hard to ask the question, but there's no doubt
the two are very closely related.. I'm not surewhat else you would
look for as "real progress"..

16. **Robert Musil**
March 29, 2007

David and Peter-

I'm not ignoring your most recent points, but one of David's earlier points is in my mind right now – and there's not that much room up there. I think it is unquestionable that Taylor-Harris, for example, represents real and tremendous progress in establishing the Langlands conjectures for local fields. But establishing the Langlands conjectures for local fields may (in my opinion as a non-specialist) be best viewed as finally making the global conjectures precise. That formulation is a kind of progress on the global case ("real" number field Langlands). But I think it is highly unlikely that Taylor would say that establishing the global conjectures (as now more precisely defined) has been moved significantly closer by his or anyone else's work under discussion.

17. **woit**
March 29, 2007

RM,

I believe you're thinking of earlier work by Taylor-Harris, not the recent Sato-Tate work I was referring to. I'll leave it to people more knowledgable than me to comment on the significance of their local Langlands stuff, but the recent Sato-Tate results are for number fields, not local fields. In my pitiful understanding of the subject, they generalized Taylor-Wiles to symmetric tensor powers.

18. **Robert Musil**
March 29, 2007

Peter –
Well, OK. Sato-Tate pertains to global fields and generally fits into the original Langlands program. But so does the Taniyama-Shimura theorem – and I think it's going rather far to view Taniyama-Shimura (and Fermat?!) as essentially features of the original Langlands program. The original Langlands program is vast and visionary, bold and sweeping. But – again speaking as a non-specialist – I don't think it's best practice to see all progress made in any area of mathematics the Langlands program touches

as significant progress in
the establishment of non-abelian global calss field for number fields
.
This all reminds me of a quip recently made by an Anglican bishop following some nasty theological dust-up at a bishops' conference that pretty soon even the Ayatollah might wake up and find that he's an Anglican!

19. **Robert Musil**
March 29, 2007

Peter –

I'm sorry if this post is redundant, but I'm concerned that my last one was obscure (in part, but not totally, because of its embarrassing typos, for which I apologise).

Sato-Tate deals with points on elliptic curves reduced mod p for all p – and definitely pertains to global number fields. Moreover, Langlands personally has had interesting things to say about Sato-Tate. But while Sato-Tate generally fits into the Langlands program and pertains to global number fields, it does not seem best practice (to me, as a non-specialist) to view Sato-Tate as a creature of the Langlands program. After all, Taniyama-Shimura (and Fermat!) also generally fit into the Langlands program and pertain to global number fields. In my opinion, Sato-Tate and Taniyama-Shimura can well be taken as evidence that the original Langlands program is on target. But I don't think any of these things significantly advances us towards a proof of a global nonabelian class field theory for number fields.

So, in summary, I don't think Sato-Tate is a significant advance of the classical Langlands program, even though Sato-Tate is a very significant advance!

20. **bb**
March 30, 2007

Disclaimer: I am, at best, an interested outside to number theory and might suffer from severe delusions about the mathematical content of what I say.

Robert,

I think it's incorrect to claim that Shimura-Taniyama does not represent a significant advance towards the global Langlands program, and to claim that it's "rather far" to view the former as being a "feature" of the former. Here's why:

The Langlands program relates automorphic representations and Galois representations over global fields (or, more philosophically, automorphic objects and geometric ones). Given class field theory, the first non-trivial case is the two dimensional one. In this case, there's a standard method to produce tons of interesting examples on both sides. For the automorphic side, one takes (weight 2) modular forms, and for the Galois side one takes the Tate modules (homology) of elliptic curves defined over such fields. Given this, the natural question to ask is if these two are Langlands-related (i.e: have the same L-function)? In this sense, Eichler-Shimura and Wiles' theorem provide the first non-trivial instance of the Langlands program — the former says that such forms have associated geometric objects, and the latter produces an inverse association.

Of course, I realise that this doesn't quite prove it (even for n=2, where it's still actively being researched by Kisin and company!), but it still seems like a fairly significant advance towards Langlands' conjecture to be able verify it in the first non-trivial case one can write down!

21. **Robert Musil**
March 30, 2007

bb –

As one non-specialist to another, I think I mostly agree with you. "Eichler-Shimura and Wiles' theorem provide the first non-trivial instance of the Langlands program?" Of course, although I might quibble about the "first" qualifier, since I think lots of earlier examples by Langlands and others were "non-trivial." Maybe Fermat is the first "spectacular" example. Sato-Tate? Ditto. These results are all – to my limited understanding – very good examples of the kinds of things Langlands and his school explicitly wanted to be able to get at with the classical Langlands program. That's why I think that "Sato-Tate and Taniyama-Shimura can well be taken as evidence that the original Langlands program is on target."

So, yes, seeing that various "predicted" by the classical Langlands program are correct and can be proved using techniques of the type Langlands and his school advanced is definitely progress. And in that sense I see David and Aaron as being definitely and completely correct in pointing out that classical Langlands techniques have NOT "hit a wall" in reaching such spectacular and wonderful examples.

But, as preliminary and possiblly epistomological quibble, Fermat rather predates Langlands, and lots of people made lots of progress on Fermat before Wiles – and not just Faltings. Sato-Tate is from 1960, Taniyama-Shimura from 1955, etc. Each of these conjectures have many lives and characteristic techniques that are independent of the Langlands project, even though the Langlands project had (has) something important to contribute to their resolutions. Wiles' critical use of Galois deformation in proving Fermat is not really part of the Langlands project, either – a fact that even the Langlands-imperialists (that a joke) at Columbia Math have admited in public writing! So I don't think these conjectures are best thought of as mostly creatures of the Langlands project. Rather, the Langlands project exists in large measure (but not solely) to contribute some techniques that address such conjectures!

But my second, more basic, point is that it is my impression (as an outsider) that the leading people in this field believe that (1) the classical Langlands program is a huge mass of conjectures, of which we are only beginning to scratch the surface, which tells us what the structure is, and (2) some powerful new geometric ideas are needed before real progress towards Langlands' goal of a class field theory for nonabelian global number fields. My further impression is that Geometric Langlands is thought to be a good place to look for such ideas.

None of that is intended as criticism. No one could reasonably critize Taylor or Harris or Shahidi or anyone else just because they don't yet have the tools to complete the clasical Langlands program and are looking at GL (among other places) for new ideas!

Anyway, I go on far too long and I don't mean to dominate Peter's blog. So I'll shut up now.

And, Peter, what's wrong with Hyde Park? I love Hyde Park!

Quick Links

March 28, 2007
Categories: Uncategorized

Shelly Glashow is traveling around, giving talks bashing his childhood hero Isaac Newton (and noting that he was "surely one of the greatest intellects the world has known"). He'll be at NYU tomorrow talking on The Errors and Animadversions of Sir Isaac Newton. For a copy of his talk, see here, (and here for a summary in Catalan).

Tonight is the Lawrence Krauss – Brian Greene string theory debate in DC, and next week in Berkeley Krauss is debating John Terning on the subject, at an event entitled Extra Dimensions and String Theory: Physics of the Future or Pure Mathematics? The event is organized by the FQXI funded organization Multiversal Journeys.

Krauss was at the cosmology conference that Tommaso Dorigo has been reporting on, giving a dinner talk dissing anthropic reasoning and pointing out that cosmology has a "miserable future", since everything is receding from us. His main conference talk was evidently not very optimisitic about near-term prospects for learning more about dark energy or dark matter.

For more about non-commutative geometry and number theory, David Kazhdan is giving a talk at Harvard on April 18 with the following abstract:

Discussion of Alain Connes formulation of the Andre Weil's theorem. . Alain Connes found a very interesting way to interpret the results as a computation of an asymptotic of a family of operators of finite rank.

Lieven le Bruyn has a discussion of Plato's cave and a recent paper Modular shadows and the Levy-Mellin infinity-adic transform, by Marcolli and Manin, who motivate their title by relating Plato's cave and holography in AdS/CFT.

Update: The Washington Post's publication Express has an article about Lawrence Krauss and the problems of string theory, entitled Frayed String.

Update: Science has a report on the debate. Also, there's a report (with audio) from a blogger at the Hooded Hawk blog.

   March 29, 2007

   Glashow's piece slagging off Sir Isaac makes interesting reading. I was aware of the fact that Newton was not above petty jealousies or obsessions with alchemy, astrology and other less-than-scientific pursuits, but one does wonder about Glashow's motivation in drawing attention to these … is he preparing the ground for some revelations about his own life, i.e. that he is a laudanum addict, a practising astrologer and necromancer and one who, despite the present evidence, secretly admires Superstring Theory? We should watch this space. Further revelations may be on the way.

2. **DB**
   March 29, 2007

   If his paper had included a proviso along the lines of "it's easy to criticise from the vantage point of 350 years of hindsight" I might be inclined to indulge Glashow. Rather than speculate on how Newton would have conducted himself in the modern era, Glashow might be better advised to imagine how he himself might have fared in the mid seventeenth century. A pity there are no new insights in this article, other than to learn that Glashow's childhood innocence has been cruelly undermined.
   Comparisons with Einstein are just silly. Einstein was no mathematician and no experimentalist, so why on earth compare them? And Einstein was no saint either! Instead of wallowing in the human defects of his subject, Glashow would serve his bright agenda (which I support) better by emphasising how scientific achievement enables humans to leave behind a legacy which outshines the feeble reality of their ephemeral personalities.
   By the way, Asberger should read Asperger (after Hans), somebody may be casting a spell!

3. **steveM**
   March 29, 2007

   Another of Newton's bizarre beliefs was that the law of inverse
   squares was already to be found in Pythagoras. He was also
   the first physicist to go into finance when he became Master of the Mint and sent forgers to the gallows without a second thought. Despite his intellect Newton also made a huge blunder when he lost £20,000 in the stock market–a colossal sum in its day, and still quite substantial even today–specifically when the South Sea Bubble collapsed. He then remarked " I can compute the motion of heavenly bodies but not the madness of people". The quote also suggests that dealing with people and the subtleties of human
   relationships was not his forte

4. **dan**
   March 29, 2007

   It's been claimed Newton had Asperger's Syndrome.

5. **Peter Shor**
   March 29, 2007

   Is attacking Newton for using way too many significant digits fair? The theory of and proper use of significant digits is second nature to scientists now, but I don't think it's a priori obvious, and I can't believe it was actually around at the time.

6. **Kea**
   March 29, 2007

   *Another of Newton's bizarre beliefs was that the law of inverse
   squares was already to be found in Pythagoras.*

   This is not bizarre. It is true.

7. **Chris Oakley**
   March 29, 2007

Inspired by Glashow via Peter, I went to the antechapel of Trinity College, Cambridge today where there is a statue of Newton. He looks like a P.E. teacher. Maybe all this grouchy behaviour was only because he missed a vocation here.

8. **Uncle Enzo**

How come my comment was deleted?

9. **woit**
March 29, 2007

Sorry Uncle Enzo, but there are certain topics which, once broached, lead to large numbers of comments by tedious ideologues, so I don't post about these and will ruthlessly delete comments about them. These include evolution, religion, climate change, and others I dare not even mention…

10. **Robert Musil**
March 30, 2007

Could Newton have been the model for Templeton the Rat in Charlotte's Web?

11. **Robert Musil**
March 30, 2007

I was a little disappointed that Glashow didn't mention any of the drubbing Newton took from Jonathan Swift in Gulliver's Travels. In fact, the original Frontispiece of "Gulliver's Travels" [a cartoon of Gulliver himself, reproduced here: http://www.jaffebros.com/lee/gulliver/morley/fp.jpeg%5D may be a likeness of Newton. [See: http://links.jstor.org/sici?sici=0035-9149(199607)50%3A2%3C191%3AITFO'T%3E2.0.CO%3B2-6%5D

Swift saw Newton as the essence of the immoral (or at least amoral), abstract reasoning scientist, and was especially annoyed at Newton's scheme to debase Irish coinage, which Swift believed was immoral and callous. In the book, Gulliver travels to the Flying (Floating) Island Laputa (Spanish "la puta": the whore – Swift considered excessive rationality to be whorelike). The inhabitants are distracted with very narrow interests – mathematics and music. Their clothes do not fit and are decorated with astrological symbols and musical figures. They listen to the music of the spheres, believe in astrology, worry constantly that the sun will go out and live in badly built houses. They are speculative and rationalistic philosophers who are pathetic failures as philosophers, reasoners and men. They are devoted to the most ethereal of abstract music and mathematics — but cannot play music well or figure accurately enough to build houses or tailor clothes (The tailor's mistake is directed at Newton based on the mistake made by a printer in one of the figures Newton used in computing the distance of the earth from the sun). They are completely incompetent in practical affairs.

Gulliver is then lowered from floating Laputa to Lagado, where the crops are poorly managed, people wear ragged clothing, and the houses are in bad condition – except for the house of the governor of Lagado. He tells Gulliver that 40 years before some Lagado residents visited Laputa and came away with a smattering of mathematics. They built an academy to carry out their projects they learned in Laputa. The Grand Academy of Lagado is a satire on the Royal Society, of which Newton was then President. At the Academy of Lagado, scientists are attempting to extract sunbeams from cucumbers, turn human feces back into food, erect buildings from the roof down, plow farmland with pigs, make marbles soft enough to stuff pillows and pincushions, breed sheep whose entire bodies are bald, and have students learn mathematics by swallowing wafers on which formulas are written.

And there's more.

12. **stevem**
March 31, 2007

I just read Glashow's interesting article right through. Despite his flaws, or perhaps even because of them, Newton remains a fascinating character. Yes, he got a lot of things wrong and was into a lot of strange stuff, but every so often his immense intellectual powers would just come to the surface. In 1696 Bernoulli challenged his colleagues to solve the "brachistochrone problem", which asked what is the curve between two displaced points along which a body acting under gravity alone would follow in the shortest time. The deadline for the problem was 6 months but Leibniz requested it be extend to one and half years. Newton, then 55, received the challange at 4pm on Jan 29, 1697. By the following morning he had invented the essence of calculas of variations, solved the problem and sent off the solution anonymously. But everyone knew who had solved it with Bernoulli remarking: "we recognise the lion by his claw".

Jonathan Swift's attack on the scientific community you mention in the third book of Gulliver's Travels arose from the discussions of the "Scriblerus Club". This was a group of disgruntled Tory writers who formed themselves into a literary society, and which met in the rooms of St James's Palace. The Scriblerus Club set out to redicule the learned societies of the day and Newton, being a big shot in the government establishment and the dominant scientific figure, was top of their hit list of course. A play in 1717 has a character called "Dr Fossile", who is a pompous wig-wearing scientist and the jokes clearly suggest it is a satire of Newton. For example, he is asked by a foreign philospher/adventurer who can't speak good English: "vat do you tink of de new methode of de fluxions of de quantity?". To which he replies" the greatest quantity I ever knew was three quarts a day". He is also asked if he can see a "star as big as the moon in the daylight". Looking through his telescope he (Fossile) replies" I can spy no other celestial body but the sun".

13. **anon.**
March 31, 2007

Newton isn't necessarily the only physicist or mathematician under attack since Gulliver's Flying (Floating) Island, Laputa, is powered by a loadstone (magnetite rock). This is satire on Kepler's theory that the planets orbit the sun due to magnetism, not on Newton who came up with gravity. Ever since Gilbert discovered that the earth is a magnet in 1600, it had been assumed to be the force acting between planets. Descartes had Cartesian vortices filling space to account for the planetary motions, while Kepler moved a step forward by suggesting magnetism. Newton killed off Cartesian vortices by showing that the inverse square law of gravity based on Kepler's planetary laws, supplied with Galileo's data for acceleration at earth's radius, correctly predicted the moon's known centripetal acceleration.

Newton's fluxions, not his physics, came under attack from those who claimed it is irrational and religion. Bishop George Berkeley in 1734 wrote *The Analyst; or a Discourse Addressed to an Infidel Mathematician: Wherein it is examined whether the Object, Principles and Inferences of the modern Analysis are more distinctly conceived, or more evidently deduced, than Religious Mysteries and Points of Faith.*

If you have a rectangular block height y and width x, then it's area is the integral of y*dx over the range of x: area = N*y*dx = (x/dx)*y*dx = xy, where N is the number of slices. Although this works, there was an argument that it is effectively multiplying infinity (ie. x/dx) by zero (ie. dx) which seemed irrational.

The full text of Bishop Berkeley's attack is online: http://www.maths.tcd.ie/pub/HistMath/People/Berkeley/Analyst/Analyst.pdf

One has to be a fascinating lion to have people fussing after 350 years over the mistakes and flaws – instead of just trying to remember the accomplisments!

15. **Jonathan Vos Post**
March 31, 2007

“Another of Newton’s bizarre beliefs was that the law of inverse squares was already to be found in Pythagoras”

Besides being true, this is part of a much more interesting point: that Newton, for all his battles on priority, seemed to believes that he was primarily rediscovering the “secrets of the ancients.”

Okay, his last published paper was on the Penny, that’s sensible, given his job in charge of the Royal Mint (and how nice for an alchemist to have access to all the nation’s gold!). But his last book was on the Secrets of the Pyramids.

A fine novel with Newton as protagonist is:

Dark Matter: The Private Life of Sir Isaac Newton: A Novel, by Philip Kerr

Paperback: 352 pages
Publisher: Three Rivers Press; Reprint edition (October 28, 2003)
Language: English
ISBN-10: 1400049490
ISBN-13: 978-1400049493

Publishers Weekly review:

Holmes and Watson provide the template for this very satisfying historical thriller from Kerr (The Grid, etc.), with Sir Isaac Newton acting as great detective and one Christopher Ellis serving as narrator. It’s 1696, and a series of murders are plaguing the Tower of London, where the middle-aged Newton has recently assumed (as in real life) the position of warden of the royal mint, with the younger Ellis (again as in real life) serving as his assistant. Like Holmes, the cold and cerebral Newton relies on rationalism the scientific method to solve the crimes, while Ellis, quick with sword, pistol and temper, brings the emotional counterweight provided by Conan Doyle’s Watson. The murders are accompanied by esoteric clues, most notably encrypted messages and alchemical references, that spur Newton to their resolution as forcefully as does his intense sense of duty, for the killings seem to involve not only a plot to disrupt a recoinage necessary to continue England’s war with France, but also a conspiracy to commit religious genocide against a backdrop of incessant tensions between Catholics and Protestants. The mystery elements of the novel provide a sturdy spine for the book’s main flesh: its robust recreation of life at the end of the 17th century. Ellis’s fluid narration sets the tone, illuminating a London beset by pestilence, poverty, whores and ruffians, noblemen grave or foppish, opium dens, brothels and grisly executions, and a bright array of historical figures including, in the role of blackguard, Daniel Defoe. There’s an erotic/romantic subplot involving Ellis and Newton’s niece, but the main focus is on the two leads. Both are well drawn, though Newton, ostensibly the novel’s center, is less compelling than Ellis’s full-blooded youth. That disparity, and an overly complex plot, are the drawbacks of what is, withal, a most gripping and well-appointed entertainment.

This latest news from the LHC does not sound good. One hopes it won't affect the LHC schedule.

Update: Also discussed at the Resonaances blog from CERN.

Update: Latest (4/3/07) news here.

Comments

1. **Peter Orland**
   March 30, 2007

   Does anyone know if all nine of these assemblies can be modified? Or
   do they have to be rebuilt from scratch? How many will needed altogether? More than nine?

2. **tomj**
   March 30, 2007

   It sounds like the loads were never taken into consideration during design, and overlooked during multiple reviews, which seems weird because they were testing for the load, which shows up under several expected conditions during normal and abnormal operation.

3. **Yatima**
   March 30, 2007

   These things happen in engineering. (Independent) Verification and Validation _can_ miss things. Then costs go up (politically difficult) or the supplier will be asked to fix things at his expenses (leading to finger-pointing, more delays and lower quality). Grin and bear it.

   Just be happy that this project is not called "Galileo" (yes, I have a stack of GAL requirements on my desk)

4. **woit**
   March 31, 2007

   Please, stop with the off-topic comments that have nothing to do with the magnets at CERN, I've had to delete a thread of these.

5. **anon**
   March 31, 2007

   It's just another delay tactic of the string theorists.

6. **Haelfix**
   April 1, 2007

   The vibe from experimentalists in my department who work at CERN range the entire gamut of the map. So I don't really have any good inside information about it. One seems to think its not a big deal, whereas some others are furious about it and already booking plane tickets. Its quite hush hush though, as I can't coax much information out of them.

   My best guess from what I felt is some delays, but perhaps not as bad as some thought.

7. **Aymar resigns>>Resonaances**
   April 1, 2007

   […] the start of the LHC will be delayed by several years. Following these reports, the CERN Council had a special meeting today, during which Director General Robert Aymar resigned from his post. I assume full responsibility for what has happened, he said […]

8. **Chuckles**
   April 1, 2007

   I think its about time to start a String Theory Costs ticker, just like all those Iraq War Costs tickers on so many websites. Until people are convinced that we are actually spending good money day after day on what is quickly becoming cultic activity within the realms of natural science, the kind of public reevaluation we need will not be forthcoming.

9. **Ari Heikkinen**
   April 4, 2007

   "These things happen in engineering."

   Actually no.

   When you design a pressure vessel (as I understand it was) you have to be right, you can't just wait for it to explode and fix it later.

10. **Bob**
    April 5, 2007

    Well, of course oversights happen while developing any major project. What is very troubling here — and every project manager's nightmare — is that the "longitudinal forces" that caused the failure were, according to Fermilab, never accounted for in the specs and were not identified as potential problem by the external oversight reviews.

    The latest update from Fermilab is at (http://www.fnal.gov/pub/today/20070403_page01.html).

John Horgan Discussion With George Johnson

March 31, 2007
Categories: Uncategorized

Bloggingheads.tv now has some video up with an interesting discussion between John Horgan and George Johnson on a range of topics. One segment is entitled String theory deemed load of crap!, and discusses the controversy over string theory. Both Horgan and Johnson agree that things are not look good for a physical theory when there start being public debates on the subject. Johnson also discusses his time at the KITP and mentions this blog. He seemed to be particularly struck by the behavior of the participants at the session he ran there which involved a lot of bashing of Lee Smolin, with Mark Srednicki raising his hand when Johnson said he didn't think anyone would call Smolin a crackpot.

Johnson also described the "echo chamber" effect of blogs like this one. I guess I better keep this going by blogging about his commentary about my blogging…

Update: Sean Carroll has a posting about this over at Cosmic Variance entitled String Theory is Losing the Public Debate. Probably best if people join the discussion over there, which so far includes John Horgan and others.

Update: If you like this sort of thing, more blog discussions about string theory here, here, and here… and here and here.

5. **Arun**
   April 1, 2007

   There is an interesting claim there in the comments. If true, on Monday, everyone who doubted string theory will have egg on their face.

6. **Chris Oakley**
   April 1, 2007

   I was forwarded this from a former HEP colleague, who allowed me to post it on condition that I remove the sender's & receiver's e-mail.

   I am not sure quite what to make of it. If it is what it appears to be, then I am surprised that nothing got out earlier. I guess that we can expect a public announcement soon, though. You heard it here first!

   > [Snip]
   > But for Lee, Peter Woit and the club of disgruntled losers that follow them, we would have made an announcement in January.
   > [Snip more personal attacks]
   > As you see, with Joe's insight, there is anomaly cancellation in 3+1 dimensions and the theory exists perturbatively at all orders, with no infinities – not even cancellations, just finite! The tree-level amplitudes agree with the SM, and the (finite) loops, which Joe calculated in December not only get the Lamb shift and electron anomalous magnetic moment absolutely right, but get a new value for the muon a.m.m. that suddenly puts it back into 1 s.d. territory vis a vis experiments … this really is one in the eye for the superstring critics, and just as they were beginning to get far too much air time.
   > [Snip more personal attacks]
   > the so-called "wild goose chase" has turned out to be nothing of the sort! – as for supersymmetric partners, the SS breaking puts the photino at 1.35 TeV, the selectron at 1.1 TeV, and the squarks between 1.2-1.5 TeV – all within reach of the LHC! So we will find out very soon, but personally I have no doubt.
   > [Snip lengthy comment about CERN politics]
   > It seems our intuitions were right … superstring theory doesn't just feel right – it probably IS right! And that's not the half of it – Mike's group have come up some amazing stuff on the QG side – wormholes, time travel – everything you ever fantasised about. He's is a bit cagey about this, and isn't likely to make an announcement until he's checked and double-checked the sums, but it seems that they'll soon have something to give to the experimenters, and if it turns out to be right, it extends GR in truly mind-blowing ways!

7. **Thomas Larsson**
   April 1, 2007

11. **Mondrian**
April 1, 2007

No, sorry.

12. **anon.**
April 1, 2007

I was wondering if it is Lubos' 2-minute explanation of string theory.

13. **Mondrian**
April 1, 2007

Seems likely. In that case I would really appreciate if he could do an english
version too, maybe including a quick enumeration of string vacua.

14. **Chris Oakley**
April 1, 2007

That clip with the prancing Lubos has only made me hungry for more string theorist music videos. What about, for example
• Brian Green as Alice Cooper, singing "I wanna be elected".
• Peter West as Pete Townsend, including the climactic destruction of his "axe" on stage.
• Susskind as a "Kiss" lead singer. He has the attitude – all he needs is the eye makeup.

15. **mclaren**
April 1, 2007

Left a comment at Cosmic Variance, but did want to mention here that Sean Carroll's analogy twixt the theory of evolution and string "theory" (so-called) seems unacceptably inaccurate.

For an analogy to hold, there must be some points of similarity between the two items being compared. Darwinian macroevolution, with libraries full of supporting evidence, does not make a valid comparison with string "theory" (so-called) because at present stringy speculations have not a single piece of hard experimental evidence to back 'em up. Indeed, unlike Darwinian macroevolution, string speculations at present make not even a single testable prediction.

Too, as usual Peter Woit seems to be getting quoted so grossly out of context that it's almost not worth correcting the record. It's sort of like taking a historian's offhand remark that his grandfather died in WW I but his granfather was only one man, and misquoting it to try to "prove" that the historian is denying the existence of WW I because "only one person died in the entire war."

Dr. Woit mentioned that he's surprised that string theorists have done such a poor job defending string theory in public.

I'm not.

To effectively defend a point in debate, you must cite evidence and logic to back up your point. The string theorists have no evidence. That leaves them with hand-waving, which is bound to be an extremely weak debating tactic. As Aristotle remarks in his *Rhetoric*:

if we have no evidence of fact supporting our own case or telling against that of our opponent, at least we can always find evidence to prove our own worth or our opponent's worthlessness.

And isn't this exactly what we find happening with string theorists?

16. **rho**
April 1, 2007

anon, there is nothing about string theory in that video. It is just the Czech title song for the cartoon series of "Tom and Jerry".

Anyway, there is something seriously irritating to see this…

17. **anon.**
April 1, 2007

Sean Carroll has now denied in a comment on his blog that he was comparing string theory to evolution.

18. **anon.**
April 1, 2007

On the subject of 1 April, Google has put up one at http://www.google.com/tisp/ and if you follow to http://www.google.com/tisp/install.html and then click on professional installation service you get the error report mentioning grand unified theories:

‘The requested URL was not found … (far less plausible, but theoretically possible, depending on which ill-defined Grand Unifying Theory of physics one subscribes to), some random fluctuation in the space-time continuum might have produced a shatteringly brief but nonetheless real electromagnetic discombobulation which caused this error page to appear. …’

– http://www.google.com/tisp/notfound.html

19. **anonymous**
April 1, 2007

I guess everyone has heard by now. There is a forthcoming paper (by Ludwig Poehlmann) concerning the fatal flaw in the implementation of extended objects such as strings and branes. This appears to be the nail in the coffin for some of the mainstream theories.

20. **wolfgang**
April 1, 2007

Ludwig Poehlmann = Archimedes Plutonium ?

21. **Michael**
April 1, 2007

“Sean Carroll has now denied in a comment on his blog that he was comparing string theory to evolution.”

Well, he clearly did compare the situations: public debate over string theory and public debate over evolution. I don’t know how to take his comment on evolution. Is he more skeptical of evolution due to the outcome of the debates, or does he simply not care anymore?

22. **Haludza**
April 1, 2007

I believe Sean Carroll was simply saying that the existence of public debate of a physical theory doesn’t necessarily imply that it’s on shaky ground. These debates will tend to happen if there’s some perceived public interest in what’s being debated!

So, clearly, evolution is debated because it touches some nerves and not due primarily to whether the evidence suggests it.
Carroll only compares string theory and evolution in so far as they’re things involving scientific questions which are being debated.

23. **Peter Woit**
April 2, 2007

Arun,

The amazing thing about that paper

http://www.arxiv.org/abs/hep-th/0703280

is that Sean Carroll and others seemed to be pretty convinced that it is an April Fool’s joke, but its authors seem to be serious (and it was submitted on March 29, not April 1). Looks to me like people in string theory have completely lost the ability to distinguish between a joke and serious science.

24. **anon.**
April 2, 2007

“The electron mass is about 6.5 times larger that the expected value, while the muon mass is about 40% smaller.” – http://www.arxiv.org/abs/hep-th/0703280 p4

What’s the experimental error bar/standard deviation on the electron and muon masses, nowadays?

25. **Peter Orland**
April 2, 2007

It doesn’t look like a joke to me. Assuming it is technically right, the
right question to ask is, “how many parameters are put into this
theory/model to get something realistic”. If the number of
parameters is more than the number of observables, the idea isn’t
useful (I think this is the case). If the numbers are equal, it is a parametrization.

26. **wolfgang**
April 2, 2007

anon.,

the reason (according to the paper) the electorn and muon come out wrong is their low mass and the fact that the calculation is tree-level only.
They provide a reference to a paper in preparation which shall discuss and “fix” this issue (I assume based on some approximation at 1-loop).

27. **Chris Oakley**
April 2, 2007

> They provide a reference to a paper in preparation which shall discuss and “fix” this issue (I assume based on some approximation at 1-loop).

I will look forward to seeing this paper on April 1, 2008.

28. **april fool**
April 2, 2007

Peter,

Doesn’t it seems more likely that the speculation about

http://www.arxiv.org/abs/hep-th/0703280

being a joke has more to do with the fact that it hadn't yet appeared on the arxiv and that nobody had read it when they were speculating that? I'm not defending (or, for that matter, deriding) the physical content of the paper but I just don't see what part of this paper could be interpreted as funny. I don't claim to have read the whole thing very carefully, but if the paper is a joke, then it doesn't seem to be a very funny joke to me.

29. **anon.**
April 2, 2007

Wolfgang, why would one lepton mass be underestimated while another be overestimated? I could understand if both lepton masses calculated were both too low because of some vacuum corrections.

Other questions: To what degree are the predictions subjected to the arbitrary assumptions of the model? How much variation is there in the predictions if you take other assumptions? Obviously if this is wrong, at most it will only falsify this particular model in a landscape of models.

On the other hand, can even this model be falsified? Or – by making small adjustments – can it be fine-tuned to fit virtually any LHC data? On p4 they list a lot of parameters they "choose" to plug into the model in order to make it generate the masses they want. To what extent it this just numerology?

30. **Peter Woit**
April 2, 2007

april fool,

Sure, if you look at the paper, you realize it's not funny, and thus not likely to be an April Fool's joke. But, based on the claims made in the comment section at CV about the paper by one of its authors, Sean Carroll and others assumed it had to be a joke. We have a situation right now where there's a whole field of "string phenomenology" full of researchers making claims like this, with most theorists well aware that there is no hope that these claims can be sustained, so assume they are some kind of a joke if made around April 1.

This is kind of like the situation with the Bogdanov papers. They clearly weren't a joke because they weren't funny. What was disturbing was that mainstream journals were publishing stuff that was pretty universally acknowledged to be nonsense by the physics community.

31. **Michael**
April 2, 2007

"What was disturbing was that mainstream journals were publishing stuff that was pretty universally acknowledged to be nonsense by the physics community."

there's also the Schon scandal (2001/2002).

http://en.wikipedia.org/wiki/Jan_Hendrik_Sch%C3%B6n

i don't know if this publishing "total nonsense" started with Sokal or not. while it's possible to dupe a bunch of lit crit postmodernists with a physics article, it should (in theory) be harder for a physicist to dupe another physicist.

32. **Phen Phen**
April 2, 2007

Mayes's comment on CV: "Eric Mayes on Mar 31st, 2007 at 11:54 pm"

Submission history: "Thu, 29 Mar 2007 20:03:58 GMT (11kb)"

unless there is a delay in the arxiv, the paper was sitting there the entire time people were labelling it a joke. or did i look at the wrong paper? all those stringy papers look the same to me.

33. **Peter Woit**
April 2, 2007

Phen Phen,

arXiv papers don't appear until a set time later when they are made publicly available in a batch. From the submission date, this paper would normally not be available until 8pm Eastern time on Sunday April 1. Someone did claim that the arXiv schedule did seem to be different this weekend, with that paper available earlier (or, maybe, if you accessed the paper by number you could get it, listings were just not yet available). I think most of the people who assumed it was a joke did so based on the description of the paper's claims made by one of its authors, don't know if any of them actually accessed the paper and looked at it. Since the claims in the comment were similar to previous claims by this author, I assumed it probably wasn't an April 1 joke.

34. **Eric**
April 2, 2007

Apparently, someone had access to the preprints before they actually came out. I made my post in reaction to previous posts such as one by PW that string theory couldn't make contact with particle physics. Hopefully, you guys will realize that it can. Can you admit it?

35. **april fool**
April 3, 2007

Peter,

"…based on the claims made in the comment section at CV about the paper by one of its authors, Sean Carroll and others assumed it had to be a joke. We have a situation right now where there's a whole field of "string phenomenology" full of researchers making claims like this, with most theorists well aware that there is no hope that these claims can be sustained, so assume they are some kind of a joke if made around April 1."

But, at least according to the authors, those claims were sustained! Presumably people thought it was an april fool's day joke because it's a bold claim. One might interpret this as meaning that the paper is extremely important…

"This is kind of like the situation with the Bogdanov papers. They clearly weren't a joke because they weren't funny. What was disturbing was that mainstream journals were publishing stuff that was pretty universally acknowledged to be nonsense by the physics community."

I don’t see how it’s anything like the Bogdanov affair. In that case a paper that was clearly nonsense got published in a peer reviewed journal. In this case people heard a bold claim about a potentially important result (nobody had actually seen the paper) on a blog and thought it might be a joke just because the problem the authors claim to have solved is a difficult one. In the case of the Bogdanov affair the problem, presumably, was a lazy referee who didn’t actually read the paper. In this case I don’t see why you think this reflects so poorly on Sean Carroll and friends. Nobody had actually read the paper.

36. **Peter Woit**
April 3, 2007

“One might interpret this as meaning that the paper is extremely important…”

It seems to me you’re joking here, making my point that this field has a real problem with telling the difference between a serious scientific argument and a joke.

I wasn’t criticizing Sean Carroll. He’s quite right to have thought that these kind of claims were a joke, because it’s not possible to take them seriously as science. Other commenters here have already pointed out why.

37. **Thomas Larsson**
April 4, 2007

It might be emphasized that it was a strong string advocate, Sean Carroll, which jumped to the conclusion that news of successful stringy phenomenology had to be an April’s fool. I don’t think that Peter ever claimed that the paper was a *deliberate* joke.

Various Stuff

April 3, 2007
Categories: Uncategorized

The list of speakers for Strings 2007 is now available. Titles of talks are not available, but as far as I can tell they're not taking up Lee Smolin on his suggestion that they have someone there to talk about developments in the LQG approach to quantum gravity that string theorists might find interesting. Also, no mathematicians on the list and fewer mathematically inclined string theorists than at Strings 2006. One experimentalist from CERN (Rolandi), presumably to talk about the LHC. Lots and lots of people who work on the landscape and various string compactification schemes, with the Stanford group well-represented.

If you're in Princeton tomorrow there are a couple of interesting math talks. The talk by Simons at the IAS on *Some Results in Differential Cohomology* (with Sullivan, presumably about this) should set some kind of historical record for the highest net worth of a speaker giving a technical math talk. Ed Frenkel is giving the colloquium at the math department on *Langlands Correspondence for Loop Groups*; I wish I had time to go down there to hear it.

The conference in Paris on non-commutative geometry in honor of Alain Connes is continuing this week. Fabien Besnard reports on the talk by Michael Atiyah, where evidently there was some commentary on the role of mathematical beauty in physics, and warning to the young that working on the kind of idea he was discussing would be dangerous for their careers. And no, in French "Physique Retardee" does not carry the same meaning as a naive translation to English would imply…

The web-site of representation theorist Ivan Mirkovic has lots of interesting things, including notes about geometric Langland and the recent work of Witten-Kapustin-Gukov. Another interesting representation theorist web-site is that of Alistair Savage, which includes various lecture notes and an overview about quivers and geometric representation theory.

See here for the program and some lecture notes from the recent spring school at Trieste. Especially interesting are the lectures by Martin Schmaltz about Physics Beyond the Standard Model and the LHC. The Resonaances blog also has a report about a recent talk by Schmaltz at CERN. The bottom line seems to be that, contrary to what was previously thought, in many of the kinds of supersymmetric models supposed to come from string theory, you can't run the observed scalar superpartner masses back up to the unification scale, so, even if you see such things, you won't get information about grand unification out of them. Schmaltz gives a graphical representation of the reaction of various people to this. I'm in category A.

Tommaso Dorigo has an excellent suggestion for experimental collaborations worried about the information that their blogging members are putting out. Don't fight them, join them! He suggests that large experiments like CDF, D0, ATLAS, CMS should be putting out a collaboration-approved blog, getting their story out to the public through this medium.

Update: I realized there is another event I should mention. This Saturday I'll be giving a talk at a symposium at the University of Central Florida in Orlando, organized by the Society of Physics Students and the Campus Freethought Alliance. Also speaking there will be Jim Gates, who presumably will be taking a somewhat more optimistic view of string theory. I'm still trying to figure out what to talk about, current plan is to cover some of the material in my book, emphasizing the parts everyone ignores that are not about string theory…

Comments

1. **Who**
   April 4, 2007

   the emblem on the main page of the Strings '07 website
   is a 1789 oil painting by Goya called THE BLIND CHICKEN
   (La Gallina Ciega) or translated into English "Blind Man's Buff".

   The blindfolded girl is in the center of a circle of dancers,
   who elude her attempts to strike them.

   There is a sunset, the players are aristocrats, it is pretty but
   inexplicably melancholy.

   To get further information about the Strings '07 conference,
   click on individual dancers in the circle.
   http://gesalerico.ft.uam.es/strings07/

   To me, the blindfolded young lady looks like M-theory, something which so far has never been seen, surrounded by elusive entities who joined by the duality of holding each other's hands. No one is like Goya.

2. **Peter Orland**
   April 5, 2007

   Among the list of speakers at Strings '07 are Bern
   (maybe N=8 supergravity is finite) and Beisert (advances
   in N=4 Yang-Mills and the AdS/CFT conjecture). These
   are important topics and both a bit out of the current
   string mainstream. Without this small diversity of focus
   (that is, something other than usual string stuff) the
   meeting would probably feel like Strings 1907.

MiniBooNE Announcement

April 6, 2007
Categories: Uncategorized

It seems that the MiniBooNE neutrino experiment at Fermilab is finally ready to announce results. A talk next Wednesday, 11am, at Fermilab by Janet Conrad and William Louis has been scheduled, with title *Initial MiniBooNE Oscillation Results*.

Via Alexey Petrov, who explains the significance and teases that there's a rumor that MiniBooNE sees "something interesting"…

Comments

1. **A**
   April 6, 2007

   Hi Peter, The results will also be released at Columbia by Mike Shaevitz – at the same time. It will be at 1pm EST in rm 428 Pupin Hall.

2. **Brett**
   April 7, 2007

   I wouldn't be surprised if every MiniBooNE PI is giving a talk on Wednesday. Rex Tayloe has one at Indiana.

3. **JA**
   April 8, 2007

   Your speech in Japan was terrific, Peter!

4. **Chris Oakley**
   April 8, 2007

   He's very persuasive … if I lived in Japan, I'd vote for him. Or not. Whatever he wanted.

5. **Peter Woit**
   April 9, 2007

   A,

   Thanks, I'll be there to hear the results first-hand!

6. **Marco**
   April 9, 2007

   Thank you for the heads-up. Any idea whether one of these talks (ideally the one at FNAL) will be available in streaming on the web?

7. **Marco**
   April 9, 2007

   Yes, it looks like the streaming will be available here:
   http://www-visualmedia.fnal.gov/live.htm

8. **V**
   April 9, 2007

   If MiniBooNe announces that they have evidence for a sterile neutrino, does anyone have an idea of how this fits in with the Standard Model? To me, the most natural explanation would be that this a a fourth generation right-handed neutrino which has a strongly suppressed Majorana mass so that the seesaw swings the other way and gives the fourth-generation left-handed neutrino a mass ~50 GeV.

9. **D. V. Ahluwalia-Khalilova**
   April 9, 2007

   If MiniBoone sees something like a sterile neutrino, its phenomenological consequences would strongly depend on the CP properties of the component(s) beyond the three mass eigenstates. For this twist to the problem, see hep-ph/0702049.

Talks at UCF

April 9, 2007
Categories: Uncategorized

This past weekend I was at the University of Central Florida, participating in a symposium organized by Costas Efthimiou of the physics department there. It was sponsored by two student organizations, the university's Society of Physics Students and Campus Freethought Alliance. There were two speakers, Jim Gates and myself. I suspect that the organizers and many in the audience were hoping for some fireworks between Gates and myself, taking opposite sides on the controversy over string theory, but I fear that we disappointed them.

My talk was entitled The Challenge of Unifying Particle Physics, and my intention was to avoid spending much time going over the problems of string theory, since I'm pretty tired of that, and instead to try and explain to the audience some of the basic facts about symmetries, representations and quantum mechanics, together with an outline of the current state of efforts to unify physics. Gates gave a very general talk about particle physics, unification and string theory, featuring a lot of very impressive graphics he has developed as part of a multi-media course called Superstring Theory: The DNA of Reality.

In the end, there wasn't that much for us to disagree about. My critique of string theory as a unified theory is based on the claim that the idea of using strings in 10d doesn't work because the variety of possibilities for handling the extra 6 dimensions makes predictions impossible. Gates has always been skeptical about extra dimensions and wasn't about to defend them, let alone the landscape. I take his general attitude to be similar to that of Warren Siegel, who he collaborated with in the past, and who explains his point of view here. Recently Gates has been very much interested in representation theory, in his case the representation theory of supersymmetry, where he and collaborators see fundamental problems still to be resolved, and have new ideas about using Clifford algebras to attack them. For one of their recent papers written from the more mathematical end of the problem, see here.

I very much enjoyed my time in Orlando; high points were getting to meet with and talk to some of the physics students there, meeting someone who sometimes comments here who came to the talk, and especially getting the chance to discuss things with Jim, who I found to be impressively knowledgeable and thoughtful about every topic that came up.

Comments

1. **Anton**
   April 9, 2007

   Siegel has many funny parodies on his web site. The one I liked a lot is "THe Official String Blog":
   http://insti.physics.sunysb.edu/~siegel/parodies/atchoo.html

2. **A.J.**
   April 9, 2007

   Hey Peter,

   Out of curiosity, is there anything Siegel says in his research summary that you disagree with?

3. **woit**
   April 9, 2007

   AJ,

   There are lots of different things in Siegel's research summary. On the whole I'd say his interests are just in a different direction than mine. Lots of questions about string theories and superspace, whereas I just think there are much more interesting things to think about, especially various aspects of gauge theory.

   I think Siegel gets it right that the 10 d string is a doomed idea about unification. I'd be willing to believe his work on 4d strings might someday lead to new insights into QCD. But I don't see any evidence that different ideas about string theory are going to give any insight into unification, and I'm basically agnostic as to whether string theory is particularly useful as s theory of quantum gravity.

4. **Hendrik**
   April 9, 2007

   Dear Peter,

   Concerning the mathematical problems involved with obtaining a consistent SUSY QFT, you may be interested in the obstruction theorem of Kishimoto and Nakamura at Commun. Math. Phys. 159, 15–27 (1994). A strategy for circumventing this obstruction recently appeared in http://arxiv.org/abs/math-ph/0604044

5. **A.J.**
   April 10, 2007

   Hi Peter,

   I wasn't expecting you to say anything about D=4 strings.
   But I was struck by how sober and even-handed Siegel's general comments on string theory are. No excited language, no wild claims. This sort of thing was the norm in conversation when I was a physics grad student, but seems rather rare in the blogotub.
   As for conclusions about string theory, I personally tend towards Siegel's 2nd option: There's something vaguely right about string theory, but no reason to believe that the various models which have been written down are correct. For one thing, they strike me as far too geometrical. I just can't bring myself to believe that our world is described by anything as neat and clean as a Calabi-Yau manifold, or a bunch of intersecting branes.

6. **Chris Oakley**
   April 10, 2007

   "Superstring Theory: The DNA of Reality" sounds a bit like "Superstrings are the language in which God wrote the world". Presumably this was not one of the things you agreed about – ?

7. **Coin**
   April 10, 2007

So, a question?

This jumped out at me from Siegel's research summary:

In fact, the only property of string theory not found in particle theory is Dolen-Horn-Schmid duality, which states that summing poles in one channel gives the same result as summation in another channel. This is also the only experimentally verified result of string theory.

I have to confess I don't really understand this… well… at all. A quick hit on Google indicates only that "channels" apparently means "momentum channels", whatever those are. However:

One of the most common (and common for good reason) criticisms of String Theory floating around right now is that it hasn't made any testable predictions. One of the running themes I've noticed reading blogs like this is seeing String Theory proponents offering up various results of String Theory as "predictions", but those results turning out under analysis to not fairly qualify as such.

Siegel carefully words his page in a way that seems to be almost intentionally avoiding calling the Doren-Horn-Schmid thing a "prediction", and I imagine if it were easily classified as such it would have been brought up elsewhere. But as he describes it, it *is* a result which is (1) predicted by String Theory (2) predicted by string theory uniquely, or at least not predicted by "particle theory" (3) borne out by experiment. These three things are generally the conditions I would think of when judging whether a scientific theory has made a "prediction". If it is a prediction, it certainly doesn't sound like a large or significant one, but based on the limited information I have it certainly does seem to be better than nothing.

What vaguely is this Doren-Horn-Schmid thing, if it's not too much trouble to ask? Would you say that it qualifies as a "prediction" made by String Theory? If not, why not?

8. **Doug**
April 10, 2007

Peter,

I just want to commend you for your efforts to shed light on this highly specialized subject. You seem to appreciate how difficult it is for non-specialists to grasp what is going on, and are willing to use your gift for clear articulation to help out.

However, your last slide is most revealing:

1) The math of the SM is poorly understood in many ways.
2) We don't understand the representation theory of gauge groups.
3) Future progress might require unification of mathematics.

What are the chances that you are willing to prepare a talk elaborating on those three points?

9. **woit**
April 10, 2007

Coin,

What Siegel is talking about concerns the idea of using strings to model the strong interactions. This goes back to the late sixties, early seventies, and there are good reasons to believe this is sensible. Some observed aspects of the strong interactions do appear to be well-described by a string model (but no one has a completely successful model). This has nothing to do with using strings to unify gravity and the standard model, which is what isn't working at all.

AJ,

Yes, the way string theory is represented in the blogotub does a disservice to the field. There's a well-known line from Yeats "The best lack all conviction, while the worst are full of passionate intensity"

I think Siegel and Gates see themselves as somewhat out of the mainstream of string theory. Gates at UCF explicitly said they he was in a minority, and not just because of the color of his skin…

Chris,

No, I don't agree with Gates about using that kind of metaphor. I think he sees himself as trying to be careful to distinguish speculation from solid science, but at the same time trying to transmit something about these ideas to a very large audience, including transmitting the enthusiasm of the scientists involved. This seems to me a very tricky business, all too easily giving people the impression that something that is very speculative and without experimental foundation is on a similar footing to something that we have a lot of evidence for.

10. **woit**
April 10, 2007

Doug,

At some point I do hope to write more on these topics, although at the moment I'm much more trying to find time to push my own ideas about these things further along. To make clear exactly what I had in mind with those points, here's a more specific version:

1. We don't understand non-perturbative gauge theories, especially ones with chiral fermion couplings very well at all. This is not just a mathematical problem, but a conceptual one, and new mathematical ideas might help.

2. The representations of a gauge group in 1d are understood, this is the theory of loop group or affine Lie algebra representations. This theory allows us to understand certain 1+1d QFTs, especially WZW models. In higher dimensions, very little is known, probably including the fundamental question of what the right sort of representations is to look for.

3. Absent experimental guidance, new ideas about unification may have to come from mathematics. Mathematics and physics seem to be connected in a very deep way, and understanding this connection may be our only way to make progress if we can't probe higher energy scales experimentally.

11. **King Ray**
April 10, 2007

Peter, great talk at UCF, and it was a real pleasure to meet you in person! Thanks also for autographing my book.

12. **JJ**
April 10, 2007

Hi Peter:

I would like to know if you have had the chance to read Tegmark´s last paper . It was discussed briefly at the N-Category Café . Although highly especulative I found it worth reading.

13. **Peter Woit**
April 10, 2007

JJ,

I did take a look at the Tegmark paper you mention. Philosophically I think I'm somewhat in agreement with him about the "Mathematical Universe Hypothesis", but to me it seems that to get anything out of it you need to understand what the fundamental mathematical structures out there are in a much more sophisticated way than he is doing.

14. **mclaren**
April 10, 2007

String theorists seem to be using the term "prediction" and "predictive" in a non-standard way. For example, Jacques Distler claims that "string theory is highly predictive" but when asked for published HEP journal articles making experimentally verified prediction, the string theorists refuse to provide any.

Moreover, the 3 big results from experimental HEP-related physics of the last 20 years were not predicted by anyone. Not by the SM and not by string theorists: neutrino oscillation, dark matter, dark energy.

Some will jump in to claim dark matter was predicted by the string theoretic superpartners but no one knows whether dark matter is due to superpartners. It could just as well be due to neutrino oscillation, or something else might be going on that we're just not aware of yet. And no published HEP experiment has yet verified the existence of superpartners. In some cases, we haven't even experimentally verified the existence of the original SM particle (graviton), let alone the superpartner (gravitino). So it sounds like that's really putting the cart before the horse.

So when people like Siegel say *"This is also the only experimentally verified result of string theory,"* it's not clear what they mean. In the sense that string theory collapses down into all of current physics at low energies, string theory can be technically said to have lots of experimentally verified results… But they're trivial results. The real test of a new theory isn't whether it reproduces the results of a perfectly adequate existing theory like the Standard Model. It's whether the new theory predicts phenomena which aren't predicted by the old theory, and which are then confirmed by experiment.

So far I'm not aware that string theory has done that.

15. **theoreticalminimum**
April 11, 2007

Peter,

Maybe you should fix the following in your slides:

pp 4, 5 : "different from", not "different than"
p 11 : -1 factor missing in Schrodinger equation.
p 21 : At the time "it" was unclear…
p 24 : As several generations of new accelerators have [been] come…
p 24 : "… everything they have seen is compatible with the predictions of the SM" – Even neutrino masses? Dark matter?(?)
p 29 : 1974 "Used" to quantize…
p 31 : .. as to whether any "is" possible.

Feel free to delete this comment after you've read it.

16. **Warren**
April 11, 2007

mclaren Said:

> So when people like Siegel say "This is also the only experimentally verified result of string theory," it's not clear what they mean…The real test of a new theory isn't whether it reproduces the results of a perfectly adequate existing theory like the Standard Model. It's whether the new theory predicts phenomena which aren't predicted by the old theory, and which are then confirmed by experiment.

Please see my previous sentence on that same webpage:

"In fact, the only property of string theory not found in particle theory is Dolen-Horn-Schmid duality…"

So far, no one has been able to derive DHS duality from any particle theory, the Standard Model in particular.

Coin Said:

> What vaguely is this Doren-Horn-Schmid thing, if it's not too much trouble to ask? Would you say that it qualifies as a "prediction" made by String Theory?

In particle physics, you need to sum over exchanges of particles in both the s & t channels:

Figure 1

In string theory, you only have to sum over just s or just t, not both: The 2 sums are equal. That's because either sum represents the exchange of a string worldsheet, which when stretched thin in one direction (s) or the other (t) looks like a particle worldline in that direction. Here's a more complicated worldsheet for string scattering (I guess I need more figures on my webpages):

Figure 2

I guess you could call DHS duality more of a “postdiction”: The 1st string (then called “dual model”) amplitude was derived by requiring this property.

theoreticalminimum,

Thanks for the editorial assistance. I fear that those slides ended up getting created under too much time pressure, so there’s a lot wrong with them, some of which you’re helping fix.

Math and Physics Roundup

April 10, 2007
Categories: Uncategorized

The latest "This Week's Finds" by John Baez discusses Felix Klein and his "Erlanger Programm", which essentially was the idea that geometry should be understood as the study of Lie groups G, their subgroups H, and coset spaces G/H. This, supplemented with Cartan's notion of a connection, allowing things that only locally look like G/H, is very much at the heart of our modern view of geometry. John gives links to quite a few things worth reading by and about Klein here. Another very interesting document is Klein's own history of 19th century mathematics "Development of mathematics in the 19th century".

I'm very much looking forward to the next installment of TWF, where John promises some insights into Hecke algebras. He also has a wonderful posting that generated an interesting discussion at the n-category cafe on the topic of mathematical exposition, entitled Why Mathematics Is Boring.

For some more mathematics blogging of the highest possible quality, see Terry Tao's postings on his Simons lectures at MIT, here, here and here.

I wrote a bit about the LHC Theory Initiative here last year. They have just announced the award of two graduate fellowships and say that they will be awarding postdoctoral fellowships in the future. Unclear from this if they were successful in their efforts to get NSF funding, the solicitation of applications for the fellowship just mentions an older grant to Johns Hopkins.

NPR has run a two part series on the LHC (here and here). The first part features CERN theorist Alvaro de Rujula. I had the great pleasure of taking a particle theory course from him when I was a student at Harvard a very long time ago. He cut an impressive figure, and provided a survey of the subject that was both enlightening and entertaining.

Scott Aaronson provides quotes from someone else (Gian-Carlo Rota) whose lectures I attended around the same time, including one that ends "You and I know that mathematics, by definition, is not and never will be flaky". I kind of agree with the sentiment in the full quote, but my experience with Rota back then was a rather weird one. For some misguided reason I had decided that since category theory was the most abstract kind of mathematics I had heard of, it would be a good idea to take a course on it. The only course on the subject was a graduate course down at MIT offered by Rota, so I started going down there to sit in on it. A few lectures into the course Rota all of a sudden announced that he had decided that only those students actually enrolled for credit should be taking the course, and that the several of us who were just auditing should leave. So we did, somewhat mystified (it's not like the room was over-packed or anything). To this day, I still don't know what that was about. Perhaps Rota knew that he was doing me a favor by stopping me from thinking about category theory at that point in my education, when in retrospect it seems likely that it really would have been somewhat of a waste.

There's a lot more about Rota at this web-site. His capsule reviews in the back of the journal he edited, Advances in Mathematics, provided outrageous entertainment for many years (although some might at times think that they were, well, flaky…).

Comments

   April 10, 2007

   (Gian-Carlo Rota) whose lectures I attended around the same time, including one that ends "You and I know that mathematics, by definition, is not and never will be flaky"… although some might at times think that [Rota was] well, flaky.

   Ahh, you must be careful always not to mistake *mathematics* for *mathemeticians* 🙂

2. **ObsessiveMathsFreak**
   April 11, 2007

   I don't understand physicists' almost fetish like obsession with Lie groups. I know it's nice and all, but I'm a bit confused as to what use all this mathematical theory is to the physics community? I thought physicists "just want the numbers". I'm finding it hard to believe that you make use of all this when you compute electron shells, solve GR equations, etc, etc. Do you make use of it?

3. **Peter Woit**
   April 11, 2007

   OMF,

   Computing electron shells is a classic application of representation theory of the SU(2) group. Angular momentum operators correspond precisely to a basis of the Lie algebra of SU(2), all that stuff in QM books about how to use them to analyze atomic spectra is pure SU(2) group theory and representation theory.

   For particle physics, you definitely need SU(3), not just SU(2), and this is a quite non-trivial example of a Lie group. Then there's all that stuff about energy, momentum, special relativity: the Poincare group. Lie groups are extremely useful in physics.

4. **MathPhys**
   April 11, 2007

   Peter,
   While I never liked Rota's book reviews in Advances (I found the ones I read too superficial), I highly recommend his "Indiscrete Thoughts", which is a collection of biographical sketches of matehmaticians he knew and many shorts essays on various topics.

   If you have no time for anything else in the book, please read the 4 page biographical sketch on Alonso Church (who was a professor of logic at Princeton when Rota was a student there). And the one on Solomon Lefshetz. Pure gold.

5. **andy**
   April 11, 2007

   Well, back in the days when I was doing nuclear structure shell model calculations, it very often was the case that diagonalizing the two-body matrices in a basis of irreducible representations of SU(3) — the "nuclear SU(3) model" [not to be confused with QCD SU(3)!] — gave very nice and elegant results that had a physical "meaning" (rotational bands). However, that's probably not what you meant! 🙂

6. **Brett**

April 11, 2007

Except for 18.03 (Differential Equations–the largest class at M.I.T.), Rota disliked teaching large classes. I don't know exactly why this was, but it was something that he was completely open about. He would frequently try to convince anyone who thought that they weren't "getting it" to drop a class, as well as other tricks like asking those not enrolled to leave (but if they came back at the next lecture, he wouldn't actually care). To his common refrain, "If you do not see this, I cannot explain it!" he would sometimes add, "And you should drop the course now!" Other professors certainly tried to winnow their classes down to what they felt were more manageable sizes too; only Rota was the least subtle. Perhaps this had something to do with his popularity, since most of his upper-level classes were indeed partially populated with people not up to grasping the material.

7. **ObsessiveMathsFreak**
   April 12, 2007

   > Except for 18.03 (Differential Equations–the largest class at M.I.T.), Rota disliked teaching large classes.

   He didn't paticularly like teaching that either. Well, at least not as much as he would have liked.

   I always find it uplifting to encounter such diatribes from experts in the field, especially when one always found the subject opaque. It's nice to see mathematics presented in a more human light instead of the rather dry and almost dogmatic presentations you normally get. It's a bit like Feynman's lectures, almost half apologising for the subject instead of handing down edicts from above. I think it's better to learn a more fallable subject than a polished one.

8. **Coin**
   April 14, 2007

   He didn't paticularly like teaching that [link goes to fascinating Rota talk on teaching undergraduate Ordinary Differential Equations courses] either.

   Wow. I feel almost kind of ill reading this link. In a lot of ways it's like reading a laundry list of the reasons why the DiffEQ classes I took as an undergraduate did not go well.

   —

   Something that interested me in that link– in one brief section of that talk Rota appears to be advocating using differential algebra not as an advanced tool for those people who already have a firm grounding in working with differential equations, but actually as a teaching tool for giving introductory students a better understanding of what exactly is happening when differential equations are worked with. Is this tactic Rota proposes something which there are actually examples of out there in the world? I would be very interested to see an example of such a thing, since I personally find I have a much easier time with those mathematical subjects where I have been given a clear idea of how the math is to be viewed in the light of abstract algebra (or some other tool which similarly forces the foundational or axiomatic parts of the mathematical techniques at hand to be made explicit). Rota makes reference to "Cohen's book of the twenties" as an example of an introductory treatment of differential algebra; does anyone have any idea what book exactly is being referred to here, or even which "Cohen" he refers to?

9. **anon.**
   April 15, 2007

   Maybe: Abraham Cohen, 'An elementary treatise on differential equations', 2nd ed., 1933?

10. **Coin**
    April 15, 2007

    Sounds like it, thanks.

11. **D R Lunsford**
    April 27, 2007

    Klein and Weyl are somewhat like Maxwell and Einstein as a pair. As time goes on, my respect for them just grows and grows – the luckiest thing that ever happened to me academically was to be shown the books "Elementary Mathematics from and Advanced Standpoint" at an early stage.

    Thanks for that pointer.

    -drl

MiniBooNE Results

April 11, 2007
Categories: Uncategorized

I won't bother to write up something about the background of today's MiniBooNE results, since Tommaso Dorigo has already done a better job than I ever could. He also provides a link to where the live feed of the seminar will be, starting at 11am CDT. I'll be in class at that time, but an hour later will try and attend the local seminar here at Columbia featuring Mike Shaevitz discussing the results.

And the result is….

No mu-neutrino to electron-neutrino oscillations of the sort that would explain the LSND result and require an extension of the Standard Model (beyond giving masses to the 3 known neutrinos). MiniBooNE was designed specifically to look for this, and has successfully ruled it out at 98% confidence level. They do see something anomalous in their data at low energy, but it is not compatible with being due to the kind of neutrino oscillations they were looking for. It's also true that they just first got a look at this data two weeks ago, still have a lot of work to do to see if there is some sort of background contamination they hadn't expected at these energies, or something they didn't know about low energy cross-sections. Maybe it will take them a while to sort this out, but the bottom line is that what they were looking for is definitely not there.

Press release here, paper to come soon.

Update: For an excellent description of the result from Heather Ray, one of the MiniBooNE experimenters, see this guest posting at Cosmic Variance.

Update:

Warning: serious people should stop reading now, the rest is a low form of entertainment.

For something truly hilarious, you really should be following Lubos's continually evolving misunderstandings of this experimental result, which he has taken as a reason for launching into another bizarre rant about me and Lee Smolin. As near as I can figure out, Lee and I are responsible for the misguided idea of designing an experiment like MiniBooNE to check into the possibility that LSND was seeing evidence of a sterile neutrino. His posting keeps changing (its URL is miniboone-confirms-lsnd, title now "Miniboone Refutes LSND"), with the early versions saying:

Evidence for several types of neutrino oscillations have been known for a decade or more. That includes atmospheric neutrino oscillations, solar neutrino oscillations, and a lab experiment called LSND in Los Alamos.

A simple oscillation in between two neutrino flavors – electron neutrino and muon neutrino – was a natural candidate to explain the observations but it couldn't explain details of the LSND data which is why the LSND results were questioned. Another natural candidate was a two-flavor oscillation that includes a sterile neutrino, a new kind of neutrino without a charged partner.

Today, Fermilab's MiniBooNE experiment has confirmed that the LSND results were correct and a more subtle explanation than the simple two-flavor oscillation is necessary. The result rules out the possibility that the observed oscillation is a two-flavor oscillation involving a new sterile neutrino. Their results indicate that there is something surprising that doesn't fit the most obvious model.

He does seem to have more recently gotten a clue about this and noticed that it doesn't confirm the LSND results, editing his posting and adding the standard obsessive rant. I see that in his previous posting (about a Harvard faculty meeting), according to him the proposed new Harvard core curriculum states that "All of science education must lead to increasing food production for the working class in the next 5 years ".

It seems that I am not only determining the course of neutrino experiments, but also setting the Harvard core curriculum. My powers are truly immense…

Update: Lubos has now changed the file-name from "miniboone-confirms-lsnd.html" to miniboone-refutes-lsnd.html, and deleted the comments from people explaining to him that he was confused. The new version starts off with:

I have erased several comments that only increased the amount of confusion, changed the filename to break links from crackpots' blogs, and hope that the text below is now more or less OK.

Comments

1. **a quantum diaries survivor**
   April 11, 2007

   Well, Peter, thank you: as they say around here "drink what you like, it's on me".

   I think it will be quite interesting to see if they kill their own upgrade or what…

   Cheers,
   T.

2. **Shantanu**
   April 11, 2007

   Unfortunately I am getting a "User Limit Exceeded" message. looks like
   lots of people have connected.

3. **Thomas Love**

6. **John**
April 11, 2007

Lubos is getting a little flak in his comments I see. ha.

7. **Peter Woit**
April 11, 2007

John,

Don't worry, he has dealt with that problem in the usual way.

8. **Bob Jones**
April 11, 2007

Peter,

I guess I am one of the less serious readers of your blog. And apparently you have REALLY pissed Lubos off. I only read his blog by linking from yours…and now he is blocking that with a hilarious message that reads:

"Error
Sorry but I really don't intend to share readers with that particular aggressive liar, parasite, and crackpot. If you find it appropriate to read Not Even Wrong, you're just not welcome on The Reference Frame. This type of direct links won't work. I've had huge problems with the scum pumped onto my blog by the Not Even Wrong website. I apologize if you're not a part of it but there's no way to distinguish.

You can open motls.blogspot.com if you wish.

L.M."

Wow!! Thanks as usual for the useful information and sometimes entertainment!!!

9. **gunpowder&noodles**
April 11, 2007

Still, I'd rather read LM's [current] summary than Heather Ray's hilariously anticlimactic and infinitely tedious explanation of the fact that they didn't find *anything*…..

10. **Heinrich**
April 11, 2007

This blog is not totally correct. True, miniBooNE ruled out standard neutrino oscillations as a solution for the LSND anomaly, but that possibility was already at the verge of being ruled out by combinations of results from solar, atmospheric, reactor and collider neutrino experiments. On the other hand we proposed a spectacular solution to the LSND anomaly involving neutrino shortcuts in extra dimensions, published in Phys.Rev.D72:095017,2005 [hep-ph/0504096]. If you look at Fig. 5 in this paper, you will see that for a choice of the resonant energy in the region 200-300 MeV we not only predicted the small counting rate for electron neutrino events above 475 MeV, but also the large rates in the 300-475 MeV region!
While the anomalous effect seen by miniBooNE might have a conventional explanation, it might well be the first hint for extra dimensions of spacetime!

11. **mclaren**
April 11, 2007

Like most people, as soon as I encounter the word "Lubos" or "motl" I stop reading.

Clearly something odd is going on with neutrinos. Does anyone have any take on whether this new result rules out neutrinos as the putative source of the missing dark matter? I.e., as I understand it, neutrino oscillation of the standard kind requires that neutrinos have mass, which in turn implies that they *might* be responsible for some or all of the missing matter.

Does this new result, in short, imply anything about neutrino mass?

12. **Kea**
April 12, 2007

mclaren

No, it doesn't rule out DM sterile neutrinos that appear in weird CP sectors, as Dharam points out.

13. **Matti Pitkanen**
April 12, 2007

The neutrino energies of LSND and MiniBoone are 60-200 MeV and
300-1500 MeV and oscillations in LSND mass range are found to be absent above 500 MeV. Evidence for oscillations is found below 500 MeV.

Hence LSND and MiniBooNE are consistent if one accepts that neutrino mass scale depends on its energy as TGD strongly suggests. For details see the posting at [my blog page](#).

Matti Pitkanen

14. **Kris Krogh**
April 12, 2007

We’ll also hear the preliminary results from another major experiment this week. Those from Gravity Probe B will be announced Saturday at the meeting of the American Physical Society in Florida, preceded by a NASA press/media event. (My prediction: general relativity fails.)

15. **woit**
April 12, 2007

mclaren (and others),

Remember, this is a null-result. All that happened is that this experiment was looking for something specific seen by LSND inconsistent with the standard picture of three massive neutrinos (the masses and abundances are considered too small to explain dark matter), and they showed it’s not there. You can’t claim this as evidence for your favorite exotic theory. The only anomaly they see is the low energy one, and this is based on data they just first looked at two weeks ago, and have not had the time to properly evaluate. They are in no way claiming this as a reliable measurement, their only claim is to have ruled out the supposed oscillations.

16. **Thomas Larsson**
April 12, 2007

OT: A review of NEW and TWP by Martin Gardner can be found here. He ends by quoting Glashow’s poem.

17. **tomj**
April 12, 2007

So if it rules out the inconsistent LSDN result, that is pretty important science, isn’t it?

Does this mean that the LSDN result is no longer considered a valid result, like oops, never mind?

18. **Peter Woit**
April 12, 2007

tomj,

Yes, the importance here is ruling out LSND, specifically the idea that it was seeing neutrino oscillations. The experiments were not the same, so you can still try and come up with something consistent with both LSND and MiniBoone, but that is very hard.

19. **Thomas Love**
April 12, 2007

The two experiments, LSND and MiniBoone, yielded inconsistent results. Doesn’t that mean we need a third experiment to see which was correct? It doesn’t seem right to accept MiniBoone uncritically just because it is more recent.

20. **Bee**
April 12, 2007

but didn’t LSND use anti-neutrinos where MiniBoone has neutrinos? I mean, yes, MiniBoone rules out the sterile neutrino scenario (which, as Heinrich pointed out was pretty much ruled out by the SNO neutral current data anyhow), but if one argues there might be an asymmetry between nu/anti-nu this does neither confirm nor refute LSND?

21. **Bee**
April 12, 2007

Thomas: the point is in the 3-flavor scenario LSND *is* inconsistent with the other neutrino data (lots of: solar, atmospheric, reactor). You need to come up with some ad hoc additional explanation to incorporate LSND (like e.g. sterile neutrinos) if you believe their data analysis is correct (LSND data is commonly excluded for global fits of neutrino osci). MiniBoone has re-checked the LSND energy sector and did not find any evidence against the standard 3-flavor scenario and its parameters (mix. angles, \Delta m^2).

22. **Peter Woit**
April 12, 2007

Bee,

Yes, in principle anti-neutrinos could behave differently, and I gather MiniBoone is now running with anti-neutrinos, but I don’t know if they will have the statistics to directly test LSND. Also, I don’t know how hard it is to construct models where antineutrinos would oscillate but not neutrinos, without violating CPT or running into contradiction with other experiments.

23. **tomj**
April 12, 2007

What is the importance of the results being collected in this tamper proof box? Is this just a metaphor for computer data that nobody can see while the experiment is being run?

24. **Peter Woit**
April 12, 2007

tomj,

It’s not that it’s tamper-proof. The idea of a “blind” analysis like this is to try and do the data analysis while not knowing how the choices one makes affect the final result, to keep oneself from subconsciously skewing one’s choices to get a certain result. The problem with a blind analysis is that you may miss problems with the data that only show up in the final result, not in the partial results you allowed yourself to look at. This may be the cause of the low-energy anomalies they found in their final result.

25. **Brett**
April 12, 2007

For neutrinos and antineutrinos to oscillate differently, you need CPT violation, and you can’t break CPT very easily. To have CPT violation, you need to give up Lorentz symmetry, or locality, or unitarity, or energy positivity, or something equally basic. You can’t just resolve the discrepancy between LSND and MiniBooNE by introducing a “CPT-violating mass”; no such operator exists. You instead have to introduce a neutrino mixing interaction that violates one of the conditions that I mentioned, and–very importantly–these kinds of exotic operators will not give oscillations with the same L/E dependence that is seen in mass oscillations. For example, with Lorentz violation, it would be quite possible to have oscillations only at lower energies (where they were seen by LSND) without actually violating CPT, and thus have the oscillations in both neutrinos and antineutrinos.

26. **M**
April 12, 2007

even LSND interpretations based on sterile neutrino(s) were already significantly incompatible with bounds from other neutrino experiments: this is why viable models for LSND already involved ingredients such as extra dimensional sterile neutrinos with CPT-violating varying masses. Using these tools, it is probably possible to write down models that fit both the anomalies in MiniBoone and LSND.

About the part of the post that serious readers should not read, I signalled to Lubos that what he wrote in the comments to his post contains mistakes in both neutrino physics and string theory. But instead of censoring his comments, he preferred to censor mine.

27. **H-bar**
April 12, 2007

I get forwarded to this site from the link to Lubos' posting: http://www.physics.harvard.edu/~motl/crackpot-not-even-wrong.html

28. **Wolf-gang**
April 12, 2007

> by introducing a "CPT-violating mass"; no such operator exists.

I think Gabriela Barenboim has found one though I don't have the arXiv reference handy now.

29. **Bee**
April 12, 2007

now how did that happen? I certainly haven't said I want to break CPT to explain LSND, it doesn't even seem to me remotely appealing. I was just wondering why an experiment set up to clarify LSND wasn't as close to the LSND experiment as possible to begin with.

30. **Ari Heikkinen**
April 12, 2007

Heh, that bit in your "entertainment" section nicely proves that people who think are experts at everything (no one is) will sooner or later end up making themselves look like fools.

31. **M**
April 12, 2007

Bee, because LSND and MiniBoone have many persons in common, so they cannot confirm LSND by repeating it. This is why they did a blind analysis and moved from neutrinos to higher energy anti-neutrinos, that are detected in a different way.

The present unclear situations arises because MiniBoone was planned to confirm or exclude LSND oscillations, but in the meantime the oscillations suggested by LSND had been indirectly disfavored by other experiments, and more exotic interpretations have been proposed.

For example, one proposal was oscillations among active neutrinos (without any sterile neutrino) with CPT-violating masses, but this was indirectly excluded by KamLAND. At this point both CPT-violating masses and sterile neutrinos were considered socially acceptable, so that desperate theorists could move to sterile neutrinos with CPT-violating masses…

32. **Thomas Love**
April 12, 2007

Brett Says:

"For neutrinos and antineutrinos to oscillate differently, you need CPT violation…"

But we live in a sea of neutrinos. We do not live in a sea of antineutrinos. It would be very possible "For neutrinos and antineutrinos to oscillate differently" if that oscillation is due to the interaction with the background sea.

We do not need CPT violation.

33. **Brett**
April 12, 2007

Barenboim's model is indeed CPT-violating, with a term that can be cast in a form that looks like a mass. It gets around the CPT theorem by being nonlocal, something which tends to cause a lot of problems when nontrivial interactions come into play. (I don't claim that this particular model necessarily suffers from those problems though; I myself have worked on similar Hilbert-transform-type nonlocal models that can circumvent some of the usual difficulties.)

I don't think this theory has a mass term in the usual sense though. The theory has non-canonical commutation relations for the field, which is problematic for a particle interpretation. More generally, in theories that violate one or more of the conditions that ensure CPT, different notions of the mass (which are equivalent in ordinary physics) may diverge. The inertial mass, gravitational mass, rest energy, and location of the pole in the propagator will not generally coincide.

34. **Bee**
April 12, 2007

Bee, because LSND and MiniBoone have many persons in common, so they cannot confirm LSND by repeating it.

This seems to me like a rather weird reason. If its a scientifically performed experiment it shouldn't depend on the persons.

so that desperate theorists could move to sterile neutrinos with CPT-violating masses…

That's what I am afraid going to happen. Everybody whose model is in danger now will jump and add some extra parameters, try to get published before also this window closes …

35. **Matti Pitkanen**
April 12, 2007

I would still emphasize that the neutrino energy ranges in LSND and MiniBoone 60-200 MeV and 300-1500 MeV. Low energy in MiniBoone means something still above LSND and at low energies the effect was found. For some reason this point has not been emphasized explicitly in blog discussions and has not prevented people from drawing quite strong conclusions in most blog discussions.

To me the result says that the two experiments are consistent if one accepts the possibility that neutrino mass depends on neutrino energy measured with respect to rest frame defined by laboratory. This combined with relativistic invariance of course means that neutrinos must have rather delicatate kind of interaction with matter. For my own proposal see my blog.

36. **Marco**
April 13, 2007

Bee,
I think the point in not repeating the exact same experiment is that you want to have different systematics. The important quantity that governs oscillations is L/E (= baseline of the neutrino beam / energy of the neutrinos). The strategy for MiniBooNE was to increase both L and E with respect to LSND, while keeping a similar L/E. At a different Energy, one has different cross sections, different backgrounds etc etc: in short, different possible sources of systematic errors. But since the L/E was similar, if the LSND result had been due to (oscillation) physics, it should have popped up. Which it did not.

As for more "extreme" theory models: well, what M was saying in the comment above is that CPT violation + sterile neutrinos has already been put on the market (hep-ph/0308299), because CPT violation alone or sterile neutrinos alone were already in trouble before MiniBooNE. It's up to your taste to like it or not.

Now let's see what these "desperate theorists" (as you said) will find to explain that little excess at low energies in MiniBooNE. For the moment, hats off to Heinrich's model (see his comment above)! It's certainly a bit of an extreme model, but they had predicted something like this sort of excess. I think he is celebrating with some good Alabama whiskey…

37. **Bee**
April 13, 2007

Hi Marco,

🙂 I've played around some years with extra dimensional neutrino models, and believe me, some of them were far more extreme. These models with mass varying neutrinos – well, interesting, but I admittedly find it very implausible. But yes, I see. I guess the intention was to check several points in which LSND was different but not mingling them all together?

Hi Matti,

thanks for pointing out that the energy range was different as well, I must have missed that. I would suspect though that if there really is an effect in this case it's less a neutrino effect, as a data analysis problem. As Marco mentions, for analyzing the detected neutrinos you need 3 factors: production (how many start), oscillation (where do they go), and detection (cross-section). I can't recall all the details but at some point I tried to figure out how the cross section for neutrinos are modeled in the monte-carlo analysis and found some are based on really poor data. Best,

B.

39. **Bee**
April 13, 2007

sorry, I always forget that HTML doesn't like 'smaller than' …

What I meant to say, look at the available data points in the region smaller than .5 GeV

http://www-boone.fnal.gov/cross-sections/boone_reference.html

And this is for neutrinos. For anti-neutrinos it's even worse.

(Peter, feel free to delete the previous comment)

40. **Marco**
April 13, 2007

Hi Bee,
first of all, I have also played with neutrinos in extradimensions, but my models were perfectly natural and incredibly compelling. 😉

But since we are on the topic, here is my partial list of things proposed for LSND, and we could rate them on a scale of "extreme" or "plausible": it could be an interesting exercise in the sociology of science. I am not sure it is very scientific though. (I don't cite references but of course I can provide them. And if I'm forgetting some category I'd like to know.)

– the well known sterile neutrinos with about 1 eV mass (but they were disfavored by a number of things even before MiniBooNE, among which cosmology)
– Heinrich's model: sterile neutrinos + one extradimension with hawaiian waves (how does this score??), still it predicted the right thing for MiniBooNE.
– models with CPT violation in the usual 3 neutrinos: disfavored, so people moved to CPTv+sterile
– on another side: models with Mass Varying neutrinos (their mass varies according to the matter around them, or according to the density of other neutrinos), both for LSND and for a connection to Dark Energy
– and now: can you guess what's coming? yes, people also proposed Mass Varying Sterile Neutrinos

So you see you definitely need to work as soon as possible on a model of Mass Varying Sterile CPTviolating ExtraDimensional neutrinos, but maybe our friend M above is already on it.

More seriously, I think this shows that the LSND anomaly was really hard to reconcile with a number of things. So it's good that MiniBooNE settled the issue. Unless, of course, we have now something anomalous again from MiniBooNE itself…

41. **Bee**
April 13, 2007

Hi Marco,

but my models were perfectly natural and incredibly compelling yeah, yeah, that's what I say in my talks as well 😉 . Regarding your partial list, I would add the above mentioned uncertainties for the cross-sections. I mean, one could go so far to ask if they have actually measured the oscillation with knowing the cross-section or vice versa. I am generally sceptic about having only one extra dimension, not to mention that this most often doesn't really explain anything. It just gives you another parameter. For all points the question is: why would such an effect only be important for the neutrinos? Best,

B.

42. **Marco**
April 14, 2007

Hi Bee,
I tend to agree that neutrino cross sections (and their energy dependance) are a delicate point. I think however that the MiniBooNE people have been very careful on this, using data from other experiments etc. Still, if you find some flaw let us know.

If I understood correctly, your other comment is that it looks a bit artificial that people invoke all those exotic things always for neutrinos and not for other particles. I.e.: why should neutrinos always be the odd ones in town?

Well, yes, but I think that in reality there is a different reason for any one of the oddities invoked. Some are more convincing, some are less.
For example, when one says "sterile neutrino" one really is taking a shortcut to say: one of all the possible "spin 1/2 fermions that are neutral under the SM SU(2)L x U(1)Y gauge group"; and since there are many of these on the market (from SuSy, from additional simmetries, even from strings!…) a sterile neutrino is not toooo exotic. If in addition it is light for some reason, the mixing with the ordinary neutrinos is likely, so here we are.
For the case of extra-dimensions, you know, once you have bought a large extra-dimension you should make the most of it and put in it everything that can fit, so the graviton and also a sterile neutrino, because they are not tied to our brane by SM forces. So here we are again having neutrinos play the exotic.
For the case of Mass Varying Neutrino models, I think the motivation was the observation that the density of Dark Energy in the Universe today is similar to the energy density of massive neutrinos today, so DE and neutrinos could be coupled. So again neutrinos end up being singled out.
And so on.

But of course the underlying reason in all this might be (more mundanely) that neutrinos are the least tested of the Standard Model particles, so we still have freedom to play.
Sorry if I talked too much.
Best, Marco

43. **Bee**
April 14, 2007

Sorry if I talked too much. No problem. You can't beat me. I managed to give a talk today which I though would take one hour, but I wasn't finished after two hours.

Regarding extra dimensions and neutrinos, what I found intriguing about this approach is that it explains why the neutrino IS the odd one out. The reason being that a right handed neutrino (if there is one) does not carry any charges of the standard model (electrically neutral, electroweak singlet), and therefore – like the graviton – is not bound to the brane. One doesn't have to invent another sterile (left handed) neutrino (though one can of course, one can always make things more difficult).

But yes, it always seems to me kind of odd to include a new feature but then only include it for part of the particles. It would seem more natural to assume it exists for all particles (but it might be only observable for some).

Regarding the cross-section, I am sure the MiniBoone people have been careful! It is just not clear to me what the errorbar on that cross-section is (its a line! can it be there is no errorbar to it?). The point I was trying to make is if I look at the data points it seems to me there aren't so really many (in fact, none) in the relevant energy region. If I look at the paper from which the curve comes, it is not clear to me how large the theoretical uncertainty is (there is a lot of talking about Method I and II, and I admit I didn't look into to details), and whether this uncertainty can be fixed with the data points in the higher energy region? I'm not saying this is a flaw, this is just something I don't understand.

Best,

B.

44. **CG**
April 15, 2007

Sorry to cut in, but I have a rather naive question which seems somewhat tangential to your discussion, though theoretically based, rather than experimental. I was really wondering what the basic arguments were in favour of only having 3 flavours to each of the particle families (eg neutrinos) in the Standard Model. From a lay-scientist's point of view (mine), it does not seem at all obvious why this should be the case. i.e, why not 4? 5? 6? infinity?

Thanks.

45. **woit**
April 15, 2007

CG,

In the standard model, particles come in generations, with one neutrino in each generation. We've seen all the particles in three generations, no evidence at all for a 4th generation, although in principle there could be one (or more). In addition, the observed decay width of the Z particle implies that there cannot be more than three low mass neutrinos. If there is a 4th generation, it has to be unlike the others, having a neutrino of a much much higher mass than the other 3.

April 15, 2007

Poor Lubos,

I worry that he is losing touch with the real world. You would think Harvard could afford to find medical help for whatever it is that’s really bugging him. I fear that a rather brilliant mind is going largely to waste.

47. **D. V. Ahluwalia-Khalilova**
April 16, 2007

The L/E for the MiniBoone at 475 MeV is nearly coincident where KARMEN data starts, while LSND’s L/E range has an overlap with that very line for 2nu oscillation analysis (as chosen by MIniBoone).

The KARMEN, LSND, and MiniBoone data are hard to understand in the context of any oscillation analysis (irrespective of any mismatch between the CP properties of the SM and the sterile mass eigenstates). Indeed, neutrino sterility should come from some new physics; and one has a big playing field for that. But, in the absence of a constraining principle, or strong experimental data, such a game is at best a good mathematical science fiction.

48. **Thomas Larsson**
April 16, 2007

The MiniBooNE paper is now available on [the arxiv](#).

Lumo’s behavior is highly typical of extremists and fanatics who grasp at any straw that they can reach in order to rationalize their belief system in the face of reality. He initially attempted to do exactly that when he first heard them talking about the low energy descrepancy and “other exciting physics”.

I would expect to find lubos trying to vindicate string theory long after it’s dead and gone to the rest of the world.

50. **Robert Oerter**
April 16, 2007

CG:

As far as the math is concerned, the Standard Model can accomodate any number of particle families, and hence any number of neutrinos. (Note: only one neutrino per family.)

There are two independent ways we know there are only 3 neutrinos in nature. One is the decay rate of the Z0 particle. Since the Z0 can decay into a neutrino and an antineutrino, the more families there are, the faster the Z0 must decay. The decay rate has been measured and shows there are 3 families.

Secondly, in the first millisecond after the Big Bang, extra neutrinos would affect the amount of hydrogen, deuterium, and helium that gets produced. Astrophysicists have measured the relative amounts of these in intergalactic space, so they can constrain the number of neutrino species out there. Their results also give 3 families.

51. **Bee**
April 16, 2007

Hi CG,

I was about to write the same as Robert. One should add that this applies for flavour neutrinos with masses smaller than 1/2 times the Z0 mass (somewhere around 45GeV) , you find [a very brief summary here](#). Best,

B.

52. **CG**
April 16, 2007

Thankyou very much Bee and Robert for your comments. I still admit that I find the idea of there only being 3 families very strange, though it is possible that, if there were heavier eigenstates, they might not be stable, ie only the first 3 eigenstates are stable, and hence are observed. Or it is possible that the notion of being able to think of a neutrino as a particle also becomes meaningless after reaching a certain energy because the local structure of space encompassing the object is no longer properly Lorentzian, but I am starting to wander into the realm of the highly speculative here.

Nonetheless, I just want to clarify– since the Z_{0} has a finite energy (~45GeV, you said I think)– surely this limits the analysis of which you speak to the measurement of neutrinos of mass less than or equal to this value? So you could have very heavy neutrinos that you are missing? Or is that a silly question? I understand that the first few neutrino flavours are [[extremely]] light, and a significant mass difference between families 3 and 4 (presuming there is a 4) seems very unlikely.

Alternatively, I suppose, you might have that the transition between Z_{0}’s and eigenvalue 4 neutrinos is forbidden by limitations on how the geometry can degenerate, hence making it possible for mass

53. **CG**
April 16, 2007

(continued from last post)

54. **CG**
April 16, 2007

less than 45 GeV evalue 4 neutrinos to occur, but again this seems very highly speculative.

(for some reason my last post got clipped too, I have no idea why >

55. **Peter Woit**
April 16, 2007

My spam filter ate my original response to CG, which I just liberated.

There is some number of generations above which you lose asymptotic freedom, but otherwise, any number of generations is possible. Particles in the second and third generation are already unstable, if there are higher generations they would also be unstable. The only way to get more generations of the same kind as we know now would be if their neutrinos are very massive so that the Z can't decay into them.

If you start speculating about new generations with neutrinos having completely different properties due to changing the structure of spacetime, you can get all sorts of things, but unfortunately I have to discourage attempts to engage in this kind of speculation here….

56. **Marco**
April 17, 2007

CG,
on the issue of the number of generations and number of neutrinos I can only add that the observations of the abundances of Helium and Deuterium (ie the predictions of Big Bang Nucleosynthesis: BBN) actually constrain the total number of active + sterile neutrinos (with some caveat). The SM generations are instead active by definition. So I would keep the Z decay as the main "argument" for having 3 light SM neutrinos, with BBN being a more general probe.

Incidentally, while it is true that BBN finds roughly 3 neutrinos, some analyses in these days claim that other cosmological probes give evidence for more than 3 neutrinos. The extra ones have therefore to be sterile. But it's still uncertain ground.

Bee, regarding the cross sections you may be right in having some uneasiness. Maybe one could ask someone in the collaboration for more details.
Best, Marco

57. **Bee**
April 18, 2007

Hi Marco,

Maybe one could ask someone in the collaboration for more details.

That's what I did, but haven't yet come to any conclusions. Check my blog every now and then, I will try to write something if I can answer that question. Best,

B.

If there turns out to be a fourth generation, it will be discovered at LHC. There are strong constraints on such a fourth generation, but who knows?

60. **Bee**
April 23, 2007

so that desperate theorists could move to sterile neutrinos with CPT-violating masses…

That's what I am afraid going to happen. Everybody whose model is in danger now will jump and add some extra parameters, try to get published before also this window closes …

Here we go, these people really move fast:

http://arxiv.org/abs/0704.2593
CPT and lepton number violation in neutrino sector: Modified mass matrix of neutrino coupled to gravity
Authors: Monika Sinha, Banibrata Mukhopadhyay

Abstract: We study the consequences of CPT and lepton number violation in neutrino sector. […]

*The oscillations between different kinds of neutrino
and antineutrino flavor have been observed form solar,
atmospheric and LSND data. The three pieces of observation
indicate three values of mass-squared difference
of three different orders. With three families of neutrino,
one can obtain only two independent mass-squared differences.
Therefore, observations require the introduction
of fourth neutrino which must be sterile in the standard
model. But many difficulties arise with the introduction
of fourth neutrino as discussed in literature (e.g. see [1]).*

*As an alternate proposal to accommodate the results,
many authors have proposed CPT violation in neutrino
sector [2, 3, 4]. One can either introduce a new particle
(sterile neutrino) or allow CPT violation to take care of
all experimental results with present data. However, very*

recently, MiniBooNE results have been declared which shows that LSND experimental results can not be explained simply by neutrino oscillation.

61. **orlando**
    May 4, 2007

    Hi

    to comment about the Limit from Z0 decays. This limit did not say that you only have 3 neutrinos.
    The Z0 width count number of left neutrinos!!
    If you have any lighter massive neutrinos then half Z0 mass then you always have 3 effective neutrinos, because the the unitarity constraint.

    There is a mistake between flavor eigenstates and mass eigenstates.
    If you have very heavy massive neutrinos, above half Z0 mass, then you test steriles neutrinos because the heavier states are suppressed.

    The best, Orlando Peres

62. **orlando**
    May 4, 2007

    MINI-BOONE and LSND are correct. In this week appear a paper that says that that can made compatible the negative resulys of MINI-BOOne and positive results of LSND.

    They work in 3+2 scenario, with CP violation. why CP violation? because LSND measure anti-neutrinos and MINI-BOONE measures neutrinos.
    The paper is http://arxiv.org/abs/0705.0107.

    They compute for all parameters the best fit point and found out for a slight non-zero CP phase you can have a stronger suppression of nu_mu -> nu_e probability and non-zero anti nu_mu -> anti nu_e probability.

    The values for difference of masses is around 1 eV^2 and 2 eV^2.

    the best, Orlando Peres

String Kings – The Director's Cut

   April 13, 2007

   In the String Kings III the crime syndicate with its new ruthless and increasingly decoherent Czech boss comes crashing down in a violent showdown and in the final visceral balcony scene the gutters of arXiv will be overflowing with freshly-spilled data

2. **Kea**
   April 13, 2007

   OK, I laughed a lot. But the film is a little light on its female casting.

3. **Jimbo**
   April 13, 2007

   If this does'nt cause you to crack up repeatedly, you are BAD CRAZY ! My only critique of the casting is that Segal is approx. 1/2 meter taller than Brian Greene !

4. **joe**
   April 14, 2007

   The movie "The Red Violin" could be used as parody of the futility/tragedy of ST. Links: 1, 2, 3

   From this review are some hauntingly relevant remarks on the hubris of "Beauty":

   "The soul is born in beauty and feeds on beauty, requires beauty for its life."
   — James Hillman

   "..is a spiritually rich and musically sublime drama about the soulful dimensions of beauty. It also presents some of the ways in which beauty has been perverted by people's hubris and their treating it as a commodity."

   "..predicting a long journey [Italy, Austria, Oxford/England, China, Montreal] characterized by moments of great happiness and disaster"

   "New York expert Charles Morritz (Samuel L. Jackson) appraises it as "the perfect marriage of science and beauty."

   As I understand it, the ST "gang" is fixated & in love with mathematical beauty?

   Is this movie an example of "Life imitating Art [which is itself imitating Life]"?

   "Theory & Experiment":

   I was impressed by one scene, where the violin teacher schools the student on the important of Theory:

   "violin..cheese.
   There's something about your playing that eludes me..I've decided to analyze it systematically with a scientifc method.
   First , your bowing. And your left hand phrasing. Your detache, ornamention, and your taste.
   And theory! Theory, too, is important
   You need a lot more than inspriation to play the violin.
   You need method, you must think.. and work.
   ..
   if you play well, you'll enjoy the finest fare. My boy, play well, and there will be cheese.
   violin..cheese"

   The ST critics are claiming that 2 decades later of "stringing", there is no sign of "cheese". I guess ST gang would claim the critics are guilty of "Whine", or as the popular phrase goes "If they bring the Whine, I'll bring the Cheese". As pointed out recently, ST conferences should have a "Alternatives" to ST for balance..thus making it a "Whine & Cheese" exhibition.

   BTW, there was a good sequence where the female Communist party leader said "Sometimes the teacher can learn from the student". This is reminiscent of Feynman's philosophy, of not taking a position where teacher-student interaction is non-existent (like at IAS/Princeton). Take this metaphor further, maybe a "counter-point" to ST by critics could be useful to ST development.

   There is also a good sequence about "dogma VS revolution":

   "The [Communist Chinese] authorities denounce Western music as decadent and the old music teacher reminds them that Beethoven was a great revolutionary."

   Is ST "revolution" (its intention), or just a dogma by the "Gang of 4"?

5. **Jonathan Vos Post**
   April 14, 2007

   It still doesn't sound like Space Opera. Close, but not hitting on all 20 criteria.

   Brian W. Aldiss, in his anthology "Space Opera" [Garden City NY: Doubleday, 1974]

identifies various key indicators of “Space Opera” as (if I may interpolate
from his delightful introduction):

(1) Style and Mood staunchly traditional
(2) Hitherto unknown places to explore
(3) Continuity between Past and Future
(4) Tremendous sphere of space/time
(5) A pinch of reality inflated with melodrama
(6) A seasoning of screwy ideas
(7) Heady escapist stuff
(8) Charging on with little regard for logic or literacy
(9) Often throwing off great images, excitements, aspirations
(10) The Earth should be in peril
(11) There must be a quest
(12) There must be a man to match the mighty hour
(13) That man must confront aliens and exotic creatures
(14) Space must flow past the ports like wine from a pitcher
(15) Blood must run down the palace steps
(16) Ships must launch out into the louring dark
(17) There must be a woman fairer than the skies
(18) There must be a villain darker than a Black Hole
(19) All must come right in the end
(20) The future in space, seen mistily through the eyes of yesterday

Well, not all these indicators are valid even for each of the stories he’s assembled, but his list is indicative.

For details, see:

http://www.magicdragon.com/UltimateSF/thisthat.html#spaceopera

News From the Landscape and Elsewhere

April 17, 2007
Categories: Uncategorized

At the big annual APS meeting, now going on in Jacksonville, of the 9 plenary talks, one is about particle theory. The talk is entitled “String Theory, Branes and if You Wish, the Anthropic Principle” and it was given by Shamit Kachru of the Stanford group. Here’s the abstract, which besides the usual claims that string theory is “our most promising framework for a unified theory of the fundamental interactions” and that “the underlying theory is unique”, also makes the claim to have “testable ideas about inflation and particle physics”. No clue what these ideas are, so I don’t know if they include the testable prediction the landscape makes about the proton lifetime. Also unclear why the Anthropic Principle is being demoted to “if You Wish”. Lots of experimental talks on particle physics at the conference, here’s a Fermilab press release on CDF and D0 results discussed at the meeting. Lawrence Krauss was speaking on “Selling Physics to Unwilling Buyers”, I wonder what that was about. More about the meeting at the Physics Meetings blog.

David Ben-Zvi has put up on his web-site his lecture notes from last week’s series of lectures in Oxford on geometric Langlands. As usual, a very readable survey of the subject, emphasizing links to representation theory.

For another source of material about representation theory and the (non-geometric) Langlands program, see the web-site hosted by the Clay Mathematics Institute devoted to the collected works of James Arthur.

There’s yet another round of discussion on bloggingheads.tv between science writers John Horgan and George Johnson. This week the LHC and the state of particle physics are some of the topics they consider.

From Fermilab, various new sources for discussion of the future of experimental particle physics include:

A web-site for the steering group tasked with developing a roadmap for future use of US accelerators. This week’s meeting includes a presentation on reconfiguring the Fermilab accelerator complex to produce larger numbers (factor of 3 more) protons, for use by neutrino experiments and others.

The Fermilab Physics Advisory Committee met on March 29-31, here are the presentations and report.

Last week there was a workshop devoted to considering what effect early data from the LHC would have on plans for the ILC (via Tommaso Dorigo).

Finally, Steven Miller, author of “String Kings”, has a new blog he is working on, devoted to essays on mathematical physics, theoretical biology and the history of science.

Update: Two more.

Seed magazine has a series of “cribsheets” about science. For physics, they cover nuclear power, the elements, and now string theory. The lack of predictivity of the theory is given a positive spin as being due to the “rich diversity” of string theory. At Cosmic Variance, Sean Carroll approvingly refers to this as “it only refers glancingly to the anthropic principle, which is a much more accurate view of the state of discussion about string theory than one would get by reading blogs.”

Nature has an article about the state of the LHC and the possibility that the Tevatron might be the first to see the Higgs. LHC project manager says that they were already running about 5 weeks behind schedule before the problem with the quadrupoles appeared, but says “In my view the magnet problem has been blown out of proportion… It is a very small part of a bigger picture.” If the schedule slips much more, there might not be time for an engineering run in 2007, and the first science run might be delayed until later in 2008.

Update: Thanks to commenter F. for pointing to the slides from Kachru’s talk. It’s a clear presentation of the moduli stabilization problem and the techniques that he and others used to solve it, while at the same time making the landscape problem much worse. The “testable” ideas mentioned in his abstract are the usual sort of thing behind claims like this: not actual tests of string theory, but effects in certain very specific models among the infinite variety of ones you can get out of string theory. Kachru doesn’t much address the issue of whether the landscape framework is testable science in the conventional sense, other than to describe people’s attempts to use eternal inflation to explain how the vacuum gets selected and try and get physics out of this as “notoriously confusing.” He also describes counting of vacua as favoring high-scale supersymmetry breaking, so maybe there is a prediction: no supersymmetry at the LHC.

Update: For the latest from FNAL on the LHC magnet problems, see here.

Comments

1. **Tim**
   April 17, 2007

   Peter,

   “No clue what these ideas are, so I don’t know if they include the testable prediction the landscape makes about the proton lifetime.”

   Would you ellaborate on that? The landscape makes an experimentally testable predition?

   Best,
   Tim

2. **Peter Woit**
   April 17, 2007

   Tim,

   One of many problems with the anthropic landscape is that conservation of baryon number is rather special, typical vacua will have baryon number violating interactions. The bounds on the proton lifetime are something like 10^32 years, whereas, anthropically, all that is needed is for only a small fraction of protons to have decayed since the big bang (10^10 years ago). So, unless you can find a landscape argument for why the GUT scale has to be so high (and I don’t know of any) protons should decay much, much faster than they do in the real world. The landscape folks seem to take the attitude that they can claim “testable predictions”, while ignoring the fact that similar or even better grounded “testable predictions” of the scenario are already falsified.

3. **dan**
   April 17, 2007

Peter,
Proton decay experiments have falsified SU(5) and SUSY-SU(5), I am unsure about SO(10), but if GUT as a class are all falsified, whether through proton decay experiments or lack of monopoles, would this falsify stringy unification scenarios, or for that matter, the need for SUSY in GUT unification?

Thanks
Dan

4. **woit**
April 17, 2007

dan,

I don't think you can falsify GUTs as a class, since you can always find models with longer proton lifetimes than can be measured, in particular this is true for some SUSY-GUTs. In stringy unification scenarios you can get any proton lifetime you want, so, again, you can't falsify these.

What you can falsify is the idea that we're at some generic, anthropically allowed point in the string theory landscape, and this has already been falsified by not seeing proton decay.

5. **Dan**
April 17, 2007

Hi,
thanks for answering my question. I infer though that all stringy unification scenarios are extensions of GUT scenarios, which may or may not be physical (and the simplest sort, SU (5) and SUSY (5) has been ruled out).

6. **anon.**
April 18, 2007

Dan,

Because SU(5) has been ruled out, it is at least wrong, which is a whole class better than the not even wrong status of string based unification, where there's a landscape of theories too big to ever rule out. However, the way that some unification schemes can be fiddled to keep falsification at the door, is familiar:

'Many physicists are working very hard trying to put together a grand picture that unifies everything into one super-duper model. …

'Somebody makes up a theory: The proton is unstable. They make a calculation and find that there would be no protons in the universe anymore! So they fiddle around with the numbers, putting a higher mass into the new particle, and after much effort they predict that the proton will decay at a rate slightly faster than the last measured rate the proton has been shown to decay at.

'When a new experiment comes along and measures the proton more carefully, the theories adjust themselves to squeeze out from the pressure. … The phoenix just rose again with a new modification of the theory that requires even more accurate experiments to check it.'

– R. P. Feynman, *QED*, London, 1990, p150.

This is the interim step between definitely falsifiable theories, and definitely unfalsifiable stringy M-theory. It must be a sociological issue. Mainstream physicists didn't want to risk to their careers of being experimentally refuted after working on and popularising a falsifiable theory, so in the 1980s they started getting excited about theories that were increasingly 'safe' from experimental tests.

The usual claim that extradimensional string theory started out with the hope of being checkable but gradually the initial optimism has proved exaggerated, is maybe bit too kind to the string theorists. It didn't have any experimental evidence at the beginning, just a lot of hype and 'hopeful possibilities' (which isn't worth a dime in science, where facts alone count and hope is just faithful religion).

7. **John A**
April 18, 2007

Peter,

what do you think of [this]?

> Although the theory is not definitive, Sparling explains that several major ideas in current physics would likely play a role (such as condensed matter physics, category theory, non-commutative geometry, string theory, and the structure of superfluids). Such connections might also point the direction to a unified theory, though currently speculative.
>
> "My work can be seen as a strong antidote to the present air of pessimism surrounding modern fundamental physics," Sparling said. "As is well-known, string theory has been roundly criticized for its lack of predictive power. String theorists have been reduced to an absurd reliance on the anthropic principle, for example. Here I have a clear-cut prediction, which goes against the common wisdom, which gives experimenters a target to go for: first find the extra dimensions, then decide their signature (a very tough homework assignment!). Of course I could be proved wrong, but the effort to decide is surely worthwhile.
>
> "Actually, in the area of philosophy, I am in opposition to string theory," he said. "It is a top down theory: dream up something that works in some high dimension and then try to finagle some way of reducing to fit in with the lower-dimensional theory. My approach is bottom up: take the existing four-dimensional theory seriously and try to build up from it. This is very tough to do. Hopefully my ideas work. Note that my work only constitutes a possible beginning at a more inclusive theory."

8. **woit**
April 18, 2007

John,

I'd really like to avoid turning this into a forum to discuss very speculative ideas like Sparling's, this is something I don't have the time or energy to moderate and would quickly get out of control. A couple quick comments though: in general I think the idea of using twistor geometry is promising, it is a very fundamental idea about 4-dimensional geometry. I haven't looked yet to see exactly what Sparling is doing, but all attempts like this I've seen in the past don't reproduce the standard model QFT set-up. My feeling is that you need not just the typical kind of kinematical idea about finite-dim symmetries that people are trying, but some new insight into the structure of gauge theories that would make non-trivial use of spinor geometry.

9. **Christine**
April 18, 2007

It must be a sociological issue. Mainstream physicists didn't want to risk to their careers of being experimentally refuted after working on and popularising a falsifiable theory, so in the 1980s they started getting excited about theories that were increasingly 'safe' from experimental tests.

I often find such statements disturbing. In the same line, it has been argued elsewhere that string theorists have invested their whole careers in string theory and with the lack of experimental confirmation (or lack of predictability, for what is worth) they are making use of desperate arguments like the anthropic interpretation for the landscape, as a new shift in paradigm of the scientific method, etc.

Well, what sounds odd to me is that there is a basic principle that *any* scientist learns very early: failure is much more common than success. Or, better yet, as Thomas Edison have (presumably) said:

> I have not failed. I've just found 10,000 ways that won't work.

Whether string theory will turn out to be right or not, is not the problem here, but simply the fact that *one should not make claims in advance before effectively succeeding*. So, if some string theorists are doing such a thing, yes, they would be wrong in a very basic sense.

On the other hand, independently of making anticipated claims or not, if things look bad enough so that there is a possibility that string theory will not be successful, that would not be the case for desperation.

What, if a scientist fails? How much is that bad? It's part of the game!

Winners x losers is a strong paradigm of the american society, and I often find it funny from my latin american perspective. Yes, it can lead to useful achievements in some aspects, but not always. But it makes no sense to see scientists as winners or losers. Great scientists had their moments of discovery and failure.

So I can only conclude that the problem stands on the following general *basic* issues:

1. You should never make anticipated promises in science. Things might work, or might not, and the latter is much more common than the former.

2. In science, there are no winners or losers, but the advancement comes, in general, from brilliant people, clever experiments, incremental work, some luck and opportunity windows, failure (yes!), and, finally, (using another quote from Edison):

> one percent inspiration, ninety-nine percent perspiration.

The bottom line is a very obvious thing: any good scientist does not fear failure, does not make anticipated claims, and are not winners or losers. They're are just… scientists.

I do not have doubts that there are many good scientists working in string theory. So I can only agree that the sociological issue has a share of importance in the whole issue, which, for what is worth, will be very interesting from the point of view of the history of science.

Christine

10. **Peter Woit**
April 18, 2007

Christine,

I agree that most scientific research is speculative and ultimately won't work out. So people should be expecting to spend most of their time on ideas that will fail, or lead to very modest advances, and there's nothing wrong with this. The problems people are addressing now in particle physics are extremely difficult, and one should expect essentially everything one tries to not work. What bothers me is that I don't see people trying a lot of different things, and giving up on ones that don't work. Instead, effort continues to pour into a narrow range of ideas, especially string theory, even when a huge amount of evidence has accumulated that the idea of getting a unified theory out of a 10 or 11 dimensional string theory is inherently unpredictive and can't work.

This seem to me to involve two big questions which I don't think are being addressed, a positive one and a negative one:

1. How do you encourage people to try something new, different than what other people are doing, given that it is most likely to fail? Can one provide incentives so that young people do not feel that they are probably committing professional suicide when they try and do something new and ambitious?

2. How do you get people to acknowledge that an idea that they have a huge amount invested in doesn't work, once it becomes clear that this is the case? In the past, experimental results provided discipline of this sort, now we see a whole field devoted to ideas that inherently cannot be confronted with experiment, and thus are immune to this kind of discipline.

11. **anon.**
April 18, 2007

'How do you get people to acknowledge that an idea that they have a huge amount invested in doesn't work, once it becomes clear that this is the case?' – Peter Woit

You can't do that. If people are irrational enough to believe in an elaborate guess which just interconnects assorted speculative unobservables (gravitons, supersymmetry, standard model unification at near Planck scale energy), without any connection to observables, and without any hope of making falsifiable predictions from the landscape, it won't be possible to get them to give up!

It's like trying to debunk religion or UFOs, it can't be done because there's no evidence to be discussed, there's nothing physical to be scientifically examined. In a free country, people are entitled to believe in failed theories, crazy ideas, and whatever they want. The basis of the problem is groupthink, is the illusion that because it has a lot more people than alternatives, you get the the 'so many people can't all be wrong' dogma being used to defend the mainstream, despite the lack of science. The only way they could be defeated is by losing research grants, with the media ignoring their arrogant, unsubstantiated claims.

12. **Christine**
April 18, 2007

Dear Peter Woit,

Yes, the two points you make are important.

1. The system must definitely be reformulated. Negative results are results. Lessons learned are results. New ideas should be incentivized up to the point that they can be scrutinized by the scientific method. Number of papers cannot be taken as the absolute measure of a scientist's achievement.

2. Such an acknowledgement must arise from two fronts: an internal one, in which a good scientist will eventually reach at, and from an external consensus, which depends on how the system is structured (item one above).

However, these are simple views that I have, from a simpler world. I understand the issue is in reality much more complex than the solutions above suggest.

Christine

13. **andy**
April 18, 2007

Christine: you said *Number of papers cannot be taken as the absolute measure of a scientist's achievement*.

A noble aspiration. Regrettably, the real world does not work that way.

Sorry if I come across like a cynic. But I'm old enough to be allowed to be one.

But I respect your idealism.

14. **Tim**
April 19, 2007

Peter,

You wrote:

"One of many problems with the anthropic landscape is that conservation of baryon number is rather special, typical vacua will have baryon number violating interactions. The bounds on the proton lifetime are something like 10^32 years, whereas, anthropically, all that is needed is for only a small fraction of protons to have decayed since the big bang (10^10 years ago). So, unless you can find a landscape argument for why the GUT scale has to be so high (and I don't know of any) protons should decay much, much faster than they do in the real world. The landscape folks seem to take the attitude that they can claim "testable predictions", while ignoring the fact that similar or even better grounded "testable predictions" of the scenario are already falsified."

Now I'm at a complete loss regarding your point of view. You published a book as well as hundreds of blog postings about string theory and landscapeology being 'Not Even Wrong' because no testable prediction emerges from these ideas. At the same time you acknowledge that there is an experimentally testable prediction from the landscape (right or wrong, doesn't matter at this moment).

You changed your mind? Or what's going on? Why not change the title of the blog to 'Wrong' from 'Not Even Wrong' if your motivation for the title is the lack of an experimentally testable prediction? Will you release an errata to your book?

Please explain what you think about these matters because until now I went into great pain of understaning what you really mean and just when I thought I get your point (with or without agreeing with it, that doesn't matter at this moment) I'm just completely lost again as to what the heck your message is.

Best,
Tim

15. **Christine**
April 19, 2007

But I respect your idealism.

Thanks. And I am sure I'm one of the last idealists living today. 🙂 Enjoy yourself!

In any case, it is really difficult to have an objective measure of a "good scientist" or the potential of a young researcher, something that you can only (in general) have some judgement in a posteriori cases or when you work closely with that person. So it's more a question of acknowledging these fragile points and to decide whether one is willing to take some risks and incentivize diversity or other means as a possible paradigm for a healthy scientific activity. This is something I tend to agree with Smolin.

One other thing is the question of being very precise in defining the status of one's subject of investigation. One should be extremely careful in making use of some established convention that specifies what a theory (with "T" or "t", whatever) is, what a hypothesis is, what a set of conjectures is, what a model is, what an idea is, etc. I believe these terms are at some level reasonably distinguishable, but sometimes are used indiscriminately under different meanings in papers, talks, etc. In this respect, I think that the high energy community should attempt to reach a consensus on the status of string theory. Somewhat in analogy, astronomers met and changed the status of Pluto as no longer a planet as it was realized for some time that it did not fit the convention of what a planet is.

Christine

16. **woit**
April 19, 2007

Tim,

The point is the following: the landscape allows virtually anything, so one can't use it to make predictions. The anthropic landscape idea is something more specific, it's that one can make statistical predictions based on the idea that we must be at a "typical" point of the anthropically allowed region of the landscape. The proton decay argument shows that we're not, and this is wrong. People pushing this I suppose can argue that they still haven't worked out exactly what all the states in the Landscape are, and until this is done, one can't be sure of what will happen. But all the evidence is that there's no reason for protons to be so stable.

So, oversimplified: landscape not even wrong, anthropic landscape wrong.

The situation is more complicated than just the true statement that "string theory makes no falsifiable statements". "string theory" is not a well-defined single thing. Many versions of string theory do make falsifiable predictions that are wrong, generically string theories predict several completely wrong things. In order to evade these predictions, people have come up with these very complicated constructions designed to evade falsification.

17. **Will**
April 19, 2007

Regarding Kachru's demotion of the Anthropic Principle to "if You Wish", this may be a nod to the cyclic model of Steinhardt and Turok, which of course uses string- and brane-theoretic ideas but is emphatically anti-anthropic (as is clear from their paper "The Cyclic Model Simplified").

18. **gina**
April 19, 2007

Peter: "1. How do you encourage people to try something new, different than what other people are doing, given that it is most likely to fail? Can one provide incentives so that young people do not feel that they are probably committing professional suicide when they try and do something new and ambitious?"

Well, my opinion is that you should NOT encourage people to do
things that are most likely doomed to fail with little chance for something to show for their efforts. If they do take high risk projects, there is no way to avoid the high chance of a serious damage to their career, the way they are judged by others, and most importantly their self-judgement. There are no riskless risks.

There is one thing you can do. It is to have a culture were high risk ideas are examined, and read, and people think about them and comment on them, and mainly criticize them. In this aspect, when it comes to the string theory debate the people on the string theory side are overall much better.

19. **Thomas Love**
April 19, 2007

Christine said:

"I think that the high energy community should attempt to reach a consensus on the status of string theory. "

I don't believe that's possible right now. Physicists don't like to abandon a theory until they have a new theory to work on (one must publish, even if it is junk) and it is unlikely that a new theory would be accepted quickly. There are (at least 10 fundamental issues on which quantum theory and general relativity are incompatible, even if our choices are choosing from column q or from column r, there are 2^10 =1024 possible choices (it is possible that neither is correct).

20. **E.**
April 19, 2007

Peter,
You like to claim that string theory 'doesn't work'. Do you have proof of this statement beyond arguments against the landscape? If the difficulty of connecting with experiment is your sole criteria, then I would counter that this is not a problem with string theory, but a problem of a lack of experimental data at high energies. ANY theory of quantum gravity will have the same problems. Hopefully, within the next year this situation will begin to change as LHC begins to produce data. The smart money is on TeV scale supersymmetry which, while not proving string theory, is strong evidence in it's favor. Precision experiments that follow should allow us to determine the exact mechanism by which SUSY is broken, information which will help the string theorist. You should keep in mind that what we call string theories are really just perturbative limits of M-theory, which is largely unknown. We need experimental data to get beyond perturbation theory.
PS: I look forward to seeing you eat crow within the next two years.

21. **Christine**
April 19, 2007

Thomas Love wrote:

Physicists don't like to abandon a theory until they have a new theory to work on

That is certainly *not* what I have suggested. Please read my comment again.

Christine

22. **Christine**
April 19, 2007

E. wrote:

If the difficulty of connecting with experiment is your sole criteria (…)

Hm. I think it's more than in time for Peter Woit to write a FAQ about his main arguments.

Christine

23. **E.**
April 19, 2007

Christine,
Difficulty connecting with experiment is the ONLY possible argument against string theory. String theory is the ONLY framework which allows one to combine quantum mechanics, gauge theory, and gravity in a consistent way. If Peter has the ability to refute this statement, then I'd like to see a paper by him on the arXiv which is also submitted to a refereed journal. He can pontificate all he wants, but this is not scientific.

24. **anon.**
April 19, 2007

E., you're missing the point even if all alternatives like LQG with its prion particle model really are dismissable; *the connection to experiment is the ONLY possible criterion of science*. String theory connects only to speculations; alternatives have less speculation in them, and fewer degrees of freedom. They're more factual, which is science. Eg, see Feynman video explaining

"It doesn't make any difference how beautiful your guess is…"

– http://www.youtube.com/watch?v=ozF5Cwbt6RY

25. **E.**
April 19, 2007

Anon,

Again, the problem is not with string theory, but the fact that the energy scales involved are so large that experiments are difficult if not impossible. String theory can make contact with experiment, however it is difficult at this stage to make predictions since we are working with approximations to M-theory. At present, we can only show that it's POSSIBLE for string theory to describe our world, and then try to work backwards. Yours and Peter's arguments would essentially argue against the entire enterprise of quantum gravity, not just string theory, on the basis that it's difficult to make experimental predictions. Any other theory you want to bring up will have the same problem. However, there is only one theory which is mathematically consistent with the potential to do the job, and that is string theory.

26. **Christine**
April 19, 2007

Gina,

Woit wrote:

The problems people are addressing now in particle physics are extremely difficult, and one should expect essentially everything one tries to not work. What bothers me is that I don't see people trying a lot of different things, and giving up on ones that don't work.

So it is not that he is "encouraging people to do things that are most likely doomed to fail with little chance for something to show for their efforts". It has to do with the nature of the frontier of knowledge that high energy physics represents today in the search for a quantum gravity theory or the unification of fundamental interactions. It has to do with acknowledging the difficulties involved. So it is to encourage people to work in a difficult subject, yes, but with the expectation that ideas might turn out (more frequently than desired) to be wrong, so one has to be extremely cautious and willing to accept failure as part of such an endeavor. Such eventualities should not be seen as a failure in their scientific careers, but part of it. But yes, the system as structured today is not ready to identify such eventualities as part of the effort, nor is open to encourage new ideas. In consequence (at least, in part), the system ends up to be also insensitive to some undesired distortions.

Christine

27. **anon.**
April 19, 2007

"Again, the problem is not with string theory, but the fact that the energy scales involved are so large that experiments are difficult if not impossible. …" – E.

That is a pathetic defense and it *is* a fault of string theory. A good theory should not build upon unobservables that can't be checked. This is the whole trouble: string provides solutions for non-existent, imaginary problems on scales that can never be onserved, and in the process requires more uncheckable speculation.

28. **Christine**
April 19, 2007

E. wrote:

I'd like to see a paper by him on the arXiv which is also submitted to a refereed journal.

You are not alone in such a desire (but it should not necessarily be a paper by Peter Woit). For a long time I am willing to see a detailed technical argumentation in a refereed journal on the status of string theory, critically assessed. I would expect to see such a paper written even by a string theorist. In any scientific field, it is natural for the researcher to assess the pros and cons, the open problems and discoveries, of their current investigations.

Christine

29. **Thomas Love**
April 19, 2007

E. Says:

"String theory is the ONLY framework which allows one to combine quantum mechanics, gauge theory, and gravity in a consistent way. "

Can you prove that?

30. **E.**
April 19, 2007

Anon,
It isn't string theory's fault that nature has placed the unification scale at 10^{16} GeV. Perhaps those ancient Greeks theorizing about the existence of atoms were pathetic as well, since they couldn't possibly perform experiments to test this idea.

31. **E.**
April 19, 2007

Dear Thomas Love,
This statement was proved in 1984 by Green and Schwarz.

32. **Peter Woit**
April 19, 2007

I think I've made the arguments I want to make about what the problems with string theory are clearly and in detail in many places. For one version I recommend
http://www.math.columbia.edu/~woit/testable.pdf

Maybe I should write up this sort of thing as a formal paper to put on the arXiv, but I'd rather spend my time on other things. I simply don't believe that doing so would have the slightest effect on the views of string partisans like E., who have a long list of unshakable ideological beliefs that just don't correspond to reality (like the belief that the 1984 Green-Schwarz anomaly cancellation proves that "String theory is the ONLY framework which allows one to combine quantum mechanics, gauge theory, and gravity in a consistent way. ") For the less partisan, there are now plenty of places people can read what I and other string theory critics have to say, see how string theorists respond, and make up their own minds. A few years ago only one side of this argument was readily publicly available, that has changed a lot.

Some string theorists do still seem to believe that the LHC will see supersymmetry, with a pattern of supersymmetry breaking that will correspond to a specific class of string backgrounds, that will then used to make real predictions. From talking to many string theorists, my impression is that the "smart money" no longer has much faith this is going to happen and would not be willing to bet on it. What I'm seeing are people well aware that this hope is looking more and more unlikely to work out, so they are hedging their bets, to make sure that they won't be eating crow a few years from now.

33. **Christine**
April 19, 2007

E. wrote:

This statement was proved in 1984 by Green and Schwarz.

About this paper, here is an interesting comment from one of the authors:

[This week's citation classic](): the Consistency of Superstring Theory.

Green writes:

> A fundamental problem of all present formulations of string theory is that they are based on an approximation scheme in which the geometry of the space and time through which the string is moving is treated nonquantum-mechanically and is an input to the theory.

34. **anon.**
April 19, 2007

"It isn't string theory's fault that nature has placed the unification scale at 10^{16} GeV. Perhaps those ancient Greeks theorizing about the existence of atoms were pathetic as well, since they couldn't possibly perform experiments to test this idea." – E.

1. You don't know for sure that unification occurs at 10^{16} GeV.

2. 'Atom' is Greek for not splittable. All the Greek ideas about the atom turned out completely wrong.

35. **island**
April 19, 2007

The message that I continually get is that LGQ has failed and String Theory is pursued as the only avenue left, while Peter Woit points out that this isn't even science, yet nobody sees this as the first sign that quantum gravity and the standard model are in deep trouble, rather, they point back to the other failed solution as the better solution because it's the only "other" game in town that doesn't include *as many* unproven or semi-established assumptions.

People keep crying-out for a new Einstein, and how we need "seers", but their insights must be conditionally attatched to one of the only two games in town, or the consensus will kill Albert with its momentum to hell.

36. **Chris W.**
April 19, 2007

PS: (on anon's comment) Greek atomism was, from a modern perspective, a largely *metaphysical* hypothesis, notwithstanding some remarkably insightful comments on familiar observations by the Greeks, made in light of atomism. In the hands of Newton and his successors this metaphysical hypothesis was ultimately extraordinary fruitful, insofar as it inspired powerful ideas that were truly testable against observations.

I'll take E.'s comment as an admission that the founding assumptions of string theory are essentially metaphysical. That's fine; metaphysical ideas have had an important place in the development of scientific theories, as have criticisms of undisciplined metaphysical speculation by Mach and others. (Einstein arguably appreciated this creative tension better than anyone else ever has.)

However, by now it has become apparent that the putatively scientific spawn of string metaphysics is an interpretive mess. The appeal to observations that might be made with the LHC is cold comfort, because the interpretation of those observations will be as much a mess as the theoretical ideas employed in the interpretation. A whole generation of researchers have been encouraged to accept this state of affairs as normal, and even as defining a new way to do science. It's not; instead, it is a sign of a profound crisis, the response to which has been a largely myopic exercise in technically clever model-building that leads nowhere.

Nobody will be eating crow in the next two years. The string theory community should be eating crow now, but collectively they show no inclination to do so. Instead, I expect we'll see a slow dimunition of interest, and an increasingly restless search for alternative ideas. Edward Witten already seems to have moved on (to Langlands and other purely mathematical topics).

37. **Thomas Love**
April 19, 2007

anon. Says:

" 'Atom' is Greek for not splittable. All the Greek ideas about the atom turned out completely wrong."

No, the English borrowing of the word to describe the items in the periodic table was wrong. The atomoi of the greek philosophers are the proton, the electron, the neutrino and their antiparticles.

38. **a**
April 19, 2007

Peter, I don's see why the proton longevity falsifies anthropic arguments. If the weak scale is small for anthropic reasons, and if the Standard Model (or something like the SM) is the full physics below the Planck scale, then effective theory arguments imply that the proton decay rate is suppressed by 4 powers of the Planck scale i.e. that the proton has a uselessy long lifetime.

Certainly, anthropic arguments would have been much more convincing if the proton lifetime were just anthropically long.

39. **Peter Woit**
April 19, 2007

a,

Sure, but according to the statistical landscape philosophy, I see no reason why the SM (or something like it) should be all there is below the Planck scale. That's a very special theory: generically string vacua have larger gauge groups, and all sorts of Beyond SM physics. If you claim we are living in some generic, statistically likely such vacuum, it will have much faster proton decay, and anthropic considerations won't save you.

I think to avoid this argument, you have to come up with some reason that vacua like the SM are statistically favored over others. All that I've seen of actual attempts to look at large numbers of vacua don't show anything like this at all.

40. **E.**
April 19, 2007

Peter,
Are you against string theory or just the landscape? I can assure you that many string theorist do not particularly care for the landscape or anthropic reasoning either.

41. **A.J.**
April 19, 2007

E.

That paper doesn't even claim to prove the results you're ascribing to it. It argues that the SO(32) and E8 x E8 string theories _might_ be consistent, not that the string theories are the only possible such theories. You're really not helping anyone by making such wild claims.

42. **E.**
April 19, 2007

Dear A.J.,
Green and Schwarz proved that the string theories were quantum mechanically consistent and necessary included gravity, for two choices of gauge group, SO(32) and E8 x E8, as you say. I would agree that if someone came up with an alternative theory that had these properties, it would be important and people would pay attention to it, but certainly this is not the case to date. LQG is interesting, but I don't think it's possible to construct gauge theories within its framework.

43. **Peter Woit**
April 19, 2007

E.

It's not a question of whether string theorists "like" the landscape or not. Either pertubative string theory on these sorts of backgrounds makes sense, and you have a theory that is unpredictive, or else it doesn't, in which case you don't have a theory. Either way, the idea has failed.

44. **A.J.**
April 19, 2007

Dear E.,

I'm not very impressed by the argument that string theory must be the only consistent quantum gravity theory because it's the only theory we've found in the last 30 years which might be consistent. Quantum gravity is probably the hardest problem theoretical physicists have ever looked at, so we should probably let a few more centuries pass before putting much faith in arguments of this form.

At the very least, I want to see a compelling argument that Connes' non-commutative geometry theories aren't low energy approximations to a consistent theory of quantum gravity.

45. **E.**
April 19, 2007

Dear Peter,
I disagree with you that the idea is failed. We simply do not have the complete theory in our hands, only pieces. At present, it really is the only theory that has the potential to explain everything. That isn't to say that people shouldn't work on alternatives, as Schwarz and others did in the 1970's when string theory was decidely out of favor. Perhaps one of those alternatives will be shown to have the same special properties of string theory, but until that day string theory will hold the most interest. It's much more likely that additional progress will be made in uncovering nonperturbative aspects of string theory that will lead to unique predictions.

46. **E.**
April 19, 2007

Dear A.J.,
If there is another alternative, that would be great. I don't argue against other approaches, I only point out that at present string theory is the only contender.

47. **A.J.**
April 19, 2007

Dear E.,

That's the trouble with words, I guess. When you wrote

> String theory is the ONLY framework which allows one to combine quantum mechanics, gauge theory, and gravity in a consistent way.

many of us didn't realize that you were only referring to frameworks that we know of. Anyways, if what you're saying isn't really different from the standard explanation of string theory's current state, then we don't need to continue this conversation.

Best,

48. **Tim**
April 19, 2007

Peter,

You seem to be really losing it. You can't claim that string/M-theory is 'Not Even Wrong' and at the same time claim that string/M-theory is 'Wrong'.

Several people already have tried to point out to you what the problems are with your line of reasoning, but you failed to listen. I tried as well, but you failed to pay attention. In addition you think that you have something better to do than writing a technical research paper which clearly demonstrates that you have no intention of entering into real technical (or professional) discussions.

You are really like a classic internet troll. Everyone tries to explain to him that what he does is wrong, he doesn't listen, serious people give up explaining, others, mostly who are new to the internal keep explaining, they give up, yet new people come to whom the phenomenon is new, try to explain, doesn't work, give up, etc, etc, and the troll remains a troll and always finds innocents who try to talk to him without any progress in anything. No real audience, no real content.

Best,
Tim

49. **Peter Woit**
April 19, 2007

E,

"additional progress will be made in uncovering nonperturbative aspects of string theory that will lead to unique predictions."

People have been repeating this line for more than twenty years now, while everything that has been learned about non-perturbative string theory (branes, M-theory, AdS/CFT…) has led in exactly the opposite direction, to a wider variety of phenomena that don't look at all like they give the SM in any sort of unique way. As far as I can tell, string theorists have no reason at all for the belief that this is going to change except for pure wishful thinking.

50. **Peter Woit**
April 19, 2007

Tim,

As far as I can tell you're not even bothering to read what I wrote in response to your comment about "Wrong" vs. "Not Even Wrong", preferring to launch into a personal attack on me, all from the cover of anonymity. And I'm an "internet troll"….?

51. **Coin**
April 19, 2007

> " 'Atom' is Greek for not splittable. All the Greek ideas about the atom turned out completely wrong."
>
> No, the English borrowing of the word to describe the items in the periodic table was wrong. The atomoi of the greek philosophers are the proton, the electron, the neutrino and their antiparticles.

Hm. Wikipedia:

> In about 485 BC, the Greek philosopher Parmenides stated the ontological argument against nothingness, essentially denying the possible existence of a void. In c.460 BC, Greek philosopher Leucippus, in opposition to Parmenides' denial of the void, proposed the atomic theory, which reasoned that everything in the universe is either atoms or voids; a theory which, according to Aristotle, was stimulated into conception so to purposely contradict Parmenides' argument. **In the years to follow, specifically in about 450 BC, Leucippus' pupil Democritus went on to further develop the atomic hypothesis using the term atomos, which means "uncuttable".**
> …
> **The earliest views on the shapes and connectivity of atoms was that proposed by Leucippus, Democritus, and Epicurus who reasoned that the solidness of the material corresponded to the shape of the atoms involved. Thus, iron atoms are solid and strong with hooks that lock them into a solid; water atoms are smooth and slippery; salt atoms, because of their taste, are sharp and pointed; and air atoms are light and whirling, pervading all other materials.[2] It was Democritus that was the main proponent of this view. Using analogies from our sense experiences, he gave a picture or an image of an atom in which atoms were distinguished from each other by their shape, their size, and the arrangement of their parts. Moreover, connections were explained by material links in which single atoms were supplied with attachments: some with hooks and eyes others with balls and sockets.[3]**

I personally didn't know most of the things in that article so I'm finding it kind of interesting; either way, though, whether we view the greek atoms as atoms or some other class of even more fundamental particle, it doesn't appear that any versions of the atomic hypothesis that particularly resemble reality were proposed until Newton and Boyle. (Although the "hooks and barbs" idea, at least as Descartes formulated it after resurrecting the idea, seems to have a certain conceptual resemblance to valence electrons and shells).

So, E brought up the greek atomic theory as an analogy to String Theory, to observe that the greeks correctly postulated the atomic principle long before the ability to directly observe atoms was close to being available. Were I to try to make an analogy to String Theory here, it would be more to observe that even if the basic string hypothesis were someday found to be accurate, it could well be that *every single other idea* that today comprises String Theory is utterly wrong, just as the atomic hypothesis is right but the sensation of cold is not, as Democritus' version of Atom Theory would lead us to conclude, caused by atoms with pointy ends.

Another possible analogy to string theory suggests itself if you ask the question of *why* the greeks were able to correctly hit on the idea of fundamental atoms/particles, but then get all of the details wrong. One possible answer to that question is that the greeks were, as far as I can tell, working off of purely philosophical methods, with no particular effort being made to follow the modern strategy of developing testable or falsifiable hypotheses. Without at least some effort or ability to check their progress against reality, they were unable to see when at some point or other they started off on a wrong track in a minor way (for example, assuming atoms took simple geometric shapes), and after following that wrong track to its logical conclusion wound up with a theory of matter which was "elegant" and self-consistent but unfortunately, with the technology of a couple thousand years later, is observably obvious as totally wrong. There is probably a similar trap waiting in the modern era for anyone who tries to do too much by purely mathematical methods and does not at some point start seriously asking the question of how to verify against experiment…

It would be interesting to check a more in-depth history of the atomic hypothesis to see exactly at what point the idea of experimental science first became explicitly involved in the formulation of atomic theory, and see whether this had an immediate impact on the ability of the theorizers to come close to the way atoms or fundamental particles actually work.

52. **E.**
April 19, 2007

Coin,
I should point out that many scientists did not believe in the existence of atoms as late as the early 20th century. However, there were others, such as Boltzman, who used the concept of atoms to construct mathematical theories, e.g. statistical mechanics.

53. **E.**

April 19, 2007

Dear Peter,
I would disagree with you that the progress in understanding nonperturbative aspects of string theory has made the situation worse. The 'landscape' has always been with us, despite Susskind. String theory is a deep theory with a rich structure. It may take a much longer time before we really understand it. Thus, I would say your criticisms are premature.

54. **Coin**
April 19, 2007

E: Right, but Boltzmann's ideas– even if they were poorly accepted in their time– were not dependent on pure thought, philosophy or mathematics, but were fundamentally testable and falsifiable. Boltzmann's ideas about statistical mechanics were mathematical, but the math was such that it could predict things which could then be tested, even with the limited technology of his day. There are things about the behavior of gases which Boltzmann's mathematical theories based on the atomic model uniquely explain as an unambiguous consequence, and which mathematical theories based on other models of matter did not explain at all. In terms of *process* this is all quite different from or pre-Renniasance atomic theory or even modern String Theory.

55. **Peter Woit**
April 19, 2007

E.

The "landscape" has not always been with us. What was with us before the landscape was the moduli stabilization problem, and the hope that non-perturbative effects would stabilize moduli and lead to only a small number of consistent vacua. Instead they led to the landscape in its incarnation as an exponentially large number of stabilized vacua.

56. **E.**
April 19, 2007

Peter,
As I said, the problem of 10^{600} vacua has been with string theory from the beginning. The additional stabilized vacua via fluxes is just the same problem recast in a different form. In all probability, these vacua will turn out to be an artifact of our current perturbative formulation of string/M theory.

57. **E.**
April 19, 2007

Coin,
Perhaps a better analogy would be to DNA. From a single object, a wide diversity of living creatures are possible, a landscape if you will.

58. **Coin**
April 19, 2007

An analogy from what to what? That just seems unrelated to anything in this thread so far.

Anyway, a random question on a totally different subject:

Peter Woit wrote:

> Some string theorists do still seem to believe that the LHC will see supersymmetry, with a pattern of supersymmetry breaking that will correspond to a specific class of string backgrounds, that will then used to make real predictions. From talking to many string theorists, my impression is that the "smart money" no longer has much faith this is going to happen and would not be willing to bet on it.

What has to happen before the supersymmetry hypothesis can cease to be taken seriously by the scientific community entirely? My understanding is that supersymmetry is like proton decay– it can always avoid falsification by just tuning up the numbers. If an experiment fails to demonstrate proton decay, we can still say proton decay occurs but at a half-life so high the experiment wouldn't have been able to detect it; if an experiment fails to demonstrate the existence of supersymmetric partners we can still say the partners exist but at a mass so high the experiment wouldn't have been able to detect it.

However, there was a point where the lower bound on proton decay eventually got *so* high that people just stopped taking it seriously; I understand when we got to the current result of proton decay having minimum half-life 10^35 years, that was considered the same as demonstrating proton decay not to occur.

Does this same thing eventually happen to supersymmetry? While it would be great if they were found, if supersymmetric partners are *not* found by the LHC, will we start to assume they do not exist? What about the VLHC? What energy scale do we have to reach before physicists can no longer propose supersymmetric partners can still be found while keeping a straight face?

59. **woit**
April 19, 2007

Coin,

I don't think proton decay bounds are as good as you say, more like 10^33 at best. As far as I know, typical SUSY GUTs are not ruled out at this level. Typical non-SUSY GUTs are, and this caused people to lose interest in them. If you use the constraint of unifying couplings, that fixes the GUT scale, you can't just move it up.

For supersymmetry, you can move up the breaking scale, but at some point you lose the ability to claim that SUSY stabilizes the electroweak breaking scale/Higgs mass. This is actually already in trouble, the current bounds mean a significant amount of fine-tuning is required. I think if the LHC doesn't see supersymmetry, it will be hard to take seriously the idea of supersymmetry stabilizing the Higgs mass, but people may still keep claiming that the world is supersymmetric, just at unreachably high energies.

If you look at Tevatron predictions, you see a lot of people claiming that they were pretty sure the Tevatron would see SUSY. This failure didn't slow them down much, but an LHC failure might.

60. **E.**
April 19, 2007

Coin,
SUSY SU(5) has essentially been ruled out by the proton lifetime, however other SUSY GUT's such as flipped SU(5), SO(10) and Pati-Salam are still viable. As Peter

correctly points out, if SUSY is to solve the gauge hierarchy problem, then we expect TeV scale superpartner masses. If LHC doesn't see SUSY, then we're screwed. However, I don't think this is very likely.

My earlier comment was making an analogy of strings to DNA. DNA is a fundamental object, but can lead to many possible solutions. In this way, it is like the landscape. Even though we know the structure of the DNA molecule, we don't yet know how to predict exact features of the lifeform that would arise from this DNA. You could of course make a similiar analogy to atoms, which gives rise to a 'landscape' of molecules.

61. **a**
April 20, 2007

E., there is a little problem with your analogy: we can see cats and dogs and many animals and hydrogen and oxigen and many molecules, but I have never seen another universe. Can you post a picture of it?

62. **Lee Smolin**
April 20, 2007

Dear E,

You say, "LQG is interesting, but I don't think it's possible to construct gauge theories within its framework." In fact, there are a number of papers showing how to incorporate gauge theories coupled to gravity in LQG, see for one example in spin foam models, 0207041. For the hamiltonian framework there are earlier papers, for example Thiemann's papers which described coupling to gauge fields, fermions and scalars-and even earlier. There is also a literature about using LQG methods to study quantum Yang-Milsl theories, indeed the loop representation was first introduced by Gambini and Trias in this context, for the most recent work in this area see the recent papers of Florian Conrady. And before you ask, yes there are also papers on incorporating supergravity, in both path interagral and hamiltonian frameworks.

Please, could you be so kind in the future as to check the literature or check with someone in the field before making false statements.

Thanks,

Lee

ps as to how long the landscape has been with us, the earliest reference I know of to the issue of a vast number of equally consistent vacua is Strominger's 1986 paper on Torsion in Superstring Theory. He makes a clear statement that there is a problem with predictability. But Peter is right that many experts claimed for years afterwards that moduli stabilization and susy breaking would lead to a unique and predictive ground state. Those few of us who argued otherwise were definitely in the minority.

63. **F.**
April 20, 2007

Thanks for the link to the Jacksonville meeting.
Kachru's talk is a nice review of some of the current
directions in string theory. The very informative
slides of the talk are here:
http://www.aps.org/meetings/multimedia/upload/kachru.pdf

Cheers, F.

64. **E.**
April 20, 2007

Lee,
Thanks for the information on LQG. Has anyone been able to construct Standard-like models within this framework and can it make predictions for particle masses, gauge couplings, etc.? If not, then I'd like to see Peter et. al. hold it to the same standard that they hold string theory. From what I know, the main argument for LQG is that it is background independent, whereas string theory is supposedly not.

65. **E.**
April 20, 2007

Lee,
Just a thought, but is it possible that LQG is equavalent to Matrix theory? The quantized area and volume of LQG seem to me to be very similar to D0 branes….

66. **urs**
April 20, 2007

> literature about using LQG methods to study quantum Yang-Milsl theories

Here is a question I have:

any gauge theory may certainly be described by conceiving their configurations, which are bundles with connection, in terms of the corresponding holonomies. Smooth holonomy maps are equivalent to smooth bundles with connection.

In many (most?, all?) discussions in the context of LQG, people enlarge the configuration space from smooth holonomy maps to "generalized connections", namely to holonomy maps which need neither be smooth, nor even continuous.

Doesn't this step loose a lot of structure? For instance the possible nontriviality of the gauge bundles is lost (as every bundle in Set trivializes, as opposed to bundles in Top or in C^infty).

Isn't much of the difficulty in LQG of making contact with what are called "semiclassical" structures ultimately due to this enlargement of configuration space?

Can one expect to capture Yang-Mills theory — even classically — when connections are replaced by "generalized connections"?

Finally: are you aware of the work by Freed-Moore-Segal? This is in spirit very close to the concerns of LQG, in that one studies configuration spaces of connections and their quantization, but stays within the context of smooth connections. (Difference is that they consider only abelian connections at the moment, but also for higher degree.)

They find interesting, and rather subtle, quantization effects. I doubt that any of these interesting structures would survive a passage from smooth to "generalized connections”.

Or is there an idea of how to recover information about smooth connections from information about “generalized connections”?

67. **Peter Woit**
April 20, 2007

Urs,

This kind of technical discussion of LQG, while interesting, is completely off topic and not something I know know anything about. Unfortunately I can’t let this blog turn into a general discussion forum for whatever people are interested in, because I don’t have the time or energy to moderate such a thing. There are a small number of people in the world who can give you an informed answer to your question, I suggest you contact them directly.

68. **E.**
April 20, 2007

Peter,
I would argue that string theory is also something that you’re not an expert on (how many papers have you written on the subject?), but that doesn’t stop you. LQG should be part of the discussion, since it’s one of the supposed alternatives to string theory. The question is, is LQQ also ‘not even wrong’ since it doesn’t make any predictions either?

69. **Thomas Larsson**
April 20, 2007

E,

What is worse, not making any predictions after 2,000 man-years or not making any predictions after 20,000 man-years? If you put the bar at 10,000 man-years, it seems like funding to string theory to be nullified at once, whereas LQG has another 8,000 man-years to go.

Not that I believe much in LQG, but that’s another matter.

70. **Peter Woit**
April 20, 2007

E.,

I have a Ph.D. in particle theory, and have spent a sizable fraction of my time during the last 23 years learning about string theory, following the subject closely, and discussing it with many experts. I’m quite comfortable that I know what I’m talking about when I criticize it. String theorists seem to often feel that the way to respond to my criticisms is, when their scientific arguments fall apart (e.g that Green-Schwarz proved that string theory is the only possible theory of quantum gravity), to try and attack my credentials and my right to speak on this topic. This tactic hasn’t worked for them so far; it’s kind of transparent that it’s what one does when one has lost a scientific argument.

I’ve spent a much, much smaller time learning about LQG, and, as you must know if you read this blog, my main interests are in particle theory and in mathematics, not in GR or in quantum gravity. I leave the arguments about whether LQG or string theory is a better theory of quantum gravity to others, and stick to what I know about, particle physics. As a purely sociological matter though, the main problem with string theory is the way it overwhelmingly dominates the formal end of particle theory research, despite its complete failure to tell us anything about particle theory beyond the standard model. By contrast, the amount of effort being devoted to LQG seems to me quite reasonable and healthy.

71. **E.**
April 20, 2007

Peter and Thomas,
Don’t get me wrong, I have absolutely nothing against LQG. I merely make the point that it suffers from the same issues that you constantly ascribe to string theory, namely predictability. As for time and money allocation, if more people thought LQG gravity had the same potential as string theory, I’m sure that it would get more attention.

Peter: A quick check on Spires shows that you haven’t been an active researcher in nearly twenty years. At any rate, if you have legitimate arguments against string theory, write a paper on it and submit it to the arXiv and a peer-reviewed journal. That’s the proper place to have this debate, not in the public arena, where it is essentially just grand standing.

72. **dan**
April 20, 2007

Peter wroite “it will be hard to take seriously the idea of supersymmetry stabilizing the Higgs mass, but people may still keep claiming that the world is supersymmetric, just at unreachably high energies.”

Would there be any credibility to this claim, that there is SUSY at unreachably high energies, should LHC not find SUSY? A major reason for accepting SUSY to begin with was stabilizing Higgs mass against radiative corrections. Another was that it would allow GR to be renormalizable.

73. **Cecil Kirksey**
April 20, 2007

E:

Peter can defend himself, but I am a lay person (retired engineer) and I have a valid legitimate argument against string theory: After 22-23 years ST has not made single quantitative connection with the real world, none, nada, zilch, nil. Got it! It is based on two premises that were and still have not been validity, i.e.., > 4 dimensions and supersymmetry. Why continue to pursue some theory that has no connection with the real world?? I cannot think of a single instance in physics research where this has occurred for 20 odd years can you??

74. **Walt**
April 20, 2007

Wow, E, you just totally lost this argument.

75. **Ptolemy**
April 21, 2007

E.,

String is the mainstream theory, hogging the limelight. There's no mention of LQG in the popular media. However, LQG certainly sticks closer to trying to model phenomena that can be observed. This should really be a paradox for all to worry about: why have people have lost faith in simplicity?

If Peter discusses LQG as well as string, that will be convenient to string theorists, who will be able to say he's just against everything. This is the opposite of the facts, it seems, since the problem is that there needs to be more alternative ideas, not consensus on unchecked speculation like string.

String is unique – and thus singled out for criticism – because it is entirely based on unobservables and speculation of the uncheckable variety. Excuse unification problems and quantum gravity problems by introducing unobserved extra dimensions. Excuse the huge landscape of models resulting therefrom by using the anthropic principle. Excuses for speculative failures.

76. **Arun**
April 21, 2007

I wish we knew who E was – what I mean is his intellectual history. I'd like to know where E got the notion that Green and Schwarz proved in 1984 that ""String theory is the ONLY framework which allows one to combine quantum mechanics, gauge theory, and gravity in a consistent way". Was it in a physics classroom? Seminar? Who was the speaker? etc.

———

On a different note, it seems to me that the Wilsonian teaching about renormalization was that a landscape of high energy theories would all lead to pretty much the same low energy effective theory; and now string theory is telling us that a landscape of low energy effective theories results from a single high energy theory. We cannot bootstrap ourselves from having to examine each energy scale experimentally; there is no point at which we know enough that physics can become axiomatic and deductive like mathematics.

——

77. **Peter Orland**
April 21, 2007

It is interesting that E. questions Peter W.'s competency by discussing his lack of publications in SPIRES. I wish people who disagree with Peter would stop using this tactic, which ultimately undermines whatever else they have to say.

So E:

1) Peter is a mathematician these days. So what if his papers aren't on SPIRES?

2) Can't someone who is not working in an area be capable of making an evaluation of that field? By necessity, we all have to do this, to decide what to work on, or simply to maintain perspective. We often look at ideas in high-energy physics and classify them as useful or as dead ends, even if we haven't actually written papers on these ideas.

78. **woit**
April 21, 2007

I'll let E's arguments speak for themselves, but I've often been hearing from string theorists his complaint that criticism of string theory outside a peer-reviewed scientific publication is somehow illegitimate.

I would have some sympathy for this were it not for the huge amount of pro-string hype produced for public consumption over the last twenty-some years: from magazine articles to books to TV and radio programs, etc., etc. Much of this material is highly misleading and gives a completely inaccurate picture of the state of string theory research, so much so that it leads to people like E. repeating exaggerated and bogus claims like the one about Greene-Schwarz. One reason for my book was to provide scientists and the public with the other side of this story. One can argue pro or con about whether conducting debate on this topic publicly is a good idea, but I don't think one can argue that the earlier status quo, only pro-string hype allowed in public, was a healthy or honest situation. I know of a few string theorists who were privately unhappy with the public hype, no examples of any string theorists who publicly expressed any displeasure, until public criticism of the theory started to get attention.

79. **James**
April 21, 2007

It's quite sad, that someone really spends time writing anti-string theory books and blogs, when he could be doing real research instead. So far, no one has a unified theory that works, but that does not mean one should not pursue the goal. But I admit: philosophising and nagging about problems is easier than doing the real work!

80. **Peter Orland**
April 21, 2007

Hey James!

Read what I just wrote about E. above.

81. **woit**
April 21, 2007

James,

I'm not in any way opposed to pursuing the goal of a unified theory, quite the opposite. I just happen to think that the current way string theory is being pursued and promoted is very much hurting the pursuit of that goal and someone should speak up about this. Preferably someone other than me, but that wasn't happening. Sure, I'd rather be spending my time on more positive pursuits, but I just don't see the problems with string theory being addressed. Instead I see a refusal to seriously address legitimate criticism, continued outrageous and misleading hyping of the theory, coupled with ad hominem attacks on anyone who dares to make such legitimate criticism. Given these circumstances I'm not too motivated to shut up about what is going on.

82. **E.**
April 21, 2007

Peter,
To me, your complaints about the 'attention that string theory receives by the media' don't seem to have anything to do with science. It really just seems like you and others are envious of that attention. Particle physicists have had the same experience for years from condensed matter physicists who feel that it receives too much money and attention. In fact, such jealousy is partially what lead to the cancellation of the SSC in 1993. There are reasons that people pursue string theory having to do with science that have nothing to do with how 'glamorous' the subject is in the popular culture.

83. **Peter Orland**
April 21, 2007

E.

You are off the mark here. The issue isn't high-energy physics versus others in the science community. The issue is how to allocate time and resources within high-energy physics.

84. **E.**
April 21, 2007

Peter O.,
Very little money actually goes to theory at all when compared to other science disciplines. However, I don't think attacking string theory is going to help this situation. Personally, I would like to see all areas of high-energy physics receive more money, not just string theory. I do think that within the string theory community itself, too much influence over what topics are important is in the hands of too few people, in particular the Princeton/Harvard/Stanford groups.

85. **E.**
April 21, 2007

Also, for those who like to think of LQG as a viable alternative to string theory, the basic problem with it is perturbative renormalizability. As Lee Smolin pointed out, it may be possible to include gauge theory within the framework of LQG, but not in a unique way. One of the reasons for the initial excitement of string theory is that it was found that the anomalies canceled for only two choices of gauge group SO(32) and E8 x E8, in particular since E8 contains within it groups like SO(10) which hold great phenomenological interest.

86. **Peter Orland**
April 21, 2007

E.

When you say "Very little money actually goes to theory at all when compared to other science disciplines. However, I don't think attacking string theory is going to help this situation", it seems as though you mean we should shut up about our concerns for the field, because others might get wind something isn't right. Such arguments are used to persuade people not to rock the boat within every elite. Should goverment officials, police, etc., not dispute what their communities do, because it hurts their image? On the contrary, disputing how a community often helps that community.

I think a serious debate (even peppered with nasty insults, as this one seems to be), might increase positive public interest in high-energy physics. In fact, I think it is already doing that.

87. **E.**
April 21, 2007

Here's a suggestion, why doesn't Peter Woit denote all money he receives from his book and speaking engagements to people studying alternatives to string theory?

Peter O.: There's nothing wrong with debating the merits of string theory. I think it holds up well in an honest debate. It's the attacks that have nothing to do with science that are not helpful. They only serve to give the impression among the public that physicists don't know what they're doing and will in the end hurt all of high-energy physics. I do believe that the discovery of SUSY at LHC will provide some vindication, since this has been theorized on for thirty years 'without showing any results'.

88. **Peter Orland**
April 21, 2007

E.

Attacks are not helpful? Then what was all that about Peter W.'s publication record? Why this nonsense about his donating his money to alternatives?

89. **anon.**
April 21, 2007

'Here's a suggestion, why doesn't Peter Woit denote all money he receives from his book and speaking engagements to people studying alternatives to string theory?' – E.

Smolin and Woit, the biggest critics who have written books, are both working on alternatives to string. The revenue from their writing and presentations (if these are actually commercial ventures??) isn't a reliable or sustainable way to fund alternatives!

'It's the attacks that have nothing to do with science that are not helpful. They only serve to give the impression among the public that physicists don't know what they're doing and will in the end hurt all of high-energy physics.' – E.

It's not the *attacks* but *string theory* which isn't even a speculative-yet-falsifiable *theory,* let alone *science*. The physicists working on non-falsifiable ideas, whether these are in mathematics or telepathy like Josephson's http://arxiv.org/abs/physics/0312012 or supersymmetry, aren't acting as *physicists* or *scientists* when they do this.

Seeing the amount of public hype these people sell in books, it's fortunate there is some public-arena backlash, or the public would remain duped.

90. **Peter Orland**
April 21, 2007

By the way, E. a lot of theoretical physicists who work on supersymmetry
are not as optimisitic as you are about its vindication at the LHC.

http://www.strings.ph.qmul.ac.uk/~dsb/dbwager.pdf

91. **E.**
April 21, 2007

Anon: I respect Lee Smolin and the work he has done.

Peter O.: I would say that only a small minority are not optimistic about the discovery of SUSY at LHC. There are some very good reasons why we should see it. At any rate, we'll soon find out. Who knows, maybe there will be some nice surprises. For the critics of string theory, I would say wait a couple of years until we have the results from LHC. If there is no SUSY, it would indeed be a big blow to string theory.

92. **E.**
April 21, 2007

To add one note, as John Ellis has said, it is only the optimists who accomplish anything.

93. **Peter Orland**
April 21, 2007

E., said "I would say that only a small minority are not optimistic
about the discovery of SUSY at LHC. "

I think you are wrong about this. I don't have any hard
statistics, but I talk with a lot of theorists and most privately think
superpartners won't be seen. I don't know if they would admit to
this in public.

By the way, since you bring up the subject of optimists, I am an optimist. My guess is that the LHC will eventually show us
something nobody anticipated. It's not very optimistic to
think that all we'll find is what people have predicted for
decades.

94. **island**
April 21, 2007

> I would say wait a couple of years until we have the results from LHC. If there is no SUSY, **[or higgs]** it would indeed be a big blow to string theory **[and the standard model]**.
>
> Amen

95. **E.**
April 21, 2007

Peter O.,
Of course, there are the large extra dimensions people who believe TeV scale gravity will solve the hierarchy problem and the experimentalists at LHC will have black holes coming out of their ears, but don't count on it.

96. **E.**
April 21, 2007

As for what we'll find at LHC, I think we can say that if the Higgs mechanism is correct, then you have to solve the hierarchy problem. There are two ways to solve the hierarchy problem, either there is TeV scale SUSY or the Planck scale is really TeV scale and gravity only seems weak because of large extra dimensions. If the Higgs mechanism isn't correct, then we'll be back at the drawing board.

My guess is that there may be some new states discovered besides the superpartners, perhaps the quarks and leptons of a heavy fourth generation or something completely exotic.

97. **Reader**
April 21, 2007

After reading some of the comments over at Clifford Johnson's blog I just have to ask…if E. and James have actually bothered to read Woit and Smolin's books? And bets on their answers?

98. **E.**
April 21, 2007

Reader,
Yes, I've read them both.

99. **woit**
April 21, 2007

Peter O.

Thanks for the link to the betting document, very interesting. I suspect even fewer would now be willing to bet on SUSY at the LHC.

E.,

The total income so far from my speaking engagements would support one postdoc for about one week. As for the book, it hasn't quite yet earned back its advance, a sum which, after taxes would support a postdoc for about one semester. I suspect people's ideas about the amount of filthy lucre I'm making on the backs of hard-working string theorists are unfortunately exaggerated.

I don't think one or more postdoc- years to support people for whom there are no permanent jobs would change much. What's required is a change in what is going on at the places that train the next generation of theorists. If Harvard or Princeton will offer me a discount and endow a permanent faculty position for non-string formal particle theory using the funds generated by my book and speaking engagements, I'm willing to make the donation.

100. **M**
April 22, 2007

E.: actually, if instead LHC finds that the hierarchy problem is a fake problem (e.g. by discovering no new physics beyond the Standard Model), this would be a great victory for anthropists, and a great Phyrric victory for string-landscape-anthropists.

101. **N. Nakanishi**
April 22, 2007

I would like to make two comments.

1. Even if LHC does not observe Higgs boson, it is still possible to save the standard model by slightly modifying it within the framework of the manifestly covariant quantum field theory. See hep-th/07042645.

2. I believe that the Green-Schwarz anomaly cancellation condition is based on the claim of the existence of gravitational anomaly by Alvarez-Gaume and Witten. But they committed a fundamental mistake. They confused the T*-product quantities with the T-product quantities. Those are different for the matrix elements containing the energy-momentum tensor, because its expression contains time differentiation in contrast to the current in gauge theory. The argument based on the path integral is also misleading, because the path integral gives the T*-product quantities only. For detail, see Prog. Theor. Phys. 115 (2006), 1151 or hep-th/0503172 v2.

102. **E.**
April 22, 2007

M: I'm not sure how this would help the anthropists. If the Higgs mechanism is right, then you have the hierarchy problem. If the Higgs mechanism isn't right, then we have no idea how to break the electroweak symmetry and generate mass for the quarks and leptons. I don't think technicolor is a viable option.

For those who don't think LHC will see SUSY (or hope that it doesn't), all I can say is we'll see who's right within two years or so.

103. **Cecil Kirkey**
April 22, 2007

Peter:

Your last response gives me an opportunity to ask for further explanation on the funding for theoretical physics research. If I am a capable theoretical researcher all I need is pencil and paper and access to the internet. I could get a job teaching at a CC and work at night or even become a patent clerk. I heard that has worked in the past. Why does a post doc need outside funding?

I guess this goes back to the whole issue that you and Lee and to some degree Bee have written about, i.e., giving capable people the opportunity to pursue their OWN research interests. How are they being prevented from that? The financial rewards should come AFTER a demonstration of capability; before that you only have potential.

I know of no first job where one can pursue their own interests and get paid a good salary unless you are a professional athlete.

To a layperson this seems like a major issue driving the anti-ST dialogue that is why I am asking about it. Thanks.

104. **Eugene Stefanovich**
April 22, 2007

Cecil Kirkey:

I like your ideas.

If I am a capable theoretical researcher all I need is pencil and paper and access to the internet.

I would add to this list a good scientific library nearby.

I could get a job teaching at a CC and work at night or even become a patent clerk.

The great advantage of this arrangement is that you are free from various artificial pressures, such as the pressure to publish or the pressure to groupthink.

Eugene.

105. **M**
April 22, 2007

E.: the weak scale might be unnaturally small because of anthropic selection, see hep-ph/9707380. See you within 3 years or so.

106. **JC**
April 22, 2007

offtopic post

Cecil, Eugene

Teaching at a CC is ok, though a full time assignment may be quite heavy. (ie. You may have to do all the grading too).

What's NOT ok these days, is teaching high school physics and/or math. It's a complete nightmare these days. (Long story, which I won't go into).

107. **anon.**
April 22, 2007

'If I am a capable theoretical researcher all I need is pencil and paper and access to the internet.' – Cecil

'I would add to this list a good scientific library nearby.' – Eugene

Maybe you also really need to interact with other people in the field, attend conferences, give talks, put papers with preliminary results on arxiv and submit papers to journals? Otherwise – although in isolation you will be safe from the perils of groupthink and consensus – with no critical discussion and feedback, there's no motivation to tackle hard questions needed to make progress and generate interest? Patent clerks haven't been doing much theoretical physics since Einstein resigned as one in 1909 to become a lecturer.

108. **E.**
April 22, 2007

M,
Hmmm..I'm not sure how an unnaturally low weak scale keeps the Higgs from getting radiative corrections that give it a Planck scale mass…unless the Planck scale is small too. How do you explain this without large extra dimensions? Also, what about the logarithmic running of the coupling constants and their unification, with SUSY, at 10^{16} GeV? Coincidence and/or illusion?

109. **Peter Orland**
April 22, 2007

E. (and M.)

The radiative corrections to the Higgs mass don't have to be of order the Planck scale. This means that the bare Lagrangian has to be fine-tuned, but this is an esthetic problem, not a fundamental one (maybe this esthetic problem could be solved by condensation of top-prime pairs, should there be more generations).

And as to the last two questions I think extra dimensions and unification of running couplings are not illusions but delusions. There is no field-theoretic or string-theoretic derivation of dimensional compactification to four dimensions. The existence of a unification scale is not so obvious as people seem to believe.

110. **Eugene Stefanovich**
April 22, 2007

'If I am a capable theoretical researcher all I need is pencil and paper and access to the internet.' – Cecil

'I would add to this list a good scientific library nearby.' – Eugene

'Maybe you also really need to interact with other people in the field, attend conferences, give talks, put papers with preliminary results on arxiv and submit papers to journals?' – anon.

Yes, these things should be certainly present. However, being a patent clerk does not reduce ones ability to do all these things. Maybe just a little bit.

111. **E.**
April 22, 2007

Eugene,
I think the idea of some brilliant, young guy working out secrets of the universe in isolation is a nice, romantic idea. Sadly, it really isn't practical anymore. The complexity and sophistication of modern theoretical physics is such that it's almost impossible to work on it in one's spare time and without working with others.

112. **E.**
April 22, 2007

Peter O,
It's always possible that we're in for surprises. Perhaps it is only an aesthetic judgement, but I think that fine-tuning and the anthropic principle were made for each other. Personally, I believe that the simplest and most natural explanation is best. Clearly SUSY falls into this category.

113. **Peter Orland**
April 22, 2007

Ok, if you think the supersymmetric standard model is simple and natural. I think it's an abomination!

114. **E.**
April 22, 2007

Personally, I think the MSSM is very beautiful.

115. **Cecil Kirkey**
April 22, 2007

E said:

"The complexity and sophistication of modern theoretical physics is such that it's almost impossible to work on it in one's spare time and without working with others."

So why should anyone, before proving themselves, be paid a full time salary to set around and think about modern theoretical physics with or without the direct inputs of others?? Do the work first and then get compensated.

It seems like as soon as some person gets recognized and rewarded with a tenured or life time position the output really falls. One example that readily comes to mind is Alan Guth. One shot in the dark, great position and then essentially no significant output. At least from what I can judge.

116. **E.**
April 22, 2007

Cecil,
Students in theory are expected to start proving themselves in grad school. One usually needs a substantial publication record to just get a postdoc, which are highly competitive, but don't pay especially well. It usually then takes several postdocs before one is able to get a full-time untenered faculty job. It is not an easy road.

117. **Peter Orland**
April 22, 2007

Cecil,

Alan Guth did other important things besides inflation. I suggest Peter W.'s blog not be used as a forum to point out the shortcomings of individuals, whether real or apparent (which I would argue is the case, in this instance).

118. **urs**
April 23, 2007

> This kind of technical discussion of LQG, while interesting, is completely off topic and not something I know know anything about.

Sorry. I thought it would be okay to reply to Lee Smolin's comment.

119. **Gina**
April 23, 2007

Dear Christine,

You quoted Peter Woit who wrote: "people should be expecting to spend most of their time on ideas that will fail, or lead to very modest advances, and there's nothing wrong with this." and added among other things: "But yes, the system as structured today is not ready to identify such eventualities as part of the effort, nor is open to encourage new ideas."

You certainly raise interesting points, and I should think about them more. As a quick reaction let me say that the notion of success is a multi-scaled notion, so I think people are expected to be successful at least on some scale. Thinking only about the largest scale is not healthy. This is why I disagree with Peter's quote above. As for changes in the current system it can be interesting to discuss alternatives. But I am not aware of any good suggestion.

120. **Christine**
April 23, 2007

I think people are expected to be successful at least on some scale.

Dear Gina,

Well, most people would like to succeed in life. The notion of success, however, is highly subjective and varies from people to people, from culture to culture. What do you mean when you say "people are expected to be successful" — expected by "whom"?

I do agree with you (if I understood you correctly), that there are many "levels" of success. I think it is a healthy posture to acknowledge success as not an absolute thing. Also, it is not something to pursue "above everything", but only up to the point where you are not damaging someone else in order to achieve it.

In science the notion of success should be, in principle, formal, that is, related to the issues I have outlined previously. One should first be very precise about the terms "theory", "hypothesis", "idea", etc, and the level of success on them measured against an objective standard. Mainly, the scientific method sets the machine running, and a sober community of scientist evaluates the progress from time to time — *if* they are in the position to do so.

Under such a basis is where — at some level — the success of string theory is supposed to be evaluated. First, is it a theory? Second, having defined what it is, then in its present stage, what is the objective evaluation of it from the scientific community?

One question that often comes is: are really only string theorists able to evaluate string theory? Is the rest of the community really excluded from such an evaluation, even at the more conceptual level? Even given a set of objective criteria that string theory (or whatever) should fulfill, if is is to be considered a theory (or whatever)?

How deep are the intricated technical issues of string theory, how fundamental they really are in order to set the stage for its conceptual understanding, so that it fixes a clear frontier against debate to a larger community? What is exactly such a frontier?

I do not have really many suggestions to offer, but hope to read reasonable ideas in due time.

Christine

121. **Cecil Kirkey**
April 23, 2007

Peter Orland:

I was not picking on Alan just using him as an example of someone who apparently has not published much original work after his inflation idea. I did check AXIV. I think it only goes back to 1992 though. My comment was meant to indicate that sometimes researchers are rewarded with a good position with maybe the expectation that they will continue to make break throughs and then end up contributing very little. Maybe the person ends up being a great teacher or not.

122. **Thomas Love**

“I think the idea of some brilliant, young guy working out secrets of the universe in isolation is a nice, romantic idea. Sadly, it really isn’t practical anymore. The complexity and sophistication of modern theoretical physics is such that it’s almost impossible to work on it in one’s spare time and without working with others.”

Young? What’s youth got to do with it? It is a myth that only the young can do innovative physics. Just learning the necessary mathematics can take many years.

Why work with others? “Inspiration was never known to strike a committee.”

Really good ideas are radical and more than likely will be shot down in a group setting by mediocre minds (to use Einstein’s phrase).

123. **anon.**
April 23, 2007

‘As for changes in the current system it can be interesting to discuss alternatives. But I am not aware of any good suggestion.’ – Gina

The change needed to the current theoretical high energy physics is to bring it into line with experimentally-substantiated scientific disciplines by discouraging the complacency which string theory has introduced over the past twenty years. It was fine for people to investigate strings in the 80s, but it’s now well and truly failed. M-theory is not the crowning glory of physics, a grand unified theory of everything, but is more like a dunce’s tin foil hat. It’s simply better to wear no hat than that of a charlatan or, at best, loser.

High energy theoretical physics is the one science in existence which is currently crowned by a piece of ‘theory’ which isn’t a single theory but 10^500 theories, and which is neither based on experimental data, not falsifiable even in principle. Falsify one in the landscape of 10^500 string theories, and you get nowhere because there are always plenty more where that came from.

M-theory is to physics what parapsychology is to psychology. It will certainly be a success in generating overwhelming media interest and drawing in excited gullible crowds at circus time (attracting the losers who read horoscopes and believe in other faith-based-phenomena), but it is damaging to scientific discipline, a travesty to the objectivity needed by genuine physicists, and frankly it’s no more than mathematical metaphysics.

124. **E.**
April 23, 2007

Just out of curiousity, suppose that we find one string theory vacuum that completely describes the world we live in and even predicts something that is later discovered. Would this constitute proof that string theory is on the right track?

125. **Peter Orland**
April 23, 2007

Cecil,

That’s not the point – you shouldn’t use this blog as a forum for critically evaluating individuals. It just upsets people without contributing anything positive. It is not just that I don’t agree with your evaluation (use SPIRES, not arxiv).

126. **E.**
April 23, 2007

Cecil,
What did Einstein do in the last thirty years of his career?

127. **anon.**
April 23, 2007

‘Just out of curiousity, suppose that we find one string theory vacuum that completely describes the world we live in and even predicts something that is later discovered. Would this constitute proof that string theory is on the right track?’ – E.

No it wouldn’t prove it, because it would likely be a coincidence, seeing that it is just one theory picked out of a landscape of 10^500. If one monkey at a typewriter types out a poem, it’s impressive evidence for monkey intelligence. Not so if the monkey is just one selected from 10^500 monkeys at typewriters, because there is then the large possibility that it is merely coincidence.

The landscape of alternative’s to string theory is not that big. Even if everyone on earth has an alternative idea, that’s say 10^10 theories, which is trivial (one part in 10^490) compared to the oft-quoted string theory landscape population of 10^500 theories. It’s just a lunacy that people want to investigate the string theory landscape when it will be a failure whatever it produces, instead of trying new things, like modelling the facts of the particle physics using new techniques, to gain deeper insights into the masses and symmetry breaking problems before experimental results come in from the LHC.

128. **E.**
April 23, 2007

Anon,
I disagree that it wouldn’t prove string theory. If there was one string theory vacuum that completely discribed our universe in every detail and was predictive, I would hardly think this is a coincidence. We simply then have the problem of understanding why this particular vacuum is selected. If we ever find such a vacuum, perhaps the answer to this question will present itself.

129. **anon.**
April 23, 2007

E., if you write down 10^500 different sets of predictions at random, one of them may turn out to be ‘right’, without actually being the correct theory, merely because of the coincidence that such a large number of possibilities holds.

Vagueness, i.e., a big landscape, increases the probability of agreement to nature by pure coincidence. The larger the number of possibilities, the greater the chance of agreement by coincidence.

As for ‘proof’, physics is about *useful* theories. String has popularly claimed to be useful since it is claimed to have been proved a renormalizable theory of quantum gravity and perturbatively finite, but it turned out that Mandelsham out proved it finite for certain types of infinite terms, and only three out of an infinite number of terms in the perturbative expansion are really known to be definitely finite. The Maldacena conjecture, hailed as a great result, again is unproved. So M-theory is not even proved to do what it claims with mathematical rigor.

Whatever the best fit in the 10^500 theories of string is to the real universe, it will need to have its Calabi-Yau manifold fixed to prevent the moduli or parameters of the extra dimensions from drifting in nature due to instabilities in each particle containing the 6 rolled up extra dimensions. This requires moduli stabilization with a Rube-Goldberg type machine, involving fields to hold the extra dimensions in place. The whole thing is so artificial and convoluted, it's just epicycles, caloric or phlogiston all over again, minus the (faked) 'evidence' of experimental agreement that epicycles, caloric and phlogiston had.

What you hope for is that string theory will advance from being not even wrong to being wrong like epicycles, caloric and phlogiston. Dream on.

130. **JC**
April 23, 2007

What would be hilarious is if in the year 2100, some kid finds a "theory' which replicates all the "exact" solutions to the S-matrix of the Standard Model, with only high school math (ie. basic algebra).

131. **E.**
April 23, 2007

Anon,
You're completely wrong. If string theory can provide a complete description of our world and can make predictions that turn out to be right, it is progress, even if we cannot understand why a particular vacuum is selected. As I've pointed out in my previous posts, string theory as we currently understand is a perturbative formulation. We do not have the 'real' theory, only approximations. If we could go beyond the perturbative description, it may be that the vacuum that corresponds to our universe is selected. However, in the absence of the nonperturbative description, we can only work backwards.

Also, I should point out that much of what you say are inaccuracies quoted directly from Smolin's book.

132. **anon.**
April 23, 2007

"You're completely wrong." – E.

If I'm completely wrong, I take it you have just proved the Maldacena conjecture? And you've just found the long awaited proof that perturbative string theory is finite?

"If string theory can provide a complete description of our world and can make predictions that turn out to be right, it is progress, even if we cannot understand why a particular vacuum is selected." – E.

That's exactly Ptolemy's argument in favour of the 'progress' of using epicycles to model the earth centred universe in 150 AD. Except, string theory doesn't even model anything real and observable in a predictive way, unlike epicycles.

"If we could go beyond the perturbative description, it may be that the vacuum that corresponds to our universe is selected. However, in the absence of the nonperturbative description, we can only work backwards." – E.

No, you can work forward from empirical facts and build theories on those, like Newton's dictum, *hypotheses non fingo*. You can make checkable predictions from a theory which is built on a framework of solid facts. You can't do that with a theory based on unobserved extra dimensions, branes, gravitons, supersymmetric partners, unification at 10^16 GeV, and other wishful thinking or abject, non-checkable speculative guesswork.

"… much of what you say are inaccuracies quoted directly from Smolin's book." – E.

Now you are being vague and inaccurate, much like string theory. Name one inaccuracy, instead of making up such vague, guesswork speculation.

133. **E.**
April 23, 2007

Anon,
People like you really aren't worth my time.

134. **E.**
April 23, 2007

Anon,
Can you prove that perturbative string theory isn't finite? And what does Ads/CFT have to do with my arguments? It's clear to me that you really don't know very much except whatever propaganda Woit and Smolin have told you, which you just repeat.

135. **Michael Bacon**
April 23, 2007

E wrote: "If string theory can provide a complete description of our world and can make predictions that turn out to be right, it is progress, even if we cannot understand why a particular vacuum is selected."

Well yes . . if it could do those things it would be progress, but it can't, can it? I'd be curious who thinks it is even possible to provided a "complete" description of the world and make "predictions", while not be able to undersand why a particular vacuum is selected?

136. **woit**
April 23, 2007

I've been under the weather with a migraine headache the last day or so, in retrospect probably should have deleted most of the comments in this thread. If people have something substantive to say, please do so, but I'll delete any more repetitive and pointless bickering, whether it's pro or anti-string theory. And Peter O. is right, this isn't the right place for public expression of views denigrating particular people.

137. **Cecil Kirkey**
April 23, 2007

Peter:

Sorry to offend. You and Lee and Bee to some degree have suggested that part of the problem in fundemental theoritical physics is the alck of a system that allows a young researcher to pursue their OWN interests. My point in the posts was to try to understand exactly how these people are being stopped from doing whatever research they choose.

Tenured positions are rewarded on past accomplishments and maybe future expectations. But I think if an objective study was done in theortical physics that the output of tenured researchers is significantly less than that of non-tenured researchers.

I see NO reason why any researcher cannot work on something other than string theory and prove themselves worthy and then earn a coveted tenured position based on accomplishments and not potential.

138. **Peter Orland**
April 23, 2007

Cecil,

People can win tenure on either accomplishments or potential. Most
Universities want people who can win grant money. Generally speaking, potential wins out over accomplishment in this regard.

A small number of physicists have obtained tenured positions doing
neither exclusively string theory, phenomenology nor numerical lattice work, but instead pursuing their own ideas over their entire careers. They are lonely, ignored and happy.

139. **Peter Woit**
April 23, 2007

Cecil,

I don't think you're very aware of what the realities are for young theorists. It's not just that they need to get tenure. Typically they are in postdoc positions with terms of maybe three years. Starting such a position, knowing that in two years you'll have to apply for another postdoc (competition is stiff) or a tenure-track job (competition is extremely stiff), should you try and work on something outside the mainstream, assuming that in those two years you'll have impressive enough results to convince hiring committees to hire you? It's not an easy position to be in. I think anyone who knows how the system works, and looks at the pressures and incentives it puts on young people, has to acknowledge that this is a major reason why few young people work on very ambitious ideas.

I think you're also highly unrealistic about the possibilities for doing important work in this area in spare time after a full-time job. Few people have the energy for this, and contact with smart people (grad students, colleagues, visiting people from other institutions) with similar interests is invaluable and something you'll not get.

140. **Eugene Stefanovich**
April 23, 2007

Peter,

What you described is just a perfect recipe for groupthink.

You correctly pointed out that current system forces young people to stick with mainstream ideas. Then you suggested that the benefit of remaining within this system is the opportunity to interact with other people (who presumably are sticking with the same mainstream as well and pulling you inside the same vicious circle).

Can we assume that if these "smart people" have something interesting to say, they already published that in the arXiv? So that I can benefit from their ideas while keeping a safe distance from the deadly mainstream current?

141. **woit**
April 23, 2007

Eugene,

Universities are not so homogeneous, they often contain people who have found a way not to work on mainstream ideas. Even people who work mainly on mainstream ideas often cannot avoid having acquired some wisdom on one topic or another. One can make progress just by oneself, but having smart people who know things you don't know to talk to is often very helpful. And not everything they know is on the arxiv, or, especially for mathematicians, if it's there it may be in a form that is much much harder to get at than by talking to someone who understands the field and can explain the basic ideas. Mathematics is still in some ways an oral tradition.

The other great benefit of universities is getting the opportunity to teach, if you can do it at a quite advanced level. Teaching something to people is an invaluable way of learning it deeply oneself.

My own experience has mostly now been in math departments, where I have learned a huge amount from colleagues, talks and from teaching. It's true that this is an environment inherently pretty far removed from current mainstream particle theory and its concerns.

142. **anon.**
April 24, 2007

Peter, have you heard any whispers leaking from Brian Greene's office at Columbia about the progress of deciding a winner for Discover magazine's competition for a 2 minute explanation of string theory? The deadline was about 6 weeks ago. Must be a tough call to decide the best one. http://discovermagazine.com/

143. **Peter Woit**
April 24, 2007

anon.

For some reason, neither Brian nor the people at Discover have decided to consult me about the choosing of the winner for that competition…

144. **Dan**
April 24, 2007

Personally I think you should have been consulted as a dissenting voice in the PBS Nova special Elegant Universe, along with computer graphics with the problems with string theory and supersymmetry.

145. **Coin**
April 24, 2007

Um, wasn't that all the way back in 2003?

146. **island**
April 24, 2007

Coin and Dan together make a good point, though, I think. Peter and others have been saying the same thing for many years, but professional and popular recognition didn't occur with any real impact until Peter and Lee started writing books about it, so at least now, future "specials", (and his peers), will more seriously consider his, Lee's, and others' dissenting opinions are real concerns of physicists that should be considered with the rest, rather than to allow things to appear to be more than they really are strictly for the advancement of egos and popularity. That cannot be good for science.

147. **Shantanu**
April 26, 2007

Peter, sorry for the OT comment as this is FYI. I was looking at the webcast
of the on-going
black hole conference at STSCI. although all talks are superb, you will be interested in the talk by
Horowitz which is on black holes in string theory (and in particular the discussion) See the answers to Narayan and Livio's questions.

Witten on Gauge Symmetry Breaking for Mathematicians

April 25, 2007
Categories: Uncategorized

Edward Witten has a new expository article, aimed at mathematicians, to appear at some point in the Bulletin of the AMS, but now available here. It's based on colloquium-style lectures to mathematicians he has given over the last few years (including here at Columbia) and is entitled "From Superconductors and Four-Manifold to Weak Interactions". The paper is organized around describing various aspects of gauge-symmetry breaking, but pretty much sticks to aspects of the problem that don't involve the full quantum theory, just analysis of classical Lagrangians.

He begins with a description of the Landau-Ginzburg model of superconductivity, and various physical phenomena that it describes including the Meissner effect, Abrikosov-Gorkov flux lines, and Type I and II superconductors. Solutions for a special case are described using complex-analytic techniques. Exploiting an analogy to the Landau-Ginzburg case, he next takes up the Seiberg-Witten equations and their use by Taubes to get invariants for symplectic 4-manifolds and existence theorems for pseudo-holomorphic curves in them.

Witten's final topic is electroweak gauge symmetry breaking and the Higgs mechanism in the Standard Model. He ends by remarking that in the superconducting case the analog of the Higgs field is just an effective field for a different underlying physics, and mentioning technicolor as an implementation of something similar in the electroweak case, while noting that precision electroweak data shows no signs of anything other than an elementary Higgs field. He comments "But it is always possible that the right alternative has not yet been proposed" and explains how the LHC should definitively see a Higgs particle if the SM is correct since current bounds place its mass between 115 and 200 GeV.

The paper is purely expository, and aimed at mathematicians. It's interesting to see that, even though there aren't any really new developments in the area of gauge symmetry breaking, Witten clearly sees it as a fundamental problem every bit as deserving of being explained to non-physicists as string theory.

   This and the lower bound U cite, put the mean at about 130 Gev."

   At the end of the quoted article is the link to the next article:
   "Mathematician suggests extra dimensions are time-like"

   Oh well, the real physics was nice while it lasted.

5. **Daniel Doro Ferrante**
   April 26, 2007

   Hi Peter,

   Just to point out a couple of things:

   (a) One can find a more detailed historical account of the facts leading to the discovery of Spontaneous Symmetry Breaking in the following link: A Physics History of My part in the Theory of Spontaneous Symmetry Breaking and Gauge particles with a mix of modern ideas (PDF, 194Kb).

   (b) Thus, in all fairness, there should have been a link [in Witten's article] to Global Conservation Laws and Massless Particles (GHK). As can be seen in Spontaneous Breakdown of Symmetry in Axiomatic Theory (page 515) and Spontaneous symmetry breaking in local gauge quantum field theory; the Higgs mechanism, there are some "subtleties" treated in the GHK which had not been previously considered — and those were important for the future development of the ElectroWeak symmetry breaking and the Standard Model.

Lastly, i would personally say that there have been some "new developments" in this area: Computational High Energy Physics Group at Brown. For instance, we have some new numerical methods (which we're still improving and sharpening) that are able to deal with Symmetry Breaking and different phases in a given QFT (something that ordinary Monte Carlo simulations cannot do): We've been using some Stochastic Quantization techniques, together with some techniques from Wiener Polynomial Chaos, and have been able to tackle the issue of symmetry breaking in simulations of QFT quite well. Also, we've been working on the relation between Symmetry Breaking and Topology Change (there will be a new [sequel] paper coming out on this topic shortly); a topic that has potential implications to Quantum Gravity at large, once it deals with Topological Transitions, explaining them in terms Symmetry Breaking (and Morse Theory). So, i think the playfield is still active… 😉

Cheers, Daniel.

6. **Jimbo**
   April 26, 2007

   DB,
   Suggest U keep an open mind. That mathematician is Penrose's former student, George Sparling. U might be impressed if U attempted to read the article. Itzhak Bars has also investigated Xtra time-like dimensions as well.

7. **Kea**
   April 26, 2007

   Jimbo

   That's fantastic! Thanks for the link. FINALLY, some decent physics makes the news.

8. **Daniel Doro Ferrante**
   April 27, 2007

   Just a quick note in order to stress points (a) and (b) of the comment above: Both, Weinberg's (PDF, 76Kb) and Salam's (PDF, 1.16Mb) Nobel Lectures credit GHK and, in fact, Salam goes as far as saying that he was tutored by Kibble [in the technique of Symmetry Breaking]. Furthermore, Glashow's (PDF, 59Kb) [Nobel Lecture] also cites GHK and Symmetry Breaking, albeit in a "funny" remark (see paragraph 3 of page 498 — here i mean "funny" under the context given by Bob Marshak's remarks on the 3rd Shelter Island conference).

   And, to drive those points home, note the acknowledgements in Spontaneous Symmetry Breakdown without Massless Bosons. 😉

   Cheers, Daniel.

9. **joseph smidt**
   April 27, 2007

   Thanks for posting this. I love these kind of papers.

10. **Jonathan**

Various Events and Other News

April 29, 2007
Categories: Uncategorized

Upcoming events in and around New York, including several I'm planning to attend:

The New York Academy of Sciences is having an evening of lectures this Wednesday, hosted by Frank Wilczek, on the topic of Expanding Frontiers of Physics and Cosmology. Speakers will be Max Tegmark and Nima Arkani-Hamed.

The YITP at Stony Brook is having a symposium to celebrate its 40th anniversary, and many former students, faculty and postdocs will be in attendance. I plan to definitely spend Thursday out there, maybe also Saturday.

One reason I likely won't be out at Stony Brook on Friday is that I'd like to attend at least some talks at another event that will be downtown at the new location of the New York Academy of Sciences. It's the 9th Northeast String Cosmology Meeting, co-sponsored by Columbia's ISCAP. Edward Witten will be among the four people speaking.

There will be an event entitled When the Scientist Becomes the Story at NYU next week, on May 8th, featuring a discussion about John Nash and Francis Crick with their biographers.

Much farther in the future will be next year's program on representation theory, algebraic geometry and physics at the mathematics division of the IAS in Princeton. This will include a conference November 26-30 with a title reflecting my favorite topic "Gauge Theory and Representation Theory". Presumably much of the focus will be on the Geometric Langlands program.

Closer in time, but farther in distance, I'll be speaking at a science festival called FEST in Trieste on May 18th. In June my book is supposed to be coming out in an Italian edition. I have to be in London the evening of May 23rd, then will head back to New York the next day. Currently trying to come up with a plan for how to spend the time in between, with the leading possibility a train trip through the Alps to Geneva, then a stop in Paris on the way to London.

In other news:

Lee Smolin has put up on his web-site a response to the review of his book and mine by Joe Polchinski.

On the Fields Medalist blogging front, there's a report from Terry Tao about a symposium at UCLA where he and three other Fields medalists gave talks. He gives a detailed description of the talks, including one by Richard Borcherds on QFT that sounds somewhat mystifying to me. Alain Connes at his blog gives his take on some of the talks delivered at the recent conference in his honor.

I've recently for no particular reason run into various interesting domain-names that some mathematicians and physicists are using for one purpose or another: monodromy.com, cohomology.com, and stringvacua.org.

A couple links mentioned by commenters here that deserve more visibility:

Neutrino Unbound is a site devoted to all things neutrino.

An interesting document concerning a bet made several years ago about whether supersymmetry will be found at currently (or soon-to-be) accessible energies is available here. Maybe someone can think of a way to get more particle theorists on the record about this…

Update: For upcoming events really far afield from here, I should mention that the new Kavli Institute for Theoretical Physics in Beijing is starting to get organized. Jonathan Shock reports that there will be an opening ceremony at the end of May, a two month program on Quantum Phases of Matter starting in June, and a program on String Theory and Cosmology in the fall.

Update: I've just heard that Discover Magazine has chosen the finalists in its "String Theory in Two Minutes or Less" contest. No, I didn't enter. Here they are.

Comments

1. **CapitalistImperialistPig**
   April 29, 2007

   Peter,

   Thanks for pointing out Polchinski's review and Smolin's response. This is dialog that actually is instructive – and which was unfortunately missing from some earlier reviews of your book and Smolin's by ST er's.

   If the protagonists will concentrate on the physics, as I think you and Lee did, and as Joe seems to have, the debate not only becomes more informative but more pleasant to observe.

2. **Peter Woit**
   April 29, 2007

   CIP,

   I think both Lee and I have been surprised at how little serious, substantive public reaction our books have gotten from string theorists, with Polchinski one of the welcome exceptions. I certainly have found that, in private discussions, most string theorists and I find lots of common ground, and that we agree about much more than we disagree. The kind of fanatical response that one sees on various blogs I don't think reflects the views of many serious string theorists, although it does provide evidence of some of the sociological problems afflicting the subject.

3. **Marco**
   April 30, 2007

   Just a short request: if your stop in Paris becomes reality, and if some public event is planned for it, please don't forget to mention the details here so that one can attend. Thanks.

4. **Thomas Love**

April 30, 2007

Peter said:

"Maybe someone can think of a way to get more particle theorists on the record about this…" (supersymmetry).

Suppose we speak our piece here? Supersymmetry will never be found. It was one of those crazy ideas that wasn't crazy enough.

5. **V**
April 30, 2007

My prediction: Low energy supersymmetry will be discovered within the next two years, as well as the Higgs. Huge triumph for the theoretical physics of the last thirty years. Certain people will be humbled.

6. **Ari Heikkinen**
April 30, 2007

About that Smolin's response, you still have to admit that those top string theorists (like Greene or Kaku) are still damn good at public relations and selling string theory to the public.

I wish I had as good speaking and presentation skills as say Brian Greene..

7. **Coin**
April 30, 2007

From Smolin's response thing:

the technical argument I had in mind… begins with the fact that supersymmetry requires that the cosmological constant be zero or negative
…wait… what?

Is this true? I'd never heard anything about this, and it seems like if it were true it would be a big enough deal to have come up before now– since there are indeed still people who expect we will see supersymmetry at the LHC, yet we've got this Dark Energy thing now that at is at least analogous to the positive cosmological constant. Right?

If this isn't too big a question to ask within a a blog comment: *Why* does supersymmetry require that the cosmological constant be nonpositive, if indeed it does?

8. **Aaron Bergman**
April 30, 2007

The condition is for unbroken supersymmetry. It arises because the only term in the SUGRA lagrangian that can give rise to a cosmological constant is negative definite. Once you break SUSY, however, you can have positive contributions and are able to get a positive cc.

9. **Coin**
April 30, 2007

That helps a lot, thanks.

10. **woit**
April 30, 2007

Coin,

There's more to it than what Aaron writes. If you want more of the story and some references to follow, it should be possible to extract the physics from the vitriolic attacks by multiple string theorists on me in this thread:

http://www.math.columbia.edu/~woit/wordpress/?p=454

11. **Thomas Larsson**
May 1, 2007

I once saw a quote by Witten in APS News, where he said that the discovery of the negative cc was the most disturbing fact he had ever learned. My impression is that it is not so much the magnitude as the sign which is troubling; de Sitter space apparently lack the right kind of asymptotic regions where you can put holographic data, cf hep-th/0106109. You can almost hear from its name that AdS/CFT will run into problems if spacetime is de Sitter rather than anti-ditto.

12. **Cecil Kirkey**
May 1, 2007

Peter:
Re: String Theory Videos

I looked at a couple of the videos and they finally inspired me to ask your opinion of the following.

Assuming ST to be correct for sake of argument are particles really strings or do the physics suggest that all interactions can be modelled AS IF the particles were strings?

This has always bugged me. What is the reality? Vibrating strings, tension, total unobservable properties. I suppose that this is really a big question on what constitutes physical reality, but don't physical theories attempt to model reality not actually describe what reality is?

In this same vein when the string is quantized it leads to the requirement of more 4 dimensions. Is there more than one way to quantize a system or is quantization unique? Do you know of any work that attempts to avoid quantization of a classical system and just start right away with an already defined quantized system? Thanks for the feedback.

13. **Jean-Paul**
May 1, 2007

You've got to live with it: the world is NOT holographic — it is truly 4-dimensional. QCD is NOT holographic, it is NOT topological. Standard model is NOT a

topological QFT.
Welcome to the world of real dynamics where you have to work harder than just to count instantons and everything is fixed by some analycity constraints. I wished we paid more attention to the failure of (bootstrap) S-matrix theory. Actually, the most interesting non-perturbative results in QCD were obtained long ago, just after it replaced the S-matrix approach to strong interactions. Later, holomorphic SUSY took the bandwagon on another funride, diverting attention from serious dynamical problems: the bootstrap lesson was quickly forgotten.

14. **Peter Woit**
May 1, 2007

Cecil,

People can have different philosophical viewpoints, but to me what is physically "real" at a fundamental level is whatever are the fundamental elements of our most successful physical model. Right now, that's the standard model, so certain quantum fields are the fundamental things. If string theory were right, it would be something different, depending on what was the successful string theory model (e.g. it might be quantized fields on the space of strings, or matrices if you believe some versions of M-theory, or something else).

It's somewhat of a mystery that our most successful quantum theories are formulated by "quantizing" a classical system. One can come up with quantum theories that don't arise in this way, the quantum mechanical formalism is inherently more general.

15. **V.**
May 1, 2007

Cecil,
Very good question. I think the idea of the elementary particles being extended objects is supposed to model the fact that the spacetime geometry breaks down at the Planck length. It may very well be the case that quantiziing a classical string is accurately modeling reality, provided that the different ways that it may vibrate are restricted, e.g. through compactification of extra dimensions. That is to say that the extra dimensions and their compactifed geometry aren't actually 'real', but rather a mathematical device required to model the 'true' reality with a classical string. In this view, their will be one and only one compactification that corresponds to the true theory, while the landscape of string vacua is a mathematical artifact left over from starting with a classical object.

16. **Chris Oakley**
May 1, 2007

Cecil,

Quantization is far from being unique. One can very easily get contradictory results by choosing the "wrong" Poisson brackets to turn into quantum commutators. What rescues the situation is the restrictions on the space of possible quantum solutions owing to group-theoretical considerations. For example, the basic Poisson bracket to commutator substitution for [x, p] follows from the notion that the Q.M. momentum operator is the generator for space displacements – Planck's constant merely being a scaling factor determined by our unit of classical momentum; similarly for time displacements and rotations to get the Q.M. Hamiltonian and angular momentum operator.

For quantum fields the basic Poisson bracket → commutator quantization fails for all but the simplest case – hence (e.g.) the need for Gupta-Bleuler quantization for helicity 1. But once again the situation is rescued by group theory – in this case the need to produce a spectrum of physical states that are an irreducible unitary representation of the Poincare group.

If you are interested, have a look at these notes on my web site that develop QFT without mentioning quantization.

17. **Chris W.**
May 1, 2007

Thomas,

In mentioning Witten's remark, did you mean to write "discovery of the *positive* cc"? See the exchange between Coin and Aaron Bergman.

18. **Chris W.**
May 1, 2007

V,

Would it be fair to say, given the viewpoint you sketched in response to Cecil, that the classical string might eventually be understood as a classical image of something embedded in spacetime, which arises from some more primitive "pregeometric" object in a dynamical substrate that generates spacetime as a kind of mean-field classical approximation?

Maybe this should become a central element in the effort to push string theory forward, instead of ongoing elaboration on differential geometry and its abstract connections with other areas of mathematics, in which questions of ontology (and the early misgivings of Green and Schwarz) have been largely pushed aside as irrelevant.

19. **Leonard Ornstein**
May 1, 2007

Peter:
We try to approximate aspects of reality with what our senses and instruments detect and measure. We appreciate that, at best, the measurements can only be incomplete approximations, subject to measurement noise and (in spite of our best efforts), possible undetected bias.

These observations are used to try to generate self-consistent models of that reality. And we use further observations to determine the closeness of match between the models' predictions and what we can access of that reality.

Against this background, it's difficult to understand "what is physically 'real' at a fundamental level is whatever are the fundamental elements of our most successful physical model".

Unobservable singularities and infinities, at least temporarily, would become part of your reality. That reality is a compromise of the moment (and might not easily provide motivation for going beyond present observation).

It may be the best we presently can do. (And I appreciate the compelling and amazing matches between QED predictions and magnitudes like that of the fine structure constant.) But QED still 'only' a model.

The Platonist believes that in the limit, the ideal model will ultimately provide more perfect descriptions of reality than our senses and instruments can ever provide; and that theoretical physics will be indistinguishable from a branch of mathematics..except for its 'content' of 'physical reality'.

Your 'definition' above implies that you are a Platonist. This seems to conflict with my understanding of your usual positions in this blog…and in your book!?

20. **V**
May 1, 2007

Chris,
Yes, I'm trying to say something similiar to this. Most string theorists would say that M-theory will be such a formulation. One of the striking things about perturbative string theory is that the strings are quantized, but the spacetime they live in is purely classical.

21. **Peter Woit**
May 1, 2007

Leonard,

Sure, I'm a Platonist, even often describing my views as radically Platonist. Many people don't seem to have read my book very carefully, a large part of it is about the relation of mathematics and physics, claiming that they are very deeply connected, and it ends by suggesting more attention to this.

We know the world through our senses and through experiment. These are how we know that our mathematical models of physics have to do with "reality", and are not just random abstract structures. I've always made clear that I don't object to string theory on the grounds that many people do, that it is "too mathematical". My objections to it are two-fold:

1. When you try and use string theory to make a model of reality, you are forced into huge amounts of complexity and ugliness.

2. String theory is inherently unpredictive, there is zero experimental evidence for it.

I see 1. and 2. as closely related problems.

22. **V**
May 1, 2007

Dear Peter,
I have to take objection with your first point that string theories models are complex and ugly. On the contrary, models in Type II theory involving intersecting D-branes are very geometric and beautiful, and the standard model is very naturally accomadated. Regarding your second point, perhaps there is some validity to this at present. However, this may not always be the case as further progress is made.

23. **a quantum diaries survivor**
May 1, 2007

Hi Peter,

since bets on supersymmetry are mentioned here, let me mention that I had a more substantive bet open on my site last year.

Jacques Distler and Gordon Watts have bet respectively 750$ and 250$ with me that new physics (SUSY, or something else beyond a SM Higgs) will be found at the LHC within two years from having collected 10/fb per experiment. If SUSY is found, I lose $1000. If
nothing is found, I win $1000 with which I can try to cheer up my saddened soul.

Cheers,
T.

24. **Peter Woit**
May 1, 2007

V.,

I'll just quote Zwiebach, page 346, about these models:

"the models seem contrived, at least in the sense that they are engineered to give the physics that we observe, rather than obtained naturally as the simplest solutions to string theory. The Standard Model is an intricate construct, and present-day attempts to describe it within string theory are not simpler."

25. **Nameless**
May 1, 2007

Smolin mentions in his reply to Polchinski's review that N=4 SYM has not been rigorously constructed yet. I wonder (and this is certainly the most stupid question ever asked in this blog) whether N=4 SYM is asymptotically free?

26. **Peter Woit**
May 1, 2007

Nameless,

The N=4 SYM beta-function is zero, so the coupling constant doesn't run, there's an ultraviolet fixed point at non-zero coupling. It's not asymptotically free, since the coupling doesn't go to zero.

One of the big problems with using string-gauge duality to understand QCD is exactly this: you don't get asymptotically free theories like QCD.

27. **V**
May 1, 2007

Peter,
If you'd ever get your hands dirty with real work, you'd actually have a better sense of these models, rather than relying on a comment in Zweibach's book. There are many, many constraints that one must satisfy in order to build realistic models, so that it very definitely not contrived. See hep-th/0612087 for a beautiful example.

28. **woit**
May 1, 2007

V,

Sorry, but that looks completely contrived to me. Then again, it may look less contrived to those doing the contriving….

29. **Nameless**
May 1, 2007

> One of the big problems with using string-gauge duality to understand QCD is exactly this: you don't get asymptotically free theories like QCD.

And even in the conformal case, only the large N limit, I gather?

Thanks for your reply!

30. **V**
May 1, 2007

Peter,
I doubt very seriously that you have the knowledge and experience in either string theory or particle theory to make such judgments. In any case, you will claim everything is contrived since it suits your purposes, regardless of the reality. I would have some respect for you if had something postiive and constructive to say, rather than just continually nagging.

31. **woit**
May 1, 2007

V.,

You've chosen to remain publicly anonymous, while making it clear to me who you are. I really don't think you're in a good position to attack my or anyone else's credentials, and in any case that's not something you have any business doing from behind the cover of anonymity. Please cut it out.

32. **kuos**
May 1, 2007

Wow V, the number of matter generations in that beautiful noncontrived model only differs from reality by 33%. You've made a believer out of me.

33. **dave tweed**
May 1, 2007

V wrote "There are many, many constraints that one must satisfy in order to build realistic models, so that it very definitely not contrived." I want to understand the logic implied by this statement. Are you saying (where "we" just means "people who understand string theory") "We understand genuine principles of physics (which aren't just "we need to end up with a realistic model" conditions in disguise) that give lots of constraints. If we build a model which satisfies those constriaints, we get a realistic model" or "We know various things must be constrained to get a realistic model. If we build a model satisfying those constraints, we get a realistic model"? I'm just trying to understand precisely what is being claimed.

34. **V.**
May 1, 2007

Peter:
By no means have I let you know who I am anonymously. You can make whatever assumptions you like. I point to this model as one that I'm familiar with which is very simple, yet from it comes the entire structure of the MSSM. All essentially from a set of numbers which are all plus/minus one.

kuos:
How do you know there won't turn out to be four generations, with the fourth generation being heavy? In any case, is this not an experimental prediction?

Dave:
In constructing models, there are many nontrivial consistency conditions which must be satisfied such as tadpole cancellation, conditions for supersymmetry, K-theory charge cancellation, etc.. Never mind getting the right matter spectrum.

35. **Aaron Bergman**
May 1, 2007

And even in the conformal case, only the large N limit, I gather?

No. The AdS/CFT conjecture in its most powerful form holds for finite N. Gauge/geometry duality is also not only restricted to CFTs.

36. **dave tweed**
May 1, 2007

V, I'm not a physicist so I don't understand what those terms mean in detail, and in the details you seem to have avoided commenting one way or another on whether these conditions are _primarily understood on their own terms_, or just understood as necessary in order to avoid producing features in concrete instances of the model which are not realistic. To put it another way, suppose tomorrow we were to observe something that implied, eg, "incomplete tadpole cancellation" happened in the universe (whatever that might mean), presumably the fact that it's a consistency condition of string theory means no variety of string theory would be unable to model this, right? (I'm just trying to clear up what seem like vagueness about which conditions are put in to ensure a match the observed world — and could be removed if experimentally falsifed — and which are logically inviolable parts of the mathematics.)

37. **dave tweed**
May 1, 2007

Ugh: double negative is just a typo, should be "no variety of string theory would be able to model this".

38. **anon.**
May 1, 2007

Peter wrote:

One of the big problems with using string-gauge duality to understand QCD is exactly this: you don't get asymptotically free theories like QCD.

Aaron wrote:

Gauge/geometry duality is also not only restricted to CFTs.

It might be worth expanding on these two statements for the benefit of the reader who doesn't know about gauge/gravity duality. I would say they are both correct. First, there are *non*conformal theories for which the duality is really under control. These are not asymptotically free theories, but theories which are strongly coupled even in the UV. The canonical example is Klebanov-Strassler, but there are many others.

For asymptotically free theories, the trouble is that the gravity side becomes strongly coupled when the gauge side is becoming weakly coupled. One can get interesting theories in the same *universality class* as gauge theories of interest; e.g. Witten found a supergravity black hole background in the universality class of nonsupersymmetric Yang-Mills. This background seems to have a tunable parameter that can be adjusted to reach the true non-SUSY Yang-Mills, but the problem is that in trying to take this limit one runs into a regime where calculations cannot be done. Similar almost-dual backgrounds exist for theories with flavor (Sakai-Sugimoto, etc.).

In that sense, gauge/gravity duality provides something much like the lattice strong-coupling expansion: a way of calculating in a theory very much like the theory of interest, weakly coupled where the dual is strongly coupled, with a limit one can take to reach the theory of interest (and no phase transition when taking that limit). In both cases the desired limit is not tractable, but qualitatively most of the properties of the theories are similar. In the case of the lattice, the desired limit actually *can* be done (with difficulty) on a computer, at least for calculating simple enough quantities. There's no analogue of that for the gravitational dual.

39. **dave tweed**
May 1, 2007

Third post: in case it's not clear, I'm not looking for an explanation of any of these things, just a clear statement "we have most of the model conditions as an unavoidable requirements of string theory" or "most of the model conditions are motivated by the need to obtain a realistic model", just in order to understand what level of claim for these sorts of string theory model is being made.

40. **Nameless**
May 1, 2007

Thanks, Aaron.

41. **V.**
May 1, 2007

Dave,
The requirements that I mentioned are basically for internal consistency at the quantum level, and these requirements must be satisfied apart from any considerations of matching the model to observed physics. For example, if the tadpoles are not cancelled there will be what's call a triangle anomaly. Once these conditions are satisfied, one would like to have the gauge group and matter representations of the MSSM, a full set of Yukawa couplings (necessary for generating mass), and gauge coupling unification.

In intersecting brane models, this is accomplished by having different stacks of D-branes which wrap around the compactified dimensions. Every time the different stacks intersect, there is chiral matter localized at the intersection. The idea is to have a configuration which gives the standard model. However, as mentioned above, it is not possible to have any possible configuration, as this is seriously constrained by the need for internal consistency. The model that I pointed out has basically the simplest possible configuration, where the different D-branes wrap around each compactified direction exactly once.

42. **Peter Orland**
May 1, 2007

V.

One of the reasons some people get frustrated with string theory as a fundamental description of the universe is that arbitrary scenarios are invoked. Intersecting D-branes are of academic interest for constructing models with particles of different colors and flavors; that doesn't mean that this is how quantum numbers arise in nature.

The problem is that there are no dynamical calculations in string theory. No dynamical calculation shows that there is Calabi-Yau (or any other, including KK) compactification. No dynamical calculation shows that certain brane configurations dominate (including the one you advocate). This is what I always found unsatisfying about attempts to do string phenomenolgy, even back in the eighties – there are plenty of scenarios, but no analysis. Landscape advocates go even further in this respect. They have openly given up on justifying these scenarios.

43. **V**
May 1, 2007

Peter,
You're right that at present there are no dynamics that would choose the specific vacuum presently known. However, I think this is because we don't have the complete theory. If we can find a vacuum which correspond very closely to our universe, we may be able understand why this vacuum is selected, which may in turn lead to a complete formulation of the theory. In any case, it would be remarkable if we can find a model which provides a complete description of physics as we know it, and it would be even more remarkable if this model made predicitions that were later born out.

At the present, we don't know why the Standard Model gauge group is what it is. Afterall, a large number of gauge groups are possible and it has many free parameters. Does that stop particle physicists from using it? Absolutely not! However, some people like Peter Woit would claim that the Standard Model is 'contrived' and arbitrary. It may very well be, but that does not mean it's useless or that it doesn't help us get closer to the truth.

It will probably turn out that we will find a string theory model that completely describes our universe which may be regarded as an effective theory just as the standard model is an effective theory. However, it will be at a deeper level. Only later we will understand why it is chosen.

44. **Thomas Larsson**
May 2, 2007

In mentioning Witten's remark, did you mean to write "discovery of the positive cc"?

Oops.

45. **woit**
May 2, 2007

V.
I don't think the Standard Model is contrived, quite the opposite. I think all attempts to get it out of string theory are contrived.

46. **Nameless**
May 2, 2007

Anon, thanks to you too. I'll refrain from asking further questions… that's what review articles are for.

47. **V.**
May 2, 2007

Peter,
String theory models are no more contrived than the Standard Model itself. The standard model can only make predictions after fixing it's free parameters by hand. We have no reason for choosing SU(3)xSU(2)xU(1) in the SM except that it seems to work. We have no explanation for the charges in the SM except they seem to work. We have no explanation for the masses in the SM except they seem to work. Any string theory model will essentially do the same thing, except that it will provide a geometric explanation of all of the above AND unify the SM with gravity. Perhaps we will not be able to understand why this structure arises for some time, but it will still be useful, especially if it can make other predictions.

48. **Peter Shor**
May 2, 2007

There are 19 parameters in the standard model. Assuming each of these *on average* needs around 4 significant digits to get similar physics to ours gives one chance in 10 ^ (-84) we would have a universe looking fairly close to this one. This chance appears to be significantly better than you get with the string theory landscape.

Is this a good measure of the "contrivedness" of a theory? I don't think so, but I don't buy the argument that string theory has no free parameters, so it's less contrived.

49. **V**
May 2, 2007

I think you guys would be a lot better off if you'd stop worrying about the ability to uniquely determine the universe we live in. We're clearly not there, yet. The goal should be to effectively describe our world in a predictive way, regardless of the uniqueness question. Making aesthetic judgements is rather stupid at this point. If it works, that's what's important. We can worry about the 'why' question later.

50. **King Ray**
May 2, 2007

V, if you require anomaly cancellation and that the global gauge group of the SM is S(U(3)xU(2))=SU(3)xSU(2)xU(1)/Z_6, you get a unique solution for the hypercharges (and hence the electric charges), assuming anomalies cancel out within a family (the "Poor Man's Unified Field Theory"). The SU(2) and SU(3) reps of the quarks and leptons are inputs though.

51. **V**
May 2, 2007

King Ray,
Sorry, the Standard Model by itself cannot explain the charges, although it's true that they are constrained by anomaly cancellation. To explain the charge quantization, you have to go to a Grand Unified Theory such as SU(5).

52. **Peter Orland**
May 2, 2007

I think it's interesting that V. says aesthetic judgements are stupid. The justification of string theory by those leading the field was largely aesthetic, way back in the eighties. Now that so many people are totally committed to the strings, this justification seems to have been dropped.

53. **King Ray**
May 2, 2007

V, anomaly cancellation gives two different solutions, one the true solution and the other a bizarre solution. The bizarre solution is not consistent with the global group S(U(3)xU(2)), leaving a unique solution if you assume that amomalies cancel within each family, and that the global group is S(U(3)xU(2)).

http://prola.aps.org/abstract/PRD/v43/i8/p2709_1

54. **V**
May 2, 2007

Peter,
The justification for string theory has always been it's potential for unification of quantum mechanics and the standard model with gravity, rather than aesthetics. There are some hardcore hurdles that string theory has been able to hurdle. Like it or not, it is in fact the only known possible candidate for unification at the present time.

King Ray,
It sounds to me like what you're doing might be equivalent putting the standard model reps into representations of SU(5). Perhaps you've discovered grand unification without realizing it?

55. **King Ray**
May 2, 2007

V, S(U(3)xU(2)) indeed embeds into SU(5) in block diagonal form. However, S(U(3)xU(2)) does not have the extra gauge bosons (from the off block diagonal entries) that SU(5) does that lead to proton decay. It was because S(U(3)xU(2)) embedded into SU(5) so well that made SU(5) look so attractive initially. S(U(3)xU(2)) is a U(3)xU(2) theory with the U(3) and U(2) determinants related.

The charge quantization and ratio prediction comes from intra family anomaly cancellation and taking the global structure of the SM to be S(U(3)xU(2)), which identifies six elements of SU(3)xSU(2)xU(1).

There are 13 possible choices for the global gauge group of the standard model, and of them only S(U(3)xU(2)) is consistent with the quarks and leptons that we have observed in nature.

It is well accepted that the global group of the SM is S(U(3)xU(2)) and not SU(3)xSU(2)xU(1). See O'Raifeartaigh's book, for example.

56. **Peter Orland**
May 2, 2007

V.

Yes, we all know that that was the reason people were attracted to string theory. But it isn't clear that it is the only way to have quantized gravity. Between the energies we study experimentally and the Planck mass, there are many possibilities. Quantum gravity can be said to be a theoretical success over this entire (enormous!) range. What string theory does beyond this range is provide a cut-off at the Planck mass.

Now there are other ways to cut off gravity at 10^{-33}cm. A very crude example is some sort of Regge calculus. So I don't find the unification of gravity with quantum mechanics to be a very convincing argument for string theory. Any judgement as to how one wants to cut off the theory at the Planck mass is going to be an aesthetic one.

I am not against studying quantum gravity using string theory (I have even written a few string papers). I have no opinion as to the best way to cut off gravity in the ultraviolet. But it's one thing to study something, quite another to think there is no alternative.

57. **V**
May 2, 2007

Peter,
If there is another (serious) way to study quantum gravity, then it would be great and I'm sure people will pay attention. One thing that should be kept in mind regarding the debate about string theory, is that one of the driving forces in it's development over the last several years is a lack of experimental data. Because of this, there has been no other way to study these problems. I wonder what the development of theory over the last 15 years would have been like if the SSC had been constructed? Perhaps it would

Three String Theory Textbooks

May 2, 2007
Categories: Book Reviews

Until very recently, someone who wanted to begin studying string theory seriously had really only three possible textbooks available:

- Superstring Theory (1987), by Green, Schwarz and Witten. This is a two-volume, massive 1000 page treatment of the quantization of the superstring and ideas about Calabi-Yau compactifications dating from right after the First Superstring Revolution in 1984.
- String Theory (1998), by Polchinski. In two volumes and 900 pages this covers most of what is in Green-Schwarz-Witten, while also surveying D-branes, the second Superstring Revolution, and much of what was learned about string theory during the decade after GSW.
- A First Course in String Theory (2004), by Zwiebach. This is the textbook for an undergraduate course, so is at a lower level than the other two books.

Very recently three new string theory textbooks have appeared, each aimed at providing a textbook for an advanced one-year graduate course, assuming a background in quantum field theory and the standard model. Each of them is quite a bit shorter, while trying to cover much more than Polchinski and GSW. This is a daunting task. Polchinski in his introduction noted how difficult it was to cover even in 900 pages a literature of size around 10,000 papers. These new books are trying to cover a literature probably twice as large in sometimes half as much space. As a result all three of them necessarily often have a rather telegraphic feel, more that of a review article than the usual sort of introductory textbook.

I've spent some time reading through all three books over the last couple months, and here are some impressions. Just as these books are too short to really cover the subject, my comments here will be much too short to do justice to the 1800 pages or so of material in the books.

Michael Dine's Supersymmetry and String Theory actually probably shouldn't be thought of as a string theory textbook (and on page 310 the author notes "This is not a string theory textbook"). The first 300 pages have nothing to do with string theory, instead consisting of an introduction to the Standard Model, beyond Standard Model Physics (especially supersymmetry), and cosmology. The last 175 pages of the book give a very sketchy survey of string theory, concentrating on prospects for getting unification and particle physics out of it. Dine starts out with the standard promotional material for this idea, but does clearly explain the fundamental problems such as that of moduli stabilization that have led to the landscape and the ever-more-clear failure of this idea. He ends with a chapter about this and about the anthropic landscape. The main concern of most string theorists over the past 10 years, AdS/CFT duality, gets just two pages. For other reviews of the book, see one by Jacques Distler, and one by Lubos Motl (whose endorsement of the book's contents as "state-of-the-art picture of reality" appears on the book's cover). One peculiarity is that when he turns to general relativity and string theory, Dine switches his convention for the sign of the metric. Perhaps the book is best thought of as mostly an introduction to supersymmetry in particle physics, with the string theory material an outgrowth of that central topic.

String Theory in a Nutshell, by Elias Kiritsis, is one of what I guess Princeton University Press intends to be part of an "in a Nutshell" series, beginning with Tony Zee's Quantum Field Theory in a Nutshell. Zee's is a wonderful book, although it's best for someone who has already taken a QFT course and wants to get further insight into the theory, or read as a supplement to a more detailed text like Peskin and Schroeder. The Kiritsis book is not much longer than Zee's (they are both somewhat less than 600 pages), but is much more intended as a standalone textbook for a one-year string theory course, replacing Polchinski. It contains a wealth of exercises, nearly 500 of them (and the author warns that some are hard enough to have been the subject of research articles). While the book begins with the standard promotional pitch, Kiritsis does acknowledge that it may turn out that the subject is "an intellectual classical black hole". He pretty much completely ignores the moduli stabilization problem and the landscape. AdS/CFT gets a long chapter of about 70 pages, with 62 exercises. I don't know of any other reviews yet, but Lubos Motl's endorsement (which doesn't appear on the cover) can be found in Princeton University Press's promotional material for the book.

The most complete of the three books is String Theory and M-theory, by John Schwarz and the Becker sisters. It is more than 700 pages long and is intended as the textbook for a year-long graduate course, taking students from the basics of string theory to the latest ideas about flux compactifications and moduli stabilization. Trying to cover such a huge subject in this space means that it is done in much the "in a nutshell" style of Zee's QFT text. As a result many sections of the book have more the feel of a review article for a general audience than that of a textbook for students. The calculations leading to the landscape are covered in some detail, and there's a discussion of anthropic arguments and statistical calculations. Like Kiritsis, a 70 or so page discussion of gauge-string duality is provided. There's a review by Capitalist Imperialist Pig, and a short mention from Lubos Motl. No endorsement from Lubos on the book, instead it carries endorsements from the leading figures of the subject (Arkani-Hamed, Gross, Strominger, Vafa and Witten).

I found all three books quite interesting to spend some time going through, as they each in their own way provided an overview of the current state of string theory as a unified theory of particle physics. Of the three, Becker-Becker-Schwarz I think gives the most complete coverage of where the subject is at. Dine is a separate case, since it's mostly about other things. As you might guess I'm highly dubious of the idea of teaching this sort of material in a standard class for graduate students. The fundamental problem is that the very speculative idea that these books are devoted to, that you can unify particle physics using 10/11 dimensional string/M-theory together with compactification and branes in order to make the extra dimensions invisible, is one that has by now pretty clearly failed. Dine comes the closest to explaining how problematic the situation is, Kiritsis is at the other end, choosing to not explain the nature of the problems. These books attempt to cover a huge literature which consists of failed attempts to make some sort of connection with the real world, and I can't think of any other field of physics or mathematics where there are graduate-level textbooks that could be characterized in this way. Unfortunately, much of what has been successful about string theory is ignored in these books. Mirror symmetry, which has had a huge effect on mathematics, is not even mentioned by Dine, gets a couple pages in both Kiritsis and Becker-Becker-Schwarz. While ignoring string theory's mathematically most interesting insights, these books lead students into a horrendously complicated thicket of speculative ideas that generally don't work, but provide enough grist for decades of research projects to come. Any student who chooses to follow this path will need to devote many years to mastering this material, a one-year graduate course is not going to do the trick. There's no particular reason to believe that this kind of training is one that will lead to a solid background in techniques that are likely to have more success in the future.

Comments

1. **King Ray**
   May 2, 2007

   Hmmm… The latest edition of Ptolemy's Almagest is 693 pages. It seems that these overly baroque theories need longer texts to explain them. You would hope that the ultimate theory would be explainable in 10's of pages.

2. **baroque**
   May 2, 2007

   "You would hope that the ultimate theory would be explainable in 10's of pages."

   I would? Are you aware of any reasonable treatment of any nontrivial aspect of physics which can be explained coherently in 10 pages?

3. **Peter Woit**

May 2, 2007

baroque,

These books aren't like Peskin and Schroeder, explaining in detail how to do calculations that can successfully be compared to experiment. Mostly they're quite sketchy. Dine does the Standard Model in under 20 pages, and all of cosmology in 9 pages.

But, the problem with these string theory textbooks is not their length. Peskin and Schroeder is 800 pages long, but it explains in detail how to do a wide range of calculations that can be successfully compared to experiment. Nothing in any of the thousands of pages in these books allows you to compute anything that can be compared to experiment. The Almagest is definitely better on that score.

4. **King Ray**
   May 2, 2007

   baroque, if you can't explain your theory in 10's of pages, I think you're on the wrong track, as is becoming slowly apparent to almost all on the string theory front.

   Look at Einstein's The Meaning of Relativity, Landau and Lifschitz's Mechanics, etc. for some beautifully simple expositions.

   Beauty and Simplicity should be the key characteristics of the ultimate theory.

5. **Arun**
   May 2, 2007

   "The latest edition of Ptolemy's Almagest is 693 pages. It seems that these overly baroque theories need longer texts to explain them."

   De Revolutionibus is 330 pages as per Wikipedia.

   May 2, 2007

   Hi peter,
   What do you think of the princeton university's latest press release?
   http://www.physorg.com/news97339219.html
   Thanks

7. **Peter Orland**
   May 2, 2007

   Some years ago, I remember that Princeton supposedly dropped
   their field-theory course and taught string theory instead. I presume this has since been recognized as a mistake, but I don't know for certain.

8. **marketing**
   May 2, 2007

   I'd argue differently. If anybody is considering writing a book on these topics, they better make sure it comes out in the market right now. Two years from now will most likely be too late to try and sell this stuff. Whatever the LHC might bring, the name of the game will be phenomenology.

9. **Peter Orland**
   May 2, 2007

   Ali,

   This is interesting stuff, but the article fails to mention that the
   gauge theory which is (probably) equivalent to the string theory
   is N=4 Yang-Mills. This is very different (even qualitatively) from QCD, the gauge theory of the strong interactions.

10. **King Ray**
    May 2, 2007

    I think this is the paper of Klebanov's in question:

    http://arxiv.org/abs/hep-th/0611135

    I think that all the overhyping and distorting of results for press attention is hurting string theory, since they can't deliver on their hype. I'm sure some interesting math is going on in AdS/CFT, but it may not be related to the real world.

11. **Aaron Bergman**
    May 2, 2007

    *Some years ago, I remember that Princeton supposedly dropped
    their field-theory course and taught string theory instead.*

    I doubt that. Both classes were certainly taught when I was there.

12. **Peter Orland**
    May 2, 2007

    Aaron,

    This was a long time ago. I heard about it around 1987

13. **Jack**
    May 2, 2007

    http://discovermagazine.com/2007/feb/cover

I'm not sure I understand this, but from what I'm reading it sounds like parts of string theory was experimentally verified/tested. Is this so?

14. **Peter Orland**
May 2, 2007

Jack,

That is not how RHIC experiments should be interpreted. What they study is high-energy nuclear collisions, with goal being a plasma of quarks and gluons. There is no test of fundamental string theory (of gravity and matter) here.

Here is what is going on. The formalism of string theory is used by some theorists to try to describe QCD, the theory of these quarks and gluons. The problem is that it really only describes what is called the strong-coupling approximation. Such approximations are not new – since 1974, there has been the lattice strong-coupling expansion, which is a non-computer-based calculational scheme. Such approximations gave us the first hints that QCD might really confine quarks.

Unfortunately the strong-coupling approximation is not necessarily a good approximation. The old-time lattice people abandoned it in favor of numerical methods. There are unphysical aspects of this sort of approximation (lattice artifacts, or unphysical particles from the string).

Now people are claiming that the stringy strong-coupling methods are a good way to study QCD, and to understand RHIC physics. But the real problem with any strong-coupling approach is that you can't renormalize the theory – that is remove the ultraviolet cut-off. For this reason, I think such approximations are highly questionable.

I go to a lot of talks on this stuff, and I always raise this issue. None of the speakers have addressed it, at least not to my satisfaction.

15. **J**
May 3, 2007

What do you think of the 3 early books? Any comments?

16. **valon**
May 3, 2007

Peter,

In your review of the String books you wrote:
" Mirror symmetry, which has had a huge effect on mathematics, is not even mentioned by Dine, gets a couple pages in both Kiritsis and Becker-Becker-Dine."
Did you perhaps mean BBS?

Regards.

17. **woit**
May 3, 2007

valon,

Fixed

J.,

I haven't looked at the earlier books closely recently, so don't want to say much. In general, I think they are much less sketchy, actually work through a lot more of the details of how you quantize a string, which is an interesting thing to do. From what I remember GSW also has much more details about Kahler geometry, which could be useful. But I should look at the books again before making more comments.

18. **anon.**
May 4, 2007

How about other books dealing with string theory in slightly a less spiritual, and more practical, way? For example, check out the *Red String Book: The Power of Protection (Technology for the Soul)* by Berg, http://www.amazon.com/Red-String-Book-Protection-Technology/dp/1571892486

If you'd take a more holistic approach to string, instead of blindly Popperian one you take, you'd see it differently. The people who complain that religions are wrong or 'not even wrong', ignore the *great success* of religion as a cultural, groupthink activity.

19. **David**
May 4, 2007

Anon.
I'm not sure if your post was tongue in cheek or not. I'll assume not. That said, I'm reminded of Francis Crick's remark that over the last 2000 years philosophy has been spectacularly unsuccessful at dealing with science. I'm also reminded of attending a philosophy of science conference in the late 1970's where the discussion was about the importance of betweenness in groups of billiard balls as important for the philosophical understanding of atoms & molecules. They seemed to have missed quantum theory. Thus, while Popper may have contributed something to science, I don't think any of us (at least at this blog) believe that the standard philosophical approach of ONLY thinking will lead to great advances. Feynman often said that no matter how beautiful the theory, if it doesn't agree with experiment it's wrong. The point of science is to understand nature. We can only tell how well we are doing by comparing our theories with what nature actually does. If anyone is more spiritual and less practical, it seems to me he/she is on the string side of the debate. That doesn't mean thinking is unimportant but at some point one must compare the thinking with nature.
If I misunderstood your post, sorry.
Best,
David

20. **theoreticalminimum**
May 8, 2007

I recently came across a few shared folders of ebooks on esnip, from which I found links to some of the books mentioned by Peter, from which those interested can download the books in djvu or pdf formats. I would like to merely extend those links to this post, with the hope that Peter won't be having too many misgivings about this seeming act of "free-education-resource-for-all" *débauche*. They are:
Superstring Theory (Green, Schwarz, Witten)
Volume 1 [*http://www.esnips.com/doc/db4a2a3a-79f4-4dfb-9101-839a297f0ca3/Green-M.,-Schwarz-J.,-Witten-E.-Superstring-theory,-vol-1*]
Volume 2
[*http://www.esnips.com/doc/f904e73d-fb9c-4e06-907c-94e1a565cf4f/Green-M.,-Schwarz-J.,-Witten-E.-Superstring-theory,-vol-2*]
String Theory Volume 1 [DJVU] , Volume 2 [DJVU] **(Polchinski)**,

A First Course in String Theory [DJVU] **(Zwiebach)**,
String Theory and M-Theory: A Modern Introduction [PDF] **(Becker, Becker, Schwarz)**.

Michael Dine provides lecture notes of a course he taught in 2002, which carries almost the same title (Beyond the Standard Model: Supersymmetry and String Theory) as his book. They might be worth checking out, whether or not one unfamiliar with the book would be thinking about significant overlaps with the book's content (maybe Peter would be in a position to inform us here).

Eh ben voilà quoi!

Princeton Physicists Connect String Theory With Established Physics

May 2, 2007
Categories: This Week's Hype

The latest press release hyping a string theory paper in a misleading way comes from my alma mater Princeton, which I find quite depressing. According to yesterday's press release, entitled Princeton physicists connect string theory with established physics:

String theory, simultaneously one of the most promising and controversial ideas in modern physics, may be more capable of helping probe the inner workings of subatomic particles than was previously thought, according to a team of Princeton University scientists.

The theory has been highly praised by some physicists for its potential to forge the long-sought link between gravity and the forces that dominate within the atomic nucleus. But the theory — which posits that all subatomic particles are actually tiny "strings" that vibrate in different ways — has also drawn criticism for being untestable in the laboratory, and perhaps impossible to connect with real-world phenomena.

However, the Princeton researchers have found new mathematical evidence that some of string theory's predictions mesh closely with those of a well-respected body of physics called "gauge theory," …

This has nothing to do with the controversial failed project of using string theory to provide a unified theory of particle physics and gravity. What it is about is another check of something not very controversial at all: the pretty much universally believed idea that a very special un-physical quantum field theory, N=4 supersymmetric Yang-Mills theory, at strong coupling can be described by a weakly-interacting string. This AdS/CFT correspondence is now almost ten years old and a significant amount of evidence for it has accumulated. What the press release is referring to is this paper by Igor Klebanov and collaborators, which studies numerically an integral equation derived in this paper.

The press release has already led to stories here and here, with presumably many more to come. Should make Slashdot any moment now….

Comments

1. **anon.**
   May 3, 2007

   Maldacena's unproved conjecture of a correspondence between 5-d AdS (anti de Sitter) space and 4-d stringy Yang-Mills conformal field theory (CFT) is one of the best things to come from string theory related research. I just love the fact that by the holographic principle, that 4-d particle physics resides as a brane or surface on a 5-d anti de Sitter space.

   On the negative side,

   *AdS has a negative cosmological constant, instead of a positive one,

   *N=4 Yang-Mills CFT isn't consistent with 10-d supersymmetry.

   Other conjectured unproved correspondences which can under limited conditions model real phenomena to some extent include:

   *by using phlogiston theory, you can model combustion without oxidation, which was very handy at one time,

   *by using caloric you can model heat without needing kinetic and radiation theories, again, a useful simplification at one time (Ca/KR correspondence)

   *by using Ptolemy's epicycles, you can actually model planetary motions in the solar system, which was simple for astrologers (Pt/SS correspondence)

   *by using the FitzGerald-Lorentz aether you can model the contraction of moving bodies without needing special relativity, which is oh so useful for crackpots (FL/SR correspondence)

   So the evidence of adS/CFT correspondence conjecture holding fairly well, implies that maybe people should start taking seriously other models that are similarly based on totally unphysical assumptions?

2. **John W.**
   May 3, 2007

   Something is better than nothing. With all this arbitrary mish-mash of ideas being thrown around maybe ideas may evolve to bring more meaning into the current fundamental physics discourse; until that time more raving and ranting…

   Oh, and by the way, Peter, you still haven't written anything substantial on Rep Theory and Particle Physics for the advanced undergrad. May we expect anything of that sort within the next several months?

   Regards

3. **F.**
   May 3, 2007

   Thank you for the exciting news. I think the numerical confirmation of Beisert's inspired guess how a gauge theory in the asymptotically free high-energy limit is smoothly connected to a string theoretical description at lower energy is a tremendous step forward, well worth some publicity.
   Cheers, F.

4. **ruleman**
   May 3, 2007

   F., nobody –I think– doubts that this is interesting stuff. And potentially highly useful. Well deserving of publicity.

   But when the main author says,

   > "We have previously been able to study these interactions in detail only at the high-energy conditions within particle accelerators, but with these findings we may be able to describe what's happening inside the atoms that make up rocks and trees. We cannot do so yet, but it appears that the math of string theory

could be what we need to bridge this gap."

he's clearly saying something untrue. Much is known about the strong interactions in the low energy regime, and there are a variety of tools that have been successfully used to describe them.

After all, if the above quote is true, then, how well do they fit the Roper resonance? Can they predict the masses of the meson and baryon decuplets? Or, more to the point, what is the ratio of the rho to proton masses in their theory?

I mean, can they really do what has never been done before, as they claim? Can they do better than lattice QCD, chiral effective models, QCD sum rules, as they claim? Bring on the numbers then, we are eager to check 'em.

5. **andy**
May 3, 2007

The press release isn't all hype. Consider the following:

This is not to say that string theory is likely to become accepted as an overall explanation of subatomic physics anytime soon. Klebanov's team has found a bridge between established physics and a mathematical theory, which is only one step toward solid experimental proof that the world is actually constructed of tiny vibrating strings. And even this bridge applies to only one facet of gauge theory. Bridging this gap for other facets will be necessary to enable physicists to understand fundamentally the interiors of the protons and neutrons that make up the earth beneath our feet.

I think that's fair enough. "Other facets" clearly refers to QCD.

Peter,

Actually, string theory already is a "unified theory of particle physics and gravity"; whether it is a correct description of reality is yet to be seen…

best, Kasper

11. **Herbert**
May 4, 2007

Other folks will also find it depressing that Princeton is Peter Woit's alma mater. But the press release is exciting and Dr (!) Woit should be praised for promoting it.

12. **gunpowder&noodles**
May 5, 2007

Lubos Motl also objects to this story. On the grounds that somebody used the word "controversial" in connection with string theory.
By the way, LM has recently written a screed on the 2nd law of thermodynamics that is decidedly non-mainstream; borderline crackpot in fact. I mention this *not* to start another anti-LM tirade, *nor* to initiate a discussion on the 2nd law, but as a warning to those who, like me, previously thought that he always knows what he is talking about on technical issues of physics. Evidently he doesn't. Oh well. We'll just have to read his technical writings with a few more grains of salt.

13. **Web King**
May 5, 2007

Couple of week back I read the review of the Director's Cut version of String Kings. It seems that the Director's Cut version includes more scenes featuring a certain "man on the edge".

14. **John W.**
May 5, 2007

Peter,

[Somewhat off-topic, but I thought you may be one of only a handful of people to give an honest + critical feedback.]

What do you think is specifically important about the following works? (I'm assuming you may have perused through one of them in your academic studies; I apologize if you haven't):

"Topology, Geometry and Quantum Field Theory: Proceedings of the 2002 Oxford Symposium in Honour of the 60th Birthday of Graeme Segal"

and

"Geometry, Topology and Quantum Field Theory (Fundamental Theories of Physics)"
– P. Bandyopadhyay

Thanks.
John W.

May 5, 2007

'Actually, string theory already is a "unified theory of particle physics and gravity"; whether it is a correct description of reality is yet to be seen…' – Kasper Olsen

It's not even a unification of *particle physics* and *gravity*. It's merely a unification of the (ill-founded in view of the landscape) speculation that string can model particle physics, with the speculation that by M-theory you can include gravitons. To call string theory a unification of particle physics and gravity is misleading hype. Maybe instead you should call it a unification of unphysical speculations about particles and gravity.

Saying that string *is* does unify particle physics and gravity, but then afterwards adding that it has not yet been shown to be the correct unification, is the cause of all the confusing hype problems. You need to be completely clear and call string a speculative unification scheme.

16. **V.**
May 5, 2007

Dear Anon,
String theory does in fact unify particle physics and gravity into a consistent structure. This is not speculation. You are right that we cannot say at the present why the specific vacuum which corresponds to our universe is chosen. However, I think the defiinition of particle physics is more broad than just the Standard Model. Do you have any reasons within the bounds of quantum field theory for believing that the structure of the Standard Model is unique and no other vacuum structure is possible?

17. **Kyrie**
May 5, 2007

> You are right that we cannot say at the present why the specific vacuum which corresponds to our universe is chosen.

And what, exactly, it is that you *can* say at the present time? Does string theory predict susy or not? Does it predict extra dimensions or not? Does it predict light scalars or not? And what are the corresponding mass scales?

18. **X.**
May 5, 2007

gunpowder & noodles wrote:
"By the way, LM has recently written a screed on the 2nd law of thermodynamics that is decidedly non-mainstream; borderline crackpot in fact."

LM's opinions on thermodynamics are about as accurate as his ones on computers, numerical analysis, and climate science. BS.

19. **V.**
May 5, 2007

Kyrie,
What we can say is that string theory provides a consistent unification of quantum mechanics and gravity. Supersymmetry and extra dimensions are generic predictions. The physical properties of the universe that we live in corresponds to a specific solution. In order to make predictions, this specific solution must be found first. When and if this solution is found, we may be able to say why this solution is selected. However, even in the absence of such a selection principle, this solution would allow us to completely describe the physics of the universe we live in. So, you should give string theorist/phenomenologist time to discover this solution. Then, and only then, will we be able to make specific predictions about our universe.

20. **kyrie**
May 5, 2007

V., being on the right track to a consistent unification of quantum mechanics and GR is what most people would call an important research program. It is reasonable to expect that, if successful, such program will have a lot to say about particle physics — and gravity.

But saying that *string theory does in fact unify particle physics and gravity* is very different. It implies, among other things, that particle physics can be derived from ST. And also that there are concrete predictions for future experiments. I think it's still quite far from that. There are interesting generic predictions from ST, as you say, that have actually motivated a lot of model building. But no specific ones, as far as I know, not even about orders of magnitude.

And then, the possibility cannot (so far) be logically excluded that even if particle physics and gravity actually are unified in nature, that unification is not ST.

21. **AnOn**
May 5, 2007

Kyrie,

I think that you're missing the point. All V is saying is that string theory is a quantum theory of gravity which can incorporate gauge theories, etc. V is not arguing that it necessarily has anything to do with our universe (though, of course, it might) just that it successfully merges gravity and particle physics. Some people think that this fact alone alone is impressive. I'm not aware of any other research programme which can make this claim. The only thing which comes close is LQG which, of course, doesn't predict anything about particle physics either.

22. **matteoeo**
May 5, 2007

string theory does in fact unify particle physics and gravity

I think it might at most unify particles and the graviton, which is different from unifying particles and gravity and very far from unifying particle physics to gravitation.

23. **V.**
May 5, 2007

I think there should be define what we mean when we are talking about particle physics. Are we talking about all possible gauge theories in general or just the Standard Model gauge theory which describes our universe?

For up-to-the-minute news about the Higgs, far better informed than any media source could ever be (and thus a great example of why blogs are changing the way the media works), your best bet is Tommaso Dorigo's blog. His latest posting explains well what the current state is, and predicts that, with the data expected from the Tevatron through 2009, they should be able to have 2.5-3 sigma evidence for a 115 GeV Higgs if it is there, or if it's not, rule it out at 95% confidence level up to 130 GeV. He shows a recent plot from D0 based on 1 fb^{-1} of data, and discusses the fact that D0's limits on a Higgs are not quite as good as expected at low mass. When similar data from his own experiment (CDF) becomes available, it will be interesting to compare the results. Not being able to rule out a low-mass Higgs at the expected level probably just means that it's harder to do than expected. But there's another possible interpretation: maybe there's something there….

Tommaso also has a posting about a new Physics World article discussing the recent blog-centered discussion of statistically-not-very-significant sightings of a possible new particle that could be a supersymmetric Higgs. Evidently these events have caused some consternation within CDF and D0 about the possible implications of bloggers in their midst and how this changes communication of their results to the public.

This month's Blog Life column in Physics World covers Not Even Wrong, accurately and well.

On the mathematical side of things, Terry Tao continues to come up with amazingly good blog entries. His latest is a series of three postings (here, here and here), reporting on my colleague Shouwu Zhang's lectures at UCLA on the topic of rational points on curves. This is a fundamental issue in number theory and arithmetic geometry, and the fact that Tao is a great mathematician, but not an expert, may have a lot to do with why his explanation of Shouwu's lectures is relatively easy to follow. One of the problems with academia is that one's illustrious colleagues (like Shouwu) get invitations to give lecture series like this elsewhere, but not at their home institutions. So, while I didn't get to hear Shouwu's lectures, Tao's account of them is excellent compensation.

For an interesting article by a young philosopher about the question of beauty in physics, see this article in Perspectives in Science (based on his doctoral dissertation).

On May 22 the CUNY Graduate Center program on Science and the Arts will host an event entitled String Theory for Dummies. Unfortunately I'll be out of town that day…

A couple weeks ago there was a workshop in Tel Aviv and Jerusalem on String Theory: Achievements and Perspectives, honoring the sixtieth birthday of Eliezer Rabinovici and Shimon Yankielowicz. Videos and some transparencies from the talks are available here. Susskind gives his usual propaganda for the anthropic string landscape, but seems rather defensive, starting off saying that he "feels like he's at the center of a circular firing squad" (which maybe does describe what is going on in string theory these days), and that "some people say I'm a traitor" or that "my ideas are dangerous."

Gross ended the conference with a remarkable discussion of the current state of string theory. He put up various cartoons illustrating the fact that the public perception of string theory has turned rather negative (including the recent one from the New Yorker: "Is String Theory Bullshit?"), but took solace in a recent use of string theory in an advertisement for women's bikinis. He declared that "I am still a true believer in the sexiness of string theory", and that he continued to think it is clearly on the right road. But, after giving the standard list of string theory achievements, he did admit that he was much less optimistic than 20 years ago, and spent some time discussing what he sees as the main failure to date: the continuing lack of a fundamental dynamical principle behind string theory. The question "what is string theory?" still has no real answer, and he has "the very uneasy feeling that we're missing something big, that semi-classical intuition fails", and that this will make the landscape disappear. Perhaps most remarkably, Gross admitted to some discouragement about AdS/CFT. He noted that the recent Klebanov et. al. results promoted by press release as connecting string theory with physics were actually due to an impressive gauge theory calculation. According to him, what has happened is that gauge theory techniques have proved more powerful than string theory techniques. He went on to discuss the landscape, explaining that he found the anthropic principle impossible to falsify, completely against the way physics has made progress in the past, and just "an easy way out". Gross ended his talk by pointing out that 90 percent of the conference talks used supersymmetry, and that currently there was a "really weird situation": supersymmetry was an essential tool, but there was absolutely no evidence for it. He said that he continues to believe that supersymmetry will be found at the LHC and has been willing to take 50/50 bets on the subject for bottles of wine, etc.

I haven't yet had time to listen to many of the other talks, it looks like there are quite a few worth listening to, although as usual recently a depressingly large amount of landscape-based rather philosophical and pseudo-scientific argumentation.

I spent Thursday out at Stony Brook at the celebration of the 40th birthday of the ITP. It was great to catch up with many people I haven't seen in nearly twenty years, hear what a lot of ex-Stony Brook people are doing, and meet some interesting new people (including some blog readers!).

Yesterday I spent much of the day downtown at the headquarters of the New York Academy of Sciences, which was hosting this semester's Northeast String Cosmology Meeting, organized by Brian Greene and others from Columbia. The setting was pretty amazing, up on the 40th floor of the new 7 World Trade Center building, which has a spectacular view of lower Manhattan. Richard Bond gave a talk on topics concerning inflation and the CMB. He ended with lots of detailed calculations of CMB effects due to cosmological models involving string theory compactifications, especially a "Roulette Inflation" model. The joke was that God does not just play dice with the universe, but roulette also. In the question period Neil Turok politely pointed out that he was randomly choosing initial conditions, and getting very different imprints on the CMB, so wasn't really able to predict anything. Nima Arkani-Hamed spoke on "Quantum Horizons and the Landscape", talking about very general philosophical issues of horizons in AdS, the landscape, whether there are any "sharp observables" in this context and associated limits on the applicability of effective field theory. He ended by claiming that the situation is like that of the quantum theory in 1911, with the angst people are experiencing due to the landscape just like the difficulties physicists faced early in the century in going from classical physics to quantum physics. He didn't mention that the old quantum theory was making lots of verified experimental predictions, whereas he is giving talks on whether, even in principle, the landscape can predict anything. Seems kind of different to me.

Among the many people there was Alan Guth, who, according to this blog entry someone pointed me to, has started "to have been converted over to thinking that anthropic arguments might have some merit."

While I found these two talks depressing and all too symptomatic of the sad state of this subject, there was a huge bright spot at the workshop. Witten gave a really amazing talk about 2+1 d gravity. He has some fascinating new ideas about this, but they deserve a completely separate posting, which I'll try to get to writing up tomorrow…

   Leonard Susskind said:
   some people say I'm a traitor" or that "my ideas are dangerous."

   If he's talking about the fact that he wants to abandon the scientific method without a tested and proven theory, then yeah, he's dangerous.

Or the fact that he wants to "conditionally" abuse strong interpretations of the anthropic physics in order to blackmail others, maybe?

> If, for some unforeseen reason, the landscape turns out to be inconsistent – maybe for mathematical reasons, or because it disagrees with observation – I am pretty sure that physicists will go on searching for natural explanations of the world. But I have to say that if that happens, as things stand now we will be in a very awkward position. Without any explanation of nature's fine-tunings we will be hard pressed to answer the ID critics.

Anybody want to take bets on how fast Lenny retreats and becomes a traitor to his strong anthropic interpretation without the landscape, if the landscape does fail?

2. **Kea**
May 5, 2007

willing to take 50/50 bets on the subject for bottles of wine

Oh, goody! I'll take him on. There are some great pinot noirs from Central Otago that I don't think he'd turn his nose down at (although he won't be winning the bet).

3. **Aaron Bergman**
May 5, 2007

They certainly made it a challenge to watch the talks.

4. **M**
May 6, 2007

The complain that I hear is: "life was better before that Susskind promoted the anthropic landscape, he made a disaster".

This reinforces my opinion that many string theorists abandoned physics for something else. The physics of string theory is anthropic? Then better to address it.

5. **usuck**
May 6, 2007

even u can appreciate Witten's genius. You look so 60s', update your outlook man.

6. **Jeremy**
May 6, 2007

I'm a bit sauced off that The New Yorker contained a cartoon like that. I wish I could find it.

7. **Peter Woit**
May 6, 2007

Jeremy,

Here it is:

Yes, maybe you were ripped off…

8. **Jeremy**
May 7, 2007

Oh, probably not. That thought's not SO uncommon, is it? Plus actually looking at it, the most I could surmise is that if by the unlikely chance the writer saw our stupid little ad, it was merely an inspiration.

Witten on 2+1 Dimensional Gravity

May 6, 2007
Categories: Favorite Old Posts, Uncategorized

The high point of Friday's string cosmology workshop here in New York was Witten's lecture on his new ideas about 2+1 dimensional quantum gravity. I'll try and reproduce here what I understood from the lecture, but this (2+1 d quantum gravity) is not a subject I've ever followed closely, so my understanding of the topic is very limited. It does seem clear to me though that Witten has come up with a striking new idea about this subject, linking together some very beautiful mathematics and physics. He has yet to write a paper on the subject, but presumably there will be one appearing relatively soon. I also suspect this is what he'll be talking about at Strings 2007.

Witten began by stating his motivation: to study fully quantum black holes in an exactly solvable toy model. There's no exactly solvable model in 3+1d, and 1+1d is too simple, so that leaves 2+1d. Assuming 2+1d, for positive cosmological constant Λ he is suspicious that the theory is non-perturbatively unstable and one can't get precise observables, for Λ=0 one doesn't have black holes, so that leaves negative Λ, here the vacuum solution is anti-deSitter space, AdS_3.

Quantum gravity in AdS_3 is related to 2d conformal field theory. There have been studies of AdS_3/CFT_2 as a lower dimensional version of string/gauge duality, but here he uses not string theory on AdS_3, but a quantum field theory. In a question afterwards, someone asked about string theory, and Witten just noted that perhaps what he had to say could be embedded in string theory, and that the recent Green et. al. paper showing that one can't get pure supergravity by taking a limit of string theory did not apply in 3d. If one wants to interpret this new work in light of the the LQG/string theory wars, it's worth noting that the technique used here, reexpressing gravity in terms of gauge theory variables and hoping to quantize in these variables instead of using strings, is one of the central ideas in the LQG program for quantizing 3+1d gravity. Witten was careful to point out though that there was no 3+1d analog of what he was doing, claiming that one can't covariantly express gravity in terms of gauge theory in 3+1d (he said that LQG does this non-covariantly).

For negative Λ the theory has so-called BTZ black hole solutions, discovered by Banados, Teitelboim and Zanelli back in 1992, and it is for the quantum theory of these black holes that Witten is trying to find an exact solution. The technique he uses is one that goes back to the 80s, that of re-expressing the theory in terms of SO(2,1) (or its double cover SL(2,**R**)) gauge theory, where the action becomes the Chern-Simons action. More precisely, the Einstein-Hilbert action

$$I_{EH}=\frac{1}{16\pi G}\int d^3x\sqrt{g}(R +2/l^2)$$

(here the cosmological constant is $\Lambda=-1/l^2$) gets rewritten as an SO(2,2)=SO(2,1)XSO(2,1) gauge theory with connection

$$A= \begin{pmatrix}\omega & e \\ -e & 0 \end{pmatrix}$$

where &\omega; is a 3X3 matrix (the spin-connection), e is the 3d vielbein, and the gauge theory action is the Chern-Simons action

$$I=\frac{k^\prime}{4\pi}\int Tr(A\wedge dA+\frac{2}{3}A\wedge A\wedge A)$$

with $k^\prime=\frac{l}{4G}$ (that 4 may not be quite right…).

Witten wants to exploit the relation between this kind of topological QFT and 2d conformal field theory that he first investigated in several contexts (including one that won him a Fields medal) back in the late eighties. He notes that in this context the existence of left and right Virasoro symmetries with central charges $c_L=c_R=\frac{3l}{2G}$ was first discovered by Brown and Henneaux back in 1986, and he refers to this discovery as the first evidence of an AdS/CFT correspondence. If one really does have a CFT description, one expects that the central charges can't vary continuously, but that 2+1d gravity will only make sense for certain values of l/G, but Witten notes that there is no rigorous way to find the right values one will get upon quantization.

He then goes on to make a "guess", adding to the action a multiple of the Chern-Simons invariant of the spin connection

$$I^\prime=\frac{k}{4\pi}\int Tr(\omega\wedge d\omega + \frac{2}{3}\omega\wedge\omega\wedge\omega)$$

Now the theory depends on two parameters: l/G and an integer k.

Using the fact that SO(2,2)=SO(2,1)XSO(2,1), one can rewrite the total action as the sum of two Chern-Simons terms

$$I= \frac{k_L}{4\pi} \int Tr(A_-\wedge dA_-+\frac{2}{3}A_-\wedge A_-\wedge A_-)$$
$$ \\ + \frac{k_R}{4\pi}\int Tr(A_+\wedge dA_++\frac{2}{3}A_+\wedge A_+\wedge A_+)$$

for connections

$$A_{\pm}=\omega\pm e$$

Now instead of l/G and k we have k_L,k_R and these are quantized if we take the gauge theory seriously. By matching Chern-Simons and gravity the central charges turn out to be

$$ (c_L, c_R)= (24k_L, 24k_R)$$

and holomorphic factorization is possible in the 2d CFT for just these values

Looking at just the holomorphic part, we have a holomorphic CFT with central charge c=24k and ground state energy -c/24=-k (note, now a different k than before…).

The partition function is expected to be ($q=e^{-\beta}$)
$$Z(q)=q^{-k}\Pi_{n=2}^\infty \frac{1}{1-q^n}$$
The first term in the product is the ground state (AdS_3), the only primary state, with the other terms Virasoro descendants (excitations of the vacuum from acting with the stress-energy tensor and derivatives).

Witten then goes on to note that this expression is not modular invariant, so one expects other terms in the product, corresponding to other primary states. By an argument I didn't understand he claimed that these would be of order q^{1}, at an energy k+1 above the ground state, and his proposal was that it would be this modular invariant function that would include black hole states.

In these units the minimum black hole mass is M=k, but here one is getting states only at mass M=k+1 and above. This is because the Bekenstein-Hawking entropy of the M=k black hole is 0, so it doesn't contribute to the partition function.

Witten claimed that this proposal gives degeneracies of states that agree with the Bekenstein-Hawking entropy formula. As an example, for k=1 the partition function is given by the famous J-function

$$J(q)=j(q)-744=q^{-1}+196884q+\ldots$$

and thus for a black hole of mass 2 the number of primaries is 196883 and the entropy is ln(196883)=12.19, which can be compared to the Bekenstein-Hawking semi-classical prediction of 12.57 (one only expects agreement for large k,M).

The number 196883 is famous as the lowest dimension of an irreducible representation of the monster group, and this partition function is famous as having coefficients that give the dimensions of the other irreducibles ("modular moonshine"). There is a conjecture that there is a unique CFT with this partition function. If so, it must be the CFT that has the monster group as automorphism group. It has always seemed odd that this very special CFT didn't correspond to a particularly special physical system, but if Witten is right, now it has an interpretation in terms of the quantum theory of black holes in 2+1 dimensions.

Anyway, that's what I was able to understand of what Witten had to say and what he was claiming. Other people have worked on this problem in the past, for a recent review article on this topic by Carlip, see here. Carlip describes the understanding of the problem at the time as "highly incomplete", and one of the explanations he describes relates the black hole problem to the Liouville theory. A question from the audience after the talk asked about this, and Witten indicated that he thought the Liouville theory explanation did not work.

I'm no expert here, so unclear on the details, why some of these things might be true, and what the implications might be, but this does seem to be a remarkable new idea, involves beautiful mathematics, and seems to provide promising insight into a crucial lower dimensional toy model. I suspect it will draw a lot of attention from theorists in the future.

For this posting, I especially encourage any comments from people more knowledgable than myself who can correct anything I've got wrong. I also strongly discourage people who know little about this from contributing comments that will add noise and incorrect information. Bad enough that I'm trying to provide information about something I'm not expert on; if you can help that's great, but if not, please don't make it worse…

Update: Lubos has picked up on this, which he describes as having been "leaked", and gives the usual argument that this must be part of string theory.

   Assuming 2+1d, for positive cosmological constant Λ he is suspicious that the theory is non-perturbatively unstable and one can't get precise observables, ***for Λ=0 one doesn't have black holes****, so that leaves negative Λ, here the vacuum solution is anti-deSitter space, AdS3.*

   Stupid question: Why not?

   What happens if you just take a certain amount of mass and drop it into an area of zero-cosmological-constant 2+1d space less than that mass's Schwarzschild radius, or whatever?

2. **Peter Woit**
   May 7, 2007

   I just deleted almost all the comments on this posting, since, besides one helpful comment pointing out a typo, they were doing what I specifically requested people not to do. Please try and resist the temptation to add to the noise level here. If you have an informative and substantive comment, please post it, but the level of not-worth-reading comments followed by people pointlessly bickering about them has gotten really annoying. This creates an environment I wouldn't want to participate in myself.

   Coin,

   I don't know what the physical interpretation is, but I assume the point is that the BTZ solutions don't exist for zero CC. Maybe someone more familiar than me with this has insight into why this is.

3. **anon**
   May 8, 2007

   2+1 is special: For lambda = 0, Ricci = 0 implies Riemann = 0; there's no Birkhoff theroem in 2+1. So, a vaccum equation in 2+1 is just flat space. No curvature, so no black holes.

   More intuitively, in 3+1 one can consider the lower bound of a tottally collapsed gravitational object (Schwarzschild radius = 0) as a critical point between wave dispersion and gravitational / self attraction. Consider a radially ingoing gaussian profile of energy; say some field. For small amplitude the dispersion will exceed the self attraction and the solution puts the field on the boundary at future infinity. With increasing amplitude, eventually one finds the critical point and black holes thereafter.

   In 2+1, for Lambda >=0 there is not the same mechanism of self attraction; so no black holes. It's all dispersive instead.

4. **Coin**
   May 8, 2007

   woit/anon: Thanks!

   Anon, I think that actually makes sense, but I do have one question. What happens if, in flat (i.e. zero cosmological constant) 2+1 space, you accumulate mass into an object so dense that its escape velocity is greater than the speed of light? Would it simply not be for some reason possible to construct such an object in flat 2+1 space? Or would it be possible for such an object to exist, but the object would not be or behave like a black hole (i.e. no singularity forms)? From what you're saying it sounds like the latter would be the case.

5. **anon**
   May 8, 2007

   Well, you're thinking very intuitively about the situation, which is fine.

   However, there's an important distinction between vacuum and matter solutions and an important relationship as well. In 3+1 there's a good understanding that collapse of a matter solution will produce a singularity and subsequently an asymptotic final state that is a pure vacuum solution (all matter confined asymptotically to the singularity and so no matter elsewhere; e.g., a pure vacuum solution). The Oppenheimer Snyder analysis points the way / motivates the passage from a matter solution towards a vacuum solution final state, which logically (but not historically) is a primary impetus for looking closely at the 3+1 vacuum space of solutions. Hence consideration of Ricci = 0 solns (vacuum by defn of the Einstein equation). Einstein's original motivation for looking at Ricci = 0 was different, perhaps explaining why it took the prescient work of Schwarzschild and then Oppenheimer and Snyder after that.

Thus, the motivation for immediately jumping to Ricci = 0 solutions assumes the given of tottal gravitational collapse (which in turn presumes ideas like escape velocity).

Interrogating 2+1 for Ricci = 0 finds a suprise: All vacuum Ricci = 0 are flat.

Hence no total gravitational collapse; hence no analogous escape velocity.

2+1 is different and has special arguments.

HIH

May 8, 2007

Coin,

The idea of a black hole as an object near which the escape velocity is greater than one is a purely newtonian idea. Laplace famously wrote a paper about it, and someone else before him, but that's another story. The precise definition of a black hole in general relativity is considerably more complicated than that.

But anyway, let's think about black holes in 2+1d newtonian gravity. Whereas in 3 spatial dimensions the gravitational force from a point particle goes as the inverse of the square of the distance, in 2 spatial dimensions it just goes as just the inverse of the distance. This is just like the electric field of a line charge.

Anyway, if the force goes as one over the distance, then the binding energy goes as the log of the distance. So it would take an *infinite* amount of energy for a test particle to escape to infinity in 2+1d. Escape velocity isn't a meaningful concept in 2+1d newtonian gravity, because there just isn't any escape.

anon writes:

> 2+1 is special: For lambda = 0, Ricci = 0 implies Riemann = 0; there's no Birkhoff theroem in 2+1. So, a vacuum equation in 2+1 is just flat space.

Gotta be a bit careful here. Everything you say is true, but you can have metrics that are vacuum solutions of (2+1)-dimensional general relativity everywhere *except* for a singularity. For example, there are solutions where space looks like a cone. A cone is flat except at the tip, where the curvature is infinite. These solutions act like point particles – not black holes.

The cool part is that there's an *upper bound on the mass of the particle* in these solutions. More precisely, and even more cool, the mass of a particle is only defined modulo the Planck mass! It makes no sense to talk about a particle with mass greater than the Planck mass… past this point, the mass just 'wraps around': a particle like this is the same as a very light particle.

By the way, this stuff is true classically: no quantum gravity required! The reason is that in 2+1 dimensions one can define the "Planck mass" – a quantity with units of mass – using just Newton's constant G and the speed of light c. One doesn't need Planck's constant!

All this is much more sensible than it sounds at first sight. For more details, try week232. For even more details, try my paper with Derek Wise and Alissa Crans.

But anyway, yeah: there are no black holes in (2+1)-dimensional gravity when the cosmological constant vanishes… or is positive. One doesn't need to understand quantum gravity to see this: it's just GR.

It's nice to see equations on your blog, Peter! Good, sound, serious stuff – not just people fighting!

8. **anon**

coin writes:

> But anyway, let's think about black holes in 2+1d newtonian gravity.

This is interesting to do, but general relativity in 2+1 dimensions is funny.

Unlike the more familiar (3+1)-dimensional case, it *does not reduce to Newtonian gravity* in the limit of small masses moving much slower than the speed of light!

For example, it's pretty easy to see that in 2+1 dimensions, general relativity does not allow one small mass to orbit another in a circular orbit. Newtonian gravity does.

So, in 2+1 dimensions, 'Newtonian black holes' are a poor guide to the behavior of general-relativistic black holes — much worse than in 3+1 dimensions, where John Michell successfully computed what's now called the 'Schwarzschild radius' way back in 1784, using Newtonian gravity! (His calculation was repeated by Laplace around 1795.)

All this makes (2+1)-dimensional general relativity a rather odd subject to use as a warmup for real physics… but it's very pretty. Most researchers in quantum gravity have not been able to resist its charms — there are lots of papers about it.

10. **amanda**
May 10, 2007

"All this makes (2+1)-dimensional general relativity a rather odd subject to use as a warmup for real physics…"

Then why is Witten's work interesting? I'm not being sarcastic — I genuinely want to know what we might learn if people push on with this thing.

May 10, 2007

A.V.Pushkin (1947-2004) from Russian Federal Nuclear Centre –VNIIEF (Sarov) used in nineties The Monster Group as hardware for calculations of important dimensionless physical constants, and not only them. Very succinct exposition of his approach you could find in his presentation on the Second Int. Sakharov Conf., Moscow, 1996 (Proc. of this Conf. were published by World Scientific Publ.,1997).Here I place the annotation of this work.
"MONSTROUS MOONSHINE" AND PHYSICS
A.V.Pushkin
The paper presents some results obtained by the author on the quantum gravity theory. This theory proves related to geometry of Cayley projective plane and the algebraic structure of the theory to the commutative nonassociative Griess algebra. The theory symmetry group is the automorphism group of Griess algebra: "Monster" simple finite group. Knowledge of the theory symmetry allows observed physical quantities to be computed in the "zeroth" approximation. Results of the calculations, including those for fine structure constant ~ 1/137 and proton to neutron mass ratio, are presented, with the theory-controlled accuracy of the "zeroth" approximation being higher for some of them by 1–1.5 orders of magnitude than the accuracy of modern measurements.
If it is interesting to somebody I can send full text and additional information.
Gennady Kochemasov, RFNC VNIIEF.

12. **Peter Woit**
May 10, 2007

amanda,

In terms of physics, 2+1 gravity isn't what one ultimately wants to know about (although, for mathematics, Witten's claims may make it turn out to be very interesting). It's a toy model. If one needs to develop new ideas and new techniques for solving a problem (which is what I think quantum gravity needs), then most of the time you have to first start with simpler cases, with toy models, in order to develop these new ideas and techniques. Witten seems to have found a new sort of relationship between a fully quantum gravity theory, gauge theory, and a simple conformal field theory. Yes, it's in 2+1d, not 3+1d, but it's a new idea, and until one completely understands how it works and what one can do with it, whether or not it will help with the 3+1d problem is unclear. I think Witten would also argue that sorting out the conceptual problems of a fully quantum, exactly solvable, theory of 2+1d black holes may give insight into the more difficult conceptual problems in 3+1d, where there seems to be no hope of an exact solution.

About the work of Pushkin: this seems to have nothing to do with the topic of this posting, Witten's recent work, but I'll leave the comment, suggesting that people who want to discuss that contact the author.

13. **Kochemasov Gennady,RFNC VNIIEF,Sarov**
May 10, 2007

To Peter Woit. I think that your comment about the work of Pushkin and the topic of this posting is not exactly correct, The reason very simple: Pushkin really thought that he solved the problem of quantum gravity and had strong support for such conclusion.If this true(I am not expert in QG, but I had many talks with Sasha), then this posting had projection on wright direction.And it is good news. For explaining my point of view I place here one more citation from Pushkin book(in Russian):"In the superstring theory a striking progress has been achieved recently: as few as five theories remain which are actually based on two lattice types in 16-dimensional space. Moreover, it has been proved that they are non-perturbative equivalents and as such are the limiting cases of the more general single theory. What last step should be made in the superstring theory in the direction of the construction of a single theory? Of course, this step is the gravity quantization, which will result in disappearance of the last dimensional scale in the theory, viz. the fundamental string scale. Then the theory will possess the local scale invariance properties and may perform quantitative calculations with non-perturbative methods by translating algebraic relation between physical quantities to different scale levels, including to the level of ordinary phenomena appearing in continuum motions in standard conditions." Here I pass long but important part of text and proceed:"In geometrodynamics, i.e. upon the gravitation quantization, even this last dimensional scale disappears. In the language of the lattice theory in spaces this means that there should be the only possibility to avoid the need of appearance of dimensional scale: the fundamental root amount is equal to infinity (i.e. there is no separated cell) and the Weyl vector is therewith light-like, which also requires no a priori scale. It is evident that the last requirement is readily formalizable at the level of the elementary problem of Diophantine equation solutions . Having solved it, you will find those values of dimension of hyperbolic spaces , which determine the lattice arrangement of the geometrodynamics."

14. **urs**
May 10, 2007

> I genuinely want to know […]

It may be helpful to emphasize, as Peter mentioned above, that

a) there is a well-known relation between 2-dimensional conformal field theory and 3-dimensional Chern-Simons theory for a given gauge group G. This is a deep and powerful relation between two classes of field theories.

b) it so happens that for particular choices of gauge group, Chern-Simons theory becomes equivalent to 2+1 dimensional gravity.

This is probably a "coincidence of low dimensions": two classes of structures which are by themselves rather different happen to coincide when both are restricted to sufficiently degenerate cases (here: gravity restricted to sufficiently low dimensions), simply because there is not enough room for them to differ:

here both the Chern-Simons action and the Einstein-Hilbert action (in its Palatini formulation) must be suitably invariant functionals pairing a connection 1-form and a 3-manifold. There are not that many possibilities for that, in a sense.

So the idea is: (quantum) gravity in general is an awefully complex issue, which we arer having a hell of a hard time coming to grips with. After we are sufficiently frustrated about our lack of progress in the general case (or even the one case, 3+1 dimensions, which we started off being interested in), we fall back to the observation that if only we constrain one parameter (the number of dimensions) sufficiently, suddenly everything becomes tractable.

Before we embarked on the quest for quantum gravity we had been optimistic that progress is possible for the cases that we were really a priori intersted in and didn't care about that unphysical 2+1-dimensional case.

But now that frustration with the general case is high enough, the case we previously looked down on suddenly appears much more charming.

So we say: "Let's then at least fully work out everything in that toy example. Better than getting nowhere."

And then it turns out that even the toy example is demanding enough and that we should maybe have trained our skills at this from the very beginning.

15. **anon**
May 10, 2007

Hopefully, someone will correct me.

In 3+1 there are some deep problems with quantum gravity. One of which is the problem of time and others related to the problem of quantifying the geometry (or the arena) on which physics occurs.

Some writers originally approached 2+1 as a 'laboratory' (or as Peter calls it a toy model) where problems like the problem of time or the quantization of geometry could be considered towards the end of generating intuition / ideas about the 3+1 problem.

16. **Aaron Bergman**
May 10, 2007

it so happens that for particular choices of gauge group, Chern-Simons theory becomes equivalent to 2+1 dimensional gravity.

As I understand it, this is not at all clear. It is true that there are classical transformations that take one to the other, but the relation of the quantum theories (whatever they may be) is not obvious.

17. **urs**
May 11, 2007

> it so happens that for particular choices of gauge group, Chern-Simons theory becomes equivalent to 2+1 dimensional gravity.

As I understand it, this is not at all clear. It is true that there are classical transformations that take one to the other, but the relation of the quantum theories (whatever they may be) is not obvious.

Ah, is it not that Witten in his approach effectively *defines* 2+1D quantum GR to be G-Chern-Simons, for suitable G?

18. **urs**
May 11, 2007

(Hm, in the preview of the above comment the nested blockquote did work.)

19. **Jens**
May 11, 2007

> As I understand it, this is not at all clear. It is true that there are classical transformations that take one to the other, but the relation of the quantum theories (whatever they may be) is not obvious.

Indeed, even the classical theories are not equivalent, since in the CS formulation degenerate metrics are included. As a consequence, the gauge equivalence classes of Einstein-Hilbert gravity and "CS gravity" are not the same, see for instance gr-qc/9903040 for an elaborate discussion.

As Urs points out, Witten, in his -88 paper, rather takes the CS formulation as the definition of 2+1D quantum gravity

20. **John Baez**
May 11, 2007

One has to just take some definition of 2+1-dimensional quantum gravity, study it, and see if 'acts like a quantization of general relativity in 2+1 dimensions should' — bearing in mind that general relativity in 2+1 dimensions has a lot of weird features, and quantization will make things even weirder!

There are a number of BF theories and Chern–Simons theories that have a claim to describing gravity 2+1 dimensions, depending on the signature of the metric and the value of the cosmological constant. Derek Wise will give a thorough listing of these in his thesis (due in a few weeks).

As Jens notes, all these theories allow degenerate metrics, unlike Einstein-Hilbert gravity. That may be okay; one just need to see what happens, especially upon quantization.

The more realistic theories have Lorentzian signature, so they have noncompact gauge groups, which introduce a lot of technicalities that people don't fully understand yet. For example: the representation theory of noncompact quantum groups and noncompact affine Lie algebras.

21. **Rado**
May 12, 2007

For those you want to take a look on a simple example (among many) of 2+1 Gravity and 2-d CFT relation, you can take a look here [hep-th/0411060].
This papers starts with 2+1 CS gravity as used by Witten and derives 2-d Ward identities which are characteristic from CFT and known for long time. The key is to considers proper boundary terms, inpired by AdS/CFT correspondence.

22. **urs**
May 14, 2007

One way to think of a realization of the relation

G-WZW theory on 2D-bundary G-CS theory on 3D-bulk

seems to be to think of membranes in a Horava-Witten setup:

the membrane, propagating in some spacetime, couples to the supergravity 3-form C, which looks like

C = CS(A_e8) + CS(A_so(10,1)) + dB,

where A_e8 is an e_8 connection and A_so(10,1) an so(10,1)-connection and CS(…) are the corresponding Chern-Simons terms.

Varying the membrane configurations is a lot like varying the pulled back connections A_…, hence a lot like variation of a Chern-Simons functional on the membrane.

So we might expect a corresponding WZW theory on the boundary of the membrane. And indeed, for the e8 part we do: that should be the internal current algebra CFT of the heterotic string.

But what about the SO(10,1)-part?

At least naively, it should somehow split, locally, into the SO(2,1)-part tangential to the membrane and an SO(8)-factor transversal to it.

Possibly the SO(8)-WZW model may be merged with the E_8 one some way or other. What would be left is an SO(2,1)-CS theory on the membrane. Since that's, roughly, workvolume gravity — as discussed in the above thread — , it looks a little like part of the worldvolume kinetics of the membrane.

I am just saying this in the hope that somebody out there recognizes something in these observations that can actually be made a little more precise. I have here three Lie 3-algebras corresponding to the above three ingredients lying around, and I would like to fuse them back to the one thing they came from. It vaguely looks like understanding the above should help understand this problem. Or vice versa.

23. **Peter Woit**
May 14, 2007

Urs,

Do you really believe that a good way to think about the relation between the simplest 2d conformal field theories (WZW models), and simple 3d QFT with a single, beautiful term in the action (CS) is to embed everything in 11 dimensions, and try and relate things to 11d supergravity and an unknown M-theory?

24. **urs**
May 14, 2007

> Do you really believe […]

Yes.

By the way, maybe in what I wrote above I am being stupid with seeing a problem here where the formalism is trying to tell me that there is no problem:

On p. 79 of Wiaeo? the authors define a Chern-Simons theory parameterized by a G-bundle E->X to involve only those bundles with connection, which can be obtained from pullback of E along some map Sigma : M–>X. Then one only varies those maps Sigma.

That's *precisely* the situation we have for the 3-form coupling of the membrane!

Hm…

25. **R**
May 18, 2007

It is really nice to read unpublished newest ideas in physics as blog and to have a chance to post a comment though I am a simply beginner of string theory.
I cannot tell well but I am wondering newest 2+1 D doesnot mean usual spatial 2D + time D but spatial D + time D + extra D (or spin geometry?).

Regards,

26. **John Baez**
July 13, 2007

I say a bit more about Witten's new idea in week254.

In particular, since Urs and some of his collaborators know a lot about how to get 3d topological quantum field theories from 2d rational conformal field theories, some of them may enjoy trying to extract a 3d TQFT from the c = 24 conformal field theory Witten is considering as dual to 3d quantum gravity in his new work – the one that has the Monster group as symmetries.

If Witten's ideas are correct, this 3d TQFT could be a kind of "improved version" of Chern-Simons theory when it comes to describing 3d quantum gravity. This seems like a strange idea, but perhaps interesting.

(I'm not sure this field theory is a rational conformal field theory, or has been proved to be so. I believe Borcherds, Frenkel, Lepowsky and Meurman only consider it as a vertex operator algebra. I hope it extends to a rational CFT. But, this could be hard to show, even if it's true.)

Crash Course

May 7, 2007
Categories: Uncategorized

This week's New Yorker has a quite good article on the LHC and the state of particle physics with the title [Crash Course](). One of the main themes of the article is that of the rivalry between experimentalists and theorists. There's a quote from Leon Lederman:

If I occasionally neglect to cite a theorist, it's not because I've forgotten,… It's probably because I hate him.

CMS experimentalist Robert Cousins describes worries that triggers designed with too much attention paid to theorists could be disastrous:

There are famous high-energy-physics experiments that missed discoveries because they weren't writing them to tape… This is why we try not to be too specific about which theoretical speculations we care about. We add up all the energy, and if it's a huge number we write that event to tape. If on one side of the detector it's a not-so-huge number, but there is nothing on the other side, so it's a huge imbalance, we get excited about that, and we write that to tape, too.

The only theorist interviewed is Nima Arkani-Hamed, who, while consuming prodigious numbers of espressos, describes the perception of theorists by experimentalists as:

There is a sense among many experimentalists that theorists are a bunch of irresponsible little spoiled brats who get to sit around all day, having all these fun ideas, drinking espresso and goofing off, with next to no accountability.

and jokes that theorists will need to get a "Deep Throat" among experimentalists in order to get access to any raw LHC data.

As for the state of the LHC, the Resonaances blog at CERN [describes]() rumors from "well-informed sources" that the low-energy test run scheduled for late this year is likely to be cancelled, with a physics run at full energy not likely until summer 2008.

Comments

1. **Christine**
   May 7, 2007

   I read in the article that

   As of 2000, at least ten thousand scientific papers on supersymmetry, and several thousand more on string theory, had been written.

   So what has been learned from those thousand and thousand of papers? What is the best review paper available?

   Thanks,
   Christine

2. **anon.**
   May 7, 2007

   Christine, Einstein said if 100 geniuses all believe in the same thing, at least one of them should be able to provide some solid reasoning, and if they can't do that, you begin to wonder how ingenious they really are. That was in 1931 when *100 Authors Against Einstein* was published. Supersymmetry is pretty similar. So many people can't all be wrong in their prejudiced opinions, even though they have no solid evidence and furthermore – with the landscape problem – no conceivable way of ever getting any solid evidence. What's been learned is that the landscape undermines the credibility of the subject, but the inertia of groupthink continues.

3. **Chris Oakley**
   May 7, 2007

   > So what has been learned from those thousand and thousand of papers?

   I am sure that quite a lot has been learned, but I doubt that any of it is relevant to the LHC.

   Re: the *New Yorker* article, I am curious about some of the more wacko speculations as to what the LHC might produce, e.g. extra dimensions or mini black holes. *How would one know?* In the time-honoured particle physics tradition, all the LHC experiments use measured position and momenta of detectable particles to infer properties of the unstable particles that may have created them using relativistic kinematics. One may be able to enlarge the table of known particles by analysing these data, but how does one go from this to demonstrating the existence of extra dimensions or mini black holes? In these cases one would surely need to have a clear idea of how these esoteric ideas impacted the list of known particles and their properties first – something that at present is clearly lacking.

   Maybe I am missing something here. Does the LHC have an experiment specifically designed (e.g.) for catching mini black holes? (other than in the funding, obviously).

4. **Peter Woit**
   May 7, 2007

   Christine,

   As far as attempts to use supersymmetry and string theory to connect to the real world, the three books I wrote about recently each review this. Dine is strongest on supersymmetric field theory, Becker-Becker-Schwarz on string theory. Lots has been learned about string theory and supersymmetry that is irrelevant to the real world, but there's such a variety of things that I don't know a single source that reviews them.

   Chris,

   There are "brane-world" models in which the quantum gravity scale is low and you can estimate cross-sections for producing black-holes, and what the experimental signatures would be if you produced them. There's a whole industry of people doing this. Of course it's pretty much completely unmotivated, there's no reason at all to believe that the quantum gravity scale is around 1 TeV, carefully set so as to have zero effect at the Tevatron, but a dramatic effect at the LHC. Then there's the problem that these things maybe should already have shown up in neutrino experiments.

   As far as I can tell virtually no one believes that this kind of thing will be seen at the LHC, but a lot of people go on about how exciting it would be it this happens.

5. **Aaron Bergman**
May 7, 2007

Supersymmetry is pretty similar. So many people can't all be wrong in their prejudiced opinions, even though they have no solid evidence and furthermore – with the landscape problem – no conceivable way of ever getting any solid evidence.

There are many, many conceivable ways of getting solid evidence for supersymmetry. And what, exactly, does supersymmetry have to do with the landscape anyways? Can we please try to keep our attacks of various directions in high energy physics straight?

For Chris, in various extra dimension models, people have worked out the relevant accelerator signatures. As an example, for certain TeV scale gravity models, you can produce graviton that leaves the brane and thus manifests as missing energy. There are many others, but I'm not really up on this stuff. Similarly, small black holes have accelerator signatures as worked out, for example, by Giddings and Thomas (and again, probably many others).

6. **David**
May 7, 2007

Chris & Peter,
I heard Lisa Randall give a talk last year mod(details) when she said that some of the things in her book should be testable at the LHC. It might be interesting to have a guest posting to hear about the details.
Best,
David

7. **Peter Woit**
May 7, 2007

David,

I think Lisa Randall is at one extreme of the spectrum in terms of believing in these models, since she is one of the people who came up with them. But from what I remember of her book, even she doesn't claim a strong belief that these things will be seen at the LHC.

8. **Deep Throat**
May 7, 2007

Nima Arkani-Hamed must know something if he mentions me like that. Maybe my throat is too deep….

And I doubt theorists would be able to do anything with "raw LHC data" anyhow. Probably they would get as far as to re-discover partons, but not much more. Raw LHC data will be as raw as the tail of a live cow can be called "rare filet". Not easy to digest if you don't kill the cow first.

Cheers,
DT

9. **Peter Woit**
May 7, 2007

Deep Throat,

I think the LHC experiments should seriously consider providing "raw data" to any theorists who complain. The results might be amusing to watch.

10. **Anti-Crackpot**
May 8, 2007

Can someone please explain to me the reason for your skepticism about supersymmetry? String theory is one thing, but I think calling supersymmetry unmotivated and crazy is just plain wrong. Those of you who think this way must have never really studied particle physics. Otherwise, you would be aware of how simply and elegangly supersymmetry solves a hosts of problems.

11. **ruleman**
May 8, 2007

> simply and elegangly supersymmetry solves a hosts of problems.

Also, half the particle spectrum has already been observed, and about 20% of the couplings measured.

But it must be mentioned that at least one prominent staff theorist at CERN (who most certainly has studied particle physics) claims that the MSSM is *minimal* with respect to its credibility… We'll see, in due time.

12. **Chris**
May 8, 2007

Dear Peter,

I know it's forbidden to mention one's own paper on your blog, but my paper arXiv:0704.1476 is definitely an attempt to take TeV-scale gravity very seriously. There's unfortunately a very large amount of work still to do to have predictions ready for the LHC, but it's doable, and I'm going as fast as possible.

The most generic prediction of TeV-scale gravity is that the effects will turn on extremely fast at a certain energy, due to the very rapid increase with energy of graviton effects. Below a certain energy, that could very well lie between 2 TeV and 14 TeV, there will be nothing detectable, and above that energy, a large fraction of the large transverse momentum processes selected at the LHC will see large fractions of missing energy as gravitons are radiated into the extra dimensions. In this respect it will be similar to the J/psi.

With regard to why it should happen at the LHC:

(1) TeV-scale gravity makes it easier to fit a small cosmological constant; and

(2) There's a natural factor of 1/10 (a loop factor) between the topologically stabilized breaking of the Horava-Witten E8 to the Standard Model, and the radiative breaking of SU(2) x U(1) in modern versions of the Coleman-Weinberg mechanism, see e.g. hep-ph/0509122 by Chishtie, Elias, Mann, McKeon, and Steele.

With regard to neutrinos, Maltoni and Schwetz have shown in arXiv:0705.0107 that MiniBooNE and LSND can be in perfect agreement if there are two sterile neutrinos, i.e. a (3+2) scheme, due to a new CP violating phase. The E8 breakings in subsection 5.6 of 0704.1476 lead automatically to a number of Standard Model generations plus an unrelated number of sterile neutrinos, so can accomodate 3 + 2.

Best regards,
Chris

13. **Peter Orland**
May 8, 2007

There are a number of reasons why high-energy experimentalists have hostile feelings towards theorists (as expressed by Lederman in his book). Unlike, say, condensed-matter physics, there is rarely much contact between experimentalists and any but the most phenomenological theorists. That is because neither theorists nor expermentalists are doing something which has serious impact on the activities of the other group.

The experiments are very hard to do but produce no fundamental results (let's hope that will change soon). Hence theorists work on problems with low stakes (like unifying particle physics with quantum gravity) alienating the experimentalists.

14. **Hans de Vries**
May 9, 2007

One can appreciate Michael Peskin's recent effort to refocus the theorists attention to real world LHC issues, like finding traces of new particles in the rather complicated background of the jets.

(Although he lures them with an highly optimistic picture of finding both SUSY physics and dark matter particles at the 100 GeV scale.)

21. **Alan Reifman**
May 14, 2007

Tonight, the NY Times website has a link to an article about the LHC that apparently will run in Tuesday's papers (the online version is dated May 15).

http://www.nytimes.com/2007/05/15/science/15cern.html

The Times article covers similar ground to the New Yorker one — i.e., both the physical construction and science of the LHC — and is similarly lengthy.

New Blogs and Other Stuff

May 12, 2007
Categories: Uncategorized

Here's a few new blogs I've run across recently:

- The FQXi organization now has a blog called FQXi Community.
- Rantings of an Angry Physicist is not another Not Even Wrong, but an interesting blog so far devoted to explaining what is going on in Steve Carlip's quantum gravity course.
- The new open access journal PhysMathCentral has a blog. It's "open access" in the sense that it promises to indefinitely provide free access to published articles. Funding comes from the authors of the articles, who have to come up with an "article processing charge" of around $1500. I'll be curious to see if this funding model works out, but have my doubts. From what I remember, back in the 1970s, the fact that APS journals were charging authors a similar "Page Charge" fee was one of the reasons why many prominent theorists stopped publishing in the Physical Review and started publishing in commercial journals like Nuclear Physics B, thus entrenching commercial publishers like Elsevier. It's unclear to me now how many authors will be willing to pay to publish when they can publish for free in other (often commercial) journals.

Robert Bryant, a great geometer in the Cartan-Chern tradition, now at Duke, has accepted the post of next director of MSRI at Berkeley. Robert was here at Columbia recently as a visiting professor, and I think he's a wonderful choice for leading MSRI.

The Geometry, Topology and Physics Seminar at UCSB has some material from talks there on-line. Last month there was a quite interesting talk by Sergei Gukov on gauge theory and "arithmetic topology", meaning some analogies between 3-manifold topology and number theory.

For the past few days in Brussels there has been a Solvay workshop on "Gauge Theories, Strings and Geometry" . Talks are available here.

From the Fermilab Steering Group trying to develop a strategic roadmap, there's a presentation about possibilities for higher energy colliders than the LHC or ILC. Ideas discussed include a doubling of the LHC energy using new 17 Tesla magnets, and a huge proton-proton collider called the VLHC to be built deep underground, in the Chicago area.

Next month in Paris there will be a Smolin/Damour debate about string theory, see Dispute chez les physiciens.

For an interesting article I just ran across about Geoffrey Chew and S-matrix theory during the 1960s, see here.

   English translation of the link to the news of the Smolin-Demour debate (courtesy of babelfish).

2. **Thomas Larsson**
   May 13, 2007

   Re Geoffrey Chew, the latest issue of Cern Courier has an article about another favorite of yours.

3. **wolfgang**
   May 13, 2007

   anon.

   thanks for the translation, but when it says "theory of the cords of quantum gravity", do you think the original was strings or loops 8-?

4. **Peter Woit**
   May 13, 2007

   In French "theorie des cordes" is used to denote string theory, although "corde" is a word used to mean something more like a rope than a string. I've never understood why the translation isn't "ficelle" which would be more accurate.

   The French do have in their language the concept of "un string", but it means something a bit different, leading to snickering if one translates the term that way…

5. **theoreticalminimum**
   May 13, 2007

   > The French do have in their language the concept of "un string", but it means something a bit different, leading to snickering if one translates the term that way…

   Oh, come on Peter! I thought you would show us some of that French *audace*, and translate that term away (not that it needs translation for informed readers of this blog). I even found out that, may I say well-endowed, members of the so-called "string mafia" have made it to the Tour de France! I mean, could any unification program get that much sexy?! ;-P

   The debate between Smolin and Damour would, I believe, be worth listening to. It would be of a kind different from the ones that took place before, e.g. Smolin/Duff. Damour is one of the leading experts in general relativity and, though having written a few papers in string cosmology, is not, I would be inclined to say, a full-fledged string theorist. So, at least in that respect, it would be interesting enough to look forward to knowing to what extent Damour agrees and disagrees with Smolin.

6. **John Baez**
   May 13, 2007

   Speaking of string-loop debates, Hermann Nicolai is helping run a conference in Bad Honnef called "Quantum Gravity: Perspectives and Challenges", during April 14th-16th, 2008. It's supposed to be a kind of reprise of the 2003 workshop on "Loops vs. Strings" at the Albert Einstein Institute. It looks like I'll be going — maybe in my new role as someone who has serious doubts about both approaches.

   I'm not exactly relishing the prospect, but I think it'll be good to have people there who aren't committed to either approach, but know a little about both. Solving physics problems by gladiatorial combat between "teams" doesn't seem very productive.

7. **Markk**
   May 13, 2007

   "Solving physics problems by gladiatorial combat between "teams" doesn't seem very productive."

   Yes but from reading history it does seem to be productive at defining specific problems which can be attacked. Or at least agreeing on areas where those problems lie.

8. **Harry**
   May 14, 2007

   Concerning "cordes" and "ficelles", "ficelles" is in french associated with a few quite negatively connoted expressions : "celui qui tire les ficelles" = the one who is hidden and makes this others act, "les ficelles d'un art" = the hidden processes of an art. An old meaning (XVIIIth) is also "crafty" (i. e. "il est très ficelle" = he's very crafty).

   I guess that's the reason why "cordes" (which sounds solid and thick) has been chosen.

9. **Christine**
   May 14, 2007

   For what is worth, in portuguese the translation of "string theory" is "teoria de cordas", following the french term.

10. **Alejandro**
    May 14, 2007

    Same in Spanish ("cuerdas" rather than "hilos"). Perhaps the often-used analogy to vibrating strings in musical instruments can explain it? "Cuerda" normally (i.e. without context) would mean "rope" in Spanish, but string instruments are called "instrumentos de cuerdas". I gather the same happens in French.

11. **Aaron Bergman**
    May 14, 2007

    FWIW, Lee Smolin and Erik Verlinde will be appearing on a two person panel at the end of the month.

12. **Who**
    May 14, 2007

    Actually the October 2003 conference at the Albert Einstein Institute that Hermann Nicolai, Abhay Ashtekar and others put together was called
    "Strings meets Loops"

    and the emphasis, by all I could tell from outside, was on productive exchange. There was a fifty-fifty balance of talks. Nicolai gave the opener and Ashtekar gave the concluding talk.

    Seemed like a good idea. I'm glad that something along those lines is scheduled for 2008. Long overdue. Just want to correct a slight oversight int what John Baez said: the conference was not called "Strings VERSUS Loops", or Loops vs Strings, or anything versus. AFAIK the organizers' idea was a friendly meeting of equals.
    ==quote==
    Speaking of string-loop debates, Hermann Nicolai is helping run a conference in Bad Honnef called "Quantum Gravity: Perspectives and Challenges", during April 14th-16th, 2008.     ==endquote==

13. **Who**
    May 14, 2007

    Typo: the conference was called STRINGS MEET LOOPS
    http://www.aei.mpg.de/english/contemporaryIssues/seminarsEvents/pastEvents/index.html#2003
    I learned about it from John Baez, who posted the schedule sometime around the first week of October 2003, IIRC, but i can't find it in TWF.

14. **Viri**
    May 14, 2007

    Regarding theoreticalminimum's language reference links 🙂 I must say that in Portuguese String Theory is translated as "Teoria das cordas" "corda" being strong as opposed to "fio".

    Now the really funny part is that the pictures he linked where of "tangas" (the underwear) and that is a synonym of bullshit and has a derogatory meaning in many other contexts, usually when someone is trying to fool someone else.

    I too think the musical instrument analogy explains these translations to romance languages.

15. **Michael**
    May 14, 2007

    Peter,

    Sorry to go off subject. But I was wondering if you knew of any colloquium/seminar type events held regularly in the New York City area over the summer. Or if you knew about any upcoming lectures of interest in areas such as cosmology or particle theory. I'm having some trouble finding out about things that go on off the academic calendar. Thanks!

    -Michael

16. **Peter Woit**
    May 14, 2007

    Michael,

Sorry, but I don't know of any colloquium/seminar activities in the area this summer. People pretty much only schedule those during term time, assuming too many people are away and it is hard to get together an audience during the summer. In the New York area there are two summer programs I know of:

http://insti.physics.sunysb.edu/itp/conf/simonswork5/
at Stony Brook, and

http://www.admin.ias.edu/pitp/

at the IAS. The IAS program you probably need to have applied for to attend the lectures.

17. **Chris W.**
May 14, 2007

The conference that Aaron pointed to (re Smolin and Verlinde) also includes this intriguing talk:

Jürg Fröhlich (ETH Zürich) — "Atomism and quantization"

I wonder what exactly *that* will be about.

18. **Travis**
May 23, 2007

Regarding Open Access, while Open Access options are currently limited to "author pays" there is an initiative in Europe called SCOAP3 that would shift the payment for Open Access to the funding agency level. Few, if any, proponents of Open Access in HEP think that authors would choose to pay if the money could go elsewhere. But by earmarking, or simply paying as a consortia, funding agencies can engineer this shift.

This is important for physicists to think about, as one essential reason for moving this direction is the preservation of the peer review process against the cancellation of overpriced journals by underfunded libraries who no longer have much reason to spend money on HEP journals (why pay for articles already on arXiv?).

Salvatore Mele gave a colloquium at SLAC recently about this topic, see:

http://www2.slac.stanford.edu/colloquium/details.asp?EventID=204

for more information, including links to the SCOAP3 documents.

19. **Peter Woit**
May 24, 2007

Thanks Travis!

I was just as Oxford, where the editorial board of the Elsevier journal Topology all recently resigned, leaving to found another journal. The latest issue of Topology came in while I was there, a real collector's item. The page that normally lists the editors is blank. No one knows if Elsevier will try and keep the journal going…

All LHC, all the Time

May 15, 2007
Categories: Uncategorized

The LHC media blitz is in full swing, with last week's long New Yorker article now followed by an unusually long and detailed New York Times piece titled A Giant Takes On Physics' Biggest Questions. Dennis Overbye does an excellent job of covering the story. Besides the experimentalists actually involved in building the machines, he quotes theorists John Ellis, Joe Lykken, Nima Arkani-Hamed and Michelangelo Mangano. To distinguish this piece from the New Yorker one, here it's Mangano who is the one who consumes a lot of espresso. There are side-bars about the recent problem with the Fermilab magnets and about the implications for string theory (not much). There's a multimedia component to the Times coverage, with interactive graphics, a slide show, a podcast (an interview with Arkani-Hamed, described as "one of the physicists at the center of the project"), and a video.

I do fear all this LHC coverage is peaking too early. With still probably at least a year to go before the machine even starts taking data, the coverage may already be generating an LHC overexposure problem: see Chad Orzel's new posting Tired of the LHC. If Chad is already complaining about this, boy is he going to be grumpy about it by a year from now…

The New Yorker keeps its physics theme going this week with cover art that includes a blackboard full of basic equations from quantum mechanics.

The NY Times article includes the usual not very cogent explanation of the role of the Higgs. For something much better aimed at explaining Higgs-hunting to the general public, see the online interactive presentation Hunt for Higgs, part of a web-site about the LHC called Big Bang.

Blogging may be light the next week or so since I'll be traveling. First stop is Trieste, where I'll be speaking at 5pm on Friday as part of a large event there called FEST. From there I'll make brief visits to Geneva, Paris and London, back here in New York late next week.

Comments

1. **Ari Heikkinen**
   May 15, 2007

   All the better to hype it now and give it as much coverage as possible, as when it's running a year or two from now it'll probably end up finding nothing useful anyway.

   Then again, maybe some LHC hype makes it possible to collect some money for a few other projects while LHC is still being built..

2. **sinus**
   May 15, 2007

   > it'll probably end up finding nothing useful anyway.

   Maybe the notion of "useful" has been blurred by calling the Higgs boson "God particle", and string theory the "Theory of Everything". Those suggest that nothing short of finding "God" or "Everything" is good enough.

   I think discovery of, at least, new phenomena related to the EW interactions is guaranteed (by the usual arguments). Whatever is found, even if it's "just" the SM Higgs, will be a Real Natural Phenomenon (TM), infinitely more useful than any speculative fantasy about gods and everythings.

3. **Anti-Crackpot**
   May 15, 2007

   I think its likely that within two years, the particle physicists and string theorists will be sipping champagne, and all of the stupid people who think it will find nothing will dissappear into the vacuum.

4. **Walt**
   May 15, 2007

   It's rare you see such a pure expression of bravado outside of sports bars. Like: I think it's quite likely in two years the Philadelphia Eagles will have won two Super Bowls, and all the stupid Patriot and Colts fans will disappear into the vacuum.

5. **Anti-Crackpot**
   May 15, 2007

   Walt,
   Physics isn't sports. The people who doubt that LHC will find anything, don't do so for rational reasons. They actually hope it won't. The overwhelming liklihood is that there will be significant discoveries.

6. **jb**
   May 16, 2007

   I think you two should put some money on this.

7. **plank**
   May 16, 2007

   How can anyone seriously say whether or not new phenomena will be found at the LHC?

   Really, how? Either way it's "faith" based.

   Now saying string theorists will be sipping champagne is another thing since I would like to know of a possible discovery that would legitimately justify that. Just an example.

8. **anon.**
   May 16, 2007

The string theory landscape is so big, they probably *will* be sipping champagne in two years whatever the LHC discovers, because they will be able to pick out a vacuum which resembles the physics, whatever that physics turns out to be.

That's the whole brains of string theory! Whatever nature turns up, it's *impossible* not to come up with some version of string theory which can include that. String theory predicts everything remotely possible, so we it is right before doing the experiments. The experiments just help us identify the correct model. I can't understand why people (apart from Prof. Anti-Crackpot) don't understand.

Physicists can start celebrating string theory now, because it can't be falsified, there's no sensible alternative with as much hype as string, and even if there was a fashionable 'sensible' alternative, it would be likely to be *extremely boring* compared to the 11 dimensional 10^500 models of the string multiverse.

9. **Anti-Cackpot**
May 16, 2007

Plank,
If we weren't able to seriously say that there's a strong liklihood of discovery, LHC would not have been funded. The Higgs and supersymmetry will both likely be discovered. They are both well-motivated theoretically. You should understand that these are not just things theorists invent because they're nice. These are really necessary pieces that need to be added to the Standard Model.

10. **anon.**
May 16, 2007

These are really necessary pieces that need to be added to the Standard Model.

The Higgs or something else to unitarize WW scattering, yes. Supersymmetry, no.

11. **Bob**
May 16, 2007

I don't understand this discussion about the LHC. Surely it will find new phenomena, irrespective of whether they can be related to string theory. in some sense, failure to find a Higgs boson in the expected energy range would drive high energy physics forward even more strongly than would the confirmation of a mass within the currently favored limits. Either result would be great.

High energy physics is presently unbalanced between theory and experiment, and in serious need of experimental data in new energy regimes. *That* the LHC will provide one way or another.

12. **Anti-Crackpot**
May 16, 2007

Anon,
If there is a Higgs boson, then supersymmetry is essentially required to to stabilize the Higgs mass, otherwise known as the hierarchy problem. There may be other 'solutions' to this, but none of these is natural. The existence of supersymmetry is probably just as necessary as the existence of anti-matter, as a necessary symmetry of nature.

13. **observer**
May 16, 2007

It seems to me that there's been a curious drift in the rhetoric on this blog of late. It looks to me like SUSY is being taken as synonymous with string theory, which it's not (the latter clearly requires the former, the reverse is not true). SUSY is theoretically well-motivated and quite predictive. It should be possible to rule SUSY out with future experiments, unlike string theory. So why is everyone so pissed off about SUSY?

14. **Peter Woit**
May 16, 2007

observer,

I seriously considered deleting just about all the comments on this posting. Our string-theorist troll "Anti-Crackpot" generates lots of content-free responses. Please, no more of this on both sides. In general please resist posting contentless comments that do little except aggressively express an opinion, without even bothering to justify it.

Sure, SUSY is better motivated and more predictive than string theory. But I think there recently has been a reaction to the fact that SUSY has received and continues to receive an overwhelming amount of attention, despite the fact that SUSY scenarios are far from convincing (generally due to the fact that SUSY-breaking leads to all sorts of trouble). Many SUSY proponents way back when vigorously claimed that evidence for it would show up at the Tevatron. The fact that that didn't happen, and that effects also haven't shown up in precision electroweak data, I think has caused a lot more skepticism about whether it will be seen at the LHC.

But, it is very different than string theory, will get a real test at the LHC, and we'll find out one way or another within a few years. If the LHC sees nothing, the idea that supersymmetry stabilizes the electroweak scale will be conclusively dead.

15. **plank**
May 16, 2007

«These are really necessary pieces that need to be added to the Standard Model.»

OK, suppose both are discovered beyond reasonable doubt. In what way does that corroborate String Theory?

Neither of those ideas were created in a String context, or am I wrong?

If there were some specific predictions from ST regarding SUSY breaking or the higgs mass I could understand, but to my knowledge there is nothing serious close to this.

So my question stands, what should be discovered at the LHC in order to justify string theorists "sipping champagne"?

And what would justify its demise.

These are important questions that should be answered *before* the actual data is analyzed, otherwise I'm afraid anything will be hailed as a victory for ST.

16. **Peter Shor**

May 16, 2007

Since almost anything the LHC is likely to find will be shown to be consistent with string theory, I predict that the string theorists will be sipping champagne three years from now, no matter what the LHC finds.

17. **Anti-Crackpot**
May 16, 2007

Peter,
I could reply to your insult about being a string-theorist troll, but let's not go there. Let's leave that for Lubos. I'm really more of a particle physics person than a string theorist.

My opinion on the reason for the sentiment against supersymmetry on your blog is that it is due to the fact that it is a necessary component of string theory, which you strongly disfavor. Otherwise, it's hard to understand why anyone would be so against it., especially since it's well-motivated theoretically and testable. It seems to me that there is a strong current against mainstream particle physics on this blog, and I feel I must go against this.

18. **Anti-Crackpot**
May 16, 2007

Plank,
String theorists will be happy if supersymmetry is discovered because it is a necessary part of string theory. Don't forget that SUSY was actually discoverd in string theory first, before being formulated in normal particle physics by Wess and Zumino.

19. **Peter Woit**
May 16, 2007

Anti-Crackpot,

My opinion about supersymmetry in general is mixed, there are many things interesting about it. As for the MSSM, I've always been a skeptic, even back pre-1984 when string theory became popular. There's a whole chapter in my book about the problems with supersymmetric extensions of the standard model, this is an issue independent of string theory.

I'm getting really sick of the contentless bickering here. Please, all parties stop. Comments containing zero information, just some an expression of opinion backed by at best best a vague, tired talking point will be deleted. I can't believe anyone is getting anything at all from this kind of discussion, other than the idea that reading the comment section here is a waste of time.

20. **JC**
May 16, 2007

Anti-Crackpot,

Wasn't SUSY first discovered around 1970 by Likhtman and Golfand?

21. **Anti-Crackpot**
May 16, 2007

Peter,
I'm not sure that there has been much bickering in this thread, or that the posts have had zero content. If you don't like people disagreeing with you then perhaps you should shut down the blog altogether. Perhaps my statement about the 'stupid people dissappearing into the vacuum' was a little harsh, and I apologize.

As for supersymmetry, it's fine to be skeptical. The main point I want to make is that the subject is one that should be taken seriously and not just be dismissed as the musings of idle string theorists, whether or not it turns out to be right or wrong.

22. **Anti-Crackpot**
May 16, 2007

JC,
Yes, it may have been, but if I remember correctly they were in the Soviet Union at the time, so noone in the west knew about their work.

23. **Coin**
May 16, 2007

Don't forget that SUSY was actually discoverd in string theory first, before being formulated in normal particle physics by Wess and Zumino.

When and where?

24. **Anti-Crackpot**
May 16, 2007

Coin: Ramond, Schwarz, and Neveu in about 1971-1972.

25. **M**
May 16, 2007

Anti-Crackpot: I don't know if supersymmetry was first invented by string theorists or by communists, but surely the discovery of supersymmetry would not imply that communism is right nor that string theory is right.

The reason why LHC is interesting is not that we know that LHC must discover supersymmetry, but that we do not know what LHC will find, and exploring higher energies is the only way of sorting out physics at higher energies. Even if LHC will tell that we lost decades on a wrong idea, it will be progress, and this is why I prefer to work on testable weak-scale physics rather than on quantum gravity.

26. **dan**
May 16, 2007

Peter Woit wrote “But, it is very different than string theory, will get a real test at the LHC, and we’ll find out one way or another within a few years. If the LHC sees nothing, the idea that supersymmetry stabilizes the electroweak scale will be conclusively dead.”

Hello Peter, if LHC does not find SUSY-partners, and yes I’ve read your book NEW cover to cover, and therefore does not stabilize the electroweak scale, it doesn’t seem to me that there’s no compelling reason (other than string theory hype) to continue to pursue this as serious research. In otherwords, if SUSY doesn’t stabilize the elctroweak scale, while SUSY can be broke all the way up to the planck scale, there is no reason to believe it is a symmetry of nature if there is a LHC null result. (Presumably the theoretical difficulties of breaking SUSY and flavor changing neutral currents and large CP violations others in combintation to a LHC null result should pretty much discredit the theory).

27. **Anti-Crackpot**
May 16, 2007

M,
You’re right that the discovery of supersymmetry would not prove string theory. However, since SUSY is a necessary ingredient, it would certainly suggest that string theory is in the right direction.

28. **Michael Bacon**
May 16, 2007

The discovery of SUSY might suggest that string theory moving in the right direction. But that’s not the issue, is it? The problem is that the failure to discover SUSY wouldn’t disprove “string theory.” Apparently, that’s impossible!

29. **Anti-Crackpot**
May 16, 2007

Michael,
The honest truth is that if SUSY is not found at LHC, most interest and support of string theory will completely evaporate. Unless, of course one of the large extra dimensions/ brane world scenarios turns out to be true. In that case, there will be KK states and black holes galore, and string theory will be experimentally confirmed.

30. **anon.**
May 16, 2007

The honest truth is that if SUSY is not found at LHC, most interest and support of string theory will completely evaporate.

Nonsense — you can find plenty of string theorists who claim that high-scale SUSY breaking is actually favored, or at least not disfavored. It’s not at all clear at the moment what string theory has to say about what is likely at the TeV-scale.

Also, above:

then supersymmetry is essentially required to to stabilize the Higgs mass, otherwise known as the hierarchy problem. There may be other ’solutions’ to this, but none of these is natural.

Again, nonsense; technicolor is natural, for instance. It just happens to be highly disfavored by precision data. There is also the possibility that the Higgs mass is simply tuned. There is absolutely *no* argument that SUSY is “required” or “essentially required” by the SM. There are only debatable aesthetic or philosophical reasons for liking it.

31. **Anti-Crackpot**
May 16, 2007

Anon,
Sure, it’s always possible that the SUSY breaking scale will be high enough that the superpartner masses will be unobservable at LHC. However, then SUSY would not be able to solve the hierarchy problem, and so would lose much of it’s justification. If this happens, I don’t think people would take SUSY seriously, regardless of what ‘plenty’ of string theorists say.

I don’t think that technicolor is particularly natural. Besides the fact that it doesn’t work, it has always seemed rather ugly and contrived to me. On the contrary, supersymmetry solves the hierarchy problem, gives us gauge unification, and provides a dark matter candidate. Keep in mind that supersymmetry was not originally invented to solve these problems. This is what I would call natural. The fact remains that something beyond the standard model is required and supersymmetry is the best bet for that somethting, by far. Thus, all of your statements are complete nonsense!

32. **Mikka**
May 17, 2007

Hi Peter,

Peter, you clearly have little beyond trivial knowledge of what physics is really about… I have come across only ONE! paper by you in the last upmteen years that was worth reading through (‘Particle Physics and Representation Theory’). Clearly you spend way!! too much time trying to be critical of theories you have already decided upon are unworthy of further study… and yet you continue to quip over and over on them… sigh!

If you are genuinely a physics researcher you would engage in one of the following activities:

1. Doing physics research… of whatever kind there is to be done… (i.e. in condensed matter theory, astrophysics, biophysics, chaos theory, etc.);

2. Writing up beautiful notes for Weinberg’s QFT texts and distributing them freely on the net;

3. Doing both with one hand tied behind your back.

Regards,
Mikka

4

33. **island**
May 17, 2007

Anti-Crackpot Says:
The fact remains that something beyond the standard model is required…

The false assumption being that the resolution to the problems can't possibly come from something fundamental that was missed along the way.

I beg to differ.

34. **anon.**
May 17, 2007

On this question of distinguishing supersymmetry from string theory stuff, I thought that 'superstring' is an abbreviation of supersymmetric string theory, and since M-theory unified the five theories in 1995, string is in effect synonymous to superstring?

Many string predictions are supersymmetry predictions: unification at 10^19 GeV, s-particles with unpredictable energy, etc.

I don't see how any experimental result will be able to confirm or deny supersymmetry or string predictions.

By the time you have enough experimental data to be meaningful, you will have resolved the problem experimentally. What use is theory in that case? Dirac predicted the energy of antimatter particles, Pauli predicted the energy of neutrinos, and the Standard Model predicted the energy of weak gauge bosons. There's nothing like that kind of prediction from string/supersymmetry. String is a great theory for yellow bellies, scared of experimentally refutation.

35. **JC**
May 17, 2007

anon, Anti-Crackpot,

If string theory ever falls out of favor in physics departments, it will most likely still be pursued in math departments. Some areas of string theory have very interesting mathematics (ie. mirror symmetry, etc …), that some mathematicians would still be interested in.

On the other hand if supersymmetry is not seen at the LHC, it wouldn't be surprising to susy phenomenology fall out of favor and eventually die shortly thereafter. Though possibly some hardcore SUSY true believers will still work on it. Analytic S-Matrix theory falling out of favor in the early 1970's, didn't stop Geoff Chew from continuing work on it well into the 1980's.

36. **sinus**
May 17, 2007

"If" susy is found… "if" KK states are found… "if" substructure is found… Those are some big "if"s. The bottom line is that physics at the TeV scale is going to be experiment-driven. With exactly zero predictions, theory has lost the LHC train.

37. **L-Train**
May 17, 2007

I stumbled on your website, trying to find information about a theory about gamma ray bursts that has been written up in general interest publications, such as the Economist. I am a layman (although with a scientific background — chemistry), but I have a paranoid interest in particle physics.
The theory that I was wondering about was Dr. Clavelli's theory that GRBs are produced by a spontaneous SUSY transition in white dwarves. From what I understand, GRBs are generally thought to be caused by exploding stars, and if anything, GRBs tend to not occur in galaxies where there are not very many elements heavier than helium, which seems to negate this idea. I was wondering whether Clavelli's ideas (regarding GRBs and spontaneous SUSY transitions in general) are taken very seriously in the physics community as a whole.

38. **CW**
May 17, 2007

L-Train,

Cosmic Variance would be a better blog for you to monitor, given your apparent interests. It also links to other blogs that focus on astrophysics.

39. **Anti-Crackpot**
May 17, 2007

Sinus,
Supersymmetry makes a very specific prediction: for every Standard Model fermion, there is a corresponding boson. If these states are discovered, then supersymmetry will be confirmed. We cannot at this point make specific predictions about the mass and mixings of the supersymmetric specturm because we can't say exactly how SUSY is broken. However, if SUSY is to explain the hierarchy problem, then the states must be TeV scale.

40. **Walt**
May 17, 2007

Anti-Crackpot: You are clearly offended by the existence of skeptics. Whether or not SUSY is confirmed, would physics have been better off if there were no skeptics? Clearly not.

41. **Anti-Crackpot**
May 17, 2007

Walt,
What offends me is skeptics who spread misinformation.

42. **anon.**
May 18, 2007

What offends me is skeptics who spread misinformation.

So the landscape dwellers who are certain without hope of solid confirmation that there are 10^500 universes each with 6/7 extra dimensions curled up in different versions of the Calabi-Yau manifold, don't offend you? Bullshit with the stamp of mainstream consensus is inoffensive, while objections from skeptics of the mainstream which contradict the mainstream claims are offensive misinformation? Quite right too!

Maybe you need to increase your ability to take offense, however. Be also strongly offended by people with alternative ideas. That's spreading misinformation, if the ideas don't fit into the mainstream consensus, the superstring framework. One other thing to take offense from (when you get more sophisticated): experiments. Experiments are just an embarrassment to an irrefutable theory.

43. **a quantum diaries survivor**
May 18, 2007

Hello Peter,

sorry for dribbling most of this nonsensical thread about who believes what and why it is stupid to/not-to 😉 My comment is rather about the point made in the post, i.e. that there is an over-exposure of the LHC quite a bit too early.

There are physicists who have spent the better part of their last 15 years designing, building, simulating, testing, assembling the giant detectors that are now almost ready to take data. These people have invested maybe half of their career in the project. It is them who will arrive tired to the first day of data taking, unfortunately. These experiments are really too long shots in this respect. However, I really see no alternative, but can only hope that the next efforts will be based on more readily available technology and funds, such that the hiatus between the TDR and the data becomes more reasonable.

I agree, the media are overhyping an endeavour that is either too old or too young to be meaningfully in the headlines. It is now clear that LHC will have no chance of having produced enough data to see the Higgs boson before mid 2009. And even SUSY particles, which some simple minds believe will pop into view the moment the detector is turned on, will have to wait until then to be discovered, if ever.

My two pence ? The LHC is getting its share of spotlights because now is the time to start financing its upgrade, the SuperLHC. Projects on R&D for detectors to be installed in CMS and Atlas to sustain 10^35 luminosities are already under way…

Cheers,
T.

PS have fun in Trieste, and stay away from Casinos in Slovenia!

44. **Aaron Bergman**
May 18, 2007

Bitter much?

45. **Anti-Crackpot**
May 18, 2007

Anon,
I don't think that I've been making an argument for string theory or the landscape. My arguments have been strictly in favor of SUSY. It is quite possible for the world to be supersymmetric and string theory to not be right. As far as skepticism is concerned, I'd like to hear real alternative ideas rather than just arguing against supersymetry on the basis that we haven't yet observed the SUSY partners. If LHC does not observe them, then your skepticism will be justified and shared by many particle physicists. However, we know that the SUSY scale should be 1 TeV or less to solve the hierarchy problem, so there's no point being skeptical until the range of energy has been explored.

46. **anon. #1**
May 18, 2007

At the risk of feeling like I'm banging my head against a brick wall, let me point out some things that seem to be misconstrued or not known by at least some of the people discussing this here:

1) It would be nice if the hierarchy problem turns out to have a solution. On the other hand, it might not; the universe might just be described by a fine-tuned low energy effective field theory.

2) SUSY does solve the hierarchy, as does technicolor (whether you think it looks "natural" or not, it certainly is technically natural). Technicolor is *highly* disfavored by precision data. SUSY is also disfavored by precision data, just less so. (This is called the "little hierarchy".) You can't think seriously about TeV-scale SUSY models without running into LEP data. There is *no* beautiful model that can solve the hierarchy problem, fit the data, and that doesn't have some ugly kludges and/or fine-tunings built in somewhere.

3) There is a nice model that has gauge coupling unification, dark matter, and no real difficulties with precision constraints. It's called split supersymmetry, and it does not solve the hierarchy problem.

4) String theory does *not* have much of anything to say about whether there is TeV-scale SUSY at this point. There seem to be lots of vacua with high-scale SUSY breaking. There are some approaches that claim to favor TeV-scale SUSY (e.g. claims that M-theory on G2 compactifications tends to have TeV-scale SUSY breaking once the cosmological constant is tuned to zero), but there doesn't seem to be any reason the theory would prefer those vacua.

47. **r hofmann**
May 18, 2007

Anti-Crackpot,

seems there was quite some indoctrination going on during your scientific education.

If you had ever deeply thought about 4D Yang-Mills and its relation to real physics (meaning ideas, concepts and quantitative predictions that are experimentally falsifiable) you would have had your answers concerning alternatives to the present doctrines for solving the hierarchy `problem´.

I wont react on any of your comments.

48. **Anti-Crackpot**
May 18, 2007

Anon,
I don't really understand why you are so upset. I only make the well-known point that supersymmetry is currently the best candidate for new physics and that it is clearly testable. I do not claim that it's the only possible solution, only that it's the most plausible solution. As for string theory, I guess I need to repeat that my arguments in favor

of SUSY have nothing to do with string theory.

r hoffman,
I have a Ph.D. in theoretical physics, having learned from some of the very best particle phenomenologists and string theorists in the world. I think I know what I'm talking about it and have no trouble with your empty statements.

49. **anon.**
May 18, 2007

It is quite possible for the world to be supersymmetric and string theory to not be right. … I'd like to hear real alternative ideas rather than just arguing … – Anti-Crackpot

Well, your pseudonym doesn't encourage me to believe your claim about wanting to hear '*real* alternative ideas'. String and SUSY have had 25 years of mainstream support to work out the details. The common problem with *any* alternatives is that they are haven't had 25 years of mainstream funding, interest, and development. So you'll be able to dismiss them by definition as non-mainstream, for being less well investigated than string and SUSY. There are several real alternative ideas but this blog is not a free for all discussion of them. The question is, if you're an anti-crackpot, why are you so keen on invisible superpartners which increase the tunable Standard Model parameters from 19 to 125 or more, without delivering any useful additional predictions in return.

The worst type of physics is that which like phlogiston, a wonderful solution to why burned things weigh less than unburned things, but is always totally useless for quantitative predictions, and finally turns out to have misled everyone. So if you're really believe you're an anti-crackpot, I'm afraid you may need to buy a new mirror.

50. **King Ray**
May 18, 2007

The true crackpots may be those who believe in string theory, supersymmetry and higher dimensions. Time will tell who the true crackpots really are.

51. **David B.**
May 18, 2007

Dear anon.

There is one prediction of the MSSM that you seem to be missing and it is the most important prediction that makes the model testable: the lightest Higgs has to have a mass that is lower than the mass of the Z particle at tree level. With loop corrections one can make this number bigger, but not too big. The model barely gets by with the current precision data and bounds.

Indeed, one of the most important reasons that made supersymmetric models appealing was that the higgs selfcoupling constant was
unified with the gauge coupling constants of the standard model.
Unfortunately because the MSSM does not break supersymmetry spontaneously, that was not enough to fit data. The extra parameters that are added to the MSSM to break susy in the most "general way that does not spoil the advantages of having supersymmetry" do not change this prediction.

If the higgs that is found at the LHC is not sufficiently light, then the MSSM will be ruled out. I find that to be quite a useful prediction.

52. **Anti-Crackpot**
May 18, 2007

Anon,
Since we do we claim that the supersymmetric partners are 'invisible'. On the contrary, they should be observed at LHC if supersymmetry is right. In any case, if your alternative ideas are so good, then I would suggest writing a paper on them. If they turn out to be right, then you'll win the Nobel. You should really refrain from lumping SUSY in with string theory. There is some relation between the two, but they are not entirely the same.

If and when supersymmetry is discovered, the following work will be to understand the mechanism by which it is broken. At that point, we will be able to make some predictions, such as the relic neutralino (assuming this is LSP) density and from that get a handle on the composition of the dark matter. Are there any of you who believe dark matter isn't real?

53. **Christine**
May 18, 2007

Are there any of you who believe dark matter isn't real?

> Science is facts; just as houses are made of stone, so is science made of facts; but a pile of stones is not a house, and a collection of facts is not necessarily science.
> Jules Henri Poincaré (1854-1912)
>
> There are in fact two things, science and opinion; the former begets knowledge, the latter ignorance.
>
> Hippocrates (460 BC – 377 BC)

I do not see how this is a question of believing or not.

BTW, see http://arxiv.org/abs/0705.2462

(sorry: html tag for the link seems not to be working in the preview)

54. **Christine**
May 18, 2007

BTW, I have worked for some time with dark matter models. So, as I said, it is not a question of believing or not.

55. **Anti-Crackpot**
May 18, 2007

Hi Christine,
Sorry, I was a little loose with my language. What I meant was, is there anyone who denies that there is strong evidence for the existence of dark matter? There is a lot of evidence for it coming from many independent directions such as galactic rotation curves, microlensing and CMB. If it does indeed exist, then this is another line of

evidence that the Standard Model needs to be extended since the dark matter cannot be baryonic or composed substantially of neutrinos.

56. **Walt**
May 18, 2007

Anti-Crackpot, you originally said "I think its likely that within two years, the particle physicists and string theorists will be sipping champagne, and all of the stupid people who think it will find nothing will dissappear into the vacuum." There's nothing in this statement about skeptics who spread information (whoever that is supposed to be); it's about the existence of skeptics at all. It's not a healthy attitude. Nature will turn out to do what nature does, whatever our aesthetic judgement tell us.

57. **M**
May 19, 2007

If supersymmetry will be found, "stupid people" will start working on it rather than sipping champagne or disappearing into the vacuum. However, supersymmetry missed a number of oppurtunities for showing up, and LHC is the last call. If supersymmetry will not be found, then those people who spent their life working on supersymmetry will be really upset.

Peter thinks that it is unhealhy that so many string theorists have been hired, and here we could have a similar situation: various phenomenologists built their career working on supersymmetry, and LHC might tell that their research activity was irrelevant. Anti-Crackpot, do you guess who would pay for this situation? I mean: if you are a joung post-doc who works only on supersymmetry, you should consider extending your research activity.

58. **anon.**
May 19, 2007

Christine: thanks for that link to http://arxiv.org/abs/0705.2462 which is important. The 'evidence' for dark matter and dark energy is based on mainstream consensus in a very weak way, like claiming that the existence gravity is evidence for M-theory because M-theory predicts gravity, or claiming that SUSY must be real because, if you don't have SUSY, the three SM force strengths won't naturally converge at the Planck scale.

59. **anon.**
May 19, 2007

There is one prediction of the MSSM that you seem to be missing and it is the most important prediction that makes the model testable: the lightest Higgs has to have a mass that is lower than the mass of the Z particle at tree level. … – David B.

Unless the model makes a prediction which is *unique enough* (which usually means *precise enough*) that no other theories are likely to make the same prediction, then the prediction is not a convincing test for the model. Even if the MSSM was the only possible SUSY, the confirmation of that prediction would still be dubious. If the MSSM Higgs isn't found then they can just find another SUSY model which is even harder to experimentally refute.

Similarly, in the case the string theory landscape, *individual* vacua are testable, since each has a definite set of parameters and therefore makes concrete predictions; the problem is that there are so many different vacua that it isn't falsifiable. A theory which comes in many versions, like epicycles or string and SUSY, is likely to contain superficially impressive models by sheer coincidence.

60. **Michele**
May 19, 2007

Is there a way to get your talk at FEST? I would have liked to be there but I missed it. Thanks.

61. **a quantum diaries survivor**
May 19, 2007

Speaking of SUSY at the LHC, Marcela Carena gave a nice seminar in CDF yesterday. You might want to give a look at two plots she showed about discovery reaches of a MSSM Higgs by Atlas and CMS, in my blog.

Cheers,
T.

62. **Anti-Crackpot**
May 19, 2007

Anon and Walt,
For some reason I keep having to make this point, but supersymmetry is testable directly as the supersymmetric partners of the known fermions and gauge bosons may be produced and detected in collisons at the LHC. The present situation is no different than the previous search for the top quark, which took twenty years to be discovered after the bottom. Why? Because of it's very large mass! Now, you guys, arm-chair scientists that you are, should be aware that such a large mass was anticipated by those working with no-scale supergravity and radiative electroweak symmetry breaking, where a large top mass is required to drive the Higgs mass-squared to a negative value.

63. **sinus**
May 19, 2007

> such a large mass was anticipated by those working with no-scale supergravity and radiative electroweak symmetry breaking,

Today there are models with Higgs masses large, small, and intermediate. Those are not really predictions, since there are no solid reasons which one of those models is experimentally correct, if any. Some of those models may even give Higgs masses in the correct range, and still be completely wrong.

To give another example, naive SU(5) gives essentially all the correct low energy physics, since it contains the SM, yet it doesn't work.

If radiative SB and supergravity models (of which there are many) were validated by the large top mass, as you seem to suggest, why is people wasting their time with other approaches that ostensibly failed to predict the top mass?

64. **Anti-Crackpot**
May 19, 2007

Sinus,
Regarding SU(5), there is one piece of low-energy physics on which it is spectacular wrong: neutrino masses. As far as the Higgs is concerned, it's mass is very sensitive to such things as the top mass and the type of soft-SUSY breaking that is assumed. In the models, one can change the top mass by a few GeV and this causes the Higgs mass to change a lot. In the minimal supergravity models (mSUGRA), the gaugino masses (m_{1/2}) and scalar masses (m_0) are universal, but their actual values are

unknown. The Higgs mass and low energy superpartner spectrum depends very much on these values.

65. **Haelfix**
May 19, 2007

Susy is still fine, but its getting perilously close to where its not fine anymore. Everyone hopes the lightest superpartner as well as the Higgs arises somewhere before 140 GEV or else we run into major phenomology problems elsewhere. Things become much less well motivated, nonminimal and contrived.

If we find SUSY at say 500 GEV, and nothing other than a bare Higgs scalar before that, everyone will be horribly confused.

66. **L-Train**
May 20, 2007

CW:

Thanks for your reply, but this blog may actually be a useful place to get some info on the topic of SUSY, and whether a transition to a SUSY state is possible at this point in the evolution of the universe, as predicted by Clavelli. You guys, after all, are debating about SUSY.

67. **Anti-Crackpot**
May 21, 2007

For the anti-stringers, there is a guest post at CV by Joe Polchinksi in reaction to Smolin's reponse to his earlier review.

68. **Peter Woit**
May 21, 2007

I'm still traveling, won't be back home until late Thursday. So, for now I won't write anything much about the Polchinski posting. In any case, it's mostly specifically an on-going discussion with Lee Smolin, and I know I don't like it if, when someone is arguing a question with me, someone else tries to be helpful by taking my side, often making arguments I wouldn't really agree with.

It's also true that Polchinski is just writing about quantum gravity, not about particle physics, where he's well known to be a proponent of the anthropic landscape point of view. I'm not too interested in getting involved in arguments about who has the better theory of quantum gravity that can't be tested. It would be interesting to see Polchinski try and defend the idea of 10/11 d string-theory based unification against the claim that virtually no predictions are possible, except vague sorts of statistical "predictions" that are often wrong.

69. **elzoro**
May 23, 2007

Off-topic but worth mentionning: Fields medalist Richard Borcherds (known among other things for his work on the Leech lattice, Monstruous Moonshine and axiomatic QFT) now has a blog http://borcherds.wordpress.com/

70. **Peter Woit**
May 24, 2007

Thanks elzoro,

Maybe soon every Fields medalist will have a blog…

This Week's Hype

May 24, 2007
Categories: Uncategorized

Still traveling, but will be back soon. This week's bogus "test of string theory" is described in a [NASA press release]() about three satellite-based experiments that would look for violations of the equivalence principle. From the press release:

…it could provide the first real evidence for string theory. String theory elegantly explains fundamental particles as different vibrations of infinitesimal strings, and in doing so solves many lingering problems of modern physics… The equivalence principle could offer one way to test string theory…

"Some variants of string theory predict the existence of a very weak force that would make gravity slightly different depending on an object's composition," says Will. "Finding a variation in gravity for different materials wouldn't immediately prove that string theory is correct, but it would give the theory a dose of supporting evidence."

…string theory makes a range of predictions about how strong this new force would be, so it's possible that the effect would be too small for even these space-borne instruments to detect.

Does string theory predict violations of the equivalence principle? From a [posting]() on Lubos Motl's blog:

In reality, it will probably be impossible to falsify string theory because string theory is probably correct and you can't ever falsify correct theories. 😉 *But if string theory were wrong, there would be thousands of ways to falsify it, even in the very near future. Although string theory predicts many new phenomena whose details are not uniquely known, it also implies that many old principles are exactly valid. If string theory is correct, the superposition principle of quantum mechanics, Lorentz invariance, unitarity, crossing symmetry, equivalence principle etc. are valid to much higher accuracy than the accuracy with which they have been tested as of 2006.*

If you believe that string theory is wrong, just prove any of the theories predicting all the bizarre phenomena like Lorentz symmetry breaking, breaking of unitarity, locality, rotational invariance, and so on. I think that all these things are badly motivated – but it's mostly because I know that it seems that they can't be embedded in string theory. If you don't believe string theory, you should believe that anything can occur and every new test of Lorentz invariance has a potential to falsify special relativity. Every new test has a potential to falsify the equivalence principle. And there are dozens of such examples. Without string theory, all these laws are approximate accidental laws and symmetries. I assure you that string theory will pass every new test of this type and its foes will always lose. String theory allows us to redefine what proposals about new physics are reasonable and what proposals are not, even without the exact knowledge of the vacuum.

I guess it's all right that I don't have time to comment on this, since no comment seems necessary…

Comments

1. **Chris Oakley**
   May 24, 2007

   This [paper]() from a 2005 conference on tests of the Equivalence Principle has a table (table I, p. 3) showing some experimental limits on deviations from the E.P.; briefly, these are – neutral bulk matter: 10^-12, atoms: 10^-9, neutrons: 10^-3 and charged matter (electrons): 10^-1. I guess that the new experiment (STEP) will be able to bring the "neutral bulk matter" limit down to 10^-17 – or not, depending on what it finds.

   The neutral bulk matter tests involve systems where the electrical charges are in balance to a much greater extent than one part in 10^12, and I wonder whether one could not just say "case proven" here and concentrate on the limit for charged matter instead. Such experiments, though, seem to be hard to carry out as they require the measurement of tiny deflections of single electrons due to gravity. See [here](), for example.

2. **anon.**
   May 24, 2007

   'I guess it's all right that I don't have time to comment on this, since no comment seems necessary…' – Peter Woit

   Glad that you are not wasting time on fruitless arguments.

   Lubos is correct. Physics proceeds by asserting a theory is true and must be believed until it is disproved. Even when the theory is disproved, you must continue using it until a better theory comes along. It is very arrogant of certain people to assert that a person's defense of extradimensional dogma isn't physics. You must first prove string wrong, and provide the correct theory to go in its place.

3. **Rick**
   May 24, 2007

   anon, it should go without saying that what you've said is nonsense. Science doesn't proceed via theories that -cant- be disproven nor bring much to the table.

   I'd say a theory can't be taken seriously unless it can propose a way in which it could conceivably be disproven, even if it has some amazing utility and explains many things. Unfortunately string theory fails all 3 of these tests so it's even more useless than a generally unfalsifiable theory.

4. **Me**
   May 24, 2007

   annon is obviously nothing but a troll.
   Don't waste time answering him.

5. **anon.**
   May 24, 2007

   'There is an unwritten precept in modern physics… which states that in physics "anything which is not prohibited is compulsory".'

   – O. Bilaniuk and E. C. G. Sudarshan, *Physics Today,* May, 1969, p43.

6. **Yatima**
   May 24, 2007

You must first prove string wrong, and provide the correct theory to go in its place.

Cough. Gentlemen, it seems to me that the word you are looking for here is “sarcasm”.

7. **anon.**
   May 24, 2007

   Yatima, take the situation of the procession of the perhelion of Mercury, which was a weak point in Newton’s theory for centuries (it was eventually cleared up by general relativity).

   The situation with string theory will be identical if it is found to disagree with experiments: you have to go on using string theory until a new theory comes along which reduces to string theory as an approximation. So even if it is experimentally ‘disproved’, we will continue to use string theory until we resolve the problem, which may take centuries!

   However, as Lubos points out, it is more probable statistically that the landscape is not entirely false. Think of the 10^500 vacua as a lottery. Become a string theorist, and it’s like having 10^500 lottery tickets: you own virtually conceivable theory going. *It’s a monopoly!* 😉

8. **russellman**
   May 24, 2007

   > The situation with string theory will be identical if it is found to disagree with experiments:

   I agree. Problem is: there’s every reason to suspect that ST will never be found to disagree, nor agree, with any experiment. That’s why it’s not (even) wrong.

9. **King Ray**
   May 24, 2007

   I think it is stretching the term theory to call string theory a theory. Apparently wikipedia agrees:

   http://en.wikipedia.org/wiki/Theory

   “The term theory is occasionally stretched to refer to theoretical speculation that is currently unverifiable. Examples are string theory and various theories of everything.”

   Also, from wikipedia,

   “In physics, the term theory is generally used for a mathematical framework — derived from a small set of basic principles (usually symmetries – like equality of locations in space or in time, or identity of electrons, etc) — which is capable of producing experimental predictions for a given category of physical systems. ”

   Where are string theory’s predictions? I don’t think string ‘theory’ is even a theory!

10. **Steve**
    May 24, 2007

    anon., I’m not sure if you understand how the scientific process works in physics, so let me just give you a quick run-down:

    (1) Someone sees something and guys “Hmmm…why did that happen?”
    (2) Another someone sets up a series of experiments and comes up with a bunch of data about what happened. Publish.
    (3) A theorist sees this data and goes “Hmmm…I wonder if I can figure out why this happened…” Using existing theories, said theorist tries to explain the data.
    (4) If every theorist decides “We dunno”, you start inventing a “new” theory.

    The burden isn’t on experiments to falsify theory, it’s on theorists to try to come up with an explanation of an experiment using existing, thus far unfalsified, theories. String theory reverses the roles. Physics isn’t dictated by who has the cooler theory, it’s dictated by what God decided the universe should look like, and what the experimentalists consequently see.

11. **anon.**
    May 24, 2007

    “Physics … it’s dictated by what God decided the universe should look like, …” – Steve

    Well, maybe your understanding of physics is about 500 years out of date. But thanks for your attempt to enlighten me 🙂

12. **DB**
    May 24, 2007

    It’s interesting that a number of fairly eminent members of the general relativity community have made soothing overtures to the string community of late. Clifford Will and Thibault Damour are names to be reckoned with in the field of experimental tests of general relativity. I expect they believe variants of string theory can in principle be tested in the same way as Dicke’s scalar-tensor theory of yore. However, I fear they are getting involved in an elaborate and expensive version of whack-a-mole. They will be welcomed with open arms by a community desperate for external validation.

13. **kuos**
    May 24, 2007

    If correct theories are not falsifiable, then by Lubos Logic it follows that non-falsifiable theories must be correct.

14. **King Ray**
    May 24, 2007

    I don’t know why string theory doesn’t just declare that it is all possible theories and then declare victory… It is getting close to that point now… another 10 years maybe and then they’ll do that.

    String theory reminds me more of a Fourier series expansion that can fit anything than a physical theory.

15. **Peter Shor**
    May 24, 2007

Rick says

I'd say a theory can't be taken seriously unless it can propose a way in which it could conceivably be disproven, even if it has some amazing utility and explains many things.

Isn't it the case that any theory which has amazing utility can be disproved. If a theory doesn't predict anything, then shouldn't it be considered (like Borges' Library of Babel) by definition useless.

16. **Chris W.**
May 24, 2007

I guess one should have expected Lubos to misrepresent the established usage (in discussions of the philosophy of science) of the word "falsifiable." (*Sigh*…)

17. **pathetic and obnoxious mug of vitriol**
May 24, 2007

Great post. If Motl's original text was absolutely hilarious, quoted in this context it's irrepressible so… A masterpiece of polemical counterpoint…

18. **mclaren**
May 25, 2007

> Lubos is correct. Physics proceeds by asserting a theory is true and must be believed until it is disproved. Even when the theory is disproved, you must continue using it until a better theory comes along.

This is wise and accurate. Physics proceeds via proof by assertion. Not only is no evidence required to demonstrate that any assertion made in physics confirms with observables, the very attempt to require evidence for any assertion in antiscientific and, indeed, anti-rational. The very essence of the rational skeptical mindset which characterizes the modern Western world is credulous belief in any unsubstantiated claim regardless of how many experimental observations it contradicts.

In other breaking new, the earth is cubical in shape, 12 = -1, and plogiston will soon replace gasoline in our cars, effectively ending the Peak Oil crisis.

19. **Cecil Kirksey**
May 25, 2007

Peter:

I hope this is not considered OT but it is somewhat related to the issue being discussed. Suppose someone wants to become a theoretical physicist. The person obtains a PhD at a good university with a well known advisor; then he/she is able to obtain several postdocs and finally he/she is able to receive a position at a top notch university or research center. My question is this: How does this person judge the success of their research career? By the number of papers published in PEER reviewed journals? By being a great teacher of up and coming other theoretical physicists? By obtaining research grants based on proposals reviewed by PEER occupied committees? By having their name appear in lay publications? Write a successful textbook or book for the layperson? Or win a Nobel Prize?

Other than the last criterion couldn't everything also apply to say a person who desires to do research in say medieval Germanic literature?

Without some connection to the real world (RW) how does one define the success of one's career as a theoretical physicist? Is it just PEER review?

20. **woit**
May 25, 2007

Cecil,

If you manage to get a tenured position at a top-notch university, you're more of a "success" as a theorist than 90 percent of the other people who got Ph.D.s in the subject. If you don't consider that "success" you're basically an insecure neurotic. Beyond that, once you have a permanent job allowing you to pursue what you want, all the different things you mention are possible things to work on and aspire to. Up to you to judge how well you succeed at what you try and do. Different people value different things, and the approval of certain very specific groups of ones peers is something different people care about to different extents.

21. **tomj**
May 25, 2007

I wonder if it is possible to concede a point to the string theorists: their theory is true and can't be falsified. So why don't we just move on. I don't see the point of a theory which cannot be falsified. If a particular experiment can neither prove nor disprove a particular theory, then why even discuss the theory with respect to the experiment?

My daughter was required to design an experiment for her 8th grade science class. She decided to measure the some ill-defined difference between skimmed milk, 2% and whole milk, by bring the different samples to a boil. The measured variable was time to boil. If she were to claim that this experiment falsified string theory, how would a string theorist show that the experiment was not applicable?

22. **Cecil Kirksey**
May 25, 2007

Peter:

Thanks for the reply. But I was more interested in the research part of being a successful theoretical physicist. How does one judge that aspect of their career? After all discovering a new theory of nature does not happen that often. So in this age of ST, LQG and other estoric ideas how does one define being a "success" other than position? Which is usually governed by how your PEERS judge you.

23. **Aaron Bergman**
May 25, 2007

I can't contain my curiosity. What exactly does P.E.E.R. stand for?

24. **Chris Oakley**

Ah, Z13.

26. **Simplicissimus**
May 25, 2007

When I clicked the link in “From a posting on Lubos Motl’s blog”
(which refers to http://motls.blogspot.com/2006/10/falsifiability-in-physics.html)
I arrived at http://www.physics.harvard.edu/~motl/crackpot-not-even-wrong.html.
I’m not familiar with string theory. But I am familiar with standards of civilized communication. Is this the famous Harvard university?

27. **Eugene Stefanovich**
May 25, 2007

Cecil:

Medieval scholars designed ingenious ways to count the number of angels dancing on the head of a pin. No doubt, they earned respect from their peers, well-paid positions, and all that… at about the same time when Galileo and Giordano Bruno were grilled by inquisition, one of them quite literally. So, in those times “success” and “progress” were not synonyms. Do you think they are synonyms now?

28. **Cecil Kirksey**
May 25, 2007

ES:
That seems to be the issue.

I guess I need to be more more clear. If you are a theoretical physicist and do not contribute to a theory that makes connections to the RW can you be successful? Yes or no? Exactly what does a theoretical physicist do if there are data to support his or her pet ideas? You can teach, but what about the research? Or maybe theoretical physicist needs a different definition. (Of course I am not sure what a theorteial physicist actually does so maybe someone who is such an animal can define his or her job description.)

29. **anon.**
May 27, 2007

‘If you are a theoretical physicist and do not contribute to a theory that makes connections to the RW can you be successful? Yes or no?’ – Cecil

That’s the same as asking if string theorists are successes. Consider dictators who think they have the answer to everything, and suppress dissent. Fellow dictators may respect them, and financially they may be a success. That’s all that counts to them.

What would be a failure in their book is someone like Mallory who set off to climb Everest in 1924 and didn’t return. A ‘success’, in the dictator’s book, is a label attributed by others to someone who makes a vast fortune and acquires power and through that power, respect (though that may be respect through fear, rather than respect from genuine admiration).

Newton and Darwin both came up with their discoveries and held back from publication for decades until they had built up a convincing set of evidence to support them. They didn’t build careers on the back of revolutionary discoveries. Copernicus wrote his book when he was an old man. String theory is the very opposite of this tradition; it’s got no solid evidence yet it is deemed a popular success because it has acquired mainstream credibility.

30. **philippe**
May 29, 2007

Since money is always involved, I tend to see theoretical physics as a big fashion show. You can’t tell what is or isn’t successful before a substantial amount of time or generations have passed. I don’t think anybody can claim enough hindsight at present to carefully judge the situation in theoretical physics or the “success” of anything in a less relative way. Let the fashion show continue…and its models trip.

The Empire Strikes Back

May 25, 2007
Categories: Uncategorized

After last month's posting at Cosmic Variance about how String Theory is Losing the Public Debate, Sean Carroll seems to have decided to go on the offensive (or defensive…), with a piece in New Scientist entitled String theory: it's not dead yet, which he reproduces and has a posting about here.

I can't really disagree with Sean about either title. Yes, string theory is losing the public debate, and no, it's not dead yet. Some of Sean's claims in the New Scientist piece are descriptive claims about the behavior of theoretical physicists:

String theorists are still being hired by universities in substantial numbers; new graduate students are still flocking to string theory to do their Ph.D. work…

Ideas about higher-dimensional branes have re-invigorated model-building in more conventional particle physics… Cosmologists thinking about the early universe increasingly turn to ideas from string theory.

All of these are true enough (although the word "re-invigorated" might not be the most appropriate one), but don't address the value judgment of whether any of this activity is a good thing or not. One could also come up with other evidence for continuing activity in string theory, such as the large number of press releases being issued claiming to have found new ways to "test string theory", but the fact that these have all been bogus is relevant to evaluating whether this activity is a good thing or not.

Sean's positive case for string theory is mostly about its role as a quantum gravity theory, acknowledging that the Landscape is a problem, and that progress has slowed since the mid-90s (although more accurate would be "come to a dead halt, now moving backwards.."). He describes that period as "it seemed as if there was a revolution every month", displaying the predilection for over-the-top hype that has characterized much string theory salesmanship over the years. His claims about the achievements of string theory vary from relatively modest exaggerations ("The theory has provided numerous deep insights into pure mathematics") to standard misleading propaganda:

"a promising new approach has connected string theory to the dynamics of the quark-gluon plasma observed at particle accelerators" (connected? wonder how strong the connection is…)

"it is compatible with everything we know about particle physics" (and also compatible with just about everything we know to not be true about particle physics…)

"Michael Green and John Schwarz demonstrated that string theory was a consistent framework" (there's a lot more to consistency than canceling that anomaly…)

"It was realized that those five versions of the theory were different manifestations of a single underlying structure, M-theory" (would be nice if we knew what M-theory actually was…)

In the comment section Sean explains how string theorists have no intention of standing behind what used to be considered the main "prediction" of the theory, TeV-scale supersymmetry:

If the LHC discovers supersymmetry, string theorists will be happy, but if it doesn't there's no reason to give up on string theory — the superpartners might just be too heavy.

So, prospects for string theory remain bright, since with each new experiment the situation is: heads they win, tails doesn't count.

Also at Cosmic Variance is the latest in an exchange between Joe Polchinski and Lee Smolin, entitled Science or Sociology? (some earlier parts of the exchange are here). I'm mostly resisting the impulse to get involved in various parts of that argument since Smolin doesn't need my help: the points at issue don't seem to me central to the claims of his book, and his positions and what he wrote in the book are perfectly defensible.

While I don't see the point of arguing about things like how conjectural the AdS/CFT duality conjecture is (pretty damn conjectural I'd think though, since no one even knows what the definition of one side of the duality is…), it is interesting to see what it is that Polchinski finds most objectionable about Smolin's criticisms. In the context of an argument about how much of a problem the positive CC was considered to be by string theorists in the late 90s, he strong objects to Smolin's description of "a group of experts doing what they can to save a cherished theory in the face of data that seem to contradict it", going on to describe the work on moduli stabilization that led to the landscape as "a major success" which Smolin is trying to paint as a "crisis". Ignoring the argument about who thought what back then (although if you really care about this, for some relevant evidence, see the Witten quote), in a larger sense "a group of experts doing what they can to save a cherished theory in the face of data that seem to contradict it" describes precisely the behavior of Polchinski, Susskind, Arkani-Hamed, and many others in the face of the disastrous situation created by the "major success" of moduli stabilization.

The "anthropic landscape" philosophy is nothing more than an attempt to evade failure, and it is an failure of scientific ethics of a dramatic kind. Once one understands a speculative idea dear to one's heart well enough to see that one can't make any conventional scientific predictions using it, ethics demands that one admit failure. Instead we've seen scientists announcing a new way of doing science, even writing popular books and magazine articles promoting this. Most physicists (including even a sizable fraction of string theorists) are appalled by this behavior. If you don't believe me, consult a random sampling of the faculty in your nearest physics department, or watch Susskind's recent talk in Israel where he describes himself as at the center of a circular firing squad.

Polchinski ends by claiming that Smolin's case for "group-think" and for a "sociological" problem with string theory is "quite weak". This problem is obviously hard to quantify and a matter of perspective. While I don't doubt that Polchinski sees himself as not suffering from "group-think", if he were, he obviously wouldn't think so. One thing I think is undeniable about the "sociology" of all this is that the blog phenomenon has put a lot of evidence out there for any unbiased observer to judge for themselves, and this is one of the main reasons for what even a fervent string theory proponent like Sean Carroll has noticed: string theorists are losing this debate.

Anyone who regularly follows the most well-known blogs run by string theorists pretty soon becomes convinced that they have a real problem. Lubos Motl is the Id of string theory on uncensored display. The fact that his colleagues promoted him and show signs of only having a problem with his politics, not his behavior as a scientist (if they have any problem with his calls for my death or other attacks on me, I've never seen evidence of it) is truly remarkable. Two out of three recent string theory textbooks prominently carry his endorsement. All another prominent string theorist blogger, Clifford Johnson, has to say about Lubos is "I thank him for his physics contributions and for widening the discussion." This was in the context of an eight-part personal attack on Lee Smolin and me for having written books that Clifford steadfastly refuses to read. The other of the three prominent string theory bloggers is renowned for his sneering attacks on the competence of anyone who dares to criticize string theory, issues press releases claiming tests for string theory that other physicists describe as "hilarious", while misusing his position of responsibility at the arXiv to stop links to criticism of string theory articles from appearing there. Among those string theorists without their own blogs who choose to participate in the comment sections of others, a surprising number seem to think that it is an ethical thing to do to post often personal attacks on string theory critics from behind the cover of anonymity. Less anonymously, a large group of string theorists at the KITP seem to have thought it was an intelligent idea to act like a bunch of jeering baboons, on video, for distribution on the web.

This kind of public behavior and the lack of any condemnation of it by other string theorists is what has convinced many physicists and others that, yes, string theory does have a "sociological" problem. I have to confess that my experience over the last couple years has caused me to come to the conclusion that the string theory community has a much greater problem with personal and professional ethics than I thought when I wrote my book. The fact that so many string theorists have decided to respond to my book and Smolin's not with scientific arguments, but with unprofessional behavior I think speaks volumes for the strength of their scientific case, and this has been noticed by their colleagues, science journalists, and the general public. While I applaud Polchinski for behaving professionally in his response to the two books, I suggest that he should take a look at the behavior of many of his colleagues and ask himself again whether or not there might be a sociological problem here.

Comments

1. **kasper Olsen**
   May 25, 2007

   Dear Peter,

   Who cares, if we physicists are losing the (public) debate?

   At some points it has seemed, that real scientists are also
   losing the debate in the US over the Intelligent Design movement.

   Progress will not — in the end — be driven by sociology, or superstition.
   But instead by something completely different. This something is what is usually called "truth"….

   -Kasper

2. **Coin**
   May 25, 2007

   relatively modest exaggerations ("The theory has provided numerous deep insights into pure mathematics")

   Do you disagree with that statement as written then?

3. **Domenic Denicola**
   May 25, 2007

   This was quite a polarizing post. And yet from what I've seen, I can't really disagree with any of it.

   Coin, re: pure mathematics: I think the issue may be one of degree. I don't know if "numerous" and "deep" are the appropriate qualifiers here. Although I'm not knowledgeable enough to say for sure, I think that string theory really hasn't contributed all *that* much to mathematics, at least from the perspective of mathematicians who are actively working toward "numerous deep insights" instead of developing new tools mathematical tools as needed.

4. **Peter Woit**
   May 25, 2007

   Kasper,

   What's going on is not "physicists losing the public debate", but string theorists losing the debate among physicists. You might try asking your non-string theorists colleagues their opinion of string theory these days…

   Coin,

   While string theory has contributed to mathematics in various ways, as I wrote, I do think that saying it has provided numerous deep mathematical insights is an exaggeration.

5. **J**
   May 26, 2007

   Peter,

   The problem here is that lots of non-string theorists know very little about string theory and just follow the trend of "hating" string theory. At least I konw many people of this type. Nevertheless, I agree with you that string theory is in big trouble and some string theorists are too biased about it.

6. **Peter Woit**
   May 26, 2007

   J,

   Sure, few people actually understand much about string theory. In the past the hype surrounding the subject led to a lot of people being very impressed by it. As it has become clear that much of this was hype, and the problematic "sociology" becomes more manifest, this is leading to a backlash and to people "hating" string theory. "Hating" isn't a reasonable reaction to a scientific theory, but it is a reaction to the hype and to the behavior of some string theorists.

7. **outsider**
   May 26, 2007

   …how conjectural the AdS/CFT duality conjecture is (pretty damn conjectural I'd think though, since no one even knows what the definition of one side of the duality is…)…

   How can they talk about this duality if they don't know both sides? What do string theorists say if they explain the duality??

8. **Aged String Theorist**
   May 26, 2007

   Peter….

   wheeze-exhale

   I ..am ..your ..father!

   wheeze-exhale

More seriously, I agree with you on the fact that the statement that string theory "is a fundamental theory of physics" is "not even wrong", but to suggest that string theory is completely useless (I don't know, maybe I am taking you out of context here) is perhaps a bit of an over exaggeration. I am sure that there are many stringy inspired pieces of mathematics that will be of great interest to mathematicians for years to come, and potentially many more reserves of mathematical complexity that have yet to be tapped. Though I must admit that I could be wrong here, I think certainly one has to acknowledge that there is a whole community of theorists working in the area that think that there is definitely SOMETHING there, so, maybe there is! Just maybe not the fundamental "theory of everything" that has been (dishonestly?) hyped in the media. Something to think about anyway.

9. **Math Grad Student**
May 26, 2007

As someone who knows little about the physics involved, but a lot about the math (I'm finishing my Ph.D. in representation theory & algebraic geometry this summer), I can say that from my point of view Peter is completely right about physicists losing the argument from a sociological standpoint. I'm a long-time reader of this blog as well as other physics blogs and it has been amazing to see Peter (as well as Lee Smolin elsewhere) being unflappably polite while being subject to the most absurd ad hominem and personal attacks. I can't speak to the substance of the posts arguing physics, but when string theorists claim that Peter has no authority since he isn't publishing academic papers (as though this has any bearing at all on his arguments) or call him a crackpot or worse, it only makes them look bad. Add to this the vicious postings by string theorists on their own sites that don't address the substance of Peter's arguments but only hurl insults in his direction, and consider Lubos' quite unhinged nature — my own personal favorite post of his is the one where he claims women can't do physics or math — and it's no surprise string theorists are losing on the public relations front.

As for the claims of physicists that string theory has greatly enhanced mathematics, I can only say that I am unaware of this impact in my field. I know that string theory has had an impact on enumerative algebraic geometry (eg work of Kontsevich on curve counting) but it's not valid to claim that the impact has been huge. In fact it seems like string theorists are taking the shiniest new baubles from mathematics and claiming them as part of string theory. A case in point is new claims that geometric Langlands has import in string theory — maybe I'm off base here, but can anybody tell me how the hell, say, Hecke eigensheaves on a moduli stack have anything to do with string theory? Undoubtedly QFT has had an impact on representation theory, especially the infinite-dimensional flavor, but string theory? Color me unconvinced.

10. **Peter Woit**
May 26, 2007

Aged String Theorist,

I'm quite sure I've never claimed string theory is "completely useless". It's a huge subject, many parts of which remain worth pursuing. But the idea of unifying physics with 10/11 d string/M-theory really has pretty conclusively failed, and string theorists should start publicly acknowledging this instead of allowing Landscape pseudo-science to flourish and continuing to promote misleading hype about the theory.

The relation of string theory to mathematics is a really complicated subject, with one reason for this being that a big part of the story is 2d conformal field theory, which is an independent subject. Just as it would be a really good idea for physicists to think clearly about what string theory ideas have failed and which have led somewhere, the same is true about the interaction of string theory and mathematics. Hype about "numerous deep insights into pure mathematics" isn't really helpful.

11. **Aaron Bergman**
May 26, 2007

I think it's a pretty silly exercise to bicker about the *extent* to which string theory has influenced mathematics. In certain fields (Gromov-Witten theory, for example), string theory has inspired many results; in others not so much.

To answer the specific question, the moduli stack can be approximated by the Hitchin moduli space which arises when placing the equations of a particular 4D TQFT on a Riemann surface. (It's been argued that working on the stack is equivalent to working in the full 4D context, but I don't think that's been made precise.) One then gets a 2D model of maps into this moduli space. Using ideas from topological string theory, we can identify boundary states of this field theory with objects in the derived category. There are specific operators in the 4D theory called 't Hooft loops which operate on boundary states and thus give functors on the derived category. The Hecke eigensheaves are the same things as "eigenbranes".

12. **Eric Mayes**
May 26, 2007

Peter,
As far as I can tell, the only people who believe that string theory has failed are you and your accolytes. This certainly is not the opinion of most high-energy physicists and you should stop misrepresenting this fact. Basically, this a pseudo-controversy created by you and others, just as creationists try to give the impression that there is a controversy over evolution. It's irritating, but in the end irrelevant.

13. **Peter Woit**
May 26, 2007

Aaron,

Referring to the 2d sigma model involved as a "string theory" seems to me to be rather gratuitous. You're not summing over surfaces, you're not summing over metrics, it's an interesting TQFT with little relation to physical string theory. As I wrote in the previous comment, it really would be useful to keep straight what is what, and not try and muddy the waters. The QFT/Langlands story is about gauge theory and TQFT, not about string theory.

Eric,

You really should get out more…

14. **Aaron Bergman**
May 26, 2007

Referring to the 2d sigma model involved as a "string theory" seems to me to be rather gratuitous.

I wasn't aware I did that.

15. **Peter Woit**
May 26, 2007

Aaron,

"Using ideas from topological string theory, we can identify boundary states of this field theory"

It requires fairly close reading of this to realize that there's no string theory here, just a use of "ideas from topological string theory", which aren't about string theory.

16. **Eric Mayes**
May 26, 2007

Ok, Peter, say that in a few years when you've been completely forgotten, and all of the emnity you've created comes home to roost.

17. **Aaron Bergman**
May 26, 2007

Ummm, yeah. Ok.

18. **Math Grad Student**
May 26, 2007

. . . so am I understanding this correctly, that geometric Langlands really pertains to QFT and less to string theory? I'm already aware that there are connections to QFT (cf Edward Frenkel's notes on the topic).

As for Eric Mayes' comments, they are a classic example of what Peter is talking about — even though I don't know a lot about evolutionary theory it's patently obvious that intelligent design and arguments against evolution by religious nuts are unscientific. However, although I don't know the physics involved, it is NOT patently obvious that Peter is being unscientific; in fact it doesn't seem like that's the case at all. It's pretty great that Eric has come along to underline precisely the point that Peter makes, which is that ad hominem attacks have taken the place of reasoned conversation, and that this is making string theorists look pretty bad to those of us who don't know physics on a deep level.

19. **woit**
May 26, 2007

Math Grad Student,

Witten (with Kapustin and Gukov), over the last few years has been exploring the relation between certain 4d topological QFTs and geometric Langlands. He relates the 4d TQFT to 2d TQFT based on maps from a 2d space with boundary (such as the upper half plane) to the Hitchin moduli space of bundles over a Riemann surface. Langlands duality then is related to mirror symmetry between two such TQFTs.

This is one sort of relation of QFT to Geometric Langlands, but there's another quite different one, that is explained in many of Edward Frenkel's articles and lectures. There use is being made of ideas from conformal field theory (and especially vertex operator algebras) to do explicit constructions in geometric Langlands. As far as I know the relationship between these ideas and Witten's newer ones is not understood, but maybe someone better informed than me knows something about this. If so, I'd love to hear about it…

20. **Aaron Bergman**
May 26, 2007

so am I understanding this correctly, that geometric Langlands really pertains to QFT and less to string theory?

Yes. As I said (which apparently Peter thought was deeply hidden in my opaque prose), some ideas that had their origin in string theory have gone into the analysis, but all the theories are topological QFTs. Strangely enough, these do not seem obviously related to the CFT stuff that Frenkel discusses in his notes.

In regards to the increasingly tiresome string PR wars, I'd suggest reading various more formal reviews of the relevant books as opposed blog comment threads which involve a vanishingly small fraction of the community.

21. **tomj**
May 26, 2007

One question which keeps coming to my mind is if physicists believe that you have to fully understand (or even partially understand) their theory to discuss certain grand ideas in scientific thought.

One is Occam's razor. One arm of this principle is that a new theory must fully describe the same results as another theory, with less assumptions or somehow more simply.

Another principle is the ability to predict results prior to experiment. This seems important because if the theory doesn't predict results, it is impossible to argue that the theory even applies to the experiment.

Underlying both of these principles is the bedrock assumption: physical experiments are required, and any theory, or any part of any theory, which does not deal directly with the observable world is by definition un-necessary, it is dead weight, and must be discarded using Occam's razer.

What I'm getting from the string theorist's side of the debate is that their theory is more important than these principles, so the principles themselves must be incorrect. It's a neat trick.

22. **Math Grad Student**
May 26, 2007

I see. Thanks for the information on TQFTs — I have Frenkel's paper and I'm planning on reading through it. It's good to have some sort of rough overview of the picture when reading about the interface between mathematics & physics, which I often find confusing. Frenkel's book on geometric Langlands & loop groups comes out in a month also, and I'm hoping it'll be readable — the preprint version of the book from his website included a forward in which he said that the book should be accessible to a bright undergraduate or beginning graduate student, which made me feel kind of dumb.

23. **woit**
May 26, 2007

Math Grad Student,

Frenkel's comment about that book being accessible to someone with an undergrad math background is one of the funniest things I've seen in the math literature. That he might be serious about it is one of the scarier things…

24. **Aaron Bergman**

May 26, 2007

The deal is this:

1) Quantum mechanics and general relativity are incompatible
2) There are currently no experiments that probe regimes where this incompatibility is important.

Given (2), there are two options. The first is just to not work on number one. This applies to string theory, loop quantum gravity, causal dynamic triangulations and any other theory you can think of. None of them had made anything remotely resembling a falsifiable prediction.

The thing is, people don't having a problem in front of them and not working on it. So people have their favorite ideas for working on (1). Most people who have thought about these questions think that string theory is the best of the various ideas out there. And so they work on it.

25. **Tom**
May 26, 2007

In the end, none of this matters. The LHC will turn on and either end the debate or end particle physics. If we find something, it will clarify the direction theory needs to head. If we find nothing, we will all be working at hedge funds. Personally, I'm hoping for the latter. I've always wanted a sailboat.

26. **Intellectually Curious**
May 26, 2007

Math Grad Student wrote:

"it's patently obvious that intelligent design and arguments against evolution by religious nuts are unscientific."

While it is true that some arguments by some 'religious nuts' are unscientific, it is not true that intelligent design and (all) arguments against evolution are unscientific. There are plenty of reputable scientists who believe that the universe was designed and created, and whose reasons against the evolution theory are based on scientific facts. See here for a list.

At any rate, I thought the comment was irrelevant to the current discussion and sounded like a 'cheap shot' coming from certain string theorists :-), which was out of character of your other posts. (Your first one, for example, was fair, unbiased, and well-argued.)

27. **Peter Woit**
May 26, 2007

Any further attempt to use this blog to carry on the ID vs. evolution debate will be ruthlessly suppressed. Don't even think of it…

28. **Coin**
May 26, 2007

Frenkel's book on geometric Langlands & loop groups comes out in a month also, and I'm hoping it'll be readable

Does "loop groups" in this context mean the same thing as holonomy groups?

29. **Peter Woit**
May 26, 2007

No,

a loop group is just the group of maps from the circle into a group, with point-wise multiplication.

The holonomy group is something different. Given a connection, it's the group generated by parallel transport around a loop.

30. **Coin**
May 26, 2007

I see, thank you.

31. **Amos Dettonville**
May 27, 2007

It's interesting that while string researchers themselves have the strong impression that trememdous progress has been made at various times (e.g., "it seemed as if there was a revolution every month" in the mid 90s), from an outsider's perspective there appears to have been no progress or change at all, at least for the past 20 years or so. I base this largely on the popular book "Superstrings, A Theory of Everything", edited by Davies and Brown, published in 1988. The book (in case anyone here hasn't read it) is a fascinating collection of interviews with prominent string researchers, conducted in 1987, exactly twenty years ago. Those interviewed were Schwarz, Witten, Green, Gross, Ellis, Salam, Glashow, Feynman, and Weinberg.

Re-reading this book recently, the overwhelming impression I got was that absolutely nothing has changed in the past twenty years. In fact, it seems to me that the popular chronology of string theory (first revolution, second revolution, etc.) is wrong, or at best misleading, because already in 1987 we find every aspect of the present discussion, including the unification of the various versions into a single over-arching theory, the idea of invoking higher-dimensional surfaces (instead of just one-dimensional strings), the huge number of possible vacuum states due to the various ways of curling up the extra dimensions, the prospect of needing to appeal to the anthropic principle as a way of choosing between them, the possibility of formulating the theory in four dimensions from the start, the issue of "background independence", the difficulty with the cosmological constant and the fact that we don't know how to break supersymmetry without producing an excessively large CC, acknowledgement of uncertainty about whether it has really been fully proven that string theory will be completely finite in every sense and to all orders, and the over-riding lament that "we don't understand what string theory is", and we seem to be missing some fundamental principle. And so on.

There was also a discussion of the sociological issues, noting the "totalitarian" aspects of the string research community, and questioning whether it's a good idea to focus so much one speculative idea. The book even contains a tinge of "flame war": The interviewer mentioned that Feynman was quite critical of string research, and Green began his response by saying "I would not have thought that this was the kind of approach to physics that Feynman would favor". (How did that get past the editors? It's the only ad hominen comment in the book.)

It may be that experts in string research could "date" those interviews, but my guess is that most people would find them indistinguishable from blog discussions typed this morning. (Just about the only give-away is that they say "the LEP stands a good chance of detecting the Higgs", whereas now one says "the LHC stands a good chance of detecting the Higgs".) And yet, as I said, the string researchers themselves have the impression that they have been progressing (at various times since 1987) at breakneck speed. I can only assume that the research has generated several internal problems that have been tackled and resolved, giving workers in the field the impression of progress, despite the fact that, in overall terms, the program hasn't budged since 1987.

Here's a nice succinct question and answer.

Interviewer: It seems at the moment that this must be a rather major obstacle to further progress in the theory – not knowing how the higher dimensions curl up.

Witten: We would be much happier if we understood how the higher dimensions curl up and therefore what the vacuum state of the theory is.

32. **marcus**
May 27, 2007

Amos Dettonville,
Thanks for the pointer to that 1987 book. It was recently republished in an attractive-looking paperback edition, I see.
http://www.amazon.com/Superstrings-Everything-P-C-Davies/dp/052143775X

It is available new for $20 or so, (not counting shipping) and I see that used copies are for sale for $0. 47 on the same basis. How can anybody resist an up-to-date book on string theory for 47 cents?

Though others may have missed your reference to 1986 anticipation of M-theory, I think that must be what was meant here:

…the popular chronology of string theory (first revolution, second revolution, etc.) is wrong, or at best misleading, because already in 1987 we find every aspect of the present discussion, ***including the unification of the various versions into a single over-arching theory****, the idea of invoking higher-dimensional surfaces (instead of just one-dimensional strings), the huge number of possible vacuum states due to the various ways of curling up the extra dimensions, the prospect of needing to appeal to the anthropic principle as a way of choosing between them,…*

33. **ali**
May 27, 2007

Hi Peter,
I have a kind of off-topic question. Do you have any idea why DARPA is funding geometric langlands program? I mean, it is a military agency and I cannot see the motivation behind it. I am not in this field but this is pure math as far as I can see

34. **LDM**
May 27, 2007

If Sean's claim

String theorists are still being hired by universities in substantial numbers; new graduate students are still flocking to string theory to do their Ph.D. work…
is true, then the perceived loss of the public debate is moot -it would still appear to be business as usual. I only care about the public opinion in this debate to the extent it can influence the allocation of academic and research funding…

If somebody wants to study string theory on their own — fine, just don't ask the tax payers to support their delusion under the guise of conducting physics research. Get a philosophy grant instead.

.

35. **Cecil Kirkey**
May 27, 2007

I would like to second Amos. I have had the book in question for several years as well as other string theory books (sorry Peter I have NOT yet bought your book but intend to). I can maybe see why some researchers would really be interested in ST, but how to get rid of all those extra dimensions!!!

Aaron:
It maybe the "only game in town" but could it just be a suckers game? Just asking.

36. **Aaron Bergman**
May 27, 2007

String theory could certainly not be the correct theory of quantum gravity. It's lucky, then, that it has inspired many new ideas in the field of phenomenology and mathematics. In addition, the AdS/CFT conjecture gives us a new way to understand gauge theories. It might be disappointing if gauge/geometry duality is the only connection between string theory and more traditional physics, but it is still a remarkable discovery that deserves further investigation.

37. **Peter Woit**
May 27, 2007

ali,

From the DARPA web-site:

http://www.arpa.mil/dso/thrust/math/fathm.htm

I think DARPA has traditionally been willing to sometimes fund basic research whose possible military applications are pretty far-fetched. This seems to be a pretty extreme example.

38. **David Ben-Zvi**
May 27, 2007

Peter,
There are certainly relations between the CFT type
approach to geometric Langlands and the 4d TFT one –
I think most of the fundamental structures in geometric
Langlands can (or will) be seen from this POV.

I think the key to this is understanding the Kapustin-Witten
TFT in codimension three, i.e. on the circle, but sadly I think
neither the algebra nor the TFT (I self-censored after saying "math" and "physics" 🙂) is sufficiently developed to make such statements precise. I'll just say that both sides are pretty definitely about loop groups.

In fact I think 2d gravity/topological strings will soon
become relevant to the geometric Langlands story —
at the very least the "space of string states" seems to appear when you try to relate representation theory of loop groups to that of groups..

39. **LDM**
May 27, 2007

Peter and Ali,

DARPA of course has zero interest in string theory as a physical theory…It is only interested in any mathematics that string theory may have influenced and whether or not such mathematics can be used in defense:
"The fundamental mathematics developed in this program is expected to have broad significance in basic science and several avenues of possible long-term defense impact, including quantum algorithms and devices; cryptography; fast structured algorithms for signal/image processing and other DoD-critical applications; and high-density data coding"

Public key encryption as a secure cryptosystem relies on the mathematical assumption of the difficulty of factoring large numbers — a difficulty which apparently has never been proved. Hence the DARPA interest in number theory and Langlands.

Quantum algorithms and devices (mentioned by the DARPA link) refer to quantum computers (and also quantum key distribution)—the development of quantum computers would give an exponential increase in factoring speed , rendering public key encryption broken.
On the other hand, a successful development of quantum key distribution would solve the problem of secure distrubition of encryption keys, which would immediately make the one time pad cryptosystem (known to be secure) practical.

The DARPA funding looks reasonable.

40. **ali**
May 28, 2007

LDM, thanks for the insight. I know NSA is also very interested in quantum computers too for obvious reasons. I just did not know geometric langlands program could have any such practical realization. I am not in this field

41. **Professor Doctor Galileo Galilei**
May 28, 2007

Galileo lost the public debate.

In much of the US so did Darwin.

Not sure the public debate is very relevant for sciencitific questions.

42. **anon.**
May 28, 2007

What I don't like about military funding of science is that if anything interesting comes up, it will be classified secret to stop enemies knowing about it. This probably won't stop the enemies finding it, because you always get leaks from the Dr Klaus Fuchs sort, but it will prevent the interesting applications being known widely.

43. **changcho**
May 28, 2007

"…but it will prevent the interesting applications being known widely.' Perhaps, but only for a little while…

44. **mclaren**
May 29, 2007

String theorists are still being hired by universities in substantial numbers; new graduate students are still flocking to string theory to do their Ph.D. work…

Ideas about higher-dimensional branes have re-invigorated model-building in more conventional particle physics… Cosmologists thinking about the early universe increasingly turn to ideas from string theory. — Sean Carroll

All of these are true enough (although the word "re-invigorated" might not be the most appropriate one), but don't address the value judgment of whether any of this activity is a good thing or not. One could also come up with other evidence for continuing activity in string theory, such as the large number of press releases being issued claiming to have found new ways to "test string theory", but the fact that these have all been bogus is relevant to evaluating whether this activity is a good thing or not. — Peter Woit

Fascinating. When I made essentially the identical point in a comment on the Cosmic Variance blog, Sean Carroll deleted my post.

In particular, I went on to make a further point in the comment which Carroll deleted. Namely, that there's nothing radically new about the peculiar properties of string theory as science. Irving Langmuir called this kind of activity "pathological science," and he gave a famous lecture on the subject:
http://www.cs.princeton.edu/~ken/Langmuir/langmuir.htm

Examples of pathological science include Blondlot's N-rays, mitogenetic rays, the Davis-Barnes effect, and the Allison effect. I would add to that list phlogiston, alchemy, hard AI, and the luminiferous aether. (Some will doubtless disagree about hard or GOFAI, but the evidence there seems pretty clear after 50 years. Look at the CYC project for a classic example.)

Sean Carroll claimed that string theory is unique because it has gone on so long without getting experimentally tested in such a way as to definitely disconfirm it, but that's actually not correct. Each of the above examples of pathological science never got an experimental disconfirmation which proponents of the theory accepted as definitive. The supporters of N-rays, for example, tried to wriggle out of Wood's report by claiming that N-rays don't operate according to Snell's law, that Wood didn't know how to read the scintillations properly, that Blondlot was tired during that particular experiment, etc.

We hear exactly the same kinds of excuses today whenever new data places a lower bound on the possible mass of the superpartners. I.e., the string supporters simply move the bar.

There's nothing new about any of this. We see this in pathological science for at least the last 100 years, and if you count phlogiston, going back several hundred years.

The scientists who came up with phlogiston weren't stupid. There were superificially convincing reasons to believe in it — metals lost weight when heated, gained weight when heated. It seemed credible. (Turned out to be oxides, not phlogiston.)

There are likewise some superficially convincing reasons to believe in string theory, particularly the mathematical ones. The problem is that regardless of how convincing it might seem, string theory hasn't generated testable falsifiable experimental predictions.

One of the biggest problems with string theory is that (like all patholgoical science) it has not been fertile in a scientific sense. It *has* proven mathematically fertile. Lots of new and wonderfully fascinating math has come out of it. But after 30 years, no new areas of physics have been opened up to investigation by string theory and explored with experiments. This is very different from the case with, say, quantum theory. Initially, quantum theory merely offered a way of explaining the absorption lines of the simpler elements like hydrogen and helium, in particular the Ballmer series. But then quantum theory got applied to crystalline solids and you got band-gap theory of semiconductors, and that led all sorts of fascinating research and a wealth of new experimental results. Likewise, LInus Pauling applied quantum mechanics to organic chemistry, and that led to incredibly productive areas of research, including X-ray crystallography and eventually the decoding of the structure of DNA. Again, quantum theory was applied theoretically by Dirac to predict negative energy states, leading to the prediction and soon the discovery of the postiron, and antimatter, which opened the door to a vast new realm of experimental research in particle physics. Dirac certainly did not imagine Gell-Mann's "eightfold way" when he made the prediction about negative energy states, but Dirac's work proved incredibly fertile.

All these cases involved experimental predictions which led to further epxierments, and opened up huge new areas of active and productive research.

What huge new areas of productive research has string theory led to in 30 years?

Where are the experimentally testable falsifiable predictions from string theory? Where are the experiments based on string theory predictions which have opened up vast new areas of active productive research, and led to new technologies and new realms of applied science?

There are none. String theory has not been fertile.

That's a big warning sign.

Another big problems is string theory's prediction of 10, or, possibly, 11 dimensions (depending whether you adhere to M-theory or not). Every scintilla of experimental evidence we have amassed in the entire history of physics so far converges on the conclusion that we live in a 4-dimensional world — 3 dimensional of space, one dimension of time. There is not a single shred of experimental evidence pointing to the physical existence of more than 4 dimensions in our universe.

There's no reason why compactificaiton *couldn't* be theoretically correct, mind you — it's just that there's absolutely no experimental evidence to support it. And, if compactification occurs anywhere near the Planck length, the energies required for an experimental test lie far beyond anything anyone can hope to reasonably produce in any possible particle accelerator. That makes compactification unfalsifiable. And that's yet another big problem for string theory.

The parallels between string theory and other types of pathological science, like N-rays or mitogenetic rays, run even closer. Drs. Woit and Smolin seem to have played a similar role to the physicist Robert Wood in the N-ray affair — except that Wood pointed out that Blondlot's experimental results were incorrect, whereas Woit and Smolin are pointing out that the string theorists aren't even making any predictions that anyone can provide experimental results to test. (That's even worse than the case with Blondlot's N-Rays.) And we're getting much the same kinds of responses from string theorists that the N-ray proponents gave back in the early 1900s.

Viz., critics of the theory "don't really understand it and thus are not qualified to comment." (Rejoinder: I don't need to understand the mathematical details of a theory to know whether it has produced an experimentally testable falsifiable prediction. This is the same faulty argument as claiming "You can't judge who won the Olympic sprint, since you're not a world-class runner." Yes I can. I don't need to be a world-class runner to see who crossed the finish line.)

And again, proponents of the pathological science claim to have tests of the theory — except that the tests turn out to be phoney. We're seeing this now with string theory. Each time a new "test" of string theory gets announced, it turns out to be pure twaddle.

And again, proponents of pathological science resort to censorship of critics.

None of these tactics ever works. Eventually a scientific theory **must** produce experimentally testable falsifiable predictions, or it dies. This is why it's hard to see how string theory can be accurately described as "alive and kicking." Its proponents continue to flail around in search of some way of generating testable falsifiable predictions from their theory. Jacques Distler's swampland approach with statistics on the vacua represents one approach, Ed Witten's latest toy model represents another. These are all valiant efforts, and there's certainly a great deal of furious activity going on…but the simple fact remain that all this furious activity on the part of string theory never seems to lead anywhere. We never get a unique falsifiable hard number out of string theory for, say, the mass of the Higgs — a number that's solid and unique and can be disconfirmed by experiment. We never get a single hard testable fasifiable number for the compactification length. Maybe Ed Witten's new 2d + 1 approach will finally give hard testable numbers. But I can tell you this…I'm not going to hold my breath, based on past experience.

The acid test of a theory of physics remains: ***What does it take to disconfirm it? What experimental results will disconfirm your theory?*** String theorists have never been able to answer this crucial question.

That's the sign of what Hubert Dreyfus called "a degenerating research program." It seems clear to most unbiased observers that the string theory reserach program is degenerating badly. Despite all the furious activity by string theorists, no falsifiable testable numbers are coming out of the equations.

Some string theory proponents have made an analogy with the early days of quantum chromodynamics. Initially, those equations blew up and produced infinities — then renormalization was discovered, and things settled down. However, it's important to remember that renormalization was invented and applied within a very short time. The gap between QCD and hard testable numbers was only a handful of years. (Gell-Man and Low actually invented the renormalization group in 1954, though Fisher typically gets the credit for it.)

It's now been three decades for string theory. Still no hard testable numbers. That doesn't seem analogous to the QCD situation. In fact, it's not analagous to *any* case in theoretical physics that comes to mind, other than pathological science.

That's my take on why string theory is losing the battle for credibility. As for the continued hiring of string theorists, institutional inertia is the simplest explanation. Linda Rosa's critique of the "therapeutic touch" studies appeared in 1996 and to sensible skeptical observers, that closed the case.
http://www.quackwatch.org/01QuackeryRelatedTopics/tt.html

But hospitals still hire therapeutic touch "experts" 11 years later.
Hubert Dreyfus' book *What Computers **Still** Can't Do* appeared in 1979…but universities continue to hire and grant tenure to researchers pursuing "hard" AI. In economics, Rational Choice theory is currently on the outs, and its record of failed predictions (Martin Luther King's voting marches in the deep south couldn't have occurred because of the low utility function) is leading to a widespread abandonment of that particular theoretical framework. But, once again, some universities do

continue to hire and grant tenure to Rational Choice theorists in their economics departments.

This is human nature. People aren't perfect. It takes time for groups of people to absorb information and reach conclusions, even more time for institutions to form a consensus.

A consensus about string theory apepars to be forming within the HEP community. I would be surprised if string theory is still around in any significant way in another generation.

45. **anon.**
May 29, 2007

'… Eventually a scientific theory must produce experimentally testable falsifiable predictions, or it dies. …' – mclaren

In order to debunk string, you need to bring a new game to town, or the gamblers will only play at strings. You seem to be assuming that the field is competitive. The only competitions are those inside mainstream string theory, because it's the only game in town.

46. **Eugene Stefanovich**
May 29, 2007

anon.:

In order to debunk string, you need to bring a new game to town, or the gamblers will only play at strings. You seem to be assuming that the field is competitive. The only competitions are those inside mainstream string theory, because it's the only game in town.

In my humble opinion, entire post-Standard-model theoretical physics looks like one big casino. People throw around outrageous ideas hoping to hit the jackpot. For some reason, the "string table" attracted more gamblers than other equally destructive games. The only solution is to stop gamble and to switch to some constructive work. It may be slow and boring, but that's the only way forward… in my humble opinion.

47. **mclaren**
May 29, 2007

> In order to debunk string, you need to bring a new game to town…

Apodictically wrong. If a scientific theory persistently fails to produce testable falsifiable predictions, it debunks itself.

48. **Zathras**
May 30, 2007

In order to debunk string, you need to bring a new game to town…

Apodictically wrong. If a scientific theory persistently fails to produce testable falsifiable predictions, it debunks itself.

These two quotes demonstrate the difference between the theoretical conception of the practice of science and science as actually practiced. Since science is a human enterprise, there will always be a disconnect between the two. The practice of string theory shows this disconnect. Science as practiced will continue to have these problems. You might define the problem away by saying that what they are doing is not science, but that does not correct the actual practice issue.

49. **Peter Shor**
May 30, 2007

I don't know that string theorists are behaving that differently from scientists in other fields. It is (and should be) very difficult to dethrone an established scientific theory. The problem in this case is that string theory somehow became an "established scientific theory" with what many people consider only the flimsiest circumstantial evidence in favor of it.

How did this happen? There were several decades with no experimental evidence for anything beyond the Standard Model, and during the 80's and 90's, string theory looked very promising, so it got established as the leading contender to unify gravity and quantum mechanics during this time. Now, even if somebody comes up with a promising alternative theory at this point, sociology means that it will be very hard to battle the particle physics establishment.

50. **anon.**
May 30, 2007

'… Now, even if somebody comes up with a promising alternative theory at this point, sociology means that it will be very hard to battle the particle physics establishment.' – Peter Shor

String theorists say that the problem of alternatives being starved of funds and prestige is the same sociological issue that always arises in all the sciences, and string theory is therefore not a special problem. But in other mainstream theories (e.g., the big bang, evolution, etc.) there is plenty of evidence for the theory.

String, despite lacking evidence, must be defended using aesthetic ('beautiful ideas') and romantic ('all the real geniuses believe in string theory') arguments, backed up with serious-sounding assertions that nobody has any other serious ideas.

This seems to be the reason why string is preventing the development of alternatives. Who can develop a theory to rival strings which will be taken seriously by anybody? Will an alternative need to be developed secretly for decades to accumulate as many results as string, before being published with an expensive fanfare of hype, press conferences, advertising, etc? How on earth can any conceivable alternative capture the limelight from a 10/11-d multiverse theory? Who will pay the slightest attention? Alternatives to rival string theory may require as much effort as has gone into string theory. How can that ever happen in the current high energy physics climate?

51. **Peter Shor**
May 30, 2007

It's possible that the LHC will find something interesting, and this will lead to the next 10 years of hiring in particle theory in physics departments being predominantly non-string theorists (unless the string theorists turn out to be the ones who explain what the LHC finds). This would greatly reduce the political power of string theory. However, I think this is only likely to happen if substantial new and different physics is required to explain the LHC results.

52. **Aaron Bergman**
May 30, 2007

However, I think this is only likely to happen if substantial new and different physics is required to explain the LHC results.

Have you looked at hiring patterns over the past few years?

53. **locrian**
May 31, 2007

What? Students are still flocking to string theory? Bummer for them.

Don't get me wrong, every grad student I know involved in it is having a blast. The thing is, every grad student I know trying to get a job afterwards is just freaking miserable. Saying that string theorists are still being hired by universities in substantial numbers (assuming we actually believe it) hides the fact that many of those universities are little better than high schools and many of the jobs are temporary – and don't even ask about the pay.

One soon-to-be-phd actually approached me the other day and told me flat out not to finish my degree in physics. I suppose the lesson here is: be careful studying string theory; it may be more than some public debate you lose.

54. **Chris Oakley**
May 31, 2007

> One soon-to-be-phd actually approached me the other day and told me flat out not to finish my degree in physics.

Bad advice. Finish your physics degree and then do something other than String Theory afterwards.

55. **Christine**
May 31, 2007

Peter Shor wrote:

unless the string theorists turn out to be the ones who explain what the LHC finds

Homework exercise: find a scenario that string theory *cannot* explain.

As far as I understand it, isn't it the main problem? Is it not the question that string theory is able to accommodate a huge plethora of solutions? So the only condition I see that would make string theory falsifiable would be in a situation were a physical phenomenon was found such that it *could not* be accommodated in string theory by any means.

Christine

56. **Peter Woit**
May 31, 2007

Aaron (and others),

I'd be interested to hear about it if anyone has any actual numbers about this they can point to, other than personal impressions that the job market for string theorists sucks (the job market for all theorists has sucked since 1970, one needs some numbers to see if there have been real changes in relative suckiness…).

My own impression from seeing who is getting hired is that, while leading string theorists are going around giving talks about how one should ignore the fact that current versions of string theory can't predict anything, because we don't know what string theory really is, if you actually work on the fundamentals of string theory, trying to make progress on figuring out what string theory "is", your job prospects are dim. On the other hand, if you work on "connecting string theory with real physics", doing things like "string phenomenology", then you have a better chance of getting a job, even though most people acknowledge that this kind of research is not likely to go anywhere.

57. **Aaron Bergman**
May 31, 2007

*Homework exercise: find a scenario that string theory *cannot* explain.*

As always, I fall back on my amazement that, given the inability of anyone to produce a single vacuum consistent with the real world, people immediately postulate that everything is permissible. But whatever.

For Peter: You can read the rumor mill just as well as I can. In fact, contrary to my expectations (and that of others I know), this year was surprisingly good for formal string theorists. By that, I mean four were hired to physics departments. In addition, there were three more positions (offered or hired) in math departments. Add to that 2 more, maybe, and you get the string theory jobs in this country and Canada. A rough count (I'm lazy) gives me at least twice times as many phenomenology/astro jobs as that.

58. **Peter Woit**
May 31, 2007

Aaron,

I did take a look at the latest rumor mill (hey, what's up with Frederik going to Harvard?) and I just lost all sympathy for string theorist's complaints about the job situation. By my count there are 32 research jobs offered, very roughly half to people who haven't worked on string theory at all, half to people whose research has some connection to string theory (often black holes), even if tangential. This is consistent with your count of formal string theorists.

This number of jobs is dramatically higher than it was a few years ago, both for string theorists and non-string theorists. I remember looking at these numbers carefully several years ago, and estimating 15-20 jobs/year, consistent with one I just picked at random (2000) and counted, giving 19 jobs.

So, looks like all the hullabaloo generated by my book and Lee Smolin's has caused a huge increase in hiring of both string theorist and non-string theorists (or maybe all the people hired 1960-70 are finally starting to retire or croak…).

Anyway, if you believe the Mill, it looks like the job situation for particle theorists, string and non-string, is better than it has been at any time for nearly forty years.

59. **locrian**
May 31, 2007

Aaron,

I don't understand. Is 9 positions really a good number? My university alone will produce 3 graduates by the end of the year. Peter was looking for numbers, so do you have an idea of how many string theory students are graduating and how that compares to the 9 positions that opened up in a good year?

60. **locrian**
May 31, 2007

Peter,

I am curious as to your source for your information. I'd love to compare other physics disciplines as well. To be honest, the job market still sounds pretty awful to me, regardless of how it compares to past years.

61. **Peter Woit**
May 31, 2007

locrian,

Yes, 9 positions is a good number. These are tenure-track positions at universities that support research, and such positions have always been very scarce in this field compared to the number of people getting Ph.Ds in it.

I looked very carefully at these numbers when I was doing research for my book about 5 years ago. The best estimate I could find was that there were about 80 students a year in the US getting particle theory Ph.Ds, with roughly ten of them ending up in a permanent position. This was based on the fact that the rumor mill was showing roughly 15 hirings into tenure track jobs/year, and an estimate that a third or so of those would not turn into permanent hirings (people would not get tenure or would move some place else).

So, the job situation in particle theory has been awful, and this has been true since 1970. It does appear though that the job situation may be moving from awful (10-15% of Ph.Ds getting permanent research jobs) to less awful (20-25% of Ph.Ds getting permanent research jobs). But, in any case, if you go into this field and get a Ph.D., you're still pretty sure to not be able to get a job working in it (and pretty much certain to not get one unless you're working on one of the hot topics in string theory or phenomenology).

62. **Aaron Bergman**
May 31, 2007

Where'd you get half and half? It looked around 2:1 to me.

9 is a good number compared to previous years. Objectively, most people who graduate in string theory won't get jobs.

63. **Chris Oakley**
May 31, 2007

Peter: yes, but that is not a reason to pass up the opportunity of doing a physics Ph.D. if one has the opportunity. There are employers outside academic research, and they, generally, are impressed by a Ph.D. in a hard science (although whether (e.g.) the anthropic landscape could be classified as such is debatable).
As for the increased hirings of String Theorists since the publication of "Not Even Wrong", I would attribute it to the aura of glamour that you have endowed the subject with by lambasting it publicly.

64. **Peter Woit**
May 31, 2007

aaron,

I'd characterize things as more like 1/3 string theory, 1/3 hard-core phenomenology, 1/3 less easy to characterize (often cosmology, black holes), but of this last 1/3 a significant number have at least one paper claiming to be related to string theory.

But, I don't think we disagree about the bottom line, the job situation for string theorists is better than ever (although that for phenomenolgists maybe even more so).

65. **Aaron Bergman**
May 31, 2007

I'd say that this year was a surprisingly good year, especially for formalists. Who knows what next year will be like?

66. **Chris W.**
May 31, 2007

As always, I fall back on my amazement that, given the inability of anyone to produce a single vacuum consistent with the real world, people immediately postulate that everything is permissible. But whatever.

Aaron,

Then tell the prominent theorists who have been acting like a Landscape containing vacua consistent with the real world (however few) is a foregone conclusion to put up or shut up. I'm getting pretty tired of your insistence that people like Leonard Susskind are unrepresentative of most string theorists, while the community of which he is evidently a part allows his viewpoint to gain so much traction. (One should recognize the efforts of David Gross to counteract this phenomenon.)

Let's restate the problem. Either:

(1) string theory leads inexorably to a landscape of solutions, none of which are consistent with observation or the success of the Standard Model, requiring the abandonment of string theory as a failed project (which is inherently nothing to be ashamed of);

(2) string theory leads to a landscape of solutions, some of which are consistent with observation and the success of the Standard Model, but offers nothing but shallow, after-the-fact empirical criteria for selection ("curve-fitting") of these solutions, leading to invocations of the Anthropic Principle;

(3) string theory leads to a landscape of solutions, and also incorporates *clear criteria* for ruling out all but a small family (an equivalence class?) of these solutions on *a priori* grounds, which thereby become testable, along with the underlying assumptions of string theory itself.

One possible source of the criteria for (3) would be a non-perturbative formulation, or at least some empirically fruitful insights into the required features of such a formulation.

For the record, (2) is logically possible, but is an abdication scientifically—a 21st century version of Ptolemaic astronomy. Physics could have resorted to such a resolution of its problems at any point in its history. On what basis should it become acceptable now? Skeptics of the significance of fundamental scientific discoveries have always invoked variations on the argument that alleged agreement of theories with observation is a fraud and a fabrication, an inscrutable accident of some practical use but telling us nothing about reality, or a kind of tautology, following inevitably from the structure of our minds and senses *or the structure of our theories*. The risk of vulnerability to these arguments is always present, as is the risk of outright refutation by observation for theories with genuine empirical import. If we choose to run the latter risk we can have no final guarantee of success.

[Thanks, Christine.]

67. **anon.**
May 31, 2007

I don't understand Peter's claims that comparable numbers of offers go to string theorists and phenomenologists. Let's look at the current rumor mill data. If we neglect job offers from math departments, there are only 6 string theorists with offers out of 32 total theorists with offers. If we count the ones from math departments, it's 10 out of 36: close to 1/3, but still substantially less. And the remainder is really dominated by phenomenology, not just 1/3: there are 22 offers to phenomenologists. Below I list the people with offers, categorized appropriately (all due apologies for filing people in boxes, but I want to counter the misperception that's being spread in this thread):

String theory (10 offers, 4 from math departments)
————–
Frederik Denef
Bogdan Florea (math dept)
Yang-Hui He (math dept)
Matthew Headrick
Chris Herzog
Liam McAllister
Michael Schulz
James Sparks (math dept)
Diana Vaman
Johannes Walcher (math dept)

Phenomenology (22 offers)
————–
Kev Abazajian
Kaustubh Agashe
Rouzbeh Allahverdi
Mu-Chun Chen
Antonio Delgado
Patrick Fox
Ayres Freitas
Michael Graesser
Yuval Grossman
Dan Hooper
Jamal Jalilian-Marian
Ryuichiro Kitano
Ian Low
Markus Luty
Alexander Penin
Tilman Plehn
Stefano Profumo
Yuri Shirman
Peter Skands
Philip Stevens
Tim Tait
Liantao Wang

Other (theoretical cosmology, mostly — 4 offers)
—————
Alfredo Lopez-Ortega
Alberto Nicolis
Dejan Stojkovic
Andrew Tolley

68. **woit**
May 31, 2007

anon,

You might consider actually reading what I write. I didn't write: "comparable numbers of offers go to string theorists and phenomenologists", I wrote

"1/3 string theory, 1/3 hard-core phenomenology, 1/3 less easy to characterize (often cosmology, black holes)"

Among your 26 "non-string theorists" are many whose work is not so easy to characterize, but is not what I would call "hard-core phenomenology". One example is Nicolis, who has been hired here at Columbia, whose recent work is in the "Swampland" program.

69. **anon.**
May 31, 2007

Notice I put Nicolis in the "other" category. I'm pretty sure that all 22 of the people I listed as phenomenologists are, in fact, phenomenologists, whether or not you think they are "hard-core." One could always further subdivide them as collider phenomenologists, astroparticle phenomenologists, model-builders, etc.…

70. **anon.**
May 31, 2007

Also, while Nicolis is not readily classifiable as either a string theorist or a phenomenologist, he is nonetheless a first-rate theorist and a good example of how the theory community doesn't exclude people with good, non-mainstream ideas.

71. **Aaron Bergman**
May 31, 2007

Chris W. —

String theorists fight about this stuff *all the time*, often quite vociferously.

72. **woit**
May 31, 2007

anon.

My definition of "hard-core phenomenologist" was more or less someone who interacts with experimentalists and computes numbers they care about.

I don't know Nicolis at all, but characterizing as non-mainstream someone who has been part of the Harvard theory group, one of Arkani-Hamed's main collaborators, and working on the "swampland" program that has been heavily promoted by leading string theorists seems to me rather bizarre.

The only reason I chose him as an example was that I started going down the list at the Rumor Mill and he was the first clear case of what I meant by a non hard-core phenomenologist who has done work related to string theory. So, he was an example purely because "C" for "Columbia" comes early in the alphabet. One could waste a lot of time going through the rest of the alphabet…

73. **dan**
May 31, 2007

Chris,
I agree with your scenario 1-3. How do we decide which of these are most reasonable and when?

Let's say the MSSM is true. Well LHC results are not yet online, and the MSSM is just as unpredictive as string scenario 2.

It might look like scenario 1 to Peter now, NEW, but maybe after another 50 years of intense sustained research, with LHC results and bootstrapping from that, 2 or 3 actually holds.

Of course it's possible string theory it's actually 1, and it is starving off alternative research directions which is what Lee says is the Trouble with Physics.

My own opinion: if LHC doesn't find SUSY-partners, or its results cannot be accounted for or embedded in, a string theory scenario, I hope the HEP community pursues alternative research directions.

2 alternative post-SM post-string HEP research directions I'd like to see investigated is Smolin's preon braiding, and condensed-matter analogues such as Volvovik's fermionic points.

Dan

74. **JC**
May 31, 2007

Sometimes a "negative" result can be just as interesting, such as if the LHC doesn't find anything at all. (ie. No Higgs particle and nothing else).

75. **Dipankar Ray**
May 31, 2007

"Coin,

While string theory has contributed to mathematics in various ways, as I wrote, I do think that saying it has provided numerous deep mathematical insights is an exaggeration."

Let me quote from Faddeev/Atiyah's description of Witten's work, in the Proceedings of the ICM
(you can see the text here: http://www.icm2002.org.cn/general/prize/medal/1990/Witten/page1.htm):

"…Although he is definitely a physicist (as his list of publications clearly shows) his command of mathematics is rivalled by few mathematicians, and his ability to interpret physical ideas in mathematical form is quite unique. Time and again he has surprised the mathematical community by a brilliant application of physical insight leading to new and deep mathematical theorems."

The citation goes on to detail Witten's insights into Morse Theory, the Index Theorem, Rigidity Theorems, and Knot theory. Essentially, by 1990 Witten had re-invented all of that century's work in geometry, using his string-theory heuristics.

By the way, this was back in 1990, so it doesn't count his later work on Sieberg-Witten, or the recent stuff on Geometric Langlands; forget his and other people's (Candelas, etc) work on Mirror Symmetry, which has completely blown open Moduli of Curves, and deeply influenced the work of Kontsevich and Okuonkov, to name just two Fields Medalists who've benefited from string theory…

Just to give one personal example: in 1990, I don't think anyone expected that there would be a connection between Weyl's asymptotic formula and Mumford's conjectures on the Moduli of Curves; the glue of this particular connection turns out to be Witten's conjecture, and the various proofs by Kontsevich, Pandharipande/Okounkov, and Mirzakhani. That one conjecture has also inspired great work in combinatorics, in representation theory, etc.

As you say, you yourself have written about some of this. Can you explain to me what your criterion for "numerous deep mathematical insights" is, as this certainly qualifies in my book…

76. **woit**
May 31, 2007

Dipankar,

Your Atiyah/Faddeev quote does not mention string theory, precisely because the work that Witten got the Fields medal for has nothing to do with string theory. To say "Essentially, by 1990 Witten had re-invented all of that century's work in geometry, using his string-theory heuristics." is non-sense, I don't believe that's what Atiyah or Faddeev actually wrote. In particular, the work on morse theory, supersymmetry and the index theorem predates Witten's interest in string theory and has absolutely nothing to do with it.

If you're interested in where Witten's work came from, you might want to try reading my book, which has a chapter on the subject.

77. **Chris W.**
May 31, 2007

Aaron,

That's good to hear…

78. **Dipankar Ray**
May 31, 2007

"Essentially, by 1990 Witten had…" was from me, not Atiyah. I almost didn't put it there, since I could guess what the response would be. And indeed, I made a mistake: I should have said "Essentially by 1995…," and perhaps I should have ended with the canonical locution "using his path-integral oracle".

Had I done that, then I could have made the following list of results:
– Morse theory
– Atiyah-Singer Index theorem
– Donaldson Theory
– (you get the point)

These are (I think you'll agree) several of the handful of crowning accomplishments of 20th century geometry. And I'll note that this is why Witten, at the AMS Alg Geo conference at Santa Cruz in 1995, made the (very compelling to everyone I knew who was there) argument that, in the future, QFT would be a field of mathematics alongside of algebra and analysis, and would probably subsume differential geometry, algebraic topology, and even parts of alg geo).

Certainly, this does _not_ mean that he re-invented algebraic topology, hodge theory, etc, in terms of the basic definitions. But he definitely re-cast our understanding of such things, in much the same way that Grothendieck re-cast our understanding of algebraic geometry. Atiyah and Bott have both written about how Witten completely re-organized the way that _they_ think about Morse theory, about their own work on Yang-Mills, etc. Similarly, Witten's results on Atiyah-Singer and Donaldson theory weren't just new proofs, they were fundamentally new ways of thinking about these problems, very much "deep insights". A flurry of work and consolidation and connections followed, in each case (as I'm sure your colleague John Morgan would agree).

You distinguish between this work of Witten's and "Witten's interest in string theory". I find this disingenuous, though perhaps it is exactly this point that distinguishes our world-views.

Green Schwarz and Witten is copyrighted 1987. That tells me that Witten was pretty busy thinking about String theory precisely when he made his great original math discoveries. And certainly the Seiberg-Witten work and the Geometric Langlands work is from his "string theory" era, if we are to try and force "periods" onto his career?

But I think this is a key point: I believe that String theorists are by and large engaged in a basic, long-overdue, formal, fundamental study of QFTs. QFTs are where the problem started, since they showed (1) the incredible power of perturbative methods, (2) the lack of mathematical rigor in the methods, and (3) underscored the depth of the problem Einstein had wasted the last ~30 years of his life pursuing (Feynman-Schwinger-Tomonaga showed us how successful QFT was, and thus how crazy it was to think that the problem of unification was a tractable problem in 1920).

The Jaffe-Quinn school was one approach, but it got bogged down. String theory has become the de facto place where a basic study of QFTs is taking place (and why not, since if you're a budding grad student hoping to learn QFT, you probably want to turn to your phenomenologists and your string theorists, since they're the experts on QFT in your department, no?).

The actual sociological problem might be this: Einstein was lucky; Gauss and Riemann had already discovered the necessary math for him, so he didn't have to invent it for GR. Unfortunately "mathematicians" like you and me are blogging when we should be proving hard math theorems; as an indirect result, physicists studying QFTs are having to invent the mathematics for themselves. One can easily imagine that Einstein and a handful of grad students would have taken >20 years to invent Riemannian Geometry; well, it's taking us >50 years to invent the necessary math for QFT. So it goes.

Because of this world-view of mine (shared by many, I think), separating the results that Witten obtained by studying QFTs from his work in string theory – well, this is very weird to me, since it was surely his interests in string theory that had him write his papers on TQFTs, etc.

79. **woit**
May 31, 2007

Dipankar,

I really suggest that you learn some of the history of this subject, you might find it enlightening. Just one example: Witten's work on Morse theory and supersymmetry (which is the foundation of his work on TQFT) dates from 1980, his interest in string theory began around 1983, with his first paper on the subject in 1984.

The "path-integral" is not "string theory". These are two very different things. QFT is not string theory either. You're welcome to your view that I am "disingenuous" or "weird" for pointing out that many of Witten's most important ideas come from another source than string theory, but this happens to be a fact. The interaction between different ideas about physics and mathematics is a complicated and extremely interesting subject, I'd suggest you try learning something more about it than that everything is due to "string theory".

80. **Dipankar Ray**
May 31, 2007

Your reply seems to prove my point: you distinguish between supersymmetry and string theory here, while I believe elsewhere the lack of experimental evidence for supersymmetry is an oft-repeated example of one of the failures of string theory (perhaps not by you? my problem here is undoubtedly that I've arrived late to a debate where all the principal players are already nursing wounds from attacks from all sides).

Certainly, when Zumino said (in the 70s) that supersymmetry implied SU(n) holonomy, that wasn't string theory either. And yet SU(n) holonomy and the exchange of supersymmetries are exactly the key features of Mirror Symmetry.

In ’81, Witten was writing about Kaluza-Klein theories, and the “Supersymmetry and Morse Theory” paper wasn’t published until 1982 (of course I don’t doubt you that it was written earlier – this is before my time). In general, most of these geometry results come from duality of one kind or another.

Your point is that I should read more and learn to distinguish between supersymmetry and string theory, whereas my point is quite clearly that I think these are false distinctions that ignore the fundamental point: in reality we’re paying people to study QFTs.

Couldn’t I use your same arguments to say that string theorists themselves are in a different field today than they were 20 years ago? The string theorests of today are basically studying a completely different subject (geometric langlands? category theory?) from the string theory of 20 years ago.

The commonality between string theory then and now? Some mix of supersymmetry, kaluza-klein, and the basic (distinguishing) notion that the fundamental objects of the universe are strings.

You seem to be saying that only the last element is string theory. I’m saying that all of it is QFT (my version of “can’t we all just get along?”)

I commented on this thread, because it seemed to me that you were saying that this interaction between math and physics hasn’t provided deep insights for mathematics, which sounded like bad advice for a beginning grad student. Now I see you’re drawing a particular distinction (one which I don’t agree with, and not because I’m so ignorant of the literature/history, as you suggest; rather my interpretation is fundamentally different).

If I were a beginning grad student in math, I might easily conclude from your comments that reading Witten’s papers wasn’t fruitful. That sounded really bad to me; in fact, Kontsevich’s ’94 ICM talk tells me that, if you’re interested in math, you might do very well indeed to think hard about physics in general, and string theory in particular.

With that, I should withdraw.

81. **Dipankar Ray**
May 31, 2007

…woops, memory failing me, I think Zumino only showed U(n) holonomy…

82. **woit**
May 31, 2007

Dipankar,

“you distinguish between supersymmetry and string theory here”

“If I were a beginning grad student in math, I might easily conclude from your comments that reading Witten’s papers wasn’t fruitful.”

This is just completely ridiculous. Supersymmetry and string theory are two different things, and I’ve written voluminously about both of them and about the importance of Witten’s work, on this blog and in multiple chapters of my book. In all of these places I’ve made it very clear that I have the highest opinion of Witten’s work, that the experience of reading some of his papers has been among the greatest intellectual experiences of my life. But, you know, he’s written more than 300 papers, despite what you think they’re not all about string theory, and, surprisingly enough, some are more interesting than others.

83. **Dipankar Ray**
May 31, 2007

I came to your website because a friend pointed me to your informative post about the abc conjecture. Because I liked to that post, I went to the previous post, and then read about how you thought Sean Carroll was mildly exaggerating string theory’s influence on math, followed by comments that were fairly condescending towards Polchinski, both of whom I have a lot of respect for. This surprised me – especially the comment about string theory’s influence. So I read the comments, to see if anyone else questioned this statement. Someone did, and your comment reinforced the point that string theory was no big deal to mathematicians.

So I didn’t read your voluminous writings about how great Witten is. I reasonably conclude that others might first encounter your website the way I did, and draw the conclusions about your opinions that I did. Hence my post.

My mistake to post in the first place – I didn’t know what I was up against. You clearly have long ago formulated very strong opinions on all of this, and seem to be very ready to jump down my throat when I question the validity or (more importantly) _usefulness_ of the distinctions that you’ve drawn.

You’ve clearly rejected my umbrella metaphor, that physicists are drawing false distinctions between what they do, when all they’re trying to do is understand QFT. I don’t see any point to string theory, or supersymmetry, or Kaluza-Klein theories outside of understanding QFT, and so hence it’s all QFT to me.

Fine, you reject this. But you still don’t address my other points: that Witten was _thinking_ about string theory, and hence using string theory heuristics to guide his work on moduli of curves, on seiberg-witten, on geometric langlands. that in itself is interesting and deep.

Second, that mathematicians studying QFT in general and (yes) string theory in particular (or at least conjectures that grew out of string theory) resulted in deep work not only in mirror symmetry, but in fundamental algebraic geometry (Mumford’s conjecture, which was proven by Madsen and Weiss largely because of the renewed interest around moduli of curves sparked by Kontsevich’s proof of the Witten conjecture), in combinatorics (Ravi Vakil’s article in the Notices gives a nice presentation of that work), and in representation theory.

There are more examples, obviously (Givental’s work is of course important, and there are a number of conjectures in that area that have fallen recently, and I think we’ll find that Okounkov’s work will soon combine with Werner/Schramm’s work to show the power of stochastic methods in general; certainly Okounkov is influenced by string theory). Renewed interest in old topics, new problems solved – all of this is at least in part due to mirror symmetry. I wouldn’t be surprised if the geometric langlands thing led to similar revolutions throughout math.

anyways…

Very harsh language in addressing me. Did I do/say something to deserve condescension like “Despite what you think they’re not all about string theory”? I apologize about the mistake I made about a Zumino paper from the 70s, but perhaps you could cut me a little slack on a comment on a blog, and consider that I’m not a complete idiot? I don’t think it requires stupidity and/or ignorance to disagree with you on the precise borders between gauge theory, supersymmetry, QFT, TQFT, and string theory. While clearly these are separate topics, they are interconnected in everyone’s head. It’s like saying that the fundamental theorem of algebra is only a theorem in analysis, cause there’s no algebra involved in the proof (unless you do the Galois theory proof, or somesuch…) – technically true but misses the point a little, I’d say.

Actually, forget what I'd say. Your views are also not representative of either the physics or the math communities, and your admonishment/directive for me to read your book are not convincing me that these communities have a reason to change their behaviours, nor does your condescending tone elicit in me an overwhelming compulsion to buy your book.

84. **Peter Woit**
May 31, 2007

Dipankar,

You're the one who came here, started posting highly misleading comments that showed you don't know what you're talking about (no, path integrals, supersymmetry and string theory are not all the same thing), and started insulting me as being "disingenuous" and "weird". Given that behavior, I've actually tried to respond as politely as I can manage, giving you some factual information you might consider before going on in the way you do about Witten, TQFT and string theory. If you read more than a couple postings on this blog, you might find, in addition to a point of view that challenges your prejudices, some accurate information of interest.

85. **amused**
June 1, 2007

Re. the discussion of jobs to string/brane theorists vs others, one curious aspect revealed by the rumor mill page is that the string/braners are generally being hired sooner after their PhD, and with fewer papers. Now why might that be?…
I guess their brilliance must just be so abundantly clear that there is no need for them to prove themselves over longer periods, in contrast to the non-string plodders.

86. **Aaron Bergman**
June 1, 2007

Care to cite evidence that string theorists are being hired younger than non string theorists?

87. **amused**
June 1, 2007

It was a pain, but here's some data: it's the people listed as having recieved job offers at research uni's on the current U.S. rumor mill page as of this moment. I've ordered it according to the year they got their PhD's, and in the format "Person – N – topic(s)" where N is their current number of publications according to Spires. The people in each PhD year are listed in order of increasing N. Simple data analysis follows below.
— — — — — — — — —
2006:
McAllister 12 string cosmo

2004:
Tolley 13 stringy cosmo
Profumo 38 astro, susy pheno
Skands 39 susy pheno

2003:
Headrick 16 string
Hooper 78 astro

2002:
Nicolis 16 cosmo (recently stringy)
Sparks 17 string
Fox 17 branes, some susy pheno
Florea 20 string
Delgado 25 brane models
Chen 34 pheno (beyond SM)
Herzog 35 string
Kitano 37 susy pheno
He: 55 string
Freitas 61 susy pheno

2001:
Low 27 pheno (branes & trad)
Stojkovic 29 cosmo (non-string)
Walcher 30 string
Vaman 33 string
Abazajian 37 astro

2000:
Allahverdi 42 cosmo (susy & stringy)

1999:
Denef 27 string
Graesser 31 susy pheno, some branes and astro
Penin 55 pheno (trad)
Tait 56 pheno (trad & branes)

1998:
Agashe 44 pheno (beyond SM, branes)
Plehn 70 susy pheno (brane-free)

1997:
Shirman 29 susy pheno, branes
Jalilian-Marian 58 pheno (trad)

1996 & earlier:
Luty 68 susy pheno, cosmo, a bit of branes

Grossman 90 pheno (mostly trad)

Excluded from data:
Wang (since he already got a job last year)
———————

Average PhD year for string theorists (including stringy cosmology): 2002

Average PhD year of those for whom strings and /or branes is a major component of their research: 2001

Average PhD year of those for whom strings/branse is not a major research component: 2000

That's a less pronounced difference than I had expected, but it's still definitely there. Also, there is a clearly discernable tendency for string/brane theorists to have fewer paper than other job recipients in the same PhD year, although there is admittedly a fair bit of fluctuation in that.

88. **anon.**
June 1, 2007

amused: your counting is also a little skewed because several of the phenomenologists are moving from one faculty job to another (Grossman, Luty, …)

89. **Coin**
June 1, 2007

Care to cite evidence that string theorists are being hired younger than non string theorists?

And if it is true, does it mean "string theorists are more likely to be hired" or "string theorists are more likely to be young"?

90. **LDM**
June 1, 2007

"I guess their brilliance must just be so abundantly clear"

Maybe somebody can explain this to me, because I just don't understand. How is it even possible to be brilliant in a subject like string theory as there are no experiments (and likely never will be) to validate or invalidate your work…The "Not even wrong" logic would to me imply, also, "Not even brilliant", since physical correctness of ones work is a *requirement* of ones work also being brilliant. Or have I missed something here?

Therefore, I conclude any hiring of string theorists cannot be based on brilliance, at least not in string theory, no matter how much they might wish to think otherwise…

91. **ok**
June 2, 2007

I have a dumb question:
Why can't String Theory be thought of as a 2-d QFT(CFT)? I mean, what makes ST to be different from just a particular 2-d CFT?

92. **woit**
June 2, 2007

ok,

A CFT is defined on a fixed Riemann surface with conformal structure. To get perturbative string theory, you need to integrate over all Riemann surfaces (i.e., sum over the genus, and integrate over the moduli space for each genus. This introduces a new parameter, the string coupling.

And this (divergent) series is supposed to be an asympotic series for the true string theory, whatever that is. You're supposed to be including branes, M-theory, etc….

93. **amused**
June 2, 2007

anon.: Ok, I wasn't aware of that, but I suspect it also applies to string theorist Denef. It surprises me that the rumor page doesn't list these people under `faculty shuffle'.

LDM: In fairness to string theorists I think there is a reasonable formal theory sense in which ST work can be "brilliant" despite the lack of connection to experiment. The ads/cft correspondence and dualities between various theories are examples (at least in my book). Whether brilliant string work is overhyped and oversold compared to brilliant work on non-string topics is a completely different question…

94. **LDM**
June 3, 2007

Amused,

The whole point is to get a number. When I was in grad school, I knew a very bright Chinese student who had devised a formulation of QFT in terms of measure theory, which he thought was significant because he viewed the concept of a measure space somehow more "fundamental". But unfortunately, he could not get any new predictions with his new theory.
Similarly, who cares about Maldacena's Ads/Cft, if it does not ultimately get related to an *experimental* number?
An example of a duality which I would currently consider superior to Ads/Cft, from the point of view of physics, would be the Legendre transformation. This is an example of a duality which actually does produce measurable numbers, in both classical mechanics and thermodynamics.

95. **Urs Schreiber**
June 3, 2007

> A CFT is defined on a fixed Riemann surface with conformal structure.

Usually, a 2-dimensional CFT is defined on all Riemann surfaces. (Except, possibly, in some older statistical mechanics literature.)

In a quite precise way, a CFT is a functional that reads in "Riemann surfaces with marked points" and spits out numbers (the "correlators").

The basic idea of perturbative string theory is that one defines a theory on some "target space" by looking at a sum of values of a fixed 2-dimensional CFT evaluated over all Riemann surfaces.

The choice of the fixed CFT here is the choice of "target space background".

This idea is supposed to be the direct generalization of how perturbative quantum field theory works: there we sum the correlators of 1-dimensional QFT (known as "relativistioc quantum mechanics") over all 1-dimensional graphs of sorts.

Instead of pairing 1-dimensional QFTs with graphs, as perturbative quantum field theory on target space does, perturbative string theory pairs 2-dimensional QFTs with surfaces (to be thought of as "smeared graphs").

96. **Peter Orland**
June 3, 2007

Urs,

Of course, you are right: it is the modern terminology to define
a CFT as something on any given Riemann surface. But it is not
an especially physical viewpoint, at least not for some situations. Should we define any quantum field theory on all manifolds of a given dimension? Why stop there, and not consider all dimensions? Just as with CFT, one could regard any QFT as a functional giving correlators from the manifold.

I think the utility of such a definition depends on the problem
being studied.

97. **ok**
June 3, 2007

Thanks everyone for the clarification.

98. **amused**
June 4, 2007

LDM,
Studying the structures of QFT's (of point particles, strings,…) with the aim of getting deeper insights into them, finding relationships between them etc is a valid activity in its own right, even if it doesn't lead directly to numbers that can be compared to experiment. It is intrinsically interesting (in the same way that pure math is interesting), and the ideas generated and lessons learnt may later turn out to be very important for "real physics". (Yang-Mills theory was an example.) Actually there is quite a bit this kind of activity going on in particle theory these days, ST is far from the only case. For example there is the "fuzzy physics" approach to QFT's, and a few years back there was quite a bit of "quantum groups" activity with luminaries like Faddeev being involved. I don't think any of that was likely to directly lead to new numbers to compare to experiments. The point was to generate new theoretical insights. The complaint that ST doesn't produce new (or any!) numbers applies just as well to those other activities. The reason no one complained about them though was that they never became so dominant in formal particle theory to the extent that people who chose not to work on them were putting themselves at a disadvantage careerwise.

99. **urs**
June 4, 2007

> it is the modern terminology to define
> a CFT as something on any given Riemann surface. But it is not an especially physical viewpoint, at least not for some situations. Should we define any quantum field theory on all manifolds of a given dimension?

Yes, indeed, we should!

That's one way to make precise what an n-dimensional quantum field theory is: it is a functor

nCob –> Hilb

namely a rule which reads in n-dimensional manifolds with boundary, assigns Hilbert spaces to the boundary components (the "spaces of states") and assigns linear maps between these to the manifolds themselves: this is the quantum propagator

U(t)=exp(it H)

in simple cases, or, more generally, the path integral for the given states on the boundaries.

If this sounds obscure and "remote from physics", notice that this is, read the other way around, nothing but a clean formalization of what the "path integral" defining the QFT should really be.

Ever wondered how physicist manage to start their papers by writing down an ill-defined expression called the path integral and then nevertheless extracting lots of interesting results at the end of their paper?

There is a simple reason behind this: while the definition of the path integral as an integral mostly makes no sense at all, it often happens that this definition is in fact never used at all! Instead, what is being used are a list of properties that the path integral supposedly satisfies.

The most important of these is "sewing": this says that evaluating the path integral for a process from A to C is the same as doing it from A to B and from B to C and "summing over all intermediate states".

It is common practice in math to isolate those properties of the objects under considerations which are actually used in the constructions, theorems and proofs.

Here, it is essentially the sewing law (and also the unitary condition). The technical term for something satisfying such a law is a "functor".

So, we notice that whatever the path integral actually is, it is at least required to be a functor that reads in cobordisms and spits out morphisms of Hilbert spaces (or numbers, "correlators" if the manifolds fed in have no boundary.)

Once we are at this point, we do the obvious and declare that every such functor qualifies as a "path integral", hence as defining a quantum field theory.

So an n-dimensional quantum field theory is — by definition — a functor from n-dimensional cobordisms to Hilbert spaces.

For a discussion of this geared towards physicists, check out some notes by Kevin Walker.

> Just as with CFT, one could regard any QFT as a functional giving correlators from the manifold.

And indeed, one does!

The slogan is this:

Quantum field theory is the study of representations of cobordism categories.

But it's tough working out in detail what these functors are like, obviously. Most of the progress has been made, of course, for the simplest cases: topological field theory in 0,1,2,3 dimensions and conformal field theory in 0,1,2 dimensions.

With the advent of Khovanov homology, people are now with more intensity attacking 4-dimensional topological QFTs in this precise sense, see the recent Conference on Link Homology and Categorification in Kyoto and especially Gukov's talk Gauge Theory and Categorification

> I think the utility of such a definition depends on the problem being studied.

Certainly. Especially, if the problem is "understanding what's going on" and "organizing one's concepts" this is very useful.

100. **Peter Woit**
June 4, 2007

'So an n-dimensional quantum field theory is — by definition — a functor from n-dimensional cobordisms to Hilbert spaces."

This is a starting point for TQFT, not for QFT in general.

101. **Peter Orland**
June 4, 2007

Urs,

It is not true that path integrals are not well-defined, except after the
fact. This is a comon misconception. In regularized QFT's, there is absolutely no problem with the path integral. They are often studied numerically (that's what lattice Monte Carlo people do) and, in some cases, even evaluated analytically!

As I said, defining field theories on arbitrary manifolds depends on
the problem under scrutiny. Standard analytic methods,
1. perturbation theory, 2. strong-coupling methods, 3. semiclassical approximations, 4. exact S-matrices and form factors, 5. the Bethe Ansatz, and 6. conformal FT methods using the trace anomaly, all of which have applicability in at least some field theories do not require any but flat manifolds.

102. **Aaron Bergman**
June 4, 2007

This is a starting point for TQFT, not for QFT in general.

TQFT is a particularly simple example of this sort of axiomatization, but it is not hard to extend to QFT in general. Just choose add more and more structure to the objects in your cobordism category. (I'm beginning to become somewhat skeptical of this particular axiomatization beyond the 1-categorical structure, but that's just me.)

In regularized QFT's, there is absolutely no problem with the path integral.

That's true, but I think it can be quite hard to regularize a QFT (nonpertubatively!). Even then, to really talk about the full QFT, one needs to prove the existence of the continuum limit (presumably varying the couplings as you decrease the lattice spacing.) This is, needless to say, rather hard.

103. **Peter Orland**
June 4, 2007

Aaron,

I am not sure to what extent we disagree on this matter (perhaps not
at all).

As I tried to explain above, path integrals can in some cases be
evaluated analytically. No one who works with them seriously
questions their utility. Proving the existence of the continuum limit
is always the issue, but, generally speaking, path integrals have a better track record on this than other methods do. A stunningly
better track record!

For example, mathematical physicists (Nelson, Glimm, Jaffee, Simon, Frohlich, Aizenmann, Balaban) getting nowhere with the Wightman axioms had some real success after switching to Euclidean path-integral methods in the 70's. Furthermore, semiclassical methods
(DHN techniques in 1+1, confinement in compact QED) are best
understood with the path integral.

Sometimes other methods work better for specific cases
(integrable QFT's in 1+1 for example) , but for all-around utility
the path integral has no serious rivals.

104. **Aaron Bergman**
June 4, 2007

I'm all for path integrals. There are, I'm led to believe, some reasonably tought no-go theorems about the nonexistence of interesting measures on spaces of functions, however, so it remains a very interesting question as to what exactly a path integral is. I sometimes can't help but feel that the lack of a proper definition after all these years might mean that we're missing something important. But, then, the success of lattice gauge theories certainly speaks against that.

In some sense the axiomatizations of Atiyah and Segal and co. are an attempt to do an endrun around the lack of a proper definition of the continuum path integral. What it is an attempt to capture, I think, is the local nature of the path integral, that it must obey gluing and the existence of states in a Hilbert space to express that gluing. The structures expressed in these axioms clearly are present, but I doubt capture the whole story. One possible extension is the idea of a hierarchy of n-categorical structure, but the lack of a proper definition of the objects involved makes it tough to figure out how to go from usual physics to these rather abstract notions.

(To quote Dan Freed: "I define a mathematician's category number to be the largest n such that he/she can think about n-categories without getting a migraine.")

105. **Kea**
June 4, 2007

"I define a mathematician's category number to be the largest n such that he/she can think about n-categories without getting a migraine."

LOL! Cute. Guess for physicists we can reduce n to, say, n – 3.

106. **Peter Orland**
June 4, 2007

Aaron,

Forget all the no-go theorems (or rather, take them with a grain of salt).
Lattice path integrals are rigorously defined. The mathematicians who
have problems with them are geometers, not analysts, and the real
basis of path integrals is analysis, not geometry. The only issue is how to renormalize the answer. If there is a critical point in the space of couplings, there is a continuum limit (and then one has to address issues
of triviality).

107. **Aaron Bergman**
June 4, 2007

I'm not sure we're arguing, although I'm under the impression that there are still issues with chiral fermions and global symmetries. I'd just really, really like to see a proof of the existence of the continuum limit in an interesting QFT — the triviality issues, as I understand them, generally reflect the existence of a Landau pole, right? I'm not sure it's fair to say that its only the geometers that have problems — no-go theorems in measure theory count as analysis in my book, and analysts like to prove things just as much as any mathematician.

108. **Peter Orland**
June 4, 2007

Aaron,

I repeat that path integrals are healthy, and the best way to
look at quantum field theory in most cases.

There are of course subtleties, but the issues you are raising
are not fundamental difficulties with the path integral. There
are problems with putting the standard model on a lattice,
for example, but the origin of these is related to the
Nielsen-Ninomya theorem, which is also a problem in any regularization. Luescher may have solved this problem.

The Landau pole only suggests triviality of some QFT's. It's
less meaningful than generally believed. There are better
arguments for triviality (Ginzburg's criterion, epsilon
expansions, 1/n expansions, polymer methods) for
scalar field theories.

There are no measure-theoretic no-go theorems, at least none
which are meaningful. Look at constructive field theory for
example (I listed a bunch of names earlier). The
measure-theoretic issues for Euclidean path integrals
were first addressed by Mark Kac a long time ago. Edward
Nelson also worked on the foundations of this subject.
Take a look at Simon's book on Functional Integrals.

109. **Aaron Bergman**
June 4, 2007

Look, I agree that path integrals are the way to go, but if there were no difficulties, there would be existence proofs for interesting QFTs in four dimensions. There aren't. I'd love to believe this is just a result of the technical complexities of the limit, but until someone actual proves something who knows?

110. **Peter Orland**
June 4, 2007

Aaron,

Yes, of course there aren't existence proofs of four-dimensional theories (though there are existence proofs of two and three dimensional theories).

Anyway, I don't think rigorous existence proofs are the first step towards understanding the continuum limit (I say this as someone
who has spent some time trying to see how rigorous methods in
lattice field theory work). What we want is a good way to calculate physical quantities in that limit, using some sort of controlled approximation scheme. This is where perturbation theory fails for theories like QCD. If that can first be done, and it is a big if, then
we can worry about cleaning up the arguments mathematically.

111. **Aaron Bergman**
June 5, 2007

I'd like both thank you very much. I can say that because I'm not actually working on the subject :).

112. **Thomas Larsson**
June 5, 2007

"This is a starting point for TQFT, not for QFT in general."

TQFT is a particularly simple example of this sort of axiomatization, but it is not hard to extend to QFT in general. Just choose add more and more structure to the objects in your cobordism category.

Is this so? My impression, admittedly based on what I saw 15 years ago, is that the point with topological theories is that they are locally trivial – there are no local dofs. With only finitely many global dofs, it is hardly surprising if you don't encounter the really difficult problems of QFT, which have to do with infinitely many local dofs.

113. **Peter Orland**
June 5, 2007

Thomas,

Actually there is a sense in which some topological field theories are nontrivial. As I understand it, their correlators are purely topological, but they do have nontrivial degrees of freedom. The original models of Floer and of Witten (not Chern-Simons) are examples.

114. **urs**
June 5, 2007

The functorial definition of QFT is not restricted to topological theories. Put any structure S you like (conformal, Riemannian, etc) on your cobordisms, and you'll get a corresponding S QFT (conformal, etc).

TQFTs are just the best understood cases. But 2-d CFT is now also pretty well understood. Full rational 2-d CFT is pretty much completely understood this way. And, actually, only this way. (See this for more.)

And, as I said, this is nothing but making sense of the concept of a path integral. If you happen to have a path integral which already makes sense by itself, all the better. Then you have a way to construct such a functor using functional integrals. But if your path integral happens to be ill-defined, you might still be able to construct your functor otherwise.

At our workshop taking place currently the main focus is on understanding functorial Riemannian 2-d QFT.

(That's because Stephan Stolz and Peter Teichner noticed recently that to get elliptic cohomology over points (knows as modular forms) from the landscape of 2-dimensional QFTs, one doesn't necessarily need to restrict attention to superconformal ones. Supersymmetry alone implies that the torus partition function is a modular form (see this preprint for more).

115. **urs**
June 5, 2007

> In regularized QFT's, there is absolutely no problem with the path integral.

In most QFT cases which are physically interesting, there is absolutely no clue what the measure on the space of fields should be which we would like to integrate over.

116. **urs**
June 5, 2007

> I'm beginning to become somewhat skeptical of this particular axiomatization beyond the 1-categorical structure,

We hadn't really mentioned extended QFT yet.

But it is true, that the idea is that in the end n-dimensional QFT is really an n-functor on extended n-cobordisms instead of just a 1-functor on n-cobordisms.

This, too, though, is closely related to the path integral: namely to evaluating the path integral with certain boundary data kept fixed. The idea goes back to Dan Freed, at least, who does present it in path integral language in his papers from the beginning of the 90s (see the references given here.)

Hopkins and Freed are proposing, at least in talks, refinements of this idea to infinity-functors. As mentioned here.

117. **Peter Orland**
June 5, 2007

"In most QFT cases which are physically interesting, there is absolutely no clue what the measure on the space of fields should be which we would like to integrate over."

False.

118. **Peter Orland**
June 5, 2007

Urs,

I don't want to be a churl, but I am a bit sensitive about this issue, since I have worked on it for most of my career, and often hear statements such as yours. So let me just mention that I gave examples above where the measure is perfectly fine. The problem with the field theories we'd like to understand better is not in defining the path integral (which can be regularized), but in removing the cut-off.

119. **Aaron Bergman**
June 5, 2007

With respect, Peter, that's like saying that taking the limit isn't important in the Riemann integral. The whole point of defining the path integral rigorously is to remove the cutoff.

120. **Peter Woit**
June 5, 2007

Aaron,

I don't see where Peter is saying that taking the limit isn't important. But there are physically interesting theories (e.g. Yang-Mills) where conjecturally we think we know how to take the limit, and there is a huge amount of numerical evidence to back up this conjecture.

121. **Peter Orland**
June 5, 2007

Just to add to what Peter W. said:

There are examples above where the limit CAN be taken. In particle scalar field theories in 3 Euclidean dimensions. One can also prove that the 5 dimensional case has no interacting limit (and argue the same in 4d, though not yet rigorously).

Since no one has solved QCD, we don't yet know what the limit is, and it has not proved to be an interacting theory. Nobody who works on this problem doubts that the limit exists, however. Formal renormalizability on the lattice (just perturbation theory with a lattice cut-off) certainly indicates that the limit exists, though it is not a proof. In any case, if you are theoretical physicist, you want a calculational scheme more than a formal proof.

I have some experience with this sort of problem, so I think I have some feeling for what doesn't work (which is most of what people have tried). Perhaps the formal ideas Urs is discussing are mathematically interesting, but they do not shed light on the real problems of four-dimensional theories.

122. **Aaron Bergman**
June 6, 2007

If you believe Borcherds's notes on QFT, there does not exist a Lebesgue measure on the relevant spaces, so assuming that such a limit exists, I'd like to understand precisely what this is.

The reason why this would be useful is that there are field theories that don't admit nice Lagrangian descriptions. It seems reasonable to me that there are plenty of "measures" that aren't simply exponentials of integrals of functions involving the fields and their derivatives. I'd like to know what they are.

123. **Peter Orland**
June 6, 2007

Aaron,

I don't seem to able to get my view through to you or Urs. That may have to do with the choice of problems we work on. Unlike the two of you, I actually work on non-perturbative aspects of gauge theories an other field theories, and have for some time. That's why I have been very insistent that much of the issues you raise are not the right issues.

I am aware that there are field theories which do not (at least yet) have Lagrangian descriptions. But…

The field theories we NEED to know about for the purpose of understanding experiments in high-energy or condensed-matter physics (possibly with the exception of some special CFT's) admit a Lagrangian description.

The measure-theoretic issues Borcherds worries about may be important in certain approaches to QFT. They may give insights of one sort or another. But they may not be relevant to real problems of QFT (confinement, for example). I repeat (for the fourth or fifth time) the path-integral measure on Euclidean lattices is fine (and mathematical physicists, by which I mean people who know measure theory agree). Trying to convince yourself it isn't won't lead to progress. Proving that there is a continuum limit is not the main issue – there is no doubt that an asymptotically free theory has a continuum limit as the bare coupling vanishes. The problem is to understand the properties of that limit. Then, once that is done, one can try to clean things up mathematically.

My philosophy on such problems is that we need to study them any way we can that yields a bit of progress. For myself, this usually (though not always) means inventing techniques rather than theorems.

124. **Aaron Bergman**

June 6, 2007

I think we're talking past each other. I agree that the questions you discuss are all interesting. I agree that lattice gauge theories are beautiful, well-defined things. I'm not convinced, however, that the existence of the continuum limit is necessarily a boring technical detail. I was trained as a physicist; you won't find me arguing that all progress must necessarily involve rigorous theorems. Nothing could be further from the truth. However, I think it is important that things do get cleaned up in the end, and it is somewhat disturbing to me that QFT has not yet been cleaned up. If it's just ugly technical analysis, I'd like to know that. If it's a sign of some deeper obstruction, I'd like to know that, too.

This all goes back to the old question of what is a QFT. I think Wilson has certainly led us in the direction of a possible answer in the case of Lagrangian field theories. I want to know what the general structure this leads to. As a physicist studying the standard model, perhaps this isn't so interesting, but as someone who wants to study thing beyond the standard model, understanding fully what a QFT is strikes me as very interesting.

Not to belabor the obvious too much, but this isn't an either/or proposition; there are lots of interesting questions out there. If I had more cajones, maybe I'd even work on it, but I don't at the moment, and I think I'll stick with my derived categories for the time being. Technical analysis was never my strong point anyways :).

125. **Peter Woit**
June 6, 2007

Aaron,

The reference by Borcherds is just to the well-known fact that the things physicists write as "Dx", a putative infinite-dimensional version of the translation-invariant Lebesgue measure, don't make sense, even for a free particle moving in R^n. But there is a measure in this case that does make sense, Wiener measure. Even in quantum mechanics, to make sense of the path integral as a measure, you need to do two things:

1. Euclideanize
2. Include some version of [tex] e^{-\frac{1}{2}\int |{\dot x}|^2 [/tex] in the measure to get Wiener measure, not the non-existent Lebesgue measure

126. **Peter Orland**
June 6, 2007

Aaron,

I never said the existence of the limit is a boring detail. I said
it is a secondary detail.

127. **Aaron Bergman**
June 6, 2007

Hmmm — I read Borcherds's statement as more general than that (ie, the nonexistence of measures on field spaces — besides the Gaussian case, of course), but looking around Wikipedia, it looks like he probably does mean the more basic statement you refer to, however.

I thought there were some more general no-go theorems, but I can't seem to think of where I heard about them at the moment.

128. **Aaron Bergman**
June 6, 2007

(And, after googling a bit, it doesn't look like the Gaussian measure exists in higher dimensions, but it's not too hard to get around that in a well-defined way)

129. **Arun**
June 17, 2007

Not to belabor the obvious too much, but this isn't an either/or proposition; there are lots of interesting questions out there.

Is there a list of well-formulated questions about QFT out there somewhere, kind of like a Hilbert's problems?

Proof of the abc Conjecture?

May 26, 2007
Categories: abc Conjecture

While I was traveling this past week, there was a conference held here entitled L-functions and Automorphic Forms, which was a celebration of the 60th birthday of my math department colleague Dorian Goldfeld. From all I've heard the conference was a great success, well attended, with lots of interesting talks. But by far the biggest excitement was due to one talk in particular, that of Lucien Szpiro on "Finiteness Theorems for Dynamical Systems". Szpiro, a French mathematician who often used to be a visitor at Columbia, but is now permanently at the CUNY Graduate Center, claimed in his talk to have a proof of the abc conjecture (although I gather that, due to Szpiro's low-key presentation, not everyone in the audience realized this…).

The abc conjecture is one of the most famous open problems in number theory. There are various slightly different versions, here's one:

For each $\epsilon >0$ there exists a constant C_ϵ such that, given any three positive co-prime integers a,b,c satisfying a+b=c, one has

$$ c < C_ \epsilon R(abc)^{1+\epsilon}$$ where $R(abc)$ is the product of all the primes that occur in a,b,c, each counted only once.

The abc conjecture has a huge number of implications, including Fermat's Last Theorem, as well as many important open questions in number theory. Before the proof by Wiles, probably quite a few people thought that when and if Fermat was proved it would be proved by first proving abc. For a very detailed web-site with information about the conjecture (which leads off with a quotation from Dorian "The abc conjecture is the most important unsolved problem in diophantine analysis"), see here. There are lots of expository articles about the subject at various levels, for two by Dorian, see here (elementary) and here (advanced).

As far as I know, Szpiro does not yet have a manuscript with the details of the proof yet ready for distribution. Since I wasn't at the talk I can only relay some fragmentary reports from people who were there. Szpiro has been teaching a course last semester which dealt a bit with the techniques he has been working with, here's the syllabus which includes:

We will then introduced the canonical height associated to a dynamical system on the Riemann Sphere. We will study such dynamical systems from an algebraic point of view. In particular we will look at the dynamics associated to the multiplication by 2 in an elliptic curve . We will relate these notions and the questions they raised to the abc conjecture and the Lehmer conjecture.

For more about these techniques, one could consult some of Szpiro's recent papers, available on his web-site.

The idea of his proof seems to be to use a and b to construct an elliptic curve E, then show that if abc is wrong you get an E with too many torsion points over quadratic extensions of the rational numbers. The way he gets a bound on the torsion is by studying the "algebraic dynamics" given by the iterated map on the sphere coming from multiplication by 2 on the elliptic curve. I'm not clear about this, but it also seems that what Szpiro was proving was not quite the same thing as abc (his exponent was larger than $1+\varepsilon$, something which doesn't change many of the important implications).

Maybe someone else who was there can explain the details of the proof. I suspect that quite a few experts are now looking carefully at Szpiro's arguments, and whether or not he actually has a convincing proof will become clear soon.

Update: I'm hearing from some fairly authoritative sources that there appears to be a problem with Szpiro's proof.

Comments

1. **CG**
   May 26, 2007

   This would be most remarkable and exciting if true! I seem to recall that the good professor Terry Tao mentions the opinion of another mathematician, Shou Wu Zhang, on how the abc conjecture could be proved, namely, saying that it would follow if one assumed enough variants of the BSD and RH conjectures.

   http://terrytao.wordpress.com/2007/05/04/distinguished-lecture-series-iii-shou-wu-zhang-"triple-l-series-and-effective-mordell-conjecture"/

   So if abc is true, while it is obviously not strong enough to provide any information about these other extremely famous conjectures, the remark of Shou Wu Zhang seems to indicate that at least it doesn't rule them out (in their full generality) by contradiction.

2. **David S-D**
   May 27, 2007

   I'm told by a mathematician friend that abc doesn't imply Fermat; it implies asymptotic Fermat (sufficiently large exponents).

3. **Steve**
   May 27, 2007

   I agree with David S-D…in particular, on the site about the ABC conjecture which you link to, the consequence is said to be:

   "that there are only finitely many solutions to the equation x^n+y^n=z^n with gcd(x,y,z)=1 and n> 3."

4. **Peter Woit**
   May 27, 2007

   I should have been more precise. It's true that abc only implies Fermat for big enough n, but Fermat is known to be true by other methods for a large range of n, so abc would finish the proof (without Taylor-Wiles). You do have to check the coefficient you get in abc to make sure the ranges overlap, they do for Szpiro's proof.

5. **kasper Olsen**
   May 27, 2007

   Peter,

   The way you phrase the abc-conj above, it appears that C_\epsilon depends on a, b and c. The way I would phrase it would be to say,
   that **given** any epsilon > 0, there exists a constant C_\epsilon
   such that for any triple of positive integers a, b, c with a+b = c and gcd(a,b,c) =1… [etc]. Agree?

-Kasper

6. **Peter Woit**
May 29, 2007

Kasper,

Yes, that's right, I should have written things in another order to make that clear. The constant doesn't depend on a,b,c. Maybe I'll change it now…

7. **gaddeswarup**
May 29, 2007

According to Wikipedia Szpiro announced a proof of the 'Weak abc conjecture'. The paper http://www.math.columbia.edu/~goldfeld/ABC-Conjecture.pdf mentions a 'weak abc conjecture'.

8. **surlygrad**
May 30, 2007

How does abc connect to dynamical systems?

9. **Peter Woit**
May 31, 2007

surlygrad,

No real connection to conventional dynamical systems. What is being used here is iteration of an algebraic map of the sphere to itself.

10. **Z**
June 2, 2007

Rumours at my institution say that it is Emmanuel Ullmo, from University of Orsay, who is currently proof-reading the manuscript.

11. **layman**
June 4, 2007

I think it would be informative to flip between this blog and that of Dr. Lubos Motl – after all, it doesnt hurt to listen to a range of opinions. Unfortunately, when you follow a link from this blog, you get a message refusing you entry and, worse, refusing return.

So flipping is difficult. Too bad. Hope he changes his policy.

12. **Peter Woit**
June 4, 2007

layman,

I think you should take that up with Lubos, not much I can do about it. I suppose you could try posting a comment about this on his blog and not mine (although he'll probably delete it, following his policy of deleting comments he disagrees with).

He put that page in place the day I pointed out here that his posting claiming the MiniBoone experiment had confirmed the LSND result was wrong (actually the opposite was true).

13. **blank**
June 7, 2007

Hi,
What is your opinion about the recent paper posted in archive by T Pati disproving Riemann Hypothesis?

14. **Peter Woit**
June 7, 2007

That the Pati paper actually disproves the Riemann hypothesis seems extremely unlikely, and I don't know of anyone who has taken it seriously. The arXiv contains a large number of claims about the proof/disproof the the Riemann Hypothesis which are incorrect. The Pati paper is presumably also incorrect, but to find out why you need someone with some expertise who is willing to spend their time reading the paper and looking for the error. Perhaps the paper will get refereed and this will happen.

15. **blank**
June 7, 2007

I heard rumors that the paper has been submitted for publication (may be annals). The interest lies in the fact that Pati is a respected figure in India.
Moreover, he is not known to have such false claims before.

16. **blank**
June 7, 2007

Speaking about Riemann Hypothesis , recentle some suggestions were made by Alain Connes towards solution of Riemann Hypothesis by borrowing ideas from physics and may be non commutative geometry.

Can you shed any light on this , are there people seriously trying to prove the most important problem in number theory by borrowing ideas from physics?
Because that will have great implications……

17. **Peter Woit**
June 7, 2007

Over the years people have tried all sorts of ideas related to physics on this problem. Connes has some ideas related to non-commutative geometry, but has not claimed to have a proof of RH. My understanding is that in the case of RH for function fields (where a proof by other methods exists), there is progress on finding a proof by

Connes's methods. For comments by him about this, see this posting on his blog:

http://noncommutativegeometry.blogspot.com/2007/03/le-rve-mathmatique.html

Even More Stuff Than Usual

May 31, 2007
Categories: Uncategorized

Here are various things of interest that accumulated while I was away:

Last week there was a conference in Florence on the early history of string theory, some of the talks are available here.

Lots of blogging activity among Fields Medalists: there's a lot worth reading in Terry Tao's reporting on a series of lectures by Yau at UCLA here, here and here. At the blog of fellow Fields Medalist Alain Connes, there's mention of on a recent conference at Vanderbilt (slides here), as well as a report from Connes about a recent conference on the philosphical ideas of Wolfgang Pauli. Finally, yet another Fields Medalist, Richard Borcherds, has a blog. Not only do Fields Medalists like to have blogs it seems, but they also like to use them to discuss physics…

Some other blogs I've run across include A Strange Universe, from gravitational wave physicist Warren Anderson, which includes his Dire Straits inspired Papers For Nothing. Also John Armstrong's The Unapologetic Mathematician, which has a lot of expository material, and Julie Rehmeyer's MathTrek, a blog at the Science News web-site.

Steven Weinberg has canceled a planned public talk at an event to be held in conjunction with PASCOS 2007 at Imperial College in London in July, an event celebrating the 50th anniversary of the arrival of Abdus Salam at Imperial. In a letter to Mike Duff (available here), Weinberg says that he is boycotting the event in response to news of a boycott of Israel by the British National Union of Journalists, due to his belief that there is no possible explanation of this other than widespread anti-Semitism in Britain "especially in the intellectual establishment" or "a desire to pander to the growing Muslim minority in Britain." *Note: any attempts to use mention of this news to justify attempts to carry on the Israeli-Palestinian conflict in the comment section of my blog will be ruthlessly suppressed*.

As usual, Tommaso Dorigo is doing a great job of making current collider physics actually seem exciting and interesting. He's now spreading rumors of a 4-5 sigma excess of multi-b-jet events being seen by D0. What does CDF data show? He's keeping his mouth shut about that… Maybe there will be some excitement at the upcoming summer conferences…

There's a new Harvard College magazine about math, run by undergraduates called The Harvard College Mathematics Review. The first issue contains an article by Noam Elkies about the abc conjecture, and one by Dennis Gaitsgory about how not to teach linear algebra.

Via Mathephysique, here's an interview with theorist Edouard Brezin.

I keep running across more and more web-sites of theory groups that are putting up material from their theory seminar talks. The latest is the HEFTI Seminar Archive at Davis.

Mike Hopkins gave a Distinguished Lecture Series in Toronto recently. Only audio from the talks is available on-line, and I can attest that forcing someone to try and follow a talk they are interested in like Mike's The Topological WZW Space of Conformal Blocks just by listening to the audio without always being able to tell what he is writing on the board is just cruel.

Via the n-Category Cafe, notes from a recent conference in Kyoto on Link (also known as Khovanov) homology and categorification. Lots of interesting talks to read, but I'm especially fond of the abstract of Dror Bar-Natan's talk, which begins:

I'm over forty, I'm a full professor, and it's time that I come out of the closet. I don't understand quantum groups and I never did.

Now I don't feel so bad. Also, for inspiration, check out his Dream Map.

Update: A Chicago network news show has a recent segment about Fermilab and the hunt for the Higgs.

Update: The D0 rumor has made it to Slate.

Comments

   Regards

2. **Mike Wiest**
   June 1, 2007

   Hi,

   I'm not able to read your entire site, but I have a general question about your critical stance toward string theory. My superficial understanding has it that there are many possible vacua of the "theory," each corresponding to different physics, and we don't know which is the "true" vacuum, so one says the theory makes no predictions and cannot be falsified.

   However, I thought I had come across schemes that claimed to reproduce the standard model with very few parameters. (I don't remember details; the one author I can remember is Dmitri Nanopoulos; this was in the late 90's). Are these claims false? And if not, doesn't it count as huge progress to go from a 19 free-parameter theory to one with few parameters and a theory of quantum gravity to boot?

   Thanks!

3. **Peter Woit**
   June 1, 2007

   "Are these claims false?"

   Yes.

No one has been able to use string theory to calculate any of the standard model parameters in terms of the others. If you don't believe this, try and find a string theory prediction of the one still unknown SM parameter (the Higgs Mass) in terms of the others, or a string theory prediction of anything that will be seen at the LHC.

It would be huge progress if string theory (or any other theory) was able to reduce the number of free parameters in the SM, but this has not been done. Any claims otherwise are intentionally misleading.

4. **Eric Mayes**
June 1, 2007

Peter,
Your statements are not entirely correct. The model that we present in hep-th/0703280 is very close to reproducing the three-generation MSSM, including the standard particle masses and mixings. We can make predictions of the superparticle spectrum and Higgs mass with essentially only five parameters, the moduli VEVs and the gravitino mass. We can restrict the range of these parameters by demanding that the relic neutralino density is in the range to produce the observed dark matter density. To be fair, this is only one vacuum among many and we haven't completely addressed the issue of moduli stabilization, however the model is testable in that either this vacuum will correctly predict the pattern of superpartner and Higgs masses or it won't. By the way, the model generically predicts the Higgs mass to be in the range 117-121 GeV.
Just want to point this out. Hopefully, this doesn't trigger another round of angry post.

Cheers,
Eric

5. **M**
June 2, 2007

dear Eric, you do not have any string prediction for the Higgs mass. You just ASSUME tanBeta = 46 (page 3 of your paper) because you know that, according to a computation done 15 years ago in quantum field theory, this gives m_higgs = 91 GeV + (top loop correction) such that the Higgs mass is slighly above the LEP bound m_HIggs > 115 GeV. Had you ASSUMED a lower tanBeta, you would have obtained a Higgs mass that contradicts the LEP bound.

6. **A quantum diaries survivor**
June 2, 2007

Alas, M, your comment is at the very essence of the problem that plagues HEP today. What is the predictiveness of a model (say Supersymmetry, or string theory, or whatever) that contains (many) new parameters that can be adjusted to provide whatever outcome one wants ?

I remember years ago, when many expected SUSY would be discovered in a discrepancy in the sides of the CKM triangle… The Bs mixing delta M was expected to be 30/ps or so. Now it is 18+-1/ps, the triangle closes beautifully and what do susy theorists do ? They cook up a "MFV scheme" to keep away from inconsistencies. M is for "minimal", to imply they have grown accustomed to walking on tiptoes to avoid perturbing the beautiful consistency of the SM.

I wonder how much sense that does. Given the large phase space allowed to SUSY parameters years ago (masses of SUSY particles at 80-100 GeV, large effects in BR through loops, etcetera), and a "flat prior" assumption for their values, wouldn't it be reasonable to compute the "confidence level" of SUSY today ? We would find we have excluded it at well more than 95% confidence level.

Mind you, I do not usually give too much weight to "95% confidence levels". They are not very meaningful if you do not specify the probability distribution you have integrated. For instance, the direct limit for the higgs at 114 by LEP II is very strong, because if you go even slightly below 114 the probability becomes zero quickly – they would not have missed the higgs at 112. An example of the other kind is the "upper 95% cl limit" from indirect fits of SM observables at 166 GeV: even 200 GeV is not wildly unlikely – it just entails one or two wrong measurements of electroweak parameters.

My bottomline is: a theory which can be tuned to give just about any possible outcome is not a theory, it is an exercise. Not worth investing a large part of a budget of funding agencies!

7. **A quantum diaries survivor**
June 2, 2007

And I would like to add something to my previous comment. I remember that in the late eighties and early nineties, when the top quark had not been found yet, theoretical predictions for its mass used to follow closely the lower limits from experiments: some theoretical calculations indicated a mass of x+-x/3, then a direct limit would arrive at 1.2*x, and a new prediction then would be published at (1.5+-0.3)*x. New collider data would then exclude masses lower than 1.6*x, and guess what, new predictions would foresee masses around 1.8*x…

It looks like some theorists love to have a bet out which makes it possible for them to dream hitting the jackpot. I am not implying these are not serious scientists – just that the game is a bit silly.

8. **Peter Woit**
June 2, 2007

Eric,

Your model, like all such things, not only doesn't reproduce the SM with fewer parameters, but actually adds more undetermined parameters. And, in any case, it isn't a "prediction of string theory" anyway.

9. **The Professor in Black**
June 2, 2007

Cool Dire Straights song/link.

Many of you are familiar with Johnny Cash's song "San Quentin," which he perfomred in front of the inmates of San Qunetin, during one of his famous prison concerts.

It has recently come to light that he also traveled the world, singing to those who were placed in non-tenured postdocoral/lectureship postitions by string theorists–those everlasting prisons for today's freethinkers.

The Man in Black sang,

String Theory, you've been livin' hell to me
You've hosted me since nineteen eighty three
I've seen 'em come and go and I've seen them die

And long ago I stopped askin' why

String Theory, I hate every inch of you.
You've cut me and have scarred me thru an' thru.
And I'll walk out a wiser weaker man;
Mister Congressman why can't you understand.

String Theory, what good do you think you do?
Do you think I'll be different when you're through?
You bent my heart and mind and you may my soul,
And your m-brane walls turn my blood a little cold.

String Theory, may you rot and burn in hell.
May your walls fall and may I live to tell.
May all the world forget you ever stood.
And may all the world regret you did no good.

String Theory, you've been livin' hell to me.

Johnny Cash said to the exiled postdocs, "I was thinking about you guys yesterday. I've been here three times before, and I think I understand how you feel about some of the things. It's none of my business how you feel about some of the things, and I don't give a damn about how you feel about some of the things. But anyway, I tried to put myself in your place and I believe this is how I would feel about String Theory" — Johnny Cash @ The San Quentin String Theory Conference

10. **Ralf**
June 2, 2007

Exoneration. – Asked whether she agreed with the characterization of the present as the "age of the fakers," somebody insisted on the caveat that the popular rendering of string theory can be a source for subjective cosmological mysticism, along the lines of, say, a romance novel. Thus, it would not be fair to refer to string theorists as fakers, if they were marketing it like dime store romance novels.

11. **Chris Oakley**
June 2, 2007

Professor in Black,

I'm sure that this Johnny Cash ballad will take its place alongside that other classic of the genre, "He ain't heavy, he's my supersymmetric partner."

12. **Chris Oakley**
June 2, 2007

Ain't no selectron, at less than 10 TeV
Ain't no squark that a detector can see
But I won't give up on supersymmetry:
Just need more time, and more money.

(… or something like that)

13. **Yatima**
June 2, 2007

> A Chicago network news show has a recent segment about
> Fermilab and the hunt for the Higgs.

Umm… very nice. When did that annoying style of explaining everything through movie-teaser soundbites become so prevalent? "Shake the Higgs loose"? Oh well.

And there's an allusion to the ILC at the end! Let's not get carried away though, the Real World has a way of crushing dreams.

14. **Joseph Smidt**
June 2, 2007

"As usual, Tommaso Dorigo is doing a great job of making current collider physics actually seem exciting and interesting."

Thanks for the heads up.

15. **Mike Wiest**
June 3, 2007

Thanks very much for the helpful responses from different perspectives, and the bittersweet lyrics. I appreciate the specific examples without overwhelming technical detail.

So, to press a little further, I think I understand the point that the various string-derived particle spectra represent putative vacuum states that might not really be the true and stable ground state of String Theory, so we may want to avoid calling such theories "predictions" of string theory. But if we can find one or many of these theories that describe known physics and unify all the forces–can we afford to discard them? We would perhaps need to stop thinking of string theory as a fundamental theory, but isn't just having a unified description a major step forward? Aside from counting free parameters, if we have a theory that's in some sense arbitrary, like the standard model, but it does unify all the forces…isn't it superior (even if we KNOW it's not the true vacuum of the theory)?

Doesn't string theory unify the forces, if considered as merely a phenomenological description rather than a fundamental theory? Forgive my ignorance, but do we actually have any other theory that does this?

Finally, since you were all so straightforward, I have to demonstrate my ignorance again to ask this–is there any other theory of quantum gravity that is finite or renormalizable?

Muchos thanks!

16. **Peter Woit**
June 3, 2007

Mike,

The true ground state of string theory is presumably known, it's one of the supersymmetric ones like flat 10d space-time. Problem is that this ground state looks nothing like the real world. What string theorists are doing now is looking at metastable possible ground states that might look more like the real world. But they are extremely complicated and exist in huge number and variety. The bottom line is that string theory is not able to predict anything at all. To claim that you have "unified" physics with a theory that doesn't predict anything just makes no sense.

People now think N=8 supergravity might be finite, and there's a whole research program pursuing another idea about quantum gravity (loop quantum gravity) which arguably has been as successful as string theory in terms of coming up with a quantum gravity theory.

17. **Mike Wiest**
June 3, 2007

Peter,

When you say string theory is not able to predict anything at all, I'm taking you to mean that we have no principled way of choosing among the huge number of ground states that (might) look like the real world. But are you saying that even if we pick one of those adequate ground states we don't have a unified description of the the forces? Because the parameters are still too unconstrained? Or is it because we can't tell if any single one of the promising ground states is "adequate"?

I don't quite see why it makes no sense to think of each "adequate" quasi-ground state as a consistent unified description of all the forces. I mean, we can't derive the weak mixing angle in the standard model but we were pretty happy to get the weak interaction unified with the electromagnetic, right?

If our situation is that we have too many adequate theories, isn't that better than none?

Thanks for your patience!

18. **Peter Woit**
June 4, 2007

Mike,

There are two huge problems here, one of practice, one of principle:

1. In practice, one doesn't know what the full, non-perturbative string theory is, so one is working with various approximations and assumptions. As a result, for each conjectural metastable ground state, all one can get are various crude approximate "predictions", you can't actually extract any accurate predictions of SM parameters.

2. In principle, even if you had a full theory and could do reliable, accurate calculations in it, the number and variety of these states is so huge that no one has a credible proposal about how to get a prediction of anything out of studying them.

In electroweak unification, sure you can't predict the Weinberg angle, but you can predict a huge number of other things and test these predictions. The problem with superstring theory unification is not that there are things it currently can't predict, but that it can't predict anything at all. Again, trying to sell people on how wonderful your unified theory is, when it can't predict a single thing about anything, is obviously problematic.

19. **Mike Wiest**
June 4, 2007

Hi Peter,

I'm thinking of "predictions" as being an orthogonal dimension to "unification." If I accept that these theories (or "schemes") make zero predictions, do they still give me a unified description of the fundamental forces? Even if we have to fit every single parameter to experiment, don't we have something we didn't have before, namely, a way of seeing all the forces as arising out of one kind of stuff?

Sorry if I'm sounding like a not-too-bright broken record. You seem to feel that a unified theory is not a unified theory if it doesn't make any predictions. But isn't there a difference between a unified description as I'm imagining exists in string theory, as opposed to the mere aggregate of interactions that we have in the standard model?

Maybe your point is that if you can't do reliable calculations in any of these theories, then you don't have any unified description to speak of. Are you saying something to the effect that, even if I set all the parameters, we don't know how to calculate cross-sections and whatnot? So the indeterminacy is not just in the parameters, but somehow the theory turns to mush if you try to calculate anything even given the parameters?

In that case, would it not even qualify as a theory of quantum gravity? Am I wrong to believe there is a consistent quantum theory of gravity in there somewhere? ("No, Mike, you're NOT EVEN wrong…")

I do appreciate the importance of being able to predict things…but I also tend to see unification as valuable in itself.

20. **Peter Woit**
June 4, 2007

Mike,

As far as I'm concerned, you're just not doing science unless you can test your theory against experiment, i.e. make predictions with it and check them. One of the main reasons we want a "unified" theory is that by relating different parts of physics we should get more predictions we can check, not less. A "unified" theory that can't predict anything is just not a scientific theory.

21. **tty**
June 4, 2007

just to add a new stuff not included in your blog, there's a good article by Smolin in New York Review of Books, about some new books on Einstein.

22. **Peter Woit**
June 4, 2007

tty,

Thanks for mentioning that, I was going to include it on this list, but seem to have missed it. There's a detailed posting about this and discussion at Cosmic Variance.

23. **Mike Wiest**
June 5, 2007

Peter,

I think you've just about convinced me. It would seem that if one's putative unification doesn't constrain the different sectors by relating them to each other, then nothing really got unified. If I think of an example where the unification seems substantive but no new predictions are made, I'll get back to you…

But–is it a finite theory of quantum gravity? Or again, because it is so unconstrained, do you say there is no theory there?

24. **A quantum diaries survivor**
June 5, 2007

Hi Peter,

about PASCOS: I will attend the conference for a couple of days (so what, your readers are entitled to ask). I will be presenting CDF tests of the Standard Model (so what ?). Nothing, just to mention that I will try to blog about what I hear there. I think I will not understand much of the stringy talks, but at least I hope to give some report of the cosmology part.

Cheers,
T.

25. **Peter Woit**
June 5, 2007

Mike,

String theory really isn't a finite theory of quantum gravity. It only gives the terms in a perturbation series, and it is these that are supposed to be finite. The series doesn't converge (it's presumed to be a divergent, but asymptotic series). Conjecturally, there is some non-perturbative finite theory, to which this series is asymptotic. But, even if this conjecture is true, the problem is that the evidence then is that you'll end up with not one theory of quantum gravity, but 10^500….

26. **Mike Wiest**
June 6, 2007

Sweet!

Gotta love that.

What does divergent but asymptotic mean? Can you really be divergent and at the same time get asymptotically close to a finite number?

27. **Peter Woit**
June 6, 2007

Mike,

Asymptotic series are ones that become arbitrarily accurate for arbitrarily small coupling, also they get closer to the true answer as you compute more terms up to some point, where they start getting worse. Depending on how small your coupling is, in some cases they can give quite accurate results, even if there is an inherent limit to this accuracy. In QED the perturbation series is presumably just asymptotic, but quite accurate. In string theory you have no idea since you don't know what the coupling is. But, when you only have an asymptotic series, it's misleading to claim you have a finite theory.

28. **Mike Wiest**
June 11, 2007

Aha. Why would QED be "presumably" only asymptotic with a coupling of 1/137? Because you know things change at the Planck scale (or before)?

Thanks Peter.

29. **Peter Woit**
June 11, 2007

Mike,

There's an old argument (due to Dyson), that in QED the way things depend on the coupling constant [tex] \alpha [/tex] can't be an analytic function at [tex] \alpha=0 [/tex] since the vacuum is unstable for even infinitesimal negative coupling constant. Only for analytic functions will you get the power-series converging to the true answer. So, you expect to only have an asymptotic series in QED, this is independent of how big the coupling is. Since the coupling is quite small, even though the series is only asymptotic, at low order one expects it to be very accurate (which it is). More detailed arguments imply that the series expansion should get better and better up to order around 137, only for higher order calculations than that does it start to get worse. So, for all practical purposes, the series expansion is fine.

30. **Mike Wiest**
June 18, 2007

Interesting.

Thanks!

Endless Universe

June 2, 2007
Categories: Book Reviews

There's a new popular book about cosmology now out on bookstore shelves, [Endless Universe] by Paul Steinhardt and Neil Turok. The authors are the inventors of a competing model to inflationary cosmology, variously called "ekpyrotic" or "cyclic" cosmology. They describe coming up with the same idea simultaneously during a lecture at Cambridge on M-theory by Burt Ovrut back in 1999. Ovrut was describing his work on the Horava-Witten scenario, which involves two parallel branes (we live on one of them), and during the lecture both Steinhardt and Turok started wondering about whether one could explain the big bang as a collision of branes. They went up to discuss this with him after the talk, and continued the discussion on a train ride to London that evening to see a performance of the play Copenhagen. This train ride was a central part of a 2002 BBC TV program Parallel Universes and a recent play Strings by Carole Bugge that I saw performed here in New York late last year.

The book is very much an advertisement for cyclic cosmology, and devotes a lot of space to doing something which is rarely done, explaining the problems with inflationary cosmology. Steinhardt has worked extensively on coming up with viable inflationary models, and a large part of the book explains the story of this research. Perhaps the most interesting aspect of the book is the story that Steinhardt and Turok each tell about their careers and how they ended up working together on this alternative to inflation. The problems with inflation are described in the context of promoting their cyclic model of branes colliding, moving apart and then back together in a repeating pattern. They heavily sell the idea that a cyclic model with no beginning of time is conceptually much preferable to a standard inflationary model in which the universe emerges at a given time. Reading this made clear to me why, at the recent String Cosmology meeting here in New York, Turok was so persistently questioning one speaker about whether everything he was doing didn't just depend on an unmotivated choice of initial conditions.

Steinhardt and Turok do a pretty good job of demolishing the inflationary multiverse and the associated Anthropic Landscape philosophy that has become so popular in recent years. They correctly describe the main problem with the inflationary multiverse as the lack of any way to test the idea, even in principle, making it not really a scientific idea at all. As for the testability of their own theory, they devote an entire chapter to the question of contrasting its predictions for the CMB with those of inflation. They claim that both cyclic and inflationary cosmology make the same predictions for the WMAP results (implicitly criticizing the commonly made argument that WMAP provided strong support for inflation). The one possible test that they point to that could distinguish the inflation and cyclic scenarios is the expected more sensitive measurement in coming years of a possible B-mode polarization signal due to gravity waves in the CMB. They claim that inflation predicts a significant amount of B-mode polarization, whereas the cyclic model doesn't. Unfortunately, from what I can tell by looking at the recent literature on "string cosmology" (e.g. here), various inflationary scenarios can give a wide range of amounts of such polarization, with stringy models like "brane inflation" and "modular inflation" leading to essentially none, just like in the cyclic case. So, I guess the cyclic model is in principle falsifiable, if next generation CMB experiments turn up measurable B-mode polarization. But if this doesn't happen, I don't see how one is ever, even in principle, going to distinguish experimentally between the cyclic and inflationary scenarios, which will make this whole area of research highly problematic.

On the whole the book seems to me to be too much of an advertisement for a very speculative idea, and I don't think the public needs more of this in this kind of format. I didn't notice anything in the book about what the case against cyclic cosmology might be, so anyone who wants to find out the other side would have to go on a search of the scientific literature, something most members of the public might not be able to do. Most strikingly, since the cyclic model is based on brane ideas motivated by string theory, the book contains endless hype about string theory, without so much as a word about its problems. One would have to read extremely carefully to realize that there is not a shred of experimental evidence for string theory. As for recent public debates about the problems of string theory, the authors just pretend they don't exist. They give a long list of recent popular books in this area, such as those of Susskind and Vilenkin promoting the Landscape, but somehow neglect to include the two such books that have taken a critical point of view on string theory.

Associated with publication of the book, it looks like there will be various stories in the media promoting the cyclic vs. inflationary debate, trying to make it into a modern version of the old steady-state vs. Big Bang controversy. On the Edge web-site there's a recent piece by Turok, which gives a good explanation of his current research and point of view. From NPR, there's a very recent radio show about the cyclic model, entitled Forget the Big Bang Theory, where "renegade physicist" Turok's model is described as "fighting words in the halls of science."

Comments

1. **anon.**
   June 2, 2007

   They claim that inflation predicts a significant amount of B-mode polarization

   Many people would disagree with that. The well-known Lyth bound suggests that observable B-mode polarization implies Planckian field values. This is extremely difficult to obtain in string theory; see work by Baumann and McAllister, for instance. It's also not very plausible in effective field theory, where one expects potentials to get Planck-suppressed corrections and flatness at trans-Planckian scales would be difficult to explain. There have been attempts to circumvent this with, e.g., inflation driven by large numbers of axions, but nothing very compelling. An observation of large tensor signal would cause a real theoretical crisis, I think.

2. **Kris Krogh**
   June 2, 2007

   Peter,

   Glad to see you shine a little light on cosmology, another near-monopoly situation with many parallels to string theory. Who says the Big Bang is "the only game in town?"

3. **Coin**
   June 2, 2007

   Who says the Big Bang is "the only game in town?"

   Ah, be careful, that's the kind of statement that you'll tend to see quote-mined on Talk.Origins later 🙂

   My understanding of the "cyclic universe" model described here is that it does not supplant the traditional big bang model (at least the big bang model as the layman would understand it), but rather extends it. Is this not correct?

4. **Kris Krogh**
   June 2, 2007

   Hi Coin,

Haven't read the book, but the universe had a beginning in BB. Somehow "Endless Universe" doesn't sound like that to me.

5. **M**
June 3, 2007

Inflation predicted that primordial inhomogeneities are adiabatic, Gaussian and with a quasi scale-invariant spectrum. All of this was later confirmed by WMAP and other observations.

Bounce cosmologies have problems in postdicting these features. First, cosmological singularities in string theory are not understood well enough to know if a bounce really occurrs. Second, perturbations generated "before" the bounce do not need to be scale-invariant, in gross disagreement with observations (maybe some miracle happens during the bounce: we do not understand this critical phase). This can be fixed in specific models: by assuming ad-hoc potentials, by introducing extra fields.

This is why many cosmologists do not consider ekpyrosis as a serious competitor to inflation. And somebody jokes that ekpyrosis sounds like a beautiful name for a new illness…

6. **Alex Nichols**
June 3, 2007

'Ekpyrosis' is actually an old term derived from the Stoic philosophers, implying that the universe was created "out of fire".
Certainly, the observational evidence implies that the early universe was very hot.

S & T also revived the term 'Quintessence' in their cyclic model, originally the Aristotelean "5th element", through which the stars and planets were believed to move. They use it as an explanation for 'dark energy', suggesting that it's a slowing rolling force (currently increasing), which explains recent obervations on cosmic expansion.

Cyclic Cosomologies were quite popular in the early 20's, based on a closed universe with a negative cosmological constant.
For example, the Friedmann, Walker, Roberton, Le Maitre models.

In the 1930's, Richard Tolman showed that this would lead to an entropy build-up, so that each cycle would become larger than the previous one, eventually leading to a situation where gravitational attraction would be insufficient to cause re-contraction. This severely reduced the model's explanatory power and it went out of favour.

Then in the 1960's Penrose and Hawking showed that gravitational singularities would form in any big-bang scenario based on General Relativity. This would erase the information from previous cycles. They didn't accept that there was any evidence that the "big-bang" was preceded by a "big crunch". Penrose in particular, has argued that there is no reason why a 'crunch' would lead to a 'bounce'.

As current thinking is that the cosmological constant has a small positive value, gravitational cyclic models based on General Relativity and the Friedmann equations are not in favour.
A quantum or string based description of the events approaching a big bang singularity would be required to explain what actually caused such an event.
This is what Steinhardt and Turok are attempting to provide with the idea of a brane collision.

So far, it hasn't been disproved by the WMAP results and future experiments such as the Planck satellite should be able to provide tests of the polarisation of the CMB and Spectral tilt.

A more radical view of the situation would be that it's not meaningful to try and explain 'the universe' as a physical system and that valid physics can only be performed locally.

In such a view there is an extremal indentity between the singularity and cosmic horizon. As one approaches either, quantum and or string effects are essential in explaining what happens, but it's only possible to infer these theoretically, rather than directly measure them.

S & T certainly do list a series of observational consequences of their model that can be tested.

Then in the 1960's Penrose and Hawking showed that gravitational singularities would form in any big-bang scenario based on General Relativity. This would erase the information from previous cycles.

Interesting, if you project relativity backwards to the point where inflation is alleged to end, then that is also where you conveniently find "thermalization", reheating or, "Ekpyrosis".

The singularity arrises only if this isn't indicitive of a big bang in a universe that has pre-existing volume… which would *not* erase information from previous cycles.

8. **Peter Woit**
June 3, 2007

Alex,

At least in the book, their claim is that their model has the same observational consequences as inflation, except for the CMB polarization.

9. **Navneeth**
June 3, 2007

Associated with publication of the book, it looks like there will be various stories in the media promoting the cyclic vs. inflationary debate, trying to make it into a modern version of the old steady-state vs. Big Bang controversy.

It has made it to Slashdot. 🙂

June 3, 2007

I'm an italian physics undergraduate student. Although I took several classes in GR and cosmology, I'm no expert. But it doesn't take an expert to understand that the state of cosmology is pretty messy. I think that there is some very smart speculation going on, but on the whole it seems to me that cosmology is too young a science to really tell something about the universe. What mostly strikes me is that cosmology uses as ingredients all kinds of speculative (sometimes unscientific) hyphotesis and still unknown objects: higgsboson, SUSY breaking, superpartners, strings, branes, dark matter, dark energy, CC, quintessence, extended quintessence, GUTs an GUT simmetry breaking, and so on. As a result you can adjust inflation so to have almost any CMB, but this is not really scientific. If every ingredient had a 50% possibility to come out

true, which is the probability that cosmology makes sense at all?
I'll tell you why I feel so uncomfortable with cosmology. A few years ago italian cosmologists and theoreticians Matarrese, Riotto, Notari and american Kolb showed (here) that today's accelerated expansion might be explained as the effect of inhomogeneities in the matter distribuition (super-Hubble wavelenght fluctuation modes), which combined with standard GR act as a cosmological costant in the Friedmann equations (they assume inflation). So standard GR and a better comprehension of complex behaviour of matter coming out from the fact that the universe is not homogeneous at all might rule out ad hoc-CC and DE. But what is most interesting is to read the thread of arguments that these pepers raised, with all kinds of objections, mostly of a very general flavor: no go theorems for irrotational matter to cause negative pressure (doesn't apply to their case though), a discussion on whether or not these effects might suffice to give negative pressure and the need for a non-perturbative approach, whether or not one can use Friedmann equations and modify them while assuming an inhomogeneus universe and so on.
I'm not publicizing their idea, which I cannot evaluate; but I strongly believe that this whole thing shows that the very foundations of Cosmology (Cosmological Principle above all) are not understood and questionable, that all sorts of very general problems are not at all estabilished, and thus work in the field is easy to criticize (cosmologists dismantling others'proposals). I also think that before assuming all kinds of hyphothesis a much better understanding of GR dynamics, complex systems and collecive phenomena should be gained.

11. **Alex Nichols**
June 3, 2007

re Penrose/Hawking:-

During the 1990's Penrose suggested that the boundary condition of a collapsing universe could be distinguished by a large Weyl tensor.
Hawking agreed but said it was determined by the no boundary proposal.
Turok later worked with Hawking on an inflationary model based on this, but has moved on since then.

12. **Malo Juevo**
June 3, 2007

The paper by Kolb et al. was known to be obviously wrong from the moment it appeared. Working out precisely what the error was turned out to be not so easy, but perturbations around Robertson-Walker spacetime have been well understood long enough that something like this would not have been missed. The calculations in the paper are quite intricate, making it very difficult to keep track of what the range of validity of perturbation theory is at each step. However, if one looks at it very carefully, the perturbative technique is not valid. In some sense, this might be expected, since the whole point of the paper is to claim that a certain variety of perturbations are singular, yet the paper is done entirely in non-singular perturbation theory.

13. **Peter Woit**
June 3, 2007

If you have informed comments about Steinhardt-Turok, please post them. But this is not a general Cosmology discussion board, and I can't and won't moderate such a thing, so if it's not about Steinhardt-Turok or their book, don't post it here.

14. **Ari Heikkinen**
June 3, 2007

Peter,

It appears to me that "Endless Universe" is more like speculation on a new theory than it's cosmology, so could you suggest a good university level book (preferably self contained) on modern cosmology which would include all the relevant observations of the universe and their related math, but in a manner that it would explain what's seen, without trying to speculate on any specific theory?

15. **Cynthia**
June 4, 2007

In the "Edge" transcript, Turok uses the term "_mdash" not once but three times: "realistic&mdashspoils", "bring&mdashlike", and "argument&mdashhand". Although the meaning of the term "m&dash" is pretty obvious (to me, that is), does anyone know if it's really proper to be using this term in essay format?

16. **Chris W.**
June 4, 2007

Cynthia,

The occurrences of &mdash in the text are due to sloppy HTML editing on somebody's part; I doubt Turok had anything directly to do with it. **—** (—) is an HTML 4.0 *character entity*.

[Example: *Web developers do make mistakes—sometimes*.]

See this reference.

17. **clarity**
June 4, 2007

Peter,

I just want to make a few distinctions which are, I think, a little muddy in your posting. First off: inflation, brane inflation and the multiverse/anthropic landscape are all distinct. The simplest inflationary scenario is very well supported by the data and is certainly testable (it's already been tested!). Particular string theory embeddings of inflation (such as brane inflation) may or may not be falsifiable, though there isn't currently a way to rule out inflation from string theory (however, a positive signal for tensor modes would give stringy inflation a hard time). Eternal inflation and the multiverse are both controversial, even among proponents of inflation and are certainly not necessary parts of the puzzle. Inflation doesn't necessarily have anything to do with anthropic arguments and many cosmologists dislike anthropism as much as you do.

18. **Peter Woit**
June 4, 2007

clarity,

Sorry if I wasn't clear, I am aware of the distinctions you mention, and that simple inflationary scenarios do have some real experimental support (as well as problems that Steinhardt and Turok do a good job of describing). I didn't mean hear to be criticizing this kind of thing, I think it's serious science (brane inflation and eternal inflation/multiverse are a different story).

19. **clarity**
June 4, 2007

Peter,

Thanks, I just wanted to be sure that you weren't trying to lump all those things in together. The problems with inflation are largely conceptual and, to my mind, many of these problems have deep quantum gravity issues at their core. Personally (you are likely to disagree with this) I think that it will be hard to completely resolve all the problems of simple inflationary scenarios without coming up with some kind of UV complete, quantum gravity version of the story. So in this sense I don't think that brane inflation (and similar scenarios) are nearly as poorly motivated as you think they are. I'm not trying to argue that any of these string theory inflation models actually solves any of the outstanding problems of inflation, just that trying to embed inflation into a quantum theory of gravity is probably a step in the right direction. (I should probably mention that I don't think that the ekpyrotic/cyclic scenarios offer much, if any, resolution to these problems, but that's another story entirely…)

20. **Peter Woit**
June 5, 2007

clarity,

My own general view is that to understand inflation you will need to understand the beyond Standard Model physics that is driving it. Quite possibly this requires a good theory of quantum gravity. Historically I guess the hope was that maybe inflation came from some kind of Higgs sector, but I gather that doesn't work.

The problem with all string theory inflation scenarios that I've seen seems to me to be exactly the same as the problem string theory has with getting particle physics: compactification. You have to invoke complicated compactifications in order to avoid conflict with what is known, and this ruins predictivity. I've looked a bit recently at brane inflation papers (including a recent Klebanov et. al. one this evening), and the constructions just look complicated, ugly, and with no hope of leading to real predictions.

21. **clarity**
June 5, 2007

Peter,

"My own general view is that to understand inflation you will need to understand the beyond Standard Model physics that is driving it. Quite possibly this requires a good theory of quantum gravity."

We agree on this for sure. The thing that makes the quest to embed inflation into beyond-the-standard-model physics interesting is the fact that inflation is not at all a generic property of sensible theories of high energy physics. Typically the requirement of sufficiently many e-foldings puts stringent (often prohibitive) constraints on the underlying theory. This is one of the main points of the recent Baumann et al. papers – it's very difficult to tune the potential to be flat enough (even though a naive parameter counting suggests it should be simple). The fact that it's so difficult to come up with concrete, working models of inflation in string theory suggests, to me, that the models which do work will be at least somewhat predictive. (I'm still working through the paper you mention so I won't comment on how falsifiable this scenario is, though I think that a large tensor signal would rule it out for sure.)

Of course, as you mention, there are aesthetic issues and I won't claim that these constructions aren't complicated. It's not clear to me how complicated is "too complicated" when dealing with these kinds of theories, there's certainly some personal prejudice involved in making that call. Given that it's far from obvious that one can construct concrete, explicit, successful inflationary models in string theory, I think that any example (even a complicated one) is interesting.

22. **Peter Woit**
June 5, 2007

clarity,

I think even the authors of the paper I mentioned acknowledge how problematic the whole thing is, since they end their paper with:

"Finally there is a pressing need for a more natural model of string inflation than the one we have presented here".

which is equivalent to saying that they believe the model they are working with is highly unnatural and clearly they have little faith that it reflects the real world.

Personally, looking at the calculations done in this and similar papers, the whole thing seems to me completely absurd. You're invoking a huge amount of complicated structure, and trying to explain just a few observable numbers. This is hopeless. It's not an aesthetic question, it's a question of whether the number of assumptions that go into your calculation is larger than the number of observable predictions you can derive from it, and thus whether your framework is predictive.

Falsifiability is not enough to make a legitimate testable scientific theory. My theory that everything that happens in the universe happens because it is controlled by a malevolent being with 11 toes is falsifiable, because an omnipotent malevolent being with 10 toes may put in a public appearance at any moment. The fact that a complicated cosmological model predicts no measurable effects of primordial gravitational waves is not enough to make it a testable model in the usual sense. You have to come up with measurable effects that are characteristic of the model, and distinguish it from others. I don't see anything like that even conceivable with the string inflation models people are working on.

23. **wow**
June 6, 2007

Several experts now think cosmic strings from brane inflation (admittedly a very model dependent phenomena) may be distinguishable from the traditional abelian Higgs model networks due to different properties of intercommutation as well as (p,q) flavor structure; this is not obviously true or false, but is in any case a potential distinguishing signature that experts are sorting out.

A similar thing could be said about non-Gaussian signatures that arise from inflation with D-branes governed by the DBI action, in the regime where the kinetic structure is important (not slow roll). Experts on non-Gaussianity (including the WMAP team) use this model as a reference point to bound non-Gaussianities.

So I think your claim that characteristic measurable effects aren't "even conceivable" is not held by most of the people who actually try to build inflation models, or test them experimentally.

24. **Peter Woit**
June 6, 2007

wow,

Your first example starts out "assume we observe a network of cosmic strings…", something which most people would describe as an extremely unlikely event. From there you go on to note that this is a very model-dependent phenomenon and it's not clear if you can even distinguish it from non-string theory cosmic strings. Sorry, this just doesn't sound to me like a plausible test of brane inflation models: you're starting assuming something that isn't going to happen, then acknowledging that even assuming this, you can't necessarily make any predictions.

Your second example again assumes that we observe something that conflicts with simple inflationary models. Fine, but is this really a distinctive signal that one is seeing brane inflation? I can't help but suspect that if such an effect is observed, people will have no trouble coming up with many very different models that would explain it.

25. **wow**
June 6, 2007

By definition, a "distinctive" signature has to be something that
is not common to almost all models. So such things will be, at some level, unlikely. I suspect most working theoretical cosmologists would assign significantly greater probability to observing a cosmic string network, or non-Gaussianity, than they would to theoretical consistency (let alone experimental verification) of the Ekpyrotic/Cyclic scenario. I agree that most would also suspect absence of all these things; but that is just saying that vanilla inflation will look good, and we won't know the correct model at the level of a very specific potential or (in higher dimensional scenarios) compactification manifold.

My point was that signatures with roughly this likelihood constitute a major portion of what phenomenologists work on/hope for, and experimentalists try to measure, since by virtue of their somewhat rare nature they are very instructive when found. And it is quite conceivable to a majority of active workers in theoretical cosmology that such signatures are forthcoming sooner or later, to the extent that major current experiments use models motivated in this way as benchmarks. For me this puts your claim that there are "no conceivable" singatures of such models, in a more realistic context.

26. **clarity**
June 6, 2007

Peter,

You're way off about wow's comment about large nongaussianity. Many theorists have worked very hard to come up with inflationary models which have large nongaussianity and there are, currently, very few examples. Among those few examples most of them could be observationally distinguished by the shape and running of the nongaussianities which contain a wealth of information about the underlying theory. So a future observation of large nongaussianity (which is entirely possible) which is consistent with the results of DBI models would certainly be strong evidence for brane inflation. This is the position of most people who work on cosmological nongaussianity. It's not true that many other models could explain the same observation.

27. **Peter Woit**
June 6, 2007

clarity,

I'm making no claim to expertise in this area, so will take your word that there are few ways to get non-gaussianity. Can't help though being suspicious that if it's ever observed, people will find more….

28. **clarity**
June 6, 2007

Peter,

Of course there might be more ways to get big nongaussianity that nobody has thought of yet. I would be surprised if there are lots more ways, however, because there has been a lot of activity in trying to construct models with f_NL >> 1 and the list of models considered seems pretty exhaustive to me. It's clear that large nongaussianity requires something pretty novel to occur either during inflation or else shortly afterwards.

Also, it's worth pointing out that the bispectrum constains a lot of information and is rather model-dependent so if, as you say, many more models with big nongaussianity are discovered it still seems likely that they'll be (at least in principle) distinguishable from DBI.

All Landscape, All the Time

June 5, 2007
Categories: Uncategorized

There seems to be a peculiar trend going on in the particle theory community. Just about all theorists I talk to, correspond with, argue with on blogs, etc. claim to be quite unhappy with the Landscape, and insist that most of their colleagues share this view. On the other hand, all evidence is that Landscape research is becoming increasingly influential at the highest levels of the string theory community. The most prominent yearly string theory conference, Strings 07, will soon be taking place in Madrid, and titles of many of the talks there have just been announced. The largest contingent of speakers is from Stanford, and it appears likely that landscape studies will be the most popular topic at the conference, with various aspects of AdS/CFT running a close second. Just counting the number of times "Landscape" appears in the title of a talk, so far there are 4 such talks out of 31 with announced titles. Last year at Strings 06, out of about 50 talks, 2 had "Landscape" in the title. Naively extrapolating this eternally inflationary trend to the future, pretty much all Strings 1X talks should be about the Landscape…

Another indication of where the field is going is the yearly TASI summer school aimed at training graduate students in particle theory. This year the topic is "String Universe", and several of the lecture series are about the Landscape, with two having "Landscape" in the title. Videos of the talks are being made available now, even as the summer school is going on. I learned about this from Clifford Johnson, who writes that the talk he most wanted to look at and recommends to everyone is Raphael Bousso's on "Cosmology and the Landscape".

Harvard's Lubos Motl traditionally has been a landscape skeptic, but in recent months he has been writing more and more positive things about this subject. His latest posting advertises a new paper by Raby and Wingertner calculating statistics on (an extremely small piece of) the heterotic landscape.

Update: Lubos has written a posting entitled Landscape 2007 in response to this one. His point of view seems to be that although he doesn't like the Landscape, he doesn't have a workable vacuum selection principle, and as time goes on and no such principle is found, this makes the Landscape more and more likely to be correct. He doesn't seem to even consider the possibility that the existence of the Landscape and the lack of a vacuum selection principle means that string-based 10/11d unification is just a failed idea. I suspect his point of view may be widely shared among string theorists, explaining the simultaneous unhappiness with the Landscape and its increasingly widespread adoption as a research program.

Comments

1. **ObsessiveMathsFreak**
   June 5, 2007

   > Just about all theorists **I talk to**, correspond with, argue with on blogs, etc. claim to be quite unhappy with the Landscape, and insist that most of their colleagues share this view. On the other hand, all evidence is that Landscape research is becoming increasingly influential at the highest levels of the string theory community.

   Have you taken into account that you may be persona non grata among Landscape researchers. Of course it may also be the case that you have become ad hoc confessor for the String Theory community, whom they go to in secret outside the group to confess their doubts and heresies. I hope you're not abusing your position by giving them your own book to buy and read as a penance!

2. **anon.**
   June 5, 2007

   It's about a year since Lubos was converted from his heresy. In his June 18, 2006, blog posting entitled *Top twelve results of string theory,* Lubos' top result number 12 was:

   'The existence of the landscape, a large enough set of metastable solutions that the cosmological constant can adjust to a value small enough as to allow organized structures (which require many bits and many cycles).'

   He wrote that this result was added at the suggestion of Prof. Polchinski. It's kinda confusing to me to see the landscape hailed as a top result of string theory, something to be proud of.

   Should Prof. Baez now revise his crackpot index so that it doesn't include theories which are endlessly adjustable and so can't make falsifiable predictions?

3. **Peter Shor**
   June 5, 2007

   Could it be that everything else in string theory is just too hard to get any significant results in?

4. **Bhabha**
   June 5, 2007

   There seems to be a peculiar trend going on in the theoretical physics community. Just about all theorists I talk to, correspond with, argue with in letters, etc. claim to be quite unhappy with the theory of relativity, and insist that most of their colleagues share this view. On the other hand, all evidence is that relativity research is becoming increasingly influential at the highest levels of the theoretical physics community.

   Letter from journalist X.Y. to his friend Z.V. in 1920.

   (Note for the nitpicker: I do not think the landscape is comparable to relativity but merely would like to point out that the fact that a particular theory is unwelcome in scientific circles and yet it gains momentum can not and should not be interpreted as a defect.)

5. **Peter Woit**
   June 5, 2007

   Peter Shor,

   Yes, I think that's basically why landscape studies are so popular. The huge variety of possible "vacua" provide a huge number of possible calculations you can do, many of which are not very hard. So, instead of trying to solve a hard problem (actually find a legitimate way to unify physics via string theory, or work on an alternative), people do this, even though it can't ever lead anywhere. Seems pretty dysfunctional to me…

6. **Peter Woit**
June 5, 2007

Bhabha,

"I do not think the landscape is comparable to relativity"

Than why write a comment making the analogy?

I'll point out that my comment that most physicists are unhappy with the landscape is not my argument that there is something wrong with it. I've made that scientific argument at great length here and elsewhere.

7. **wolfgang**
June 5, 2007

Peter,

> Clifford Johnson, who writes that the talk he most wanted to look at and recommends to everyone is Raphael Bousso's on "Cosmology and the Landscape"

this is quite different from what Clifford wrote.
"I glanced for a while at Raphael Bousso's first lecture in the series "Cosmology and the Landscape", and it was clear and very well presented."

8. **King Ray**
June 5, 2007

Einstein particularly despised those physicists who looked for the thinnest part of a board and then drilled as many holes as they could there.

Sounds like the problem with the landscape, string theory, toy models, etc. is that physicists are looking for something that they can calculate and publish, regardless of whether it has any relevance to the real world. That seems secondary.

Physicists need to knuckle down, think hard for years and try to solve some real problems instead of darting off to higher or lower dimensions when things get too difficult. I think they publish too much. Just pick up any copy of Phys Rev D; 99% of the theories are inconsistent with each other, so therefore 99% of them are wrong. Or not even wrong.

9. **Ptolemy**
June 5, 2007

Wolfgang, your quotation is a bit incomplete, missing:

"(This is not entirely surprising – Raph is always an excellent lecturer.)

"This is great! I'm going to make some time to work through some of this wonderful material over the next month. Anyone else?"

10. **Peter Woit**
June 5, 2007

wolfgang,

I exaggerated slightly, but the fact remains that the Bousso talk on the landscape was the one Clifford chose to spend his time watching, not others, and I think his comments read as an encouragement to others to spend their time watching this talk. Since Clifford is known to complain that critics emphasize too much the role of the landscape and associated pseudo-scientific argumentation in current string theory, I thought it odd that he chose to watch and recommend the Bousso talk, which is about as pseudo-scientific as these things get, rather than something else, like one of the talks on aspects of AdS/CFT, which he often complains doesn't get enough attention.

Note: The above comment is as originally written, but it was not written as carefully as I would have liked. The clause "which is about as pseudo-scientific as these things get" was intended to refer to the advertised topic of Bousso's series of talks, not specifically to his first talk.

11. **anon.**
June 5, 2007

OK, I'm puzzled by your count of which topics are dominating string theory (but then, I usually am). I see four titles explicitly mentioning the landscape, maybe two more that are landscape-related. That's all. Are you counting anything related to, say, inflationary model-building as 'landscape'?

12. **anon.**
June 5, 2007

Also:

I thought it odd that he chose to watch and recommend the Bousso talk, which is about as pseudo-scientific as these things get

I watched the first Bousso lecture: it was a very straightforward description of deSitter space, FRW cosmology, and why there is a cosmological constant problem. Things that anyone interested in cosmology should know. Are you referring to a later talk?

13. **Eric Mayes**
June 5, 2007

I wonder what Einstein would think about those who like to sit and criticsize, but who don't ever do anything themselves.

14. **Peter Woit**
June 5, 2007

anon,

I chose to stick to counting whether "landscape" occurs in the title to avoid issues of interpretation, as well as not knowing what will actually be in some of these talks. I'll accept your count of 6 landscape related talks. I count 4 talks on AdS/CFT, no other single topic with more talks than this. I don't think my characterization of the landscape as the topic with the single largest number of talks is incorrect.

I didn't watch the Bousso talk, made the assumption that his series of talks with the title "Cosmology and the Landscape" would cover similar material to his recent papers on the subject. If the first talk didn't mention the nonsense about the landscape, and that's why Clifford was promoting it, my apologies to him, although I think it would have been a good idea for him to explain that the reason that it was a good talk was that it didn't deal with half of its title.

15. **Peter Woit**
June 5, 2007

Hi Eric,

And I wonder what Einstein would think of those who devote their energies to defending the practice of bogus pseudo-science by engaging in personal attacks on anyone who dares to point out that this is what is going on?

16. **John Baez**
June 5, 2007

> Should Prof. Baez now revise his crackpot index so that it doesn't include theories which are endlessly adjustable and so can't make falsifiable predictions?

No, this item on the crackpot index still stands:

> 50 points for claiming you have a revolutionary theory but giving no concrete testable predictions.

I'm not saying string theory is crackpot physics. Whether someone wins the 50 crackpot points depends on what claims they make for this theory.

17. **Eric Mayes**
June 5, 2007

Hi Peter,
I only point out that the people who criticize the most also happen to be those who contribute the least. In my experience, such people make noise in order to give the appearance of being relevant. I'm the not criticizing you, by the way. Generally, I have no problems with your arguments, only that sometimes your statements are too extreme, i.e. that string theory is 'pseudo-science' and string theorists are dishonest, etc.. You could make your points without this vitriol.

Anyway, you're right that not too many string theorists like the anthropic principle. However, most except the reality of the Landscape. It's just not possible to answer the vacuum selection problem right now, as your nemesis points out in his recent comments. This question will have to eventually be answered if string theory is too be viagle, and I think it's healthy to point this out.

Best,
Eric

18. **Joseph Smidt**
June 5, 2007

"Videos of the talks are being made available now,"

As always, thanks for the heads up. This bog is great!

19. **Joseph Smidt**
June 5, 2007

bog = blog (Above)

20. **Michele**
June 6, 2007

Dear Peter,

You are sure of the failure of superstring theory?
I think that if the Theory of String is "very elegant" also only from the point of view mathematical, it could not be wrong completely.
I am looking forward of receiving Your answer at this my opinion.

21. **Michele**
June 6, 2007

I'm studying string theory from about seven years. You think really that the string theorist, hence also me, are visionary?
For me You are a long way off from the truth and I'm sorry that You have not again understood the beauty and the elegance of mathematical verity.
I hope that You answer at these my two observations.

22. **Thomas Larsson**
June 6, 2007

I wonder what Einstein would think about those who like to sit and criticsize, but who don't ever do anything themselves.

Quite a good point, because Einstein's time was not completely unlike ours. It didn't take an Einstein to see that the Michelson-Morley experiment in 1887 was problematic for ether theory, but it did take an Einstein to discover special relativity. So what would Einstein think about those who liked to sit and criticize ether theory, but who didn't ever came up with special relativity themselves?

23. **matteoeo**
June 6, 2007

michele,

while you wait for Woit's answer (which surely won't come up until next US morning), I would like to ask you a few questions, just to warm the night up:
– why in your view is string theory such a beautiful theory? where does its beauty come from? I happen to think just the opposite, that string theory is a kind of messy zoo with no rules and principles in it, and no elegance at all.

– why should this questionable elegance be a piece of reality, if no experiment is ever going to falsify or validate ST?
– what is truth in science? You sound to me like a sort of mistic or religious when you talk about “verity” (which is not an english word by the way, maybe “truth” might work better)
– have you read Woit’s book or a wide selection of his blog entries?

24. **Yatima**
June 6, 2007

Is it really important what Einstain would have thunk before 1905? Maybe he would have been too busy examining patent applications?

Einstein just went for simplicity – he got rid of the Ether altogether (which was actually not disproved by the MM experiment series) and reused the Fitzgerald-Lorentz equations to good effect:

… the introduction of a light-ether will prove to be superfluous since, according to the view to be developed here, neither will a space in absolute rest endowed with special properties be introduced nor will a velocity vector be associated with a point of empty space in which electromagnetic processes take place.

http://www-groups.dcs.st-and.ac.uk/~history/HistTopics/Special_relativity.html

On the other hand, his post-GR opinions on force unification might be of more interest.

25. **matteoeo**
June 6, 2007

michele,

I have more questions for you. I understand you’re a young italian string theorist. Since a great deal of the string debate is on sociological issues, such as funding and student recruitment, I think these topics might be interesting:
– after seven years study, do you handle it well enough to work on it and publish?
– during these years, did you also try to take a look at alternative theories of gravity, or on advances in the mathematics of QFT, or any other subject?
– how did you get involved in ST? Did you choose by yourself or were you strongly addressed by some professor?
– when you chose, were you aware of the state-of-the-art of ST?
– did popular books such as Greene’s “L’universo elegante” have any role?
– in case SUSY weren’t to come up at LHC, would you keep studying ST? have you ever thought of abandoning the theory in case it didnt’ lead to any significant improvement, and try to study something new?

26. **Michele**
June 6, 2007

I think that is perhaps a big exaggeration suggest that string theory is completely useless.
I am sure that are many stringy inspired pieces of mathematics (with regard some sectors of string theory) that will be of great interest to mathematicians for years to come.
This is, for me, the mathematical “beauty” of string theory.

27. **Michele**
June 6, 2007

I’m not a young string theorist. I am a studious of mathematics and theoretical physics.
I think that also you have not again understood the mathematical beauty….

28. **Michele**
June 6, 2007

For matteoeo

Who are you, please?
I’m looking forward to read the answer of Prof. Peter Woit.
However, I’ve read many books of string theory (Polchinski, Green-Schwarz-Witten) and more than 500 papers concerning various sectors of string theory. I’ve also published 13 papers. I’ve “trust” in the mathematical beauty of string theory and I’m sure that the next experiments with LHC can be the confirm to it.

Message for Italian peoples

Purtroppo mi rendo conto che ci sono molte persone e molti studiosi di vedute limitate e che non hanno rispetto per quella che loro definiscono “astrattezza” della scienza matematica.
Ma chi ha fede fino in fondo verrà ricompensato degli sforzi di anni e anni di studi pazienti e sacrifici inenarrabili.

29. **matteoeo**
June 6, 2007

michele,

the point has been made very frequently in this blog’s threads that one should distinguish ST’s merits as a mathematical tool and as a theory of something physical. I also question the fact that the theory itself is beautiful; the study of strings has boosted a great amount of study in many areas of mathematics and of mathematical QFTs, and has revealed very beautiful truths (which are tautologies and have nothing to share with the platonic “truth” you talk about) belonging to these areas, but is ST itself a beautiful theory? I really don’t know, do strings themselves have any very simple and beautiful mathcmatical content? Maybe anomaly cancellation. Or is it just an instrument that reflects other theorys’ light?
If you distinguish among mathematical achievements and physical world description, you can also say that from the physiscs point of view ST is completely useless, since it cannot calculate anything.

30. **matteoeo**
June 6, 2007

LHC cannot confirm ST, since ST doesn’t predict anything hat has to do with LHC; what could happen is that LHC does not falsify it, which surely will be the case since ST is not fasifiable. as to your italian message, what stries me more is the use of the word “Faith”, which in my view shouldn’t belong to science. Will you still have faith after LHC will show no sign of SUSY?

Anyway I'll stop posting since this is becoming a personal argument and at the moment there is no moderation. And also the topic was "anthropic landscape" rather than ST in general. Sorry Peter.

31. **Peter Woit**
June 6, 2007

Michele,

I've never written anywhere that "string theory is completely useless". String theory is a mixed bag, ranging from some wonderful mathematics to some appalling pseudo-science. This posting is about the "Landscape", an increasingly active part of string theory research which is mathematically extremely ugly, as well as showing no signs at all of having any connection to physics. This is what I'm criticizing here as pseudo-science. If you're interested in my views on string theory in general, there's a huge amount of this here on the blog, and my book has just come out in Italian…

32. **Chris Oakley**
June 6, 2007

Like the host of this blog – and no doubt many others – I find Lubos's climbdown over the anthropic principle somewhat puzzling, especially as this does not seem to be based on any new evidence coming to light. I would advance the following explanation: although the String Theory community values Lubos's services as a cheerleader, they do, at the same time, recognise that he is a loose cannon, and have sent him to special clinic for reprogramming, a bit like Alex in *A Clockwork Orange*. The new Lubos, although just as hostile to critics of S.T. will now no longer resist the encroachment of anthropic arguments, or any other pseudo-science that comes his way, provided that it comes from the right sources.

33. **woit**
June 6, 2007

Apologies to John Baez, whose comment above spent all night in the spam queue of my blog software. It gets very suspicious when people use links in their comments, unfortunately it doesn't seem to be configurable in any way.

34. **Thomas Larsson**
June 6, 2007

Chris, the anthropic landscape is the language in which God wrote the world.

35. **Michele**
June 6, 2007

Dear Peter

I would Thank You for Your advices. I've determined to read Your new book.
Now, I'm writing You for ask You with regard the "Loop Quantum gravity", you think that it can be a good alternative theory as regards string theory?

36. **Brett**
June 6, 2007

I just want to point out that "verity" most certainly is an English word, one of which I happen to be rather fond.

37. **matteoeo**
June 6, 2007

strange, my dictionary doesn't quote it but I see on Word Reference it exists, must be very rare. sorry for that.

michele, would You like to answer my question about faith and science?

38. **Michele**
June 6, 2007

matteoeo

I believe in mathematics and this has not a metaphysics meaning.

39. **AGeek**
June 6, 2007

King ray wrote: "Physicists need to knuckle down, think hard for years and try to solve some real problems instead of darting off to higher or lower dimensions when things get too difficult. I think they publish too much."

True. Alas, this has a cause, known as "publish or perish". So either you pick/invent some easy problem which you can use to generate a lot of papers in a fairly limited amount of time, or you're out of academia and need to get a Real Job(TM) to put food on the table. And then you won't have much if any time to think about physics.

So academia ends up being populated by people doing things which they don't really believe in, holding on to the hope that some day, they'll end up having the time to do what they really would like to. Somehow. Someday.

Easy to criticize, but try to come up with a workable alternative.

Maybe somebody smart enough to do something really worthwile in theoretical physics should also be smart enough to become independently wealthy in a reasonable amount of time (a decade or so)? Then the best course of action might be to just fire all theoreticians and funnel the funds to experimental physics instead. An LHC is out of reach for individuals, so it can only be built using public funds. Not true of model building and theory.

40. **Leonard Ornstein**
June 6, 2007

Michele

"Believing" in anything for a while, is at least a temporary metaphysical act of faith.

Any social contracts to deal with something as "given", without proof, such as commitments to axiomatics of logic, mathematics, language, etc., are all equivalent to metaphysical acts of faith. So none of us, scientist or mathematicians, should decry metaphysic "belief" too vigorously. We can't avoid it.

But one shouldn't loses track of the difference between metaphysical, unprovable models, and those which (although also essentially metaphysical) are able to be supported or refuted by empirical observation. Because this distinguishes scientific models, and the scientific enterprise, from most other (including mathematical) models and disciplines.

The argument to which you should try to respond is that String Theories and the Landscape currently don't pass this test, as Science.

41. **fynn**
June 6, 2007

Thanks for pointing to the link to the TASI2007 lecture videos (via "Asymptotia"). Meanwhile I listened there to the first three lectures by Bousso on the c.c. problem, and found them very illuminating indeed. Without going into too much technicalities associated with string theory he makes a convincing point that the anthropic argument, taken seriously, is in fact not a mere tautology, and far from trivial, since it obliges to demonstrate that there are sufficiently many choices for the c.c. in the theory, and to derive from the theory a mechanism how these choices are populated in a way consistent with the observations about our universe.
Very recommendable lectures, also for non-experts.
Cheers, Fynn.

42. **Chris Oakley**
June 6, 2007

AGeek — you could be on to something there.

43. **Alex Mikunov**
June 7, 2007

Bousso's talk mostly based on his previously published papers, e.g.
http://arxiv.org/abs/hep-th/0702115
He's basically trying to substitute Weinberg's "observers require galaxies" with something like "observers obey the laws of thermodynamics"
What really bothers me is that, since superstring/M-theory is supposed to explain [among other things] thermodynamics as well, it's like saying "observers obey the laws of superstrings". This, of course, leads nowhere [at least logically].
(Correct me if I'm wrong)
Thus, it's obvious to assume that we need some sort of a meta-theory approach, maybe similar to what we have in mathematical logic/proof theory

44. **Raphael Bousso**
June 7, 2007

Peter,

A few years ago, you wrote about the Einstein issue of the Scientific American:

"One article in the magazine doesn't really have much to do with Einstein and I believe would make him gag if he were still around. The article, entitled "The String Theory Landscape" is by Raphael Bousso and Joe Polchinski. In it they claim credit for the pseudo-scientific idea of "explaining" the value of the cosmological constant by the existence of the "landscape" and the anthropic principle. It's sad to see this nonsense being purveyed by the most respected and well-known popular science publication in the US."

After Joe commented on this on Jacques Distler's blog (http://golem.ph.utexas.edu/~distler/blog/archives/000760.html), you offered an apology:

"First of all, you're right that the tone is quite objectionable and I'd like to apologize to you for it. I sincerely regret writing that posting in that way, and you're right to object to it. But while I agree with you about the civility issue here, I disagree with you about the issue of whether this kind of thing is legitimate scientific discussion. The example you give is a low point for my blog […]"

I am not qualified to judge the competition for low point on your blog, but the depth of your contrition is illustrated well by a more recent posting:

"I thought it odd that he chose to watch and recommend the Bousso talk, which is about as pseudo-scientific as these things get"

which, amusingly, prompted one of your readers to inform you of its content. I can't help admiring the frankness of your reply,

"I didn't watch the Bousso talk […]",

but the episode tempts me to quote the question that Welch asked McCarthy. You can google it as an exercise in checking sources.

45. **Peter Woit**
June 7, 2007

Raphael,

The only thing I regret here is that I did not express myself precisely in one of the comments I wrote, with the "about as pseudo-scientific as these things get" clause applying to your talk when I meant it to apply to the advertised topic of your lectures. I'll add something to the end of that comment to make that clear.

No, I didn't watch the talk, but I have read your recent papers, as well as a wide variety of other promotional material by you and others for the anthropic landscape, including your Scientific American article with Polchinski. I'm not about to apologize for referring to any of that as "pseudo-science", since that's what it is. I can assure you that, privately but perhaps not to your face, a large number of physicists express themselves in even stronger and less civil manner about this topic. After I apologized to Polchinski for some of the language used about the Scientific American article, I received several e-mails from people complaining to me that I had no business apologizing, since my description was completely accurate.

Many people besides me, including many of the leaders of the particle theory community, feel that what you and others are doing to (quite successfully) promote an inherently untestable research program is extremely dangerous for physics. I'm not going to apologize for forcefully making this case here.

46. **nigel cook**
June 7, 2007

If you think it permissible to bring up the McCarthy era as an analogy to criticisms of the cosmic landscape, you may escalate the hostilities because others will draw analogies between string propaganda and the propaganda of certain historical dictatorships, etc.

The following question in my opinion can more appropriately be directed to those who popularize pseudoscience, than to those who combat it:

'Have you no sense of decency?' – http://www.americanrhetoric.com/speeches/welch-mccarthy.html

47. **Bee**
June 7, 2007

well, the landscape is definitely a topic that attracts a lot of attention and very many interesting developments have been made in this field. I am presently at the String Phenomenology (this year near Rome) and we've just had a very stimulating talk by Keith Dienes who closed (among other things) with stating "just as in astrophysics, botany, and zoology, the first step in the analysis of a large data set is enumeration and classification" (slides not yet online, should be shortly). He made his points well, his talk was (as always) very good (as well as entertaining), and I understand the attempt of 'That's what we have, now let's deal with it' – which is imho as risky as courageous. Nevertheless I can't avoid finding the landscape botanics somewhat depressing.

48. **Peter Woit**
June 7, 2007

Bee,

The problem is that the landscape of supposed string vacua is NOT a "data set". Actual data about the real world is worth spending time enumerating and classifying. Endlessly complicated and useless constructions that reflect nothing except the failure of a certain research program are not worth spending time on. The fact that this is a rather easy activity to engage in, that you can keep yourself busy for years doing it, generating lots of papers, doesn't mean it's worth doing.

49. **Eric**
June 7, 2007

Peter,
If you think studying string theory vacua is is not worth your time, then you definitely shouldn't spend any time on it. However, leave the rest of us who think it's worthwhile alone. I don't see how it's any of your concern what the rest of us choose to study.

50. **Peter Woit**
June 7, 2007

Eric,

If you don't want to hear my opinions on "string vacua" and want to be left alone to pursue their study, all you have to do is not read this blog.

51. **Eric**
June 7, 2007

Ok, I won't read it anymore. I recommend this to everyone.

52. **Peter Shor**
June 7, 2007

In mathematics, I have the impression that the criterion for tenure is not counting papers, but counting really good papers. Is this different in physics? Do many mediocre papers get you tenure?

53. **Bee**
June 7, 2007

The problem is that the landscape of supposed string vacua is NOT a "data set".

Oh well. By now, you must know that I think the whole landscape is a bug not a feature. But I think the term 'data set' was just used in a somewhat vague context, referring not to 'data' as measurements, but as quantifiable features within that landscape of possibilities. Of course you can classify that stuff – isn't that what mathematicians do all the time? There's a vast number of possible mathematical structures, one can categorize them and count them, and find all kinds of interesting relations etc etc. If you like, you can try to calculate the probability for finding 9112001 within the first n digits of \pi or try to explain why there are more puddles than lakes, or why the number 17 is the most random number there is. See, I like maths, I also like zoology and botany, but I don't want it to be sold as physics. Plus I wouldn't want to categorize 10^500 things, whether vacua, herbs or butterflies. Best,

B.

54. **Peter Woit**
June 7, 2007

Peter,

People in physics do tend to write more papers than people in mathematics, but at good institutions, you're going to need to have written good papers to get tenure, not just a lot of mediocre ones. Of course, then the debate is about what is a "good paper", which is not so clear in a field like string theory unification, where no one is making real progress.

Of course, if it's too hard to write good papers, then, in terms of getting tenure, more mediocre ones is better than fewer.

55. **Peter Woit**
June 7, 2007

Raphael,

I did today watch your third TASI lecture on-line. In it you explain to the students that the Landscape is a "great success for string theory". After watching it, I'll stand by my characterization of what you presented to the students as "pseudoscience".

56. **Christine**
June 7, 2007

Bee wrote:

Of course you can classify that stuff – isn't that what mathematicians do all the time? There's a vast number of possible mathematical structures, one can categorize them and count them, and find all kinds of interesting relations etc etc.

It took 60 Gigabytes to store information on the exceptional Lie group E8… Analogously, if one considers the landscape as some type of mathematical structure *per se*, one would still have to deal — at some point — with an incredibly huge amount of information, no?

57. **Dave B**
June 7, 2007

What if the string theory is the correct theory of quantum gravity and the landscape is real? Can we really dismiss a theory just because it contains a feature we don't like? It's not impossible that the existence of our universe is completely random. Perhaps this is not a comforting thought, but it doesn't invalidate string theory. Rejecting string theory on this basis is as foolish as Einstein rejecting quantum mechanics because of its probablistic nature. Perhaps there are simply limits to our ability to know everything and make predictions.

58. **Peter Woit**
June 7, 2007

Dave B.

Yes, it's possible that the landscape is real, it's possible that we live in a Matrix overseen by superior beings, etc., etc. But an explanation is only scientific if it is possible to use it to make predictions which can be tested against experiment. This is scientific method 101, and it's something the Landscape people aren't doing. They don't have a plausible idea about how to test their theory, even in principle. This is why I claim it is pseudo-science, not science.

59. **Dave B**
June 7, 2007

I don't think it's fair to compare the landscape and string theory to some crackpot fantasy. It is a consistent body of work based upon solid mathematical underpinnings and well-motivated physically. I think your objections are philosphical rather than scientific. I don't think it's true that string theory is not able to make predictions 'in principle', it just may not be possible right now for technical reasons. If quantum mechanics has taught us anything, it's that it's impossible to know and predict everything. You would reject quantum mechanics as 'unscientific' because it cannot predict the outcome of every experiment and can only give statistical probabilities. Why is it so hard to believe that the properies and existence of our universe would be any different?

60. **Peter Woit**
June 7, 2007

The problem with the landscape is not that it doesn't predict everything, it is that it does not predict anything. QM makes a huge number of testable predictions, which have been confirmed, the landscape makes none (and the reasons for this are not "technical", but inherent in the whole concept). One of these is science, one is pseudo-science.

61. **Dave B**
June 7, 2007

No, the landscape predicts a discrete set of possible vacua, any one of which could be a description of our universe. QM does the same. For an invidual measurement, QM can only make statistical predictions by assigning probablities to a large set of possible outcomes. You can only test QM by performing a large number of individual measurements. IT CANNOT PREDICT THE OUTCOME OF AN INDIVIDUAL MEASUREMENT. I'm sure that the landscape of string theory is the same, only it's not presently known how to assign probabilities to the different vacua.

62. **Peter Woit**
June 7, 2007

Dave,

You have no idea what you're talking about. QM makes both exact and statistical predictions. The landscape of string theory is not the same. It makes no predictions whatsover.

63. **Eugene Stefanovich**
June 8, 2007

Dave B.:

I don't think it's fair to compare the landscape and string theory to some crackpot fantasy. It is a consistent body of work based upon solid mathematical underpinnings and well-motivated physically.

I would disagree about *solid mathematical underpinnings*. In my opinion, physicists were never interested in a rigorous mathematical (definition/axiom/theorem) formulation of their theories. Theoretical physics was always a patchwork of mathematical proofs, plausible guesses, and outrageous hypotheses. For centuries this worked fine, because experiment provided a mechanism of "natural selection": stupid theories couldn't survive experimental tests. Now we don't have the culture of mathematical rigor, and we don't have experimental censorship. In these conditions, the only factor of "natural selection" is sociological: if you managed to gather more supporters than your opponent, then your theory won.

64. **Anonymous**
June 8, 2007

In response to Raphael Bousso, Peter Woit wrote, "No, I didn't watch the talk, but I have read your recent papers, as well as a wide variety of other promotional material by you and others for the anthropic landscape … I'm not about to apologize for referring to any of that as 'pseudo-science', since that's what it is. I can assure you that, privately but perhaps not to your face, a large number of physicists express themselves in even stronger and less civil manner about this topic."

For those who weren't able to track down the question that Welch asked McCarthy, here's a clue: "in February 1950, an undistinguished, first-term Republican senator from Wisconsin, Joseph McCarthy, burst into national prominence when, in a speech in Wheeling, West Virginia, he held up a piece of paper that he claimed was a list of 205 known communists currently working in the State Department. McCarthy never produced documentation for a single one of his charges, but for the next four years he exploited an issue that he realized had touched a nerve in the American public." From "Basic Readings in U.S. Democracy",
http://usinfo.state.gov/usa/infousa/facts/democrac/60.htm

65. **Thomas Larsson**
June 8, 2007

Godwin's Law:
As an online discussion grows longer, the probability of a comparison involving Nazis or Hitler approaches one. Once such a comparison is made, the thread is finished and whoever mentioned the Nazis has automatically "lost" whatever debate was in progress.

It seems to me that McCarthy can be substituted for Hitler, and that prof. Bousso thus has lost the argument.

66. **Bruno**
June 8, 2007

Could it be that the Landscape is welcomed by the proponents of Intelligent Design? As soon as it is established by reputable physicists that the very delicate fundamental features of the universe were created as an extremely improbable choice out of an astronomical number of possible choices, the religiously minded will triumph.

I think science shouldn't give up trying to explain observations.

Best regards,
Bruno

67. **Peter Woit**
June 8, 2007

In response to "Anonymous" who left the address "anonymous@anon.com",

Raphael chose to write in here and say what he had to say under his own name, which I greatly respect. It's a very unfortunate aspect of this debate that many people feel unwilling (often for good reasons) to publicly get involved in it in any way. If anyone doubts though that there is strong opposition to the idea that the Landscape is a "great success" of string theory, or that there is a widespread opinion that it is not normal science and is a bad thing for the field, pick a random sample of physicists and ask them privately. Or note that Susskind, the most well-known proponent of the Landscape, recently described his experience as that of being at the center of a circular firing squad.

68. **wow**
June 8, 2007

The situation is considerably more nuanced than you describe, Peter.

Most string theorists now believe there is a landscape, in the sense that the semiclassical approximation to the theory has a huge number of consistent, metastable (or in supersymmetric or AdS cases, stable) vacua.

Most string theorists are not yet willing to buy into anthropic reasoning; they view the situation above as disturbing, but as one that can perhaps be "saved" by a selection principle. The detailed nature of this principle is however never discussed (some people talk about Hartle Hawking wavefunctions or whatever, but there is no indication at all that this helps).

The belief in a large number of consistent vacua is supported by a large body of mathematical work of varying levels of rigor, since the theory does not allow exact computations in most cases of interest. But the evidence is now accepted as fairly decisive by most theorists. This was clear even at Strings 2005, the location of the infamous anthropic poll which also demonstrates the point about hostility to anthropic reasoning. It has only become clearer over the past 2 years.

It will be interesting to see how many can continue to deny the efficacy of anthropic reasoning about the CC as the years pass, if the wished-for dynamical miracle does not materialize.

69. **Peter Woit**
June 8, 2007

wow,

I'm not sure what "most" string theorists think, it's certainly true that the situation is nuanced, with many people having trouble figuring out how to deal with it.

I suspect that your point of view may be somewhat influenced by the part of the world you are in, but, sure, what I was writing about in the posting was the increasingly widespread degree of acceptance of the Landscape as a well-founded aspect of string theory. Yes, more and more string theorists acknowledge that it is a feature of the semi-classical approximation to the theory in a metastable ground state. But there are two possible reactions to this:

1. These are physically relevant ground states for the full theory. To get the SM and actual physics out of this, then opinion splits between anthropic/statistical argumentation (also known as pseudoscience…) and belief that a cosmological selection principle will save the day (also known as wishful thinking…)

2. These are probably not physically relevant ground states for the full non-perturbative theory, whose properties we do not understand yet at all. From everything he says, I take this to be David Gross's point of view, and that of many other people, including almost all the string theorists I know personally and have discussed this with.

I find 2. to carry too much wishful thinking for my taste, although it's nowhere near as bad as the wishful thinking that Hartle-Hawking will save string theory by picking out a point in the landscape. The point of view of proponents of 2. is often that better understanding non-perturbative string theory is in any case an interesting research program that, even if it fails as a TOE, quite possibly will lead to other important results (a solution of QCD, new mathematics, etc.)

I would guess that there are more string theorists in camp 2. than in camp 1, but I don't have very good statistics. Maybe at Strings 2007, this question can be put to a public vote…

70. **wow**
June 8, 2007

Hi Peter:

Thats interesting. I don't know any who hold view 2; the
AdS/CFT correspondence pretty much kills this point of
view for many of the AdS vacua, since the field theories are well defined and hence show that string theory really does have these exact, well defined superselection sectors giving distinct stable solutions. One could hope all metastable
De Sitter or Minkowski vacua are just artifacts of the semiclassical
approximation, but I don't know any string theorists who really
believe this (well, maybe Tom Banks; you say D. Gross, though this doesn't coincide with my understanding from actual discussions I've witnessed).

Point of view 2. would require all kinds
of miraculous failures of perturbation theory, and in normal physics, we haven't seen this happen. (Almost our entire understanding of general relativity and quantum field theory is not "nonperturbative" in this sense, and we use them quite successfully every day; the Standard Model is not fully asymptotically free and this doesn't hamper us, GR cannot be quantized without invoking string theory, etc.).

Clearly, we must be talking to different (very large) samples of string theorists.

71. **Peter Woit**
June 8, 2007

wow,

My understanding of Gross's point of view is purely based on several of his talks I've attended, and an even larger number of talks of his accessible in one form or another on the net. His two main oft-repeated points are that "we don't know what string theory is", and "string theory will require us to replace space (and probably time) by something else". I take these to mean he has in mind something more drastic than a Hartle-Hawking or other cosmological selection mechanism for one of the metastable vacua in the landscape, but maybe I'm wrong.

One other confusing aspect of this question is that of identifying who is a "string theorist". Many people I talk to who have written quite a few papers on string theory, or even most of their papers on string theory, will say things like "maybe I'm not really a string theorist", or "I might be a string theorist, but I'm not part of the 'string theory establishment'". It's also true that my sample is weighted towards those working on the more mathematical ends of string theory. But I also notice that publicly many "establishment" string theorists answer criticisms of string theory by claiming that the theory is still extremely poorly understood, with some clearly having in mind a time-scale of another 100 years before real contact with experiment is made. They often make the point that multiple new "revolutions" may be needed, and I take this to mean that they see the currently known string vacua constructions as far from the final story about how unification will come out of string theory.

Peter Woit says:
"To get the SM and actual physics out of [the landscape], opinion splits between anthropic/statistical argumentation (also known as pseudoscience…) …"

On what basis do you believe that it is *impossible* for the parameters of the SM to be randomly determined?

It will indeed be disappointing if it turns out that the parameters of the SM (possibly including the number and type of gauge groups and the representations of the matter fields) cannot be predicted from a more fundamental theory, because it turns out that they are in fact the result of a random process in some sort of multiverse. But I don't see how you can know, right now, that this *cannot possibly* be the case.

And if it *can* possibly be the case, then it is surely wrong to label investigations of this possibility as pseudoscience.

After all, we don't say that the physics of planet formation is pseudoscience because we can't use it to calculate the number of planets in out Solar System and their distances from the Sun; we don't say that geology is pseudoscience because we can't use it to calculate the shapes of the continents.

And if string theory turns out to be compatible with a great variety of models of low-energy physics, then in this regard it's no better or worse than quantum field theory. Should we declare that quantum field theory has failed because it cannot be used to calculate the parameters of the SM?

73. **Peter Woit**
June 8, 2007

Mark,

I'm pretty sure we've had exactly this argument before, and the answer to your points is in some of my responses to the comments above. But, again:

The problem with the landscape is not that it doesn't predict everything, but that it doesn't predict anything. This is very different than QFT, which makes a host of testable, verified predictions. Sure, it is possible that all parameters, gauge groups, representations of the SM are environmental. It's also possible that they are chosen by an omnipotent being who wanted us to have a cozy place to live. If you want to do science, not pseudo-science, your theory has to make distinctive, experimentally testable predictions that will allow it to be checked. If you know of such a prediction made by the anthropic landscape program, let's hear it. The only ones I know of are either

1. pure wishful thinking on the order of "maybe if we calculate observables in all 10^500 vacua, the statistics will have a narrow peak and we can make a prediction". There is not a shred of evidence for this, in any of the by now many calculations people have been doing, nor any argument at all why this should happen.

2. fairly solid arguments that completely disagree with experiment. The most well-known is the anthropic landscape prediction of the proton lifetime, which is many, many orders of magnitude too low.

The reason the landscape is pseudoscience is that you can't use it to make testable predictions. If you are willing to make some assumptions that do allow non-trivial predictions, they often come out completely wrong. This kind of activity is just not science.

June 8, 2007

Peter,
Name one prediction that QFT alone can make without any input information, i.e. gauge groups, gauge couplings, and matter content. All of these things must be put into QFT by hand, and then and only then can you make predictions. As Mark has said, this is no different than string theory, which for a given vacuum would be just as predictive. If the vacuum which corresponds to the physics of our universe could be found, then this would be just as predictive as the QFT Standard Model. In fact, it would likely be more so since it would include gravity. The real questions are 1) does such a vacuum exist and 2) how is this vacuum selected. I think we would be a lot better off if we focus more on the first question and leave the second question for later.

75. **Peter Shor**
June 8, 2007

Eric,

I don't see how you can possible call quantum field theory a failure given its successful predictions over the last 30 years. The success of quantum field theory is not that it actually predicts anything a priori, but that once you constrain your quantum field theory by using the results of experiments, it predicts the results of other, apparently completely unrelated experiments. Can string theory do this? Right now, absolutely not.

If string theory is to be able to do this, I believe you will have to address one of the following questions: (a) are there effective quantum field theories that are not allowed by string theory? or (b) is there any reasonable way to actually select the vacuum? I don't believe that the landscape studies that Peter Woit is disparaging address either one.

76. **anon.**
June 8, 2007

'… this [QFT] is no different than string theory, which for a given vacuum would be just as predictive. If the vacuum which corresponds to the physics of our universe could be found, then this would be just as predictive as the QFT Standard Model. In fact, it would likely be more so since it would include gravity.' – Eric

Yeah, all you need to do is to be sure that the 1 in a 10^500 vacuum is the right one. Easy:

1. choose the best vacuum you can identify (ie one with a small positive cc, assuming that the cc is a real constant and is not evolving with time, as some recent cosmological studies with gamma ray bursters suggest)

2. use it to make new predictions.

Now the clever bit:

if the things it predicts don't show up, then it's the wrong one.

You then pick out another one of the 10^500 and start again. Eventually you'll or some distant stringy descendent will get there, providing that string theory *is* the right theory…

Of course, if you're wrong, no worries. You'll be dead and buried for billions of years before the entire 10^500 possibilities have been experimentally refuted.

I think this is the point about the landscape. Of course, *if* some version of string theory *is* reality, and *if* the it could ever be identified, then yes, it might be able to predict things in principle. You're kind of missing the small problem that nobody has ever given any scientific evidence that this *might* be the case. Consistency with spin-2 gravitons and supersymmetry isn't scientific evidence since there is no evidence for either, they're just guesses.

QFT works because its easy to plug experimentally found data into it, which identifies the real vacuum, and get predictions. You can't do this with string theory because you don't know the state of the unobservably small rolled up dimensions in the Calabi-Yau manifold which determine the details of the particle physics. You have to guess one of 10^500 possibilities before plugging experimental data into it to get a prediction. That's why it's a total failure.

77. **woit**
June 8, 2007

Eric,

The bottom line is simple and you have no argument against it: your theory has to produce a distinctive, experimentally testable prediction, otherwise belief in it is a matter or faith, not science. The landscape doesn't do this, or, to the extent it does, people ignore disagreement with experiment. This is pseudoscience, not science.

Saying "But my unpredictive and untestable theory is better than the SM, because it also includes an unpredictive and untestable gravity sector!" doesn't change the fact that you are asking people to believe something about the world that can't possibly be checked. This isn't science.

78. **Eric Mayes**
June 8, 2007

Peter S.,
I think you misunderstand me, I have not called QFT a failure. However, it should be recognized that the standard model is but one QFT out of many possible QFT's. One has to build a model consistent with QFT and then make predictions within this model, but by itself QFT can do nothing. String theory is the same. Regarding whether or not string theory can make predictions of some parameters in terms of others once it has been constrained by experiment, the answer is yes. We are presently doing this. As far as the landscape studies that Peter W. disparages, I agree that they are not likely to go very far.

79. **woit**
June 8, 2007

Peter Shor,

The "swampland" program does try and address the problem of identifying effective QFTs that can't come from string theory. The problems with this program are that:

1. Showing that some class of models that don't look like the real world can't come from string theory doesn't provide evidence that string theory actually has something to do with the real world.

2. String theory is still so ill-defined that it's not clear you can say that string theory can't produce some model or other. People keep on coming up with new compactification schemes. Typical "swampland" arguments don't actually have anything to do with string theory, but try and argue that the existence of gravity rules out certain kinds of effective QFTs.

80. **Paolo Bizzarri**
June 9, 2007

Eric,

I understand that the problem of SM against ST is that SM is much more constrained.

You are saying that you are predicting some values, given some other values as parameter (a specific selection of the vacuum).

Is this a falsifiable prediction?

In SM, if an experiment would reveal a different value for some of its parameters, we could not simply say “Ok, so we have to tune this and this other parameter”.

Am I right?

81. **Eric Mayes**
June 9, 2007

Paolo,
The model is as constrained as the CMSSM. Most of the so-called ‘tunable’ parameters are the F-terms which define how supersymmetry is broken. It’s possible to get many different spectra with these five parameters, however the spectra are constrained by phenomenological considerations. If for a given set of values for these parameters the model can get the right values for ALL of the superpartner masses, then the model would completely describe low-energy physics. If it can’t reproduce the superpartner masses, then the model is falsified. Keep in mind that all of the parameters in the model are tightly constrained by requiring supersymmetry at the string scale, gauge coupling unification, and the correct CKM masses and mixing for the normal SM particles.

82. **Paolo Bizzarri**
June 13, 2007

Eric,

just a very dumb question. Which are the right values of the superpartner masses?

Thank you.

83. **alex**
June 19, 2007

“Which are the right values of the superpartner masses?”
