In my opinion, QM is consistent with the view that although there are uncertainties about the individual events, however, the statistical results of many numbers of events are robust with respect to small changes in the conditions of the experimental setting.

However, this begs the question if it is possible to devise a way to find out more about individual events.. To me this seems almost impossible.

17. **Xu Jia**
August 12, 2014

John Bell's work. We just don't have such people as him having a clear thinking nowadays. I think if he could live longer and got his Nobel Prize in time, many things would be different. In his words, there are simply no such things as apparatus and "boundary between classical and quantum world".

18. **Matt Leifer**
August 12, 2014

Peter,

OK then, let me recommend at least one thing. I think you might like this long review article by Klaas Landsman http://arxiv.org/abs/quant-ph/0506082 The thing I like about it is that he emphasises the dual role of quantization and the emergence of classicality.

19. **Peter Woit**
August 12, 2014

Jasper,
Thanks, that's great. You're addressing exactly the sort of question that I've been wondering about and have had trouble finding a clear discussion of. If you can recommend where to read more about these issues that would be very helpful.
As a crude summary though, do you think it's fair to say that the source of supposed probabilistic nature of QM is that we only have probabilistic information about our experimental apparatus? Or does this summary miss something very important?

20. **Too Distinguished**
August 12, 2014

I second Xu Jia's comment that John Bell had the clearest perspective on these issues. And I agree with what some others have said, that complicated-sounding questions about the quantum-classical transition and measurement all reduce to the basic question of what, exactly, exists. The mathematical formalism of quantum mechanics works great, but when it comes to describing reality, it seems obvious that there have to be non-local hidden variables.

21. **Peter Woit**
August 12, 2014

Matt,
Thanks a lot! I look forward to reading the Landsman review carefully, he's great in general on the issue of the mathematical structure of the theory, I'd forgotten that he's written also on this topic.

Als,

Thanks for the reference!

22. **Peter Woit**
August 12, 2014

All,
Justin has a good point that these discussions can quickly degenerate into unenlightening discussions of hidden variables. The 't Hooft posting was about a "hidden variable" theory, this isn't, so no more of this please.

23. **nick herbert**
August 12, 2014

JUJITSU UNIVERSE
We house-broke quantum reality
Taught Schrödinger's Cat to purr
Now daily life's more uncanny
Than atoms ever were.

24. **manfred Requardt**
August 12, 2014

By the way, there does exist an alternative to decoherence by environment. See for example arXiv:1009.1220. Instead of the environment a restricted set of commuting macrovariables is introduced. It is like coarse graining and is based on a beautiful old paper by v.Neumann.

25. **Curious Mayhem**
August 12, 2014

This is certainly a compelling way to look at quantum mechanics, instead of the convoluted path that starts with classical mechanics. The problem has always been what von Neumann called R, the reduction upon measurement, not U, the simple unitary transformation in the Hilbert space.

And the right approach to come from the other direction is the "decoherence" approach — it's completely physical and can, in part, be tested in a laboratory. That sweeps away the stifling metaphysical cud-chewing of "interpretations" of QM, like Copenhagen, many worlds, etc.

26. **vmarko**
August 12, 2014

Jasper,

"I've been studying the measurement problem for the past year, and I'm currently satisfied with decoherence as a solution to the preferred basis problem"

I'd second Peter's request — can you point us to a good review which discusses this? No matter how various people phrase decoherence as a solution to the preferred basis problem, I always fail to understand it, and always find holes in their arguments.

"This is because of the form of possible interactions in physics. We cannot measure in the basis corresponding to non-local superpositions because all(/most) interactions are local"

And this is one of the things where I disagree most. People must not ignore quantum gravity — locality of interactions is based on the assumption of a classical spacetime manifold, i.e. that gravity is not quantized. As soon as you try to quantize gravity, you must allow for quantum superpositions of different spacetimes, and as a consequence locality goes out the window. And then the pointer basis problem comes back at you in its full glory, all over again.

So whatever you do to fix the pointer basis, *do not* base your argument on locality!

I would really, really like to see a serious review which systematically discusses how a pointer basis comes about, especially if "induced" by decoherence. And then I would probably have additional questions for the author. Any references, please?

Best, 🙂
Marko

27. **James Cooper**
August 13, 2014

These are targeted at a layman, and the site does have a crackpotish design, but I found them very helpful in understanding decoherence and explaining why the world must behave quantum mechanically
http://www.ipod.org.uk/reality/reality_decoherence.asp
http://www.ipod.org.uk/reality/reality_is_relative.asp

28. **Jasper**
August 13, 2014

Before I respond to some of the questions, I just want to say I have the same problem as Sabine (Bee): "I change my mind on this every couple of weeks".

@Matt:
It's fun to see you recommend the article of a my supervisor 😉 I'm a postdoc working with Klaas Landsman.

@Peter:

"As a crude summary though, do you think it's fair to say that the source of supposed probabilistic nature of QM is that we only have probabilistic information about our experimental apparatus?"
I think that's about right, but I'd rather say that if you wish to define a state of a single quantum system we need first to obtain probabilistic information about the *preparation procedure* and about the *detection procedure*. It is the robustness of this probabilistic information against known and unknown "small" changes in the procedures why we can say anything about quantum phenomena. It is hard to say what the exact conditions are in each run and this is often not mentioned. In most considerations in QM it is common to automatically jump to pure states of single quantum systems, without considering the preparation and detection procedures, but does this description really reflect nature?

As an example of some of the above: experimenters in quantum optics mostly view the polarizer to be in a certain direction and that after all photons in a finite ensemble pass the polarizer they are verified by a subsequent detection procedure to always have a polarization in the direction of the polarizer. We can thus for other experiments use these photons and simply say they are in a pure state of the polarization after passing the polarizer. However, is/was the polarizer always truly in the specified definite direction? Is the polarization detection procedure always along this very precise axis? It would seem to be better to describe the photon as entangled with the polarizer which has some spread along the mostly known direction, but this means that when restricting the state to the photon we should actually describe it by a density matrix, not a pure state.

Also, Peter, if you would like to have a discussion on these topics, please feel free to contact me!

@vmarko:
Could you help me understand your problems with decoherence as a solution to the basis problem? I'm always interested in learning the views of others, especially to see if I missed something important..
I think your theoretical argument about quantum gravity is valid, although I believe I can for the purpose of understanding the experimentally observed nature of reality ignore it for the moment, as the decoherence solution seems natural and satisfactory within this context. In my foundational research I try to stay as close to experiment as possible to not lead me astray. I do not know at the moment what is physical and observable about "superpositions of space-time" and what questions I am allowed to ask or not, and thus I simply try to solve the problems at hand in the best way possible. This is my take on research, you cannot solve all problems at once, simply solve a problem in one arena then try later to expand to the other. By using only observed effects of QM, namely entanglement, I do not see what is wrong with using the fact that the interaction between electrons and the EM-field is at a single ("local") point to understand that if I have a superposition of the electron |x1>+|x2> that after coupling with the environment it will be |x1>|E1>+|x2>|E2>. In the end this will mean that if ~0 coherence disappears on the local level of the electron. The interaction "simply" dictates how the environment couples to the system, if for example it coupled differently and would be of the form (|x1>+|x2>)|E12>, it would not lead to loss of coherence.. As you now see, in this case the interaction determines the preferred basis, it is "localized" in position space, and not in, for example, the basis |x1>+|x2>.

As for references:
Unfortunately, there are no clear explanations, but the references you have are the best starting point.

Schlosshauer's book is very good and has had considerable influence on my thoughts. Also Schlosshauer's "Elegance and enigma", which is a book with interviews of researchers of all corners of the foundational arena and gives a clear overview of how people can think about QM.

Zurek is also good, but his vision of the capabilities of decoherence might often be too far extrapolated for my taste.
The second chapter of the book by Audretsch "Entangled Systems New Directions in Quantum Physics" just for the clear explanation of some of the hidden assumptions people sometimes skip when interpreting experiments.

I recommend the following article by De Raedt, Katsnelson, Michielsen:
http://www.sciencedirect.com/science/article/pii/S000349161400102X
This article was also important for my view of QM. It overlaps with my overall view of what experiments say about nature and what can be inferred from them. However, as with almost any article, I don't fully agree with it.

Allahverdyan, Balian, Nieuwenhuizen for the references and the discussion: http://www.sciencedirect.com/science/article/pii/S0370157312004085
Do not believe any claims on their part on "solving" the measurement problem, but their summary, discussions and references on the relevant quantities to this problem are quite clear. Simply do not read most of the main text, unless you want the nitty gritty details of how to understand their specific (but semi-realistic) model describing entanglement of a certain measuring device with a system, the selection of a basis of detection and the loss of coherence of the measuring device and of the system in this basis. They do not solve the single outcome problem, but merely show the decoherence solution to the superposition and basis problem.

29. **manfred Requardt**
August 13, 2014

Certainly entanglement is an important concept in QM. But in my view decoherence by environment is similar to friction in classical mechanics, i.e. it is of a rather contingent nature. I doubt that such an unsystematic interaction with the environment is really the solution to the quantum measurement process.
A cornerstone of the decoherence philosophy is the socalled basis ambiguity (for macro staes) which is then claimed to be solved via the selection of a pointer basis by decoherence.
In arXiv:1009.1220 we showed that the construction of a subalgebra of macro observables within the larger algebra of microscopic observables does exactly the same job. We then get mixtures in the classical world living above the microscopic quantum world in which the corresponding many-body state is still pure.

30. **vmarko**
August 13, 2014

Jasper,

"Could you help me understand your problems with decoherence as a solution to the basis problem?"

I'd be glad to discuss this with you, but I am afraid that Peter's blog might not be the best way to do it. How about we take the discussion privately, via e-mail? Peter, can you connect us?

The thing with quantum gravity revolves around the issue of fundamentality of QM. If nature really obeys QM at the fundamental level, then QM should be capable of describing even cosmology. I just don't see how the measurement problem can be solved by decoherence in that setup (no locality and no environment). And if QM is not fundamental but only an effective theory, then it is not really relevant, and calls for a construction of some other, more fundamental theory.

Btw, thanks for the references! I didn't get the chance to look them up yet, but I'll certainly do it soon.

Best, 🙂
Marko

31. **Jim**
August 14, 2014

Peter,
Nice post. I think part of the problem is that these issues of interpretation force us to make a simple choice. We either 'shut up and calculate' or we acknowledge that something has gone wrong somewhere or something's missing. Adopting the second position involves indulging our inner metaphysician and speculating about what we think reality should or might be like. Unfortunately, most papers on the foundations of quantum theory never get back across the line – they're stuck in a metaphysical no-man's land with no prospect of saying anything that might eventually lead to some kind of empirical test. The few that succeeded in getting back across the line – Bohm, Bell, Leggett to name a few – have inspired some awesome experiments which have deepened the mystery but which have also opened up new areas of research in quantum information.

There's actually been quite a bit of progress but the fundamental problems remain seemingly intractable: How should we interpret quantum probability? Quantum non-locality and the collapse of the wave function? 'Spooky' action-at-a-distance? All the different interpretational schemes are designed to circumvent some or all of these, including many worlds (which simply avoids them by invoking a multiplicity of different realities in which all possible measurement outcomes are realised).

All these issues were well known and formed the basis of the famous Bohr-Einstein debate in the late 1920s.. We've been living with these problems for nearly a century.

32. **Martin**
August 14, 2014

Re decoherence: something similar at http://arxiv.org/abs/cond-mat/0303290

Unitary time evolution of the density matrix does not change its eigenvalues, yet this is necessary for thermodynamic change. Similar to decoherence: an incomplete description of the system yields nonsense.

33. **Jan Reimers**
August 14, 2014

Two things that have always bothered be about most discussions of this topic:
1) Over emphasis on the term "measurement" which implies that some sentient being is watching, which then drags the conversation off into ridiculous directions. It is really just interactions which generate a macroscopic effect that creates the illusion of wave function collapse. This can happen in lab, but it mostly happens everywhere else, including half way between here and Andromeda for example. Is there any reason we must call it the "measurement problem" rather than the "interaction problem"?

2) Ignoring basis selection (einselection) as exemplified by the http://www.ipod.org.uk/reality/reality_decoherence.asp article. The density matrix goes diagonal in a particular basis,but why is that basis selected? Local interactions select a basis that localized in position space … how does that work and is it a universal rule?

Thanks
JR

34. **James Cooper**
    August 14, 2014

    > There’s actually been quite a bit of progress but the fundamental problems remain seemingly intractable: How should we interpret quantum probability? Quantum non-locality and the collapse of the wave function? ‘Spooky’ action-at-a-distance?

    Jim,
    Why would you say these problems are intractable? Of the last 3, one could say the decoherence papers has answered them. Heisenberg himself understood much of it in an albeit vague way. There is no “collapse” of the wave function – it just decoheres. Once it does so (ie. can no longer interfere with itself) that is what we call ‘reality’ which is just another word for the decoherence. Classical physics and classical intuition is an emergent phenomenon. Nature is not realist: your physical state is only an approximation and has no real meaning.
    As much as I hate to link to something Lubos wrote- the first 2 answers in this thread really sum up this way of thinking
    http://physics.stackexchange.com/questions/3158/why-quantum-entanglement-is-considered-to-be-active-link-between-particles

    I think the 1st question (on probablity) is the interesting one. Once we accept that nature is not deterministic (BTW, If it was, I couldn’t tell my fingers to type the keys they are typing!) and that quantum mechanics is complete, we can do away with Bohm and MWI and get back to the most interesting interpretation of all – Conciousness – What is it and how does it work

35. **Martin**
    August 14, 2014

    @Jan, point 2): this is specified by the observer. A system is typically described with a density matrix that corresponds to the energy of the interaction that yields the observation. E.g. at very low energies an atom can be described as a little ball without internal dynamics. At higher energy electronics transitions must be taken into account, at very much higher energy the internal dynamics of the atomic nucleus starts to play a role, etc. This is why classical theories such as the Navier-Stokes equation work at low excitation energies (long wavelengths) even though they ignore the molecular microstructure of the system (which enters the theory as parameter values such as viscosity).

36. **vmarko**
    August 14, 2014

    Folks, please stop telling everyone that decoherence solves the measurement problem. It doesn’t, until someone finds a solution to the preferred basis problem.

    Let me explain it a bit: suppose we are about to measure the spin of an electron, which is in the initial state |u>+|d> (I’ll be ignoring normalization factors of 1/sqrt(2) throughout). The “measurement” means to let it interact with the environment (i.e. the apparatus). After the interaction, we can write the state of the big system (electron plus environment) as |Psi> = |u>|Eu>+|d>|Ed>, where “Eu” stands for “environment has recorded the spin of the electron to be up”, and similarly for “Ed”.

    Now let me formulate the problem. I can introduce a different basis for the electron, |+> and |->, which is rotated by 45 degrees, as |+>=|u>+|d>, |->=|u>-|d>, and similarly |E+> and |E-> for the environment. Then I can rewrite the final state as |Psi>=|+>|E+>+|->|E-> (it’s the same state as above, this is just a change of variables). The problem is now that in experiment we always find the apparatus in states |Eu>,|Ed>, and never in |E+>,|E->. The former is somehow preferred over the latter by experiment, but not by theory (short of invoking the collapse postulate of Copenhagen interpretation). This is called the “preferred basis problem” or “pointer basis problem”.

    I simply don’t see how decoherence can be invoked in any way to favor one basis over the other (and I am not alone in this). Until you can provide a clean resolution to the pointer basis problem, please stop endlessly repeating that decoherence solves the measurement problem. It doesn’t.

    HTH, 🙂
    Marko

37. **Jim**
    August 14, 2014

    James Cooper
    vmarko answered your point on decoherence before I could respond, and I couldn’t have put it better. I haven’t looked at the literature for a while, but my understanding is that decoherence doesn’t solve what Roland Omnes called the ‘problem of objectification’. Roger Penrose called it the problem of objective reduction and there’s a nice quote from John Bell somewhere about decoherence being unable to explain how ‘and’ is replaced by ‘or’.

    I’d be wary of trying to resolve the problems by connecting measurement with consciousness. This has a long history (von Neumann – inspired by Wigner – credited consciousness as an explanation for his projection postulate – essentially the collapse of the wave function – in his famous book Mathematical Principles of Quantum Theory published in 1932). Trying to shed light on something we don’t understand by invoking something else we don’t understand has always seemed an odd strategy to me.

38. **Jasper**
    August 14, 2014

    Simple answer to Marco ‘s problem : there are no realistic coupling terms in quantum theory which couple the system and environment in the second basis, just as I gave in my original example for the spatial superposition. To measure the spin of an electron you need to use the electromagnetic coupling.. and work from there.
    If you want to understand this important point, study a realistic model with realistic coupling between spin, measuring device and an environment.. In the end the interaction terms determine the bases which are robust and coherence terms dissappear on the level of system and measuring apparatus.

    Also, as said, decoherence does not solve the single outcome problem aka the measurement problem, only basis and superposition problem.

39. **vmarko**
    August 14, 2014

    Jasper,

    “there are no realistic coupling terms in quantum theory which couple the system and environment in the second basis”

    I don’t understand this. The state |psi> that I wrote is the *final* state (the one describing the electron and the environment *after* the interaction), and I wrote the *same* state in two different bases. The properties of the interaction are important only when calculating the final state from the initial state. But once known, the same final state can be represented in two bases, and in experiments we always see only one of them and not the other. The interaction simply plays no role in this, as I see it.

    Can you explain your point more precisely?

Best, 🙂
Marko

40. **Jasper**
August 15, 2014

This will be my last post, because this discussion is time consuming. I recommend reading Schlosshauer since it is very clear.

The coupling picks which components of the environment couple to the which components of the system. The environment is thus correlated with specific information on the system, then if the distinct environmental states are almost orthogonal you can say that on the level of the system the coherence has almost disappeared in the components of the system picked by the coupling mechanism.

Example: An environment of light particles scattering with a massive particle, which is in a superposition, using contact interactions
(|x1>+|x2>)|E> -> |x1>|E1>+|x2>|E2>
The states |E1> and |E2> become more and more distinguishable as they encode many collisions of the light particles with the massive particle. The states become more and more orthogonal, thus coherence disappears between |x1> and |x2>. Any other states of the environment would not have this orthogonality. In fact, I can derive the timescale of this orthogonality…

Another example (hope this works, since I'm making it up as I go along): Qubit encoded in hyperfine levels of a atom with monitoring by stimulated photon emission

A qubit is encoded in two levels of an atom, where the state |u> corresponds to a higher energy level than |d>. Then we couple with an EM field which has exactly one photon in with exactly the energy difference between the levels. Stimulated emission means that the EM field (read: environment) becomes entangled with the qubit:
|u>|1> -> a|u>|1>+b|d>|2>
Here |1> means 1 photon with the specific energy and |2> two photons . Note that |1> and |2> are orthogonal and that they couple in a clear way in the basis |u> and |d>.

For the down state: |d>|1> -> c|d>|1>+d|u>|0>.
A superposition of the qubit thus behaves as
(|u>+|d>)|1>->a|u>|1>+b|d>|2>+c|d>|1>+d|u>|0>
Since |0>, |1> and |2> are orthogonal, when restricting to the qubit (read: trace over EM states of density matrix) we can see that coherence between |u> and |d> can become less (Note: depends on specific details of coupling, i.e. the coefficients a b c d).

Yes, after all this I can still write the density matrix in another way, but the orthogonal states of the EM field only couple in the above specific way to the atom,in the |u> and |d> basis which is where coherence is lost. In other words, using EM field we can only "observe" |u> or |d> of this atom, not a superposition |u>+|d>, and thus this basis is preferred.

Maybe not the most clear example and a bit too ideal, but the point is that for all realistic physical systems, with some thought, the preferred basis can be identified in which entanglement occurs which results in loss of coherence.

Anyway, hope you kind of see the idea.. It's better to read the book.

41. **manfred Requardt**
August 15, 2014

These problems how a pointer basis is selected, i.e. the basis ambiguity, is discussed and in my view solved outside the realm of decoherence in the paper I mentioned above. I think decoherence is a too cheap solution to be correct under all circumstances.

42. **Martin**
August 15, 2014

@vmarko "The state |psi> that I wrote is the *final* state (the one describing the electron and the environment *after* the interaction)"

No, the interaction is the measurement. After the measurement it is known whether the spin was up or down. What you write is that the measurement has taken place but nobody is aware of the outcome and your |Psi> indicates what the experimenter might guess about what has been recorded. Probability has to do with observation. "Probability" does not mean anything without conciousness. This is why QM probability is Bayesian. Like every probability. Forget Kolmogorov.

43. **vmarko**
August 16, 2014

Jasper,

"This will be my last post, because this discussion is time consuming."

At first I thought of giving up on the discussion, but then I changed my mind, since other people reading this blog might still be confused. I'm sorry that you don't want to continue.

In the first example, you said

"The states become more and more orthogonal, thus coherence disappears between |x1> and |x2>. Any other states of the environment would not have this orthogonality."

The last statement is just false. If by "orthogonality" you mean that the scalar product between |E1> and |E2> is zero, then the basis |E+>=|E1>+|E2> , |E->=|E1>-|E2> is also orthogonal. Feel free to check.

Orthogonality of the resulting basis plays no role in the discussion. The total Hamiltonian of system and environment is always self-adjoint, and its eigenvectors are always orthogonal. But there are also infinitely many other bases which are orthogonal as well, and I don't understand the importance of the basis |E1>,|E2> in this example.

Your second example is more complicated, due to the nonconservation of the number of photons, and because you didn't specify all interactions. You said

"Yes, after all this I can still write the density matrix in another way, but the orthogonal states of the EM field only couple in the above specific way to the atom,in the |u> and |d> basis which is where coherence is lost. In other words, using EM field we can only "observe" |u> or |d> of this atom, not a superposition |u>+|d>, and thus this basis is preferred."

Once you specify the final states that correspond to initial states |u>|2>, |u>|0>, |d>|2> and |d>|0>, I will be able to change from |u>,|d> to |+>,|-> basis for the atom, and from |0>,|1>,|2> basis to another basis for the EM field, which will be a linear combination of |0>,|1>,|2> which is orthogonal and which couples to |+>|-> in exactly the same way that |0>,|1>,|2> couples to |u>,|d>. So I still don't see why |u>,|d> basis is unique in any physical sense.

What I think you're trying to appeal to is the fact that the interaction Hamiltonian is generically always local in coordinate representatation, as opposed to say momentum representation (where it is nonlocal). And then you could say that the coordinate basis is somehow physically preferred because the interaction Hamiltonian is local *only* in that basis. This argument is ok, and it is good as long as you ignore quantum gravity. However, in QG the interaction Hamiltonian will become nonlocal even in the coordinate basis, and generically there will be no basis where H_int would be local. That's where the locality argument fails.

I'll make sure to read the Schlosshauer book.

Best, 🙂
Marko

44. **nick herbert**
August 16, 2014

Elliot Tammaro has a nice review of the various quantum interpretations at http://lanl.arxiv.org/abs/1408.2093. In Tammao's view none of the present-day interpretations fare very well.

45. **HDZ**
August 17, 2014

vmarko,

you are making a trivial but common mistake. Your example is valid only if the amplitudes of both components are exactly equal. (Feel free to check!) This ambiguity just reflects the fact that there is no unique diagonal representation of a density matrix in the case of degeneracy.

However, the point of decoherence is that macroscopic properties are "permanently" (repeatedly) and uncontrollably (irreversibly) measured by their environment with respect to a given basis. So even in the case of degeneracy, the "wrong" components would immediately be decohered again and again, while the "correct" ones (those characterized by the unavoidable environment) are "robust" under further decoherence (what Zurek later called the "pointer basis"). These components are thus dynamically "autonomous" after a measurement proper. If unitarity holds globally, it must necessarily lead to a superposition of many such autonomous "worlds".

If you want to avoid that consequence, you have to modify quantum theory (such as by a collapse). This is certainly not a matter of mathematical sophistication (as Peter Woit seems to believe). Formal limits of infinite numbers of particles or degrees of freedom have often be misused in order to hide an essential physical issue.

You may like to have a look at Sect. 3 of http://lanl.arxiv.org/abs/1402.5498

46. **Peter Woit**
August 17, 2014

HDZ,
I don't at all think that any of the issues discussed here are issues requiring mathematical sophistication, rather that they are complex issues of the physics taking place. My interest in more sophisticated mathematical frameworks for quantum mechanics is aimed in a very different direction (understanding aspects of the standard model that are still mysterious, as well as the question of unification with gravity).

2014 Fields Medals

August 12, 2014
Categories: Uncategorized

I thought this wasn't supposed to be announced until late this evening New York time, but the Fields Medal announcement is now online. The winners are:

- Artur Avila
- Manjul Bhargava
- Martin Hairer
- Maryam Mirzakhani

Mirzakhani is the first woman to win a Fields medal. Congratulations to all four.

I'm not at all knowledgeable about the work of this year's medalists, for this you can consult the press releases on the ICM page.

Update: Quanta magazine has profiles of the winners. Avila, Bhargava, Hairer, Mirzakhani.

Update: For ICM blogging, clearly the place to go is the blog of a Fields Medalist.

Update: According to Tim Gowers, the Fields Medal Committee was: Daubechies, Ambrosio, Eisenbud, Fukaya, Ghys, Dick Gross, Kirwan, Kollar, Kontsevich, Struwe, Zeitouni and Günter Ziegler.

Update: For two very different sorts of blog posts about the Fields Medal, see Terry Tao and Mathbabe.

Comments

1. **Bill**
   August 12, 2014

   Peter, it's Avila, not Avial. Do you know who was on the committee? Strange for them to announce it before the opening ceremony.

2. **Peter Woit**
   August 12, 2014

   Bill,
   Typo fixed. I haven't seen the committee list, don't know if it's public yet. Yes, it is strange for this to be posted before the opening ceremony. Also strange is that from the history it looks like this was posted on Wikipedia yesterday, even before the early ICM page went up.

3. **Als**
   August 12, 2014

   Great choice.

   I think some category theorists are going to be a bit disappointed for Lurie, but he did get a 3 million dollars consolation prize…

4. **Daniel McLaury**
   August 12, 2014

   Given that the page was written in the past tense ("the winners were announced"), this is pretty obviously an accident.

   What's interesting to me is that Quanta clearly had all those profiles ready to go in advance. Who else must they have written profiles for?

5. **Peter Woit**
   August 12, 2014

   Daniel,
   In cases like this journalists are often contacted in advance and told in confidence what will be announced, as long as they agree to "embargo" their stories and not release them publicly until a specified time. I'm sure this is how the Quanta stories came about.

   The odd thing here is that one would have guessed that things were embargoed until the public announcement in Seoul (10:30pm today here in New York). It's unclear whether it was intentional or not that the news got out earlier than this.

6. **Peter Woit**
   August 12, 2014

   Googling "Fields Medal" and "embargo" turns up various things, for instance this from the 2006 version
   http://www.icm2006.org/archivos/File/icm_2006/1%20August%202006%20note%20prensa%20rey%20Eng.pdf
   where news was given to the press on August 15, embargoed until the time of the ceremony on August 22.
   For the Seoul ICM, a cached journalist registration form shows up, which says that names of Fields Medalists are embargoed until the ceremony.

7. **David Roberts**
   August 12, 2014

   The official website was probably primed to go and the page released at something like midnight Seoul time. I got the first message about this 3.30 am local, and I'm in the same time zone as South Korea. It may have been a planned thing, or a small bungle on behalf of a programmer who set the day of release, but not the time. And then other news sources could follow suit, since the cat was out of the bag.

8. **Bill**
   August 12, 2014

Quanta profiles are way over the top for my taste, even though I liked some of the comments from the winners about how they focus on the problems. Another thought that came to mind – billiards everywhere (especially, if you include this year's Abel prize). No updates on the committee yet on the IMU website.

9. **Ethan**
August 12, 2014

Congratulations to all the winners, indeed!

One question that I have though is how relevant is these days the Fields Medal compared to other awards that exist right now in Mathematics.

Certainly, at the time the medal was introduced, there were no other high profile awards in Mathematics. These days, there are many other awards which do not have the insidious 40 years old limit.

The discrimination that these medals help perpetuate, ageism, is preposterous. To cite perhaps the most visible case -although there are others-, Andrew Wiles didn't get a Fields Medals for proving Fermat's last theorem, only because of the age limit.

The New York Times had an article about how the Fields Medal got to gain its status as the "Nobel Prize of Mathematics" http://www.nytimes.com/2014/08/10/opinion/sunday/how-math-got-its-nobel-.html?_r=0 . Not sure if the argument is valid though, because there are tales of how John Nash was disappointed when he didn't get one back in the 1950s.

Any thoughts?

10. **Peter Woit**
August 12, 2014

Ethan,
The combination of no Nobel prize and the age limit have always made the Fields medal kind of unusual. The prize was always well-known among mathematicians, especially after the fifties, but little-known outside mathematics. I don't think the Smale story referred to in the NYT had that big an impact.
So far the existence of other prizes doesn't seem to have changed much. The Abel prize is set up to be a Nobel equivalent, but it gets given to people late in their careers. The Fields medal always had a significant impact since it was identifying not the grand old men of the field, but the young stars. Unclear yet what the effect of the Milner/Zuckerberg prize with its big payday will be.

Over the past 20 years I see two conflicting trends: the first is that society and academia is ever more star-driven, so more and more attention gets paid to awards and those identified as stars.

The second though is that something has changed in math research, with a lot more research mathematicians working on more and more specialized problems. The first time I went to an ICM was Berkeley in 1986, and that year I don't remember much speculation earlier about the prize, just because the results of Donaldson, Faltings and Freedman were so dramatic it seemed pretty obvious who the prize winners would be (I also suspect there was much less effort to keep the news secret). To some extent this was also true in 1990 (with that year an interesting controversy about giving the prize to Witten, a non-mathematician).

From 1994 on though, my impression is that a few of the choices have been obvious, but while the rest go to very good people, they are choices that could easily have been different and no one would have been surprised. Instead of two-four people with results dramatically more significant than everyone else's, there may be just one such person. For example, this year I think people would have been surprised if Bhargava didn't get a prize, but not surprised if the other three winners had been, for example, Lurie, Ben Green, and Sophie Morel. Similarly, last time Ngo was a clear choice, but the other three names could easily have been different.

So, these days I see Fields medalists as getting a lot more attention from outside mathematics than in the old days. From within the community, the emphasis on academic stars mean they get more attention, while the second trend means they get less, since there's an awareness that there are equally good people in the same cohort without the prize.

11. **David Roberts**
August 12, 2014

Michael Nielsen commented on Terry Tao's post

https://plus.google.com/u/0/114134834346472219368/posts/huX13ZppDAf

that the announcement on the official site was removed, then reinstated. Seems like it could have been a mistake.

12. **Ethan**
August 12, 2014

Peter,

Thank you for the detailed explanations.

I have always loved mathematics. Although I got my PhD in engineering, my adviser was a mathematician and my thesis work involved applied mathematics, so I tend to follow the discipline closer than other people in my field.

I have not been around professionally for that long but it is definitely true that when I was in graduate school both trends you mention were in full force.

While I see it as a welcome development that society at large gives due recognition to scientific work, mathematics in particular, I find the "celebrity driven culture" a bit troublesome, both in academia and society at large, but particularly in academia where the pursuit of knowledge for its own sake should trump other issues.

Thanks for this interesting blog.

13. **John McAllison**
August 12, 2014

Iran, of all places in the world, manages to produce the first female Field's Medalist in Maryam Mirzakhani?

No script writer would have the imagination to think this story line up.

14. **Ethan**
August 12, 2014

John,

Up until I went to graduate school at Stanford, I was also ignorant about Iran's very strong tradition of cultivating intellectual elites both male and female.

It is perhaps Iran's best kept secret, although if you look at the winners of scientific Olympiads for high schoolers, you see Iranians at the top every year. Some of the good friends I made in graduate school went also to Sharif University, including several brilliant females.

The real tragedy for Iran is that it educates all these bright people only to expel them from Iran, "intellectually speaking", that is.

15. **John McAllison**
August 12, 2014

Ethan,

My understanding of Iran is that women's rights were severely eroded after the 1979 Islamic revolution, and only started to recover significantly around the start of the 90s. Even today, Iran still comes across as generally being very backward when it comes to gender equality compared to more secular Islamic majority nations like Turkey.

It'll be interesting to see how the Islamic Republic of Iran Broadcasting reports this, given that the Quran claims a man's testimony is worth twice that of a woman's in an Islamic court of law.

16. **Boon**
August 12, 2014

Any idea as to why Lurie didn't win?

17. **Ethan**
August 12, 2014

My experience with Iranian scholars contradicts the general perception :). In fact, there are many Iranian women educated after 1979 who hold faculty positions in America's top universities. As I said, knowing my share of Iranian Americans, or Iranians who have settled in America, the news of an Iranian woman settled in the US receiving the Fields Medal wasn't that surprising.

I think that many here in the West confuse giving females opportunities to become brilliant scholars with embracing Western feminism. I do not know personally Maryam Mirzakhani but I know people who know her. Most Iranians that I know -in fact I would say the overwhelming majority of them-, both male and female, hold what would be considered "socially conservative values" in the US when it comes to sex outside marriage, gay marriage, abortion, etc.

18. **Bill**
August 12, 2014

Boon, see Peter's comment above for possible answers. Or let's wait and see who was on the committee. If you watch Quanta videos, Hairer's main insight came from the theory of wavelets (Daubechies was the President of the IMU and the chair of the committee, also the first female chair). Avila and Mirzakhani's main work is on dynamical systems (billiards), so I wouldn't be surprised to see people from that area on the committee. All four were great choices, but clearly Jacob Lurie would also be a great choice.

19. **Als**
August 12, 2014

"Up until I went to graduate school at Stanford, I was also ignorant about Iran's very strong tradition of cultivating intellectual elites both male and female."

Exactly. People forget that Iran is a very old and great civilisation, with many great mathematicians (actually most of so-called "arab" mathematicians were actually Persians).

"Any idea as to why Lurie didn't win?"

There's no way to know, but it's easy to guess: he didn't prove any big theorem, all the four recipients did.

20. **Ethan**
August 12, 2014

Another quick question, is there a streaming link so we can watch the plenary sessions live? I haven't found any in the main page http://www.icm2014.org/

21. **Ethan**
August 12, 2014

OK, here it comes,

http://www.ebsmath.co.kr/cosCenter/seoul2014ICMOnAirPop?type=2

The pop up blocker was preventing me from seeing it :).

22. **A.J.**
August 12, 2014

Regarding Lurie: He's done some very notable work — his proof of the cobordism hypothesis is indeed a big theorem, likewise his geometric construction of tmf — but much of it hasn't gone through traditional peer review channels. I'd guess the selection commitee is waiting to see something more formal in print.

23. **Bourbaki**
August 12, 2014

@Ala
"Any idea as to why Lurie didn't win?"

There's no way to know, but it's easy to guess: he didn't prove any big theorem, all the four recipients did."

Jacob Lurie proved the Baez-Dolan Cobordism hypothesis. Along with Denis Gaitsgory, he proved Seigel-Mass formula for function fields. Saying that Jacob Lurie didn't prove any "big" theorem is like saying Grothendeick never proved any "big" theorem.

"Any idea as to why Lurie didn't win?"

Fields Medal these days is a function of whose is in the Prize committee.
Even then omission of Jacob Lurie in the list was quite surprising.

24. **Andy**
August 13, 2014

Bourbaki – A correction: he has *claimed* proofs of those results. However, he still has not managed to produce papers containing said proofs. Moreover, it's not clear to me that either of them is particularly central to mathematics (maybe the mass formula is, but the cobordism hypothesis is pretty technical and marginal).

Also, Grothendieck had plenty of deep results to his name early in his career (e.g. Grothendieck-Riemann-Roch).

25. **Als**
August 13, 2014

"Also, Grothendieck had plenty of deep results to his name early in his career (e.g. Grothendieck-Riemann-Roch)."

And don't forget his work in analysis, where there are some beautiful results.

26. **Urs Schreiber**
August 13, 2014

Saying that Jacob Lurie did not prove any big theorem is like lamenting the lack of a rock when faced with a mountain.

27. **Bourbaki**
August 13, 2014

@Andy

Jacob Lurie has already published a detailed sketch of the proof.

Also, Grothendieck never published his Reimann-Roch theorem, as he was never satisfied with the proof. And the reason why Grothendeick is Grothendeick is not because of his results in functional analysis.

28. **Andy**
August 13, 2014

Bourbaki – A detailed sketch is not the same thing as a proof. I don't care how smart Jacob is, he is not exempt from the ordinary rules of mathematical practice. Until a detailed proof appears (written by him or someone else), the theorems are not yet proved. Period.

And Grothendieck did publish a proof of GRR in SGA6 (which I guess was not peer-reviewed in the usual sense, but it's all there). Moreover, Borel-Serre published a detailed account of GRR in 1958, long before Grothendieck's Fields medal

29. **Bourbaki**
August 13, 2014

Most mathematicians working in Lurie's area actually believe the proof is complete and correct as well. And that's what matters.

As far Grothendeick is concerned, his important works were never went through the traditional peer-review process (for the the obvious reasons.)

And yes, Edward Witten got the Fields medal with ever proving any theorem.

30. **Als**
August 13, 2014

"Most mathematicians working in Lurie's area actually believe the proof is complete and correct as well. And that's what matters."

I agree that there are precedents (Witten, Perelman, Thurston), so I don't think it's the reason the committee didn't chose him.

31. **AJ**
August 13, 2014

Technically Lurie will be qualified for 2018 since he will just be 40.

32. **mkf**
August 13, 2014

Regarding, that the names were already in wikipedia on Monday, they accidentally put the names on the official ICM 2014 page on Monday morning (Middle European time) where I also saw them (and also the other prize winners, it seemed that they wrote the entries at that time since they appeared one after the other).

33. **Bill**
August 13, 2014

Lurie will turn 40 a few weeks before January 1, 2018, so this was his last chance.

34. **jjj**
August 13, 2014

Avila is the only one I happen to know, and whose work I know something of. He certainly deserves it. Everyone has known this for a long time, and he is just 35. It has been both scary and exciting to work in this general area in recent years
(interval exchange transformations, Teichmueller flow) where much deep and fascinating work had been done by many people (to avoid offending anyone I will just

mention the first greats: Keane, Veech and Masur) when Zorich appeared with lucid explanations, an exciting conjecture and his wonderful approach to math (generous, kind) and all of a sudden many superstars were involved: Yoccoz, Kontsevich, McMullen. I stop there mentioning only the Fields medalists, since it is unfair to mention one other name without a long historical discourse and many many names, explaining all the deep and wonderful contributions. You will note I didn't even mention Thurston, though I should have.

Avila has not worked in isolation; much the opposite, he has in a very egoless way
benefited and learned from everyone else and given back to them. Basically, he just loves math, and this is what is such an inspiration. But this shows the paradox of one amazing person being singled out for a prize, when it is the whole community they represent who should (and will) celebrate; we know we are part of it. "We" doesn't just mean dynamicists, it means mathematicians, or beyond that anyone who draws inspiration from the wonders of nature, and of its interaction with the human mind.

My one real talk with Artur was after an amazing lecture of his; at lunch I asked for further explanation of some point, and he talked (rapidly and clearly) for 5 or 10 minutes. I felt like the ideas were pouring into my head, which was on the verge of exploding.

Well, that's Artur. It is so great that there have been places and opportunities like
IMPA and the CNRS where someone like this has had the conditions to work and grow and to inspire, and let's hope that the powers can be can see that these working conditions need to be made more generally available; freedom and inspiration is how you get good math done, the opposite of the bureaucratic and business-style models that are forced over every part of human existence, more and more. To think, really to think and to create, and to encourage that in others, is the revolutionary antidote, revolutionary in that it turns the apparent world right on its head and says, "really?", and laughs.

So, congratulations to all of us, and let's use the inspiration to prove some theorems!

35. **Als**
August 13, 2014

@jjj

I completely agree concerning Avila and I think Peter is wrong when he says it could have been anyone along with Bhargava. Many people were expecting him to get it for quite some time.

36. **Ethan**
August 13, 2014

Now that most media have covered the news, the emphasis seems to be on,

– First woman to ever win a Fields Medal (less emphasis on her being Iranian).

– First Brazilian/South American to ever win a Fields Medal.

This, I think, is linked to Peter's observation that we are increasingly a star driven culture, which tends to favor shallow superficial things instead of content. You can also see this reflected in the number, and content, of the comments in the respective Quanta entries.

I think that this emphasis on matters not related to the research for which they (and the other two) received the medal is bad for Mathematics. It is also bad for the winners themselves because there will always be doubts whether somebody else could have been named winner, like the aforementioned Jacob Lurie, had it not been because of the "firsts". Gowers said http://gowers.wordpress.com/2014/08/13/icm2014-opening-ceremony/#more-5567

"I think that this time round there were an unusually large number of people who could easily have got medals, including other women. (This last point is important — one should think of Mirzakhani's medal as the new normal rather than as some freak event.) I have two words to say about them: Mikhail Gromov."

37. **JG**
August 13, 2014

Congratulations to all the winners. Iran's strong tradition in the Mathematics Olympiad is impressive, they usually have performed better than Israel, France, UK, Germany for example. It is sad that this is not matched with a strong publication record. I assume this is due to emigration, as in Mirzakhani's case, though she has said that there was a big emphasis on problem solving rather than theory, and she had to learn a lot of basic undergraduate mathematics when she went to Harvard – which makes her subsequent publication record all the more impressive.

For a humbling experience, see if you can match Mirzakhani's perfect score from the 1995 olympiad (problems) . Preferably within two days 🙂

38. **egan**
August 13, 2014

Question : is it possible for a mathematician to win two Fields medals? For instance one at the beginning of his career and a second one just before turning 40 after having proved a big theorem?
Os is it explicitly forbidden by the rules of the Fields committee?

39. **Ethan**
August 13, 2014

egan,

Unclear. The IMU's nominating rules say,

http://www.mathunion.org/general/prizes/nomination-guidelines/

"No winner of one of these Medals/Prizes is eligible for one of the others. "

Which clearly excludes a winner of one of the prizes/medals from being considered for the others -something that I find odd, particularly with respect to the Chern Medal- but I don't think it necessarily follows that somebody cannot win two Fields Medals.

40. **Yatima**
August 13, 2014

@John McAllison

It'll be interesting to see how the Islamic Republic of Iran Broadcasting reports this, given that the Quran claims a man's testimony is worth twice that of a woman's in an Islamic court of law.

Well … what do you expect? Iran ≠ ISIS.

IRIB world service: [Iranian woman wins Nobel Prize of mathematics]

41. **Peter Woit**
August 13, 2014

Enough about the Iranian government here, thanks.

42. **Mathematician**
August 13, 2014

I was surprised at this, here
http://www.simonsfoundation.org/quanta/20140812-in-mathematical-noise-one-who-heard-music/
"Hairer learned that he had won the Fields Medal during a visit to Columbia University in February."
I didn't realise they were informed so far in advance. That's a long time to have to keep a secret.

43. **Bourbaki**
August 13, 2014

"The second though is that something has changed in math research, with a lot more research mathematicians working on more and more specialized problems. "

I would be interested in knowing what caused this change. It seems mathematicians are now focused more specialized and more accessible problems than going for the big problems (of course, there are exceptions to this rule).

44. **Frederick**
August 13, 2014

"This, I think, is linked to Peter's observation that we are increasingly a star driven culture, which tends to favor shallow superficial things instead of content. You can also see this reflected in the number, and content, of the comments in the respective Quanta entries."

In fairness, I believe the Quanta entries were aimed at a lay audience. Very few people outside of the profession, no matter how smart, are going to have more than a cutaneous understanding of the work produced by Fields Medalists. I'm not sure what kind of analysis you were expecting. Even Terence Tao admitted that much of Bhargava's work is beyond his ken.

Personally, I'd rather see scientists, mathematicians, novelists, and other intellectuals turned into celebrities than actors and athletes. In many Asian cultures, the results of Science Olympiads are followed with the same enthusiasm that Europeans show for soccer.

45. **Ethan**
August 13, 2014

Frederick,

Please don't take me wrong.

I am not talking about the question of which type of celebrities I rather have, in which case, I agree with you, I rather see scientists and mathematicians celebrities than professional athletes, actors or, my absolute worse, people like Paris Hilton or Kim Kardashian .

What I am saying, and I think that this is what Peter was saying too, is that I do not see the fact that increasingly academia, or my field of engineering, are becoming star/celebrity driven as a good thing for either.

Here in Silicon Valley this star/fame driven culture caused a crash of gigantic proportions in the late 1990s that had reverberations in the larger economy. Some say that it is about to cause another one in the next 1-2 years. To a certain degree, the financial crash of 2007/2008 was driven by similar forces.

Some take, in my opinion, the wrong view that increasing the celebrity status of people working in these fields will attract more high quality interested students to them but in fact I contend that those who are more prone to make significant contributions to either field (academia, engineering) are going to be attracted to it no matter what (they have always been throughout history). What "celebrity" attracts is, well, those who are attracted to "celebrity/star status" to the detriment of everybody else. In a way, we have seen the same phenomenon happening in undergraduate admissions. For many years "reputation conscious" applicants have targeted universities based on reputations/ranking alone not which school is better for them. As a result, you get a lot of burnout with many seniors graduating from top schools picking "good paying", but uninteresting, careers instead of going to graduate school to apply their talents to scholarship.

Now, this is not to say that those working on science or engineering should resign themselves to be poor. On the contrary, I am a big advocate of paying scholars well so the choice is not between poor and middle class but between upper middle class and rich, which will cause a lot of people, the ones that matter anyway, to pick the "upper middle class" over wealth and continue to work as scholars or engineers.

The problem with star/celebrity driven academia is that the stars get a disproportionate share of resources. Just as the skyrocketing of the ratio CEO salary to average salary has only managed to alienate the workforce http://blogs.wsj.com/atwork/2013/06/11/the-state-of-the-american-workplace-is-meh/ , the same is likely to occur in academia long term. Star driven cultures, by definition, concentrate resources on a few stars (otherwise they would not be stars) causing the non stars to get the message that while they are necessary to maintain the discipline, there will be no reward for them.

In Silicon Valley, smart companies have a philosophy of sharing rewards among the rank and file as well, not only the executives. Those companies who focus the rewards on those at the top, do not end up doing very well in the long run although their executives all get wonderful golden parachutes.

46. **Ethan**
August 13, 2014

Typo

"Those companies who focus the rewards on those at the top"

should say

"Those companies WHICH focus the rewards on those at the top"

47. **David Roberts**
    August 13, 2014

    @Ethan:

    Or "Those companies THAT focus the rewards at that top" 🙂

48. **Ethan**
    August 13, 2014

    Forgot to comment (there is no edit button),

    "In many Asian cultures, the results of Science Olympiads are followed with the same enthusiasm that Europeans show for soccer."

    But then these countries do not produce top notch scientific results, precisely because the top people these countries produce are more interested in continuing being "stars" than in contributing to science at large.

    What sets American higher education apart from what I hear from Asian countries (China and India in particular) is the emphasis on ingenuity and original contributions combined, and this is important, with being very open regardless of people's background and age.

    In the US it is not unusual to hear people who did badly in high school, started in a community college and went on to become leaders of their respected fields (to the surprise of the "academic stars"). The more academia becomes "star driven", the more its doors will be closed to those with unusual backgrounds.

    Touching on the topic that gives this blog its name, I think that a very convincing case can be made that certain academic "stars" who shall not be named are probably responsible for the stagnation of physics nowadays. There are too many "stars" interested in keeping string theory alive to the detriment of alternative ways to get to a theory of everything.

49. **Ethan**
    August 13, 2014

    David,

    Oh well, the point remains, THAT I have elaborated in my other comment 🙂 .

50. **Harry**
    August 16, 2014

    Hi Peter,
    the link to T. Tao's blog post is broken,
    Best,
    Harry

51. **Peter Woit**
    August 16, 2014

    Harry,
    Thanks. Fixed.

52. **Shankar**
    August 18, 2014

    Bourbaki says – Fields Medal these days is a function of whose is in the Prize committee.
    'These days'?!

53. **shaghayegh maruphi**
    August 18, 2014

    I myself am an Iranian and I'm very proud that the first female winner of this prestigious medal is Iranian…..I hope my generation can pursue her work and win more medals….

    Just for mathematics 🙂

Smashing Physics

August 14, 2014
Categories: Book Reviews

I recently finally found a copy of Jon Butterworth's Smashing Physics, which came out in the UK a few months ago, but still hasn't made it to the US. As far as I know it's the first book about the Higgs written by someone actually involved in the LHC experiments. While there are several books already out there that do a good job of explaining the Higgs story (see for instance here) this one is a great read, giving a lively picture of what it was like to be involved in one of the experiments that made the discovery.

The book is structured as a bit of a travelogue, traveling through space to CERN and to various conferences, through time as the ATLAS LHC experiment unfolded, with physics explanations interspersed. A reviewer at New Scientist didn't like this, but I think the personal and idiosyncratic approach works well. We're given here not the highly processed take of a professional science writer, but a picture of what this sort of professional life is actually like for one specific scientist, from what happens in collaboration meetings, to an overnight spree on the Reeperbahn.

The perspective is definitely British (a lot of drinking goes on, with a scornful observation of American couples at a French bistro "drinking water"), and includes a fair amount of material about recent science funding problems in Britain. Butterworth's comments are often to the point, if sometimes impolitic. For instance, about the "God Particle" business, there's a footnote:

> Yes, I know Lederman claims he wanted to call it *The Goddamn Particle* and blames his publishers for the change. But my publishers wanted to call this book something really silly, and I managed to stop them.

For readers who know nothing about the physics involved, this book may not be the right place to start, with the well-known scientific story not getting a detailed treatment, and little in the way of graphics besides some Feynman diagrams. On the other hand, if you've read one of the other books about the Higgs, Butterworth takes you a lot deeper into the subject of LHC physics, including some extensive material on his work on boosted objects and jet substructure, which may lead to important results in future LHC analyses. If you like your science non-abstract and human, this is a great place to learn about the Higgs discovery story.

There's a quite positive review in the Guardian by Graham Farmelo, which describes the book well. That review though contains (like another review and like his wonderful book on Dirac) some odd material about string theory, in this case a long paragraph defending the theory, and telling us that "he and his fellow sceptics will be proved wrong in the long term." Actually there's very little about string theory in the book other than some sensible comments about being more interested in things experimentally testable. Like Tom Siegfried, it seems some science journalists are likely to always be unwilling to admit that they were sold goods that didn't turn out to work as advertised, and uncomprehending that most physicists, like Butterworth, never were buyers.

I gather the book may appear here in the US early next year, hope it gets some attention then.

Comments

1. **Marc C**
   August 14, 2014

   The book is already available on Audible. The narrator is English and it makes the stories and day-to-day living stuff a lot of fun. The technical stuff is hit or miss as a good portion of it takes a bit more contemplation (rereading, connecting it in your head). Still, I would recommend it. . . Just be ready to buy the book too so you can 'get' the details.
   The modeling and how that relates to the detector info was really insightful.
   Thanks for te review and the site Peter
   -Marc

   August 19, 2014

   Isn't it great that many — nay, most — physicists were not "buyers" of string theory? That's that wedge that string theory has driven between certain areas of theoretical physics and the rest of science. When you enter Stringworld, you suspend ordinary scientific standards.

   And I'm glad an experimentalist didn't believe in the Higgs boson before he started at LHC. Theorists believed in the Higgs boson, or something very like it, for very good reasons. But proper experimentalists try to see it for themselves, whatever the theoretical rationale. They don't sit at the edge of convoluted cultish rationalizations and think, "Well, I'm just too dumb to understand this."

Quantum Theory is Representation Theory

August 16, 2014
Categories: Favorite Old Posts, Quantum Mechanics

For a first slogan (see here for slogan zero) I've chosen:

> Quantum theory is representation theory.

One aspect of what I'm referring to is explained in detail in chapter 14 of these notes. Whenever you have a classical phase space (symplectic manifold to mathematicians), functions on the phase space give an infinite dimensional Lie algebra, with Poisson bracket the Lie bracket. Dirac's basic insight about quantization ("Poisson bracket goes to commutators") was just that a quantum theory is supposed to be a unitary representation of this Lie algebra.

For a general symplectic manifold, how to produce such a representation is a complicated story (see the theory of "geometric quantization"). For a finite-dimensional linear phase space, the story is given in detail in the notes: it turns out that there's only one interesting irreducible representation (Stone-von Neumann theorem), it's determined by how you quantize linear functions, and you can't extend it to functions beyond quadratic ones (Groenewold-van Hove no-go theorem). This is the basic story of canonical quantization.

For the infinite-dimensional linear phase spaces of quantum field theory, Stone-von Neumann is no longer true, and the fact that knowing the operator commutation relations no longer determines the state space is one source of the much greater complexity of QFT.

Something that isn't covered in the notes is how to go the other way: given a unitary representation, how do you get a symplectic manifold? This is part of the still somewhat mysterious "orbit method" story, which associates co-adjoint orbits to representations. The center of the universal enveloping algebra (the Casimir operators) acts as specific scalars on an irreducible representation. Going from the universal enveloping algebra to the polynomial algebra on the Lie algebra, fixing these scalars fixes the orbit.

Note that slogan one is somewhat in tension with slogan zero, since it claims that classical physics is basically about a Lie algebra (with quantum physics a representation of the Lie algebra). From the slogan zero point of view of classical physics as hard to understand emergent behavior from quantum physics, there seems no reason for the tight link between classical phase spaces and representations given by the orbit method.

For me, one aspect of the significance of this slogan is that it makes me suspicious of all attempts to derive quantum mechanics from some other supposedly more fundamental theory (see for instance here). In our modern understanding of mathematics, Lie groups and their representations are unifying, fundamental objects that occur throughout different parts of the subject. Absent some dramatic experimental evidence, the claim that quantum mechanics needs to be understood in terms of some very different objects and concepts seems to me plausible only if such concepts are as mathematically deep and powerful as Lie groups and their representations.

For more about this, wait for the next slogan, which I'll try and write about next week, when I'll be visiting the Bay area, partly on vacation, but partly to learn some more mathematics.

Comments

   August 16, 2014

   Peter,
   In your opinion, should physicists worry about the fact the Stone-von Neumann theorem is not true for infinite degrees of freedom, or is it purely a mathematical interest? I mean that one can always assume an arbitrarily high, finite number of degrees of freedom and get back a unique state space given the commutation relations.

2. **Matt Leifer**
   August 16, 2014

   "In our modern understanding of mathematics, Lie groups and their representations are unifying, fundamental objects that occur throughout different parts of the subject. Absent some dramatic experimental evidence, the claim that quantum mechanics needs to be understood in terms of some very different objects and concepts seems to me plausible only if such concepts are as mathematically deep and powerful as Lie groups and their representations."

   OK. but then why complex unitary representations? There are two possible answers I can think of to this.

   1. If you imagine that the basic structures of quantum theory are fixed in advance of considering symmetry tranformations, then they have to correspond to unitary representations.

   By the "basic structures", I mean that the observables are a von Neuman algebra, the "properties" are projection operators on a Hilbert space, or some other statement like that. Then, you can derive the state space structure from Gleason's theorem, and the structure of symmetry tansformations from Wigner's theorem. Specifically, once you have derived the probability rule from Gleason's theorem, you can show that the unitary transformations are the only automorphisms of the state space that preserve probabilities and are continuously connected to the identity.

   Presumably we want symmetry transformations to preserve probability, otherwise there would be observable violations of the symmetry, and we want continuous symmetries to be continuously connected to the identity. Discrete symmetries do correspond to antiuintary transformations of course, which is the other thing allowed by Wigner's theorem when you drop the continuity requirement.

   2. If you want to say that the basic structures of quantum theory themselves come from symmetry representations, then you haven't got a state space or probability rule fixed in advance. Presumably then you could investigate whether viable physical theories can be generated by varying the kind of group representation. You would then have to investigate whether a reasonable state space and probability rule could be defined for such structures.

   Now, if you go this route, then we already know that ordinary Hilbert space QM is not the end of the story. We can construct viable theories on Jordan algebras for example, but these seem not to be instantiated in nature. It seems to me that if you want to go the "everything is representation theory" route then you have quite a job to do explaining why such things are ruled out.

   Now, personally, I take the first point of view. This means that, for me, the ubiquity of unitary representations in quantum theory is not something particularly deep. That's just the only way it could possibly be given the basic structures of the theory. It's really the only possible way that symmetry transformations could be implemented.

   This means that, for me, "quantum theory is representation theory" is wrong. I might agree that "quantum physics is representation theory" because the fact that modern physics is based on symmetry is something that I regard as deep, so representation theory is the way to embed the physics, i.e. the physical interpretation of the operators, into an otherwise abstract probabilistic theory. But, the abstract probabilistic theory comes first, and needs its own justification independent of symmetry considerations.

3. **Peter Woit**
   August 16, 2014

   Alex,
   Yes, you can approach any QFT problem by cutting off the number of degrees of freedom, and then studying what happens as you make that number larger and larger. What makes things tricky (and interesting…) is that the limit is generally going to be singular, with the limiting theory having different properties. This is why renormalization theory is very non-trivial. Also, in condensed matter systems you get phenomena that only occur in the limit. I guess this is one example of "emergence".

   If you can bypass this, and directly mathematically formulate the limiting theory, that could be very powerful. The failure of Stone-von Neumann tells you that certain things that make life much simpler are no longer going to be true in the limiting theory.

4. **Peter Woit**
   August 16, 2014

   Matt,
   In representation theory in mathematics in general, one mostly works with complex, unitary representations. One could instead work with quaternionic or real representations, but this is most easily done by starting with a complex representation and asking for some extra structure. For many groups (e.g. finite or compact Lie groups), all representations are unitary (or, more precisely, unitarizable). Even for non-compact groups and infinite-dimensional irreducible representations, it's typically the unitary representations that are interesting.

   But non-unitary reps do occur in physics, for example the spinor rep of SL(2,C), and the state space of "ghosts" used in dealing with gauge symmetry. So, I'm just not convinced of the primary role of the probabilistic interpretation. Of course, sure, when you look at those parts of the theory where a probabilistic interpretation is going to connect the theory to experimental predictions, in those parts of the theory you'll have to have unitarity.

   In some sense the point of the slogan is to argue that there's more structure in fundamental quantum systems than just a von Neumann algebra. One is typically dealing with a universal enveloping algebra of a Lie algebra (not e.g. a Jordan algebra). The operators that generate the algebra of observables are given by the representation operators for a basis of a Lie algebra. From the point of view of the conventional formalism, it's very surprising that the Q,P operators that generate the operator algebra come from a Lie algebra and a group representation.

   Of course, this slogan has nothing to say about why certain Lie algebras occur, that remains a mystery.

   August 16, 2014

   Hi, Peter. Have you ever taken a look at these papers:

   > Bayen, F., Flato, M., Fronsdal, C., Lichnerowicz, A. & Sternheimer, D. Deformation theory and quantization. I. Deformations of symplectic structures. Annals of Physics **111**, 61-110 (1978),
   >
   > Bayen, F., Flato, M., Fronsdal, C., Lichnerowicz, A. & Sternheimer, D. Deformation theory and quantization. II. Physical applications. Annals of Physics **111**, 111-151 (1978),

   which were seminal in launching the idea of *quantization as deformation*, with representation theory playing a secondary role?

   The thing is that a classical Poisson algebra is more than just a Lie algebra, it also has a commutative product and a Leibniz rule for the bracket with respect to the product. Quantizing by simply representing the Lie algebra part of the structure can easily "break" the product structure and cause lots of problems, like Groenewold-type no-go results, the need to choose polarizations on the phase space, the need to choose the appropriate Lie sub-algebra to represent, deciding which of these choices lead to equivalent or inequivalent quantizations, deciding what constitutes a classical limit, etc.

   All of these issues are dealt with head on in deformation quantization. Moreover, once a classical Poisson algebra is deformed to a quantum non-commutative algebra, the non-commutative product defines the commutator bracket, allowing Lie algebras of symmetries to be represented in it. GNS type constructions give you representations of the quantum algebra on Hilbert spaces. Thus, unitary representations of Lie algebras of symmetries still appear.

   Of course, deformation quantization is not a construction or a prescription, rather it's a definition. On the other hand, the same can be said about quantization as Lie algebra representation. However, once given a definition, one can go and find constructive methods that satisfy it. This has actually been done with great success for deformation quantization.

   August 16, 2014

   verissimo,
   Thanks, fixed.

   Igor,
   Thanks for the explanation, I've never completely understood how deformation quantization works. I gather the idea is to get a notion of quantization that gives something for any symplectic manifold. That's very interesting mathematically, but kind of an opposite direction to what I'm most interested in, understanding how quantization works in the very specific cases that occur in fundamental physics.

8. **Thomas Larsson**
   August 17, 2014

   Experience with CFT makes one expect that the infinite-dimensional groups of gauge transformations and diffeomorphisms should acquire an extension after quantization.

   The group of gauge transformations in 3D has two types of extensions: the central extension [Etingof-Frenkel 1994] and the Mickelsson-Faddeev extension [Pressley-Segal section 4.10]. Only the latter corresponds to gauge anomalies in QFT.

   The MF group is a "bad" extension in the sense that it lacks natural unitary representations [Pickrell 1989]. IMO this explains why gauge anomalies must cancel in the

SM: nature abhors groups without good unitary representations.

The central extension can hence not arise in QFT except in 1D. To realize it, a more general theory is necessary.

The situation is analogous for diffeomorphisms. There are no diff anomalies at all in QFT in 3+1D, but the diffeomorphism algebra has Virasoro-like extensions in every dimension. Hence these can only be realized in a more general theory than QFT.

When the diffeomorphism algebra acquires an extension, it ceases to be a gauge symmetry, and local observables become possible in QG.

And look, I managed to say that without any self-reference at all.

9. **Igor Khavkine**
August 17, 2014

Peter,
Those original papers are actually quite good in providing motivation for the deformation quantization (DQ) point of view even for the specific cases I think you have in mind (free particle, oscillator, hydrogen atom). Personally, I like to view specific cases as instances of something more general, and DQ does just that.

Here's an example of how it helps. In your own notes (Ch.14), you say that going beyond quadratic polynomials, the assignment of operators to classical observables is highly ambiguous/non-unique, referring to the well-known *operator ordering ambiguity*. So, just how much of this ambiguity is there, is any of it redundant (gives physically equivalent quantizations)? Turns out that this question is well posed in DQ and has even been answered. All inequivalent classes of quantizations are parametrized by the 2nd de Rham cohomology of the phase space. In particular, standard R^2n has a unique quantization. Note that this result is independent on the Stone-von Neumann theorem (no need to exponentiate observables), and even says something stronger, because it looks not only at the quantum algebra itself but also the specific choice of assignments of quantum operators to classical observables. I have not seen this question well formulated, let alone answered, in other points of view on quantization.

So, to answer the question of how DQ works, one could say that it's main benefit is to provide a good set of physically motivated definitions, sufficiently precise yet flexible for meaningfully answering questions such the one above.

Peter, sorry to be off topic, but have you seen Gordon Kane's letter to SciAm? Perhaps you might be willing to bet him that super partners won't be found in the next CERN run? He seems to be having trouble finding people willing to bet against it 🙂

11. **Reader297**
August 18, 2014

Peter,

I know this is a bit of a philosophical, unfalsifiable discussion, but I think I'm on Matt Leifer's side here.

It's not enough to say simply that quantum theory is representation theory. You also have to say that information is encoded in density matrices, or, at the very least, that you've got a theory of probabilities here, and then appeal to Gleason's theorem to argue that the probability measure must be encoded in density matrices.

The postulate of probabilities is a nontrivial additional postulate you have to make, and once you've made it, and have density matrices in hand to encode it, the necessity of unitary (or anti-unitary) transformations becomes inevitable from the Wigner representation theorem, or, more intuitively, to preserve information under symmetry transformations.

You say that "non-unitary reps do occur in physics, for example the spinor rep of SL(2,C), and the state space of "ghosts" used in dealing with gauge symmetry." I don't think I follow. On the physical Hilbert space, all representations must be unitary or anti-unitary. Ghosts are not physical states—they're vectors states put in to make the given system's Hilbert space more symmetric-looking and easier to work with. And non-unitary representations directly on fields are not fundamental features of quantum theory, but again are mere conveniences.

12. **Peter Woit**
August 18, 2014

Reader297,

After spending more time with Schlosshauer's book on decoherence while on a long plane trip, I'm more than ever suspicious that probability is not fundamental to QM, but just what you need to do when you break a quantum system up into two subsystems (e.g. a system under study and the apparatus/enviroment). But also spending time with his book "Elegance and Enigma" of interviews shows that opinions differ. Of the people in that book, I find myself most sympathetic with what Zurek has to say.

Given any structure, you can start with one end of it, and if it's rigid enough, get to the others. Besides not seeing the necessity or desirability of starting with probability, I also don't see how it gets you to any kind of explanation of the basic structures of QM: why are observables self-adjoint operators on a complex vector space? Why the Heisenberg commutation relations? Why Poisson bracket goes to commutator? Starting by taking as fundamental the mathematics that explains those structures seems to me more promising than starting with probability. I also suspect it is a more promising approach to QFT and the things we don't understand about unification than starting with probability and trying to add other axioms with "physical" motivation.

Of course you get unitary representations in those cases where your state space is going to have an interpretation that will require unitarity. The point of the comment was just that the fundamental mathematical structure involves lots of use of representation theory, including non-unitary representations. One person's "convenience" is another's deep and powerful insight…

13. **Peter Woit**
August 18, 2014

Jeff M,
Just saw that. Seems implausible that anyone would have trouble finding physicists who think odds are now no SUSY at the LHC. In any case, it should get interesting starting a year or so from now when results at higher energy start coming in. But, yet more discussion of this should wait for a more appropriate topic…

14. **Florin Moldoveanu**
August 19, 2014

SL(2,C) is another possible number system for QM besides reals, complex, and quaternionic numbers. SL(2,C) arises out of a subalgebra of SO(2,4) ~ SU(2,2) by eliminating the "ghosts" and it provides another decomposition of the d'Alembertian. In fact QM over SL(2,C) is mathematically equivalent with spinors and Dirac's equation. This gives rise not to a C* algebra but to a C*-Hilbert module. There is no QM over octonions because it can be proven that QM obeys a "dynamic correspondence" between observables and generators which rules out the only special Jordan algebra. This "dynamic correspondence" is related to Noether's theorem.

Deformation quantization is a well established mature domain which builds up recursively in powers of hbar an associative start product. There are inequivalent ways of building the star product (related to 2nd deRham cohomology) and this makes the area hard (the symmetric part of the star product forms a Jordan algebra, while the skew-symmetric part generates a Lie algebra). The typical examples are the Weyl quantization and Berezin quatization. Weyl quantization preserves symmetries but has convergence problems outside of flat R2n while Berezin preserves positivity. Berezin is best understood in terms of creation and annihilation operators which form z and zbar in complex numbers. Deformation quatization maps QM in phase space to QM in Hilbert space and is a transition in a larger sense from non-commutative to commutative geometry. All Kahler manifolds admit a Berezin quantization if positivity is present, but if one starts from a pure classical system, one uses geometric quantization which requires the Born-Sommerfeld quantization condition as a pre-requisite.

The topic of Poisson manifolds is an active research area due to symplectic reduction. Some classical systems admit both an odd-dimensional Poisson manifold description and an even-dimensional symplectic manifold description. Even better, some systems are bi-Hamiltonian (solitonic systems).

15. **manfred Requardt**
August 19, 2014

Well, in my view the structure of quantum theory is a low energy phenomenon (a little bit jokingly: perhaps only a small deformation of classical mechanics) whereas various modern frameworks seem to believe that it holds unaltered down to the Planck scale. But that is against our scientific experience. I would bet that quantum theory is emergent (perhaps even an epiphenomenon). There is a lot of deep mathematics around which may live on a microscopic scale with quantum theory emerging as some coarse-grained effective theory.

16. **Hendrik**
August 19, 2014

Dear Peter,

Three comments;-
1) On the Stone – Von Neumann Theorem.
This concerns only integrable representations, not any representation of the Heisenberg Lie algebra. This is physically justified as one can only perform finite measurements, not infinitesimal ones.
2) On the Groenewold – Van Hove theorem.
This also requires some integrability condition for some basic set of observables, see http://xxx.lanl.gov/abs/math-ph/9809015. Also, it has been generalized to other symplectic manifolds, see http://xxx.lanl.gov/abs/math-ph/9809011 or http://xxx.lanl.gov/abs/dg-ga/9605001
3) On the metaplectic algebra being a maximally quantizable Poisson subalgebra of the full Poisson algebra on R^{2n}. This is true, but it is not the only maximally quantizable Poisson algebra containing the q_i and p_i, see Sect. 5 of the first reference above.

17. **Reader297**
August 19, 2014

Hi Peter,

Let me address your points in turn.

You write:

"After spending more time with Schlosshauer's book on decoherence while on a long plane trip, I'm more than ever suspicious that probability is not fundamental to QM, but just what you need to do when you break a quantum system up into two subsystems (e.g. a system under study and the apparatus/enviro[n]ment)."

Suspicion is a wonderful and insufficiently appreciated sensibility. However, after decades on this idea, all we have are still only suspicions.

There have long been hopes of "deriving" probability ab initio from the bare mathematical formalism of quantum theory. Any such derivation, in particular, would represent a fundamental solution to the measurement problem without any a priori assumption of, say, the Born rule.

Advocates of the many-worlds interpretation have long argued that this goal is achievable, and much of their conviction derives from Zurek's envariance and decoherence arguments. (These arguments have led to the idea that "decoherence alone solves the measurement problem.")

However, no rigorous proof exists, and for good reason: Probability is more than just mathematics. The problem of understanding what probability actually means is a deep one in philosophy. Getting to probability from non-probability is hard a problem.

On the other hand, once you assume a priori something probability-like — namely, that we should be talking about a probability measure for vectors in a Hilbert space — then you can follow Zurek or Gleason (or even Hugh Everett, if you read his original papers) to show that the probability formula has to be the Born rule.

But simply starting from abstract vectors and somehow deriving the existence of probability from scratch has long been regarded as an impossible problem. On the other hand, if you've found a way to solve it, I'm sure we'd all love to see it!

You write: "Given any structure, you can start with one end of it, and if it's rigid enough, get to the others."

That's quite true. But not all ends are necessarily on the same footing. If one end is more general than the other ends, then the more general end is the safer starting place.

As I've said, starting without probability and getting to probability runs into some long-known and deep metaphysical obstructions. But if we do start with probability, then going the other way is easier and more general. If we start with the axiom that probability is encoded in density matrices through the Born rule Tr[(density matrix)(…)], then the necessity of unitary (or anti-unitary) representations for symmetries is a mathematical consequence. When decoherence diagonalizes the density matrix in a basis approximating coherent states, we get a structure that closely resembles classical phase space, and the commutator behaves algebraically similarly to Poisson brackets without having to assume any classical system a priori. (And that's important, because quantum theory appears to be more fundamental than classical physics. We shouldn't be starting with classical systems in the first place.)

You write: "Besides not seeing the necessity or desirability of starting with probability, I also don't see how it gets you to any kind of explanation of the basic structures of QM: why are observables self-adjoint operators on a complex vector space?"

Once you say that probabilities are encoded in density matrices through the Born rule, then reality of the probabilities implies that all observables must be self-adjoint.

That obviously still leaves the deeper question of why we have to work with complex numbers. Of course, that's a question whether one starts with probabilities-in-density-matrices or one starts with the quantum-theory-is-representation theory. We're not going to be able to "derive" quantum theory starting from just one axiom!

But there are definitely some simple cases that motivate the idea of working with complex numbers. If we consider, say, a two-state system (which, by the way, doesn't have Heisenberg commutation relations [q,p] = ih), then even if we write down a real density matrix, there are observables we can write down that always give real probabilities. That is, if we consider the most general matrices that combine with density matrices in the Born rule to give real probabilities, then those are self-adjoint complex matrices.

Moreover, as you know, there are certain symmetry transformations you can do that are generated by self-adjoint operators.

So the motivation is that it's a matter of generality. One could self-consistently consider just real-valued quantum theory (whether in the probabilities-in-density-matrices or the quantum-theory-as-representation-theory approaches), but it's not the most general structure that is consistent with real probabilities. At the end of the day, however, someone has to postulate that complex numbers are a part of the story, whichever point of view one takes.

After all, even if we declare that quantum theory is just representation theory, we could always imagine a finite-dimensional real vector space acted on by real orthogonal matrices. That's certainly not the most general thing we can do, but there's no logical reason why we have to consider complex numbers unless we postulate that we must do so.

Finally, you write: "Of course you get unitary representations in those cases where your state space is going to have an interpretation that will require unitarity. The point of the comment was just that the fundamental mathematical structure involves lots of use of representation theory, including non-unitary representations. One person's "convenience" is another's deep and powerful insight…"

That's true. But I suppose the issue here is that some things can be regarded as conveniences, whereas other things cannot be. And to a lot of folks, anything that cannot be regarded as a convenience is the deeper and more powerful insight.

18. **Zathras**
August 19, 2014

PW: "After spending more time with Schlosshauer's book on decoherence while on a long plane trip, I'm more than ever suspicious that probability is not fundamental to QM, but just what you need to do when you break a quantum system up into two subsystems (e.g. a system under study and the apparatus/enviroment). "

I don't get this distinction at all. Any observation requires (is?) a breakup of the quantum system. Discussing quantum mechanics without this means you are not doing anything empirical. I thought we were against that here.

19. **Peter Woit**
August 19, 2014

Hendrik,
Thanks. In comments here I'm often not even trying to be precise, am trying to do so in the notes I am writing, so that's helpful.

Reader297,
I wouldn't claim to get probability from nothing, but it seems to me to come into play only at the point when you try to deal with the difficult issue of how to extract predictions about experimental results, formulated in terms of idealized descriptions in classical terms of your experimental set-up. This just seems to me at the other end of things from the question of what the fundamental theory is, but to some extent that's a matter of perspective.

Experts I have been reading seem to agree that you need something beyond just decoherence to get the Born rule, but it's unclear to me what it is. Zurek claims to derive the Born rule, presumably making some kind of assumption about "interpretation", but also at other points claims to be agnostic about choice of interpretation. I'm having trouble putting my finger on where "probability" enters, and your comment referring to a deep problem in philosophy of course tempts me to see the question as one that might be on the other side of the nebulous philosophy science divide from what I feel I have to be concerned about.

By the way, for decoherence experts, I'm curious whether when you "derive" the Born rule you are making some assumptions that could be in principle violated. Is there even a thought experiment in which you would see something that could be interpreted as a violation of the Born rule (or even thought experiments where there is ambiguity about what the Born rule means or says)?

I don't think you answered my question about the Heisenberg commutation relations. Yes, for the two-state system, all you have is linear algebra of 2 by 2 matrices, so there's likely only one way to do things. For canonical quantization though (which is the basis of our understanding not just of single-particle QM, but of the quantization of linear fields), how does one explain where the Heisenberg relations come from, other than by invoking a Lie algebra representation (and one that is not a "symmetry") of the theory?

Zathras,
First of all, you're making the mistake many people make of thinking my complaints about string theory/SUSY etc are just based on lack of connection to experiment. That's just not the case, if they were mathematically compelling I'd be a fan. In the case of QM my main interest is not in the hard problems of its connection to experiment (everyone seems to agree there is no such thing as an experiment in contradiction with the theory, and such a thing seems unlikely). Physical theories are also mathematical objects, with deep connections to mathematical issues, and those are what I'm often most interested in (with one justification the lack of relevant experimental clues about how to improve the theory).

20. **Igor Khavkine**
August 19, 2014

It has always struck me that people seem to have much less trouble accepting how probability enters in classical mechanics. If you forget about phase space, then all you have is the Poisson algebra of observables. Probability distributions, aka *states*, are then (positive, normalized) linear functionals on this algebra, physically interpreted as "expectation values". A measure that is concentrated on a single point of the would-be phase space describes a given deterministic configuration of the system. Purely algebraically, such a state is an extremal (a boundary point) of the convex space of all allowed states and is called *pure*. Thus, a statistical classical theory completely supersedes deterministic classical theory. For practical purposes, all our models are really statistical, and pure state are only idealizations that could be achieved on special subsystems of the universe and only under very special circumstances (these are the preparation protocols for controlled experiments).

Now, turning to quantum mechanics, the whole preceding paragraph can be repeated word for word and carry the same exact meaning, with the exception that the algebra of observables is no longer Poisson, but is rather non-commutative. This changes also the condition of positivity. Pure states are still extremal points of the convex set of all allowed states, and are still only idealizations. Note that wave functions, Hilbert spaces or the Born rule need not be brought in at this fundamental level of description of quantum mechanics, yet one has enough machinery to make some calculations and associate them with experimental outcomes.

At this point, pure mathematics tells us that given a positive, normalized state on a possibly non-commutative algebra with conjugation (such as the quantum algebra of observables) always gives rise to a unitary representation of that algebra on a Hilbert space (this is the GNS theorem), such that application of the state is equal to the

(Hilbert space)-trace of this representation against some density matrix. Further, if the state is pure, then the representation is irreducible and the corresponding density matrix has rank one. It is in this way that pure states are associated with vectors in a Hilbert space (by factoring the corresponding rank-one density matrix) and it is in this way how the Born rule arises. Namely, if one associates pure states with vectors in a Hilbert space, as described above, then we already know that we need to `square' that vector to get a density matrix, which is then paired with observables inside a trace to get expectation values: the essence of the Born rule.

Granted, there was a notion of probability put into this discussion at the very beginning. So it does not address the desires of those who would like to see probabilities emerge from the formalism itself. However, given that probabilities are introduced in the same way as in classical theory, which I see very few people complain about, the Born rule follows automatically. To all those who are concerned by these issues, is this argument not already satisfactory to justify the Born rule?

August 19, 2014

Hi Peter,

I like your response a lot. Let me address your comments in turn.

You say: "I wouldn't claim to get probability from nothing, but it seems to me to come into play only at the point when you try to deal with the difficult issue of how to extract predictions about experimental results, formulated in terms of idealized descriptions in classical terms of your experimental set-up. This just seems to me at the other end of things from the question of what the fundamental theory is, but to some extent that's a matter of perspective."

I happen to agree with you. I think a lot hinges on one's perspective.

That is, I think it all depends on whether one regards quantum theory from a purely instrumentalist standpoint, namely, as nothing more than a tool for extracting the probabilities for measurement outcomes obtained by abstract observers "outside" of quantum theory. In that case, I agree with you that we can put those experimental questions aside for the moment and just talk about the internal, bare (and sublime) mathematical theory absent any questions about observers, measurements, or probabilities. (However, then we don't have the complete quantum theory, because those probabilities ultimately need to get in there somehow!)

But there are other perspectives in which one tries to put observers into quantum theory as physical quantum systems in their own right, and then one runs directly into what it means to be an observer who is a quantum system in the Hilbert space. What does it mean to say that such an observer experiences probabilities, and why? How do bare mathematical state vectors turn into probabilities? Presumably, a quantum observer living in the Hilbert space has some state of being or experience — or maybe not! And is there some probability for an observer to be in a certain state of being? What does that even mean?

If one takes this more realist/physicalist perspective as I have just described it, rather than instead taking the instrumentalist perspective I mentioned above, then one cannot put the probability questions aside, because they are somehow entirely contained inside the bare mathematical theory at a very deep level.

You also write: "I'm having trouble putting my finger on where "probability" enters…" Me too. So far nobody has offered more than a hand-wavy "insert magic here" argument for deriving where probability exactly enters, which is why other people just bite the bullet and postulate probabilities as a fundamental axiom.

But, again, even if one takes an instrumentalist/bare-mathematical/representation-theory definition of quantum theory, one still has to deal with this step of getting probability into the theory somehow — axiomatically, I'd argue. And that means quantum theory is more than just representation theory. It's also a theory of probability, and that's something more than just representation theory per se. You need another axiom at least.

One can choose to ignore temporarily this additional probability axiom, of course, and focus on the mathematical of representation theory, but then one wouldn't be doing actual quantum theory, but an (again sublime) mathematical shadow of quantum theory.

Later, you write: "I don't think you answered my question about the Heisenberg commutation relations."

Woops! I apologize! Let me try to do it in the context of your next several comments.

You write: "Yes, for the two-state system, all you have is linear algebra of 2 by 2 matrices, so there's likely only one way to do things."

Right. There's no classical counterpart to this system, and that's part of the reason why I've argued that one shouldn't take classical systems as a fundamental starting point for quantum systems, nor regard canonical quantization as a physical thing, but merely a helpful mnemonic. Quantum systems appear to be more fundamental than classical descriptions, and so the arrow of reasoning goes from quantum to classical (in the appropriate decoherent/macroscopic/semiclassical limit).

Next, you write: "For canonical quantization though (which is the basis of our understanding not just of single-particle QM, but of the quantization of linear fields), how does one explain where the Heisenberg relations come from, other than by invoking a Lie algebra representation (and one that is not a "symmetry") of the theory?"

Here I think I would cite Steven Weinberg, who addresses precisely this question in the introduction to his new textbook on quantum theory. ("Lectures on Quantum Mechanics.") I think we can probably all agree that the guy who coined the term "Standard Model" knows a thing or two about quantum field theories (fallacy of appeal to authority—I'm guilty as charged!), and he has long believed (and vehemently argued) that the canonical-quantization procedure is nothing more than a convenient mnemonic that works at a practical level in certain situations, but is actually quite misleading especially in more general circumstances.

Instead, as I think you would enormously appreciate, Weinberg has argued that quantum systems should be defined by imposing symmetries on their Hilbert spaces. In particular, he argues in his QFT books that symmetries must be represented unitarily (or anti-unitarilty for certain discrete symmetries), and when you consider the unitary action of the Poincare group on states of a Hilbert space, the generators can be shown to satisfy the Poincare algebra (after much annoying work fixing phases, as Weinberg goes through in gory detail), and the P^0=H operator becomes what we identify as the system's Hamiltonian H. For a system whose H is local, Weinberg argues that the subspace spanned by low-energy eigenstates can always be approximated by a local QFT, and, as you no doubt know, he calls that idea effective field theory.

However, because the effective field theory is only to be regarded as an approximate description of the low-energy part of the full Hilbert space, the field operators are not fundamental entities, and the Heisenberg commutation relations satisfied by the field operators (at least in the bosonic case in which we have them at all) are not fundamental, let alone axiomatic.

In the non-relativistic single-particle limit, one can show that this Hamiltonian reduces to p^2/2m + V(x), where [x,p]=ih. In fact, one can even write down what x is in terms of K (the boost generators) and P (the momentum/translation generators). (Exercise!)

At no point does Weinberg invoke canonical quantization anywhere. And, indeed, there are quantum field theories that don't seem to have classical limits and/or Heisenberg-type commutation relations, such as fermionic field theories as well as the large classes of field theories that lack a Lagrangian description. But the Hilbert spaces don't care whether there's a nice classical limit.

I suppose one could argue that specifying the Poincare group is no better metaphysically speaking than specifying the Heisenberg commutation relations. We're still effectively postulating something to constrain and define our quantum system of interest, and the end result is a set of operators that satisfy a certain algebra.

But I think Weinberg's point is that this structure isn't a universal postulate or axiom of quantum theory, but just a matter of providing one way (among many) to define a particular quantum theory of interest. That is, it's just something we do out of convenience when we know a priori that a theory has to have certain symmetries. For other kinds of quantum systems, such as two-level systems, we don't have to take that approach. We can just postulate a Hamiltonian and go from there.

Igor Khavkine– Please see my earlier comments about instrumentalism.

In particular, the situation you describe for classical systems is what one would call classical instrumentalism. That is, we just regard the formalism as a recipe for computing expectation values and probabilities, and nothing more. In that sense, there is definitely a parallel to quantum instrumentalism, with some "simple" replacements. However, I think Peter would argue that it's not at all obvious why we replace classical observables with non-commuting quantum operators. And, again, I think most people would agree that once you say "probability," there's a unique prescription (the Born rule) for those probabilities.

But I'd like to focus on your prefatory statements: "It has always struck me that people seem to have much less trouble accepting how probability enters in classical mechanics. If you forget about phase space…"

I think your last clause is the key thing. In classical physics, you can certainly forget about phase space if you wish, but you don't have to. And that's important. You can always assume a phase space if you wish, in which case you're not doing instrumentalism anymore, but are assuming that there is a reality under those probability distributions. That provides people with a metaphysical security blanket.

In particular, in classical physics, even when you have a mixed states, you can always assume (again, if you wish) deterministic, definite states can be assumed to exist, even though they're not known with certainty.

But the weirdness of quantum theory is that this trick doesn't seem to be available anymore. What if we don't want to "forget about phase space" in the quantum case? Do we have the liberty to not forget it in quantum theory? Is there something there that we could choose not to forget, something analogous to classical phase space that we can choose to regard the Born rule as a probability of, apart from just the probability of a measurement outcome? If a system has a mixed state that isn't an extremal point of the convex set of allowed probability states, can we still assume that the system has a deterministic, definite state of being that's just not known with certainty, as we could choose to do in the classical case of a mixed state?

So when you write "However, given that probabilities are introduced in the same way as in classical theory…", I think that not everyone would agree that it's the same story in quantum theory. At the level of an instrumentalist perspective, perhaps yes, with my aforementioned provisos, but we have a much richer picture available to us in the classical case for understanding probabilities, and the absence of an obvious such picture in the quantum case makes quantum theory and quantum probabilities so much more mysterious and troubling.

22. **Peter Woit**
August 20, 2014

Reader297,
I really do disagree with Weinberg here. In general I'm no fan of the "your deep, beautiful mathematical structure is just an effective theory, a low energy approximation to some more fundamental theory, although I don't know what this is" argument. And in this particular case, the mathematics is very deep, and we don't have anything better. Part of the beauty of the story is that the fermionic case runs perfectly parallel, and a big part of what I wanted to write about in the QM notes is exactly this story. Among physicists there seems to be an attitude that these are just ad hoc rules of thumb, but I think an appreciation of the coherence of the mathematics gives strong evidence against this.

23. **manfred Requardt**
August 20, 2014

Dear Peter, well, there do exist quite a few approaches which try to derive for example quantum theory from a deeper level. See e.g. the work of 't Hooft or my recent arXiv:1205.1619 (using as a technical tool among other things the concept of cellular networks). I do not claim that these speculations are conclusive but we are convinced that something in this direction will ultimately work. After all, classical mechanics (symplectic geometry) is also beautiful from a mathematical point of view while quantum theory is a beautiful theory as well but is completely different.

24. **Thomas Larsson**
August 20, 2014

Manfred,

From the point of representation theory, irreps are the fundamental objects, and irreps behave like quantum theory (although not as quantum *field* theory except in low spacetime dimensions). So if the fundamenta of math and physics are the same, quantum theory is fundamental.

It was a while since I looked at 't Hooft's Planck-scale determinism, but iirc his motivation for looking at hidden variable theories was locality. Of this I approve, but it is possible to have locality in QG without abandoning quantum theory. Recall the standard argument why there are no local observables in QG:

1) An observable in quantum theory is an operator which commutes with all gauge transformations.
2) In GR all diffeomorphisms are gauge transformations.
3) Hence there can be no observables in QG that depend on spacetime coordinates.

The flaw in this argument is that it assumes that the gauge symmetries of classical and quantum gravity are the same. If the algebra of diffeomorphisms acquires an extension (to avoid self-referencing, see [the seminal paper of Rao and Moody 1994]), this is not true.

So does it ever happens that the classical and quantum theories have different gauge symmetries? Yes, one (or 25) such cases are described in [GSW 1988], section 2. The free string can be defined in any number of dimensions, and it has a conformal (or Weyl) symmetry that is a gauge symmetry. After quantization, we must distinguish between three cases:
1) The critical free string D = 26. There is no anomaly, the theory is consistent, and the conformal symmetry is gauge.
2) The supercritical free string. The theory is inconsistent, because there are ghosts (negative-norm states) in the physical spectrum, and we can forget about it.
3) The subcritical free string. The theory has a conformal gauge anomaly, but is nevertheless consistent because there are no ghosts in the physical spectrum. However, the conformal symmetry can no longer be gauge, due to the conformal anomaly.
So in the subcritical free string, the (both consistent) quantum and classical theory have different gauge symmetries. It does happen!

(And yes, I know that the subcritical interacting string is inconsistent, but that was not what I was talking about.)

25. **Reader297**
August 20, 2014

Hi Peter,

Those are fair points!

First, I wanted to give one more concrete example of where the Heisenberg commutation relations [x,p]=ih can come from without canonical quantization or an a priori classical system.

If you are given a QM system with an infinite basis that we can label with one continuous real label x, then we can define a unitary translation operator that changes |x> to |x+a> for any real a. The infinitesimal generator of that unitary translation operator is then just p, where it's then just a simple calculation to show that [x,p]=ih. From a Noether standpoint, we call the generator of translations the momentum by definition. So this is a self-contained way to introduce and define p and obtain [x,p]=ih without reference to an a priori classical system. What's lovely is that the eigenstates of z=x+ip then form a natural QM analogue to classical phase space, but have Gaussian wave functions with a size in x,p given by Planck's constant h, so one also finds phase-space quantization. So in the limit h->0, we get back a classical phase space.

Now to your more recent comments. You write: "I really do disagree with Weinberg here. In general I'm no fan of the "your deep, beautiful mathematical structure is just an effective theory, a low energy approximation to some more fundamental theory, although I don't know what this is" argument."

There's definitely room for philosophical disagreement here. But I think there are couple of things that need to be said about it.

One of Weinberg's motivations here comes from condensed-matter theory. In many of the kinds of systems they study, there exists a well-defined long-distance regime that looks just like a field theory (sometimes even a CFT), regardless of what the microscopic exact model actually is. You could have atoms on a lattice, you could have graphene, you could have a fluid, etc. — really qualitatively different microscopic models — and yet the long-distance description looks like a field theory.

So in this case, there isn't an "I don't know what this is." In lots of cases, we know what the microscopic model actually is. And the long-distance limit still looks like a field theory.

Now, what's really interesting about this phenomenon is that the mapping of microscopic models to field theories is many-to-one — many qualitatively different microscopic models can share the same long-distance field theory — and each equivalence class (all microscopic models that share the same long-distance field theory) is called a universality class.

The existence of universality classes is a double-edged sword. On the one hand, they imply that by studying a single field theory, you can make statements and derive properties and calculate things (all in the long-distance regime) that hold for a huge class of microscopic models. That's why it's called effective field theory — because it's really effective!

However, on the other hand, if you are simply handed the long-distance field theory, the many-to-one-ness of the mapping — that is, the large number of models in that universality class — implies that you'll never be able to guess the correct underlying microscopic model, unless of course you can do some sort of high-resolution experiment to see what's actually going on at short distances.

So we have a clear case study in which an elegant looking field theory really is just a long-distance limit of something that looks qualitatively different from a field theory — and, indeed, there's a huge class of qualitatively different microscopic models that look like the same field theory at long distances. This really does happen in physics!

The upshot is that when people like Weinberg look at the field theories of particle physics, such as the Standard Model, there is no longer the belief that people had back in, say, the 1940s that the field theory is necessarily fundamental, nor that the underlying microscopic model is itself a field theory.

This hunch is backed up by the fact — which Weinberg spends his field theory books explaining — that local, weakly-interacting, Poincare-invariant quantum systems canonically look at low energies/long distances like field theories. (Even GR works this way — see the myriad papers by John Donoghue on the arXiv.)

So the fact that you have a field theory at low energy doesn't tell you either way whether the microscopic model is a field theory or something truly qualitatively different.

One can certainly posit examples (like QCD or CFTs, or even the AdS/CFT correspondence) where the high-energy limit is still a field theory. But in a given practical case, that would be a huge assumption.

You write: "And in this particular case, the mathematics is very deep, and we don't have anything better. Part of the beauty of the story is that the fermionic case runs perfectly parallel… Among physicists there seems to be an attitude that these are just ad hoc rules of thumb, but I think an appreciation of the coherence of the mathematics gives strong evidence against this."

These lines seem suspiciously similar to what string theorists like to say!

And I think there's a good reason why.

At the end of the day, you are proposing that because nature looks like a field theory at long distances/low energies, it ought to look like a field theory at short distances/high energies, because field theories are somehow mathematically elegant and coherent. That's one proposal for what the microscopic models should be, and the string theorists propose a qualitatively different microscopic model that also looks like a field theory at long distances/low energies. The LQG people propose another. Etc.

What all these approaches have in common is (1) they are motivated in part by mathematical coherence and aesthetic appeal, (2) they look like field theories at long distances/low energies, as is inevitable (a la Weinbergian EFT reasoning) given that they are consistent with Poincare invariance, local interactions, and quantum theory, and (3) they are completely beyond current experimental confirmation.

Dare I say that — dum dum dum — they are ***not even wrong***?

26. **Igor Khavkine**

Reader297 wrote: "In classical physics, you can certainly forget about phase space if you wish, but you don't have to. And that's important."

Or is it? (Warning, rhetorical question!) This situation is, to me, a clear example of a case where there are two absolutely mathematically equivalent formulations of the same theory, though one is couched in terminology that leads to all sorts of philosophical difficulties (upon quantization, that is), while the other is not. What I will perhaps never understand is how some people, when faced with a choice between these mathematically equivalent formulations, consistently go for the one laden with philosophical difficulties. Unless, they are simply not aware of the alternative (though, in my experience, many of them are).

27. **Peter Woit**
August 20, 2014

Reader297,

I understand very well Weinberg's argument, just am not convinced. He also famously argued in the intro to his GR book that another kind of mathematics, geometry, was not needed for fundamental physics (he did this right before it became clear that gauge theory, a geometrical theory, was the way forward in particle theory). Yes, there too you can argue that geometry is just a low energy effective epiphenomenon if you want, but I don't think it's a convincing argument.

The argument against the "it's just a low energy approximation viewpoint" is the LHC data: qft and gauge theory work perfectly at the shortest distances we can test (which, by the way, is rather a different situation than string theory. I was trying to keep some of these postings free of tedious arguments about string theory, please help…)

28. **Peter Woit**
August 20, 2014

For those not aware of Weinberg's views on geometry, see
http://www.math.columbia.edu/~woit/wordpress/?p=529

I've deleted some comments trying to tediously argue about string theory. Please, unless you can seriously relate this to the topic of this posting and have something new to say, just stop.

29. **Reader297**
August 20, 2014

Hi Peter,

I'm agreed about avoiding string-theory discussions here, and keeping to the current topic.

You say "I understand very well Weinberg's argument, just am not convinced."

I think that's fair. And it represents a basic philosophical impasse: If one person says s/he simply isn't convinced, then that's that, at least until experimental data can tell us which point of view is the more accurate one.

But what everyone has to admit is that the opposite point of view is a legitimate one as well — namely, that field theory won't turn out to be fundamental — again until experiment can weigh in on the issue. People aren't crazy to assume QFT is fundamental, nor are they crazy to assume it isn't, because nature would look like a QFT at low energies either way. Perhaps the proper attitude about the high-energy regime is just to be agnostic at this point in time. People should work on what they like, and be tolerant of people who have a different theology about the presently unknown and unconstrained high-energy regime.

You also write: "He also famously argued in the intro to his GR book that another kind of mathematics, geometry, was not needed for fundamental physics (he did this right before it became clear that gauge theory, a geometrical theory, was the way forward in particle theory). Yes, there too you can argue that geometry is just a low energy effective epiphenomenon if you want, but I don't think it's a convincing argument."

Gravity is a great thing to bring up in this discussion, because it appears to be something qualitatively different from a local QFT, as it seems to involve a change (now properly acknowledged by Weinberg) in the structure of spacetime itself, which is not something local QFTs do.

We have a pretty good low-energy effective QFT for general relativity for long-wavelength perturbations of the metric around a fixed background (again, see, e.g., Donoghue's work), and we can even use it to extract some quantum corrections to, say, Newton's law of gravitation, but there are basic conceptual problems that arise when one allows the geometry of spacetime to fluctuate nonperturbatively and if one wants to probe short-distance physics.

So taking seriously the geometric interpretation of GR is precisely what makes it hard to describe it in terms of a local QFT.

When Weinberg wrote that textbook in 1972, there were justifiable hopes that GR might ultimately admit a reasonably straightforward fundamental QFT description based on spin-2 massless particles, rather than the spin-1 massless particles underlying QED/QCD/Standard Model. Indeed, Weinberg showed in some papers in the late 1960s that a massless spin-2 particle had to couple to mass-energy as its source, and had to satisfy the equivalence principle. (That's pretty amazing, when you think about it.)

If the QG-as-QFT approach had worked out, and we had one big QFT that contained all of basic physics, then people could well have argued that field theory was in fact fundamental after all, as you say it is.

But it turned out that GR did not obviously admit a straightforward description in terms of a QFT. That's precisely the reason why so many people looked elsewhere for the microscopic theory of quantum gravity, knowing that any such microscopic description would look like a local field theory at low energies anyway, so why not look for something different in the short-distance regime?

What's remarkable, of course, is that we now seem to have nontrivial conjectural examples of quantum gravity with certain asymptotic boundary conditions (e.g., AdS) in which there does appear to be a highly non-obvious description in terms of a local QFT. (For AdS, famously, it appears to be a CFT.) What's ironic is that it was precisely folks who were looking at a non-QFT microscopic description (string theory) who stumbled on this discovery!

In any event, it is precisely taking a non-Weinbergian viewpoint toward the geometric picture of GR that motivated lots of people to take the Weinbergian viewpoint about local QFTs not being fundamental. But with examples like AdS/CFT, we might in the end be able to be non-Weinbergian about both viewpoints.

What are your feelings about AdS/CFT, by the way? Do you feel it has partially vindicated your hopes that we can describe fundamental quantum gravity in certain cases as a field theory?

You also write: "The argument against the "it's just a low energy approximation viewpoint" is the LHC data: qft and gauge theory work perfectly at the shortest distances we can test."

Well, yes, except that the shortest distances we can test aren't very short in the grand scheme of things — they aren't very short compared to the scales that people are actually arguing about when they talk about the question of non-fundamentalness of local QFT — unless the Planck scale is for some reason exponentially closer to us than we think it is.

That is, most people think that QFT in some form or another will work quite well at far shorter scales than we have probed at the LHC. The place people have long thought things would break down is, as you know, some 10 or 11 orders of magnitude higher in energy/shorter in distance. So the LHC isn't telling us one way or another about the regime people are actually worried about. The fact that the LHC is consistent with gauge theories isn't relevant to those questions, unfortunately.

That is, we don't have anything close to the experimental data that needs to weigh in on the question of who's correct about the fundamentalness of local QFT. That's why I referred to any present-day speculation about this question as being "not even wrong."

Igor Khavkine–

Well, what you're saying is that if we take an instrumentalist point of view toward probability theory, then quantum probability theory is no worse than classical probability theory. And that's long been pretty much accepted as true. The orthodox or instrumentalist point of view is very old, and is the refuge most people turn to when they give up trying to make more sense of quantum theory.

But what troubles people is precisely the question of instrumentalism. Not everyone wants to be an instrumentalist, for basic philosophical reasons.

In the classical case, we have the option of being non-instrumentalist if we wish — some people really like to think they personally have a state of being, and that people and detectors and measurement apparatuses are just as much physical systems as the things they examine — whereas in the quantum case, we don't seem to have such a straightforward non-instrumentalist option.

You write: "What I will perhaps never understand is how some people, when faced with a choice between these mathematically equivalent formulations, consistently go for the one laden with philosophical difficulties."

What I take from this statement is that you have no personal philosophical problem with instrumentalism, and don't appreciate why some people might not like instrumentalism.

So I think you should go out and ask them why! If you don't know of any reasons to be troubled by instrumentalism, then you might find some answers by doing a little research on the question. 🙂

30. **Peter Woit**
August 21, 2014

Reader297,
Sorry, no interest at all in yet another empty time-wasting debate about QG, see:
http://www.math.columbia.edu/~woit/wordpress/?page_id=4338
I'm making a serious effort here to discuss something different and more interesting, please stop trying to turn this discussion towards the same tedious topics that no one has now had anything new to say about for years.

31. **Reader297**
August 21, 2014

Hi Peter,

Woops! My comment was a direct response to your own comments — it definitely isn't my intention to start a discussion over QG per se, and I'm not favoring any particular direction in that regard.

I was just responding to your statement that you believe QFT is fundamental, my response being that because anything satisfying some basic properties looks like a local QFT at the scales we can reach experimentally so far, and thus that one can just as legitimately argue the jury is out on whether QFT is fundamental. I was also conceding that AdS/CFT might favor your point of view.

My other point was that we'd need to wait for experiment to weigh in, but that the question about the fundamentality of QFT referred to energies far beyond the LHC, and so might not be settled empirically for a while.

These were intended to be directly related to your statements. I too am not interested in going into a deep discussion of QG here! The only reason I brought up QG at all was that when taking the geometric picture of gravity seriously, it seems to challenge the QFT-as-fundamental idea — but, again, there are possible ways around that issue.

By the way, thanks for the link to your FAQ. Which of the questions on your FAQ did you mean to point me to?

32. **manfred Requardt**
August 21, 2014

Dear Thomas, many thanks for your interesting remarks. As I understand it, it is argued that gravity and the presumed underlying quantum gravity have different diffeomorphism groups. It is a nice coincidence that recently (1206.0832; sorry for selfreferencing) I argued that diffeomorphism invariance is spontaneously broken due to the emergence of classical spacetime with the gravitons as Goldstone particles. This entails that observables need not be diff-invariant. More specifically, there exist two classes of observables, the Dirac ones and the broken ones.
I hope that your remarks are helpful in this context.

33. **Marty Tysanner**
August 21, 2014

Reader297,

It's a pleasure to read your comments, both their content and phrasing. Your discussions are very clear and well-reasoned, and I like the way you include ample context/background with your responses to explain why others may take positions different than Peter. It's certainly a quality of communication to aspire to! I assume your explanations are as complete as they are because you want to make your arguments clear to readers whose background is more limited than Peter's.

Peter,

I think this discussion is worthwhile to many of us in clarifying your apparent position that QFT is fundamental. I'm certainly finding it interesting at least. I hope you won't shut it down because Reader297 brought up QG… My impression was that he wasn't promoting an approach to QG — he was being responsive to your disagreement with some of Weinberg's viewpoints and the question of how to assess whether QFT is indeed fundamental. (In fact, I was surprised you interpreted his response as an attempt to steer the discussion toward QG or other non-topical issues.)

Anyway, I hope this discussion can productively continue!

34. **Reader297**
August 21, 2014

Hi Marty,

That's very kind of you to say. Thanks so much.

Peter,

I also wanted to add that I, too, have found your recent blog posting and subsequent discussions very enlightening.

I'm always happy to see blog postings here in which you articulate your own proposals and explain your reasoning for them, as well as open them up for conversation. Thanks!

35. **Peter Woit**
August 21, 2014

Marty/Reader297,
I'm afraid I have all too much experience with what happens here (and on many other blogs) once an argument over QG/AdS/CFT/string theory starts, so, trust me, if you want this comment section to be something worth reading (which I think it has been, thanks to Reader297 and others).

My sloganeering is intentionally challenging to what I think is some dubious received wisdom, and Reader297 has done a good job or laying out the standard point of view that I'd like to challenge. That's all well and good, but getting into the usual arguments over string theory/QG is something different and not going to lead anywhere interesting.

For the specific FAQ entry
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=what-do-you-think-about-question-x-in-quantum-gravity

36. **Thomas Larsson**
August 21, 2014

I thought the comment about QG refered to me, because when I checked earlier today my last post seemed gone. However, before I had the time to get home and check the references for my scathing reply, the post was there again. So either I did not look hard enough, or the post reappeared. I plead guilty of having rehashed old arguments about QG in the past, but this time I think my comment was quite on topic.

Anyway, since I did spend quite a bit of time on this, let me say something else that Peter will also dislike: representation theory cannot be quantum **field** theory except in low dimensions.

Reps of finite-dimensional Lie groups is QM, and reps of infinite-dimensional Lie groups living on the circle (affine Kac-Moody and Virasoro algebras) are QFT in 2D, or really in one complex dimension. However, the corresponding representations in higher dimensions are not QFTs, although they are quantum theories.

For definiteness, consider Yang-Mills theory in 3+1D. As is well known, this theory has gauge anomalies proportional to the third Casimir, and in particular the anomaly vanishes if the gauge group is SU(N) with N != 3. However, as is clearly stated in [Pressley-Segal, Loop Groups, 1988, section 4.10], the corresponding current group admits two inequivalent extensions: the MF extension, which is also proportional to the third Casimir, and the central extension, which is proportional to the second Casimir. The second Casimir is non-zero for all gauge groups including SU(N) for all N, and hence cannot be related to the gauge anomalies arising in QFT.

Let me let this fact sink in, because very few physicists seem to appreciate it, including those who have studied the Pressley-Segal book for decades.

Not all extensions of the algebra of gauge transformations in 3+1D correspond to gauge anomalies in QFT. The others arise in – something else. Definitely not in QFT.

Worse, the MF algebra which does arise in QFT does not have any interesting quantum representations [Pickrell 1989]. Mickelsson tried to generalize the Pressley-Segal methods to higher dimensions, but after the Pickrell show-stopper he switched gears and looked for some kind of representations acting on a family of Hilbert spaces parametrized by a classical gauge field. This may be fine and dandy, but it is not really a true quantum theory. In a fully quantum theory, the gauge fields must be quantized as well, but then Pickrell's no-go theorem returns with a vengeance. So the extension that does arise in QFT does not have any good representations. This is of course in agreement with the fact that gauge anomalies cancel in the standard model.

In contrast, the central extension does not arise in QFT, but it does have representations, some or maybe all described somewhere in Pressley-Segal section 9.1. One example is the rep induced from an affine algebra living on some circle embedded in the higher-dimensional ambient space. They possibly show (I think I have seen such a claim but I cannot find it any more) that all irreps are achieved in this way. Since this result is somewhat boring from some people's point of view, it may be what Greg Moore refers to when he talk about discouraging no-go theorems [here, section 4.7]. Another reason why this extension cannot arise in QFT is that there is no privileged one-dimensional curve in QFT.

To summarize, there are three cases:

1) No extension. Then there is no non-trivial reps at all, by the same argument that the centerless affine algebra lacks reps.
2) MF extension. Arises as a gauge anomaly in QFT, but has no good representations. Besides, the gauge anomalies cancel in the standard model.
3) Central extension. Has unitary reps, but does not arise in QFT. Both because it has the wrong structure, and because the reps depend on a privileged 1D curve.

Since the extensions that arise in QFT don't have representations, and the extensions that have representations don't arise in QFT, I propose a better slogan:

*Representation theory is quantum theory, but not quantum **field** theory except in low dimensions.*

37. **Marty Tysanner**
August 21, 2014

Hi Peter,

Thank you for clarifying that you weren't specifically objecting to Reader297's mention of quantum gravity — you foresaw that bringing up QG would probably cause others to hijack the discussion with pointless, repetitive arguing. I agree.

Although it isn't your primary topic, you indicated in the comments that you believe the Standard Model may be fundamental. It would easier to understand this position if I knew specifically what it means (in your sense) to say that the Standard Model QFT is fundamental. Let me propose three alternatives; yours may be different.

1. The Standard Model is fundamental in the sense that its Lagrangian is inevitable. That is, whatever the ultraviolet completion of the SM might be, it will uniquely imply the SM as its low energy limit.

(Note: By an "ultraviolet completion" I include the possibility of explanatory microscopic models for which a Lagrangian can be specified.)

2. The SM is fundamental in the sense that it is the best description we can ever hope to empirically verify. Attempts at an ultraviolet completion may succeed in reproducing the SM at observable energies, but they will forever remain little more than "stories" we tell to reassure ourselves that we really can and do understand Nature "all the way down."

3. The SM is fundamental in that it already describes physics at all energy scales, or at least up to the Planck scale. This view doesn't preclude future extensions that explain the values of the various Yukawa couplings and gauge constants, provided those discoveries don't modify the SM Lagrangian in any basic way.

I won't argue with your definition since it stems from your own philosophical views.

My other question is about your statement,

> The argument against the “it’s just a low energy approximation viewpoint” is the LHC data: qft and gauge theory work perfectly at the shortest distances we can test.

Reader297 also asked about this. In what way do you disagree with the conventional view, i.e., that the LHC and future practical colliders can only probe “low” energies compared to the regime where the SM is expected to break down, so that collider data cannot help us determine whether the SM remains valid in the ultraviolet?

38. **Peter Woit**
August 22, 2014

Marty/Reader297,
This is getting rather far afield from the question of the relation of QM and representation theory, but a few comments:

I just don’t think that describing the highest energy you can study as “low energy” and thus irrelevant to fundamental questions is sensible, nor is basing arguments on highly speculative assumptions about what is taking place at 10^12 or whatever times the highest energies you know anything about. And on this I don’t think my point of view is unconventional. Sure, at low energies, lots of other things may look like QFT, because they have to for consistency reasons, but if you don’t actually have a non-QFT theory at high energies that has evidence for it or explains anything in a compelling way, the conjecture that it’s QFT all the way down is a viable one.

I don’t think the SM is a fully satisfactory model, since it doesn’t explain a list of things one would expect a fundamental theory to explain. But I have no idea what does explain those things and what a better theory than the SM is. My argument is just that given how well the SM works, it’s a good idea to take very seriously the mathematical framework it uses and try and understand where that might come from and whether there is some aspect of it we are missing, instead of dismissing it as “just a low energy approximation”, and looking for something completely different. Especially since conjectures about something completely different have gone nowhere.

39. **Reader297**
August 22, 2014

Hi Peter,

Again, fair remarks.

All I would say at this point is that we have enough physical examples now, e.g., from condensed matter, of systems that look like field theories at long distances but aren’t microscopically field theories that any speculations about fundamental physics being QFT “all the way down,” while perhaps viable, are not singled out by experiment. There’s no way to say that they’re even wrong.

And, again, it doesn’t help the situation that, as you note, “at low energies, lots of other things may look like QFT, because they have to for consistency reasons…”

What’s unfortunate is the dearth of hard experimental data high-energy physics has been suffering from for the past several decades. We’re flying blind. And it means that, at this moment in time, hypotheses about the fundamentality (or not) of QFT are mostly a matter of personal preference. Not that there’s anything wrong with that, but it does mean that people are going to argue a lot without changing each other’s minds.

40. **j.c.j.vandervelde**
August 22, 2014

Gentlemen,

you seem to agree that “at low energies, lots of other things look like QFT.”
Can you give some examples or references?

41. **Peter Morgan**
August 23, 2014

Peter: what’s your feeling about taking a signal processing approach to QM, instead of a classical mechanics approach? Hilbert spaces emerge naturally in signal processing through fourier transforms, and, through the elementary (and not very rigorous) mathematics of Leon Cohen’s Foundations of Physics 18, 983(1988), complex structure and incompatible operators are natural too when we take fourier transforms of probability distributions. Leon Cohen is at CUNY, so perhaps you know him?

Modern high energy physics seems to be more about feature detection in statistics of complex sets of signals than about particles.

42. **Reader297**
August 24, 2014

Peter (Morgan),

Working in an instrumentalist framework, Cohen seems to have been motivated by a theorem of Khinchin’s that a complex-valued function M(u) is the characteristic function for some probability distribution P(x) if and only if M(u) can be expressed as the integral over x of a product of the form g*(x)g(x+u) for a complex-valued function g(x) for which |g(x)|^2 integrates to 1. Cohen notes that this construction looks suspiciously like we have a wave function g(x).

But there isn’t anything surprising here. We could have skipped M(u) altogether and just noticed that we can express P(x) as g*(x)g(x) for any complex function g(x) for which |g(x)|^2 integrates to 1. Taking the extra step of going through M(u) doesn’t actually buy us anything. One can derive all of Cohen’s results just from expressing P(x) in terms of g(x).

Cohen notices that characteristic functions can be used to define joint probability distributions that are positive but not bilinear in wave functions. But he doesn’t address how to pick a canonical such distribution, nor how to write down the time evolution for them, nor how to handle matching his joint distributions onto the probability distributions of a larger system in the presence of nontrivial entanglement.

43. **Peter Morgan**
August 24, 2014

Reader297, certainly Cohen’s paper is no more than indicative, and certainly there could be other approaches. That’s a large part of why the paper I mention is in Foundations of Physics. Cohen’s academic output is more usually found in IEEE and other signal processing journals.

My only claim would be that a signal processing approach is more abstract (even while being closer to experimental data) and avoids having as much classical mechanics baggage, albeit I’m not sure whether that’s a good or bad thing (particularly for a new student of QM). To some extent, it’s taking Heisenberg without the Schrödinger.

Grand Unification of Mathematics and Physics

August 20, 2014
Categories: Favorite Old Posts, Quantum Mechanics, Uncategorized

For a second slogan about quantum mechanics I've chosen:

> Quantum mechanics is evidence of a grand unification of mathematics and physics.

I'm not sure whether this slogan is likely to annoy physicists or mathematicians more, but in any case Edward Frenkel deserves some of the blame for this, since he describes (see here) the Langlands program as a Grand Unified Theory of mathematics, which further is unified with gauge field theories similar to the Standard Model.

This week I'm in Berkeley and have been attending some talks at an MSRI workshop on New Geometric Methods in Number Theory and Automorphic forms. Number theory is normally thought of as a part of mathematics about as far away from physics as you can get, but I'm struck by the way the same mathematical structures appear in the representation theory point of view on quantum mechanics and in the modern point of view on number theory. For example, the lectures on Shimura varieties have taken as fundamental example the so-called Siegel upper-half space, which is the space Sp(2n,R)/U(n). Exactly the same space occurs in the quantization of the harmonic oscillator (see chapters 21 and 22 of my notes), where it parametrizes possible ground states. Different aspects of the structure play central roles in the math and the physics. In the simplest physics examples one works at a fixed point in this space, with Bogoliubov transformations taking one to other points, something which becomes significant in condensed matter applications. In number theory, one is interested not just in this space, but in the action of certain arithmetic groups on it, with the quotient by the arithmetic group giving the object of fundamental interest in the theory.

The workshop is the kick-off to a semester long program on this topic. It will run simultaneously with another program with deep connections to physics, on the topic of Geometric Representation Theory. This second program will deal with a range of topics relating quantum field theory and representation theory, with the geometric Langlands program a major part of the story, one that provides connections to the number theoretical Langlands program topics of this week's workshop. I've got to be in New York teaching this semester, so I'm jealous of those who will get to participate in the two related MSRI programs here in Berkeley. Few physicists seem to be involved in the programs, but these are topics with deep relations to physics. I do think there is a grand unified theory of some kind going on here, although of course one needs to remember that grand unified theories in physics so far haven't worked out very well. Maybe the problem is just that one hasn't been been ambitious enough, that one needs to unify not just the interactions of the standard model, but number theory as well…

Comments

1. **Urs Schreiber**
   August 22, 2014

   What underlies the striking "unification" of concepts of QFT with concepts found in number theory generally and in automorphic representation theory particularly is to a large extent attributable to the function field analogy. This together with the Weil uniformization theorem is what makes one guess geometric Langlands (and hence QFT phenomena) from number theoretic Langlands.

   However, to date this is really just that, educated guessing based on analogy. What is missing would be a theory that makes the "unification" here a systematic theorem.

   For instance at the Oxford meeting on the Langlands program that you mentioned a while back here, Sergey Oblezin had reported on his work with Gerasimov and Lebedev on topological sigma-model mirror symmetry computations related to geometric Langlands, and when asked afterwards if any of these insights could conceivably be carried over to the number theoretic Langlands correspondence, the answer was something like "We could, if only we really knew what it would mean to systematically consider p-adic sigma-models".

   This is open. It is probably somehow related to the phenomenon, maybe not widely appreciated, that also the construction of the refined Witten genus by Ando-Hopkins-Rezk passes all the way through arithmetic geometry (elliptic curves, hence string worldsheets, defined over Spec(Z); in fact complex worldsheets never even appear explicitly in the computation and only the elliptic curves in positive characteristic (the supersingular ones) contribute at the stringy height 2.)

   Last week at CUNY in New York I gave a talk (notes and video are here) on what I would modestly suggest might be a mathematical theory that would allow to turn the analogy here into a systematic theorem unifying automorphic mathematics with QFT.

2. **David Ben-Zvi**
   August 22, 2014

   Urs' notes look really exciting and suggestive! such unifying geometric structures are definitely needed to get a deeper understanding of these analogies, or to see the arithmetic world directly in the light of QFT.

   I would disagree though with the suggestion that the geometric Langlands analogy is only an educated guess to date (if it ever was that – starting from Drinfeld's original work). In fact one of the main themes of our current MSRI semester is the really exciting interactions going on between geometric Langlands and classical Langlands – for the first time in the last couple of years people (in particular Xinwen Zhu and Zhiwei Yun) are directly taking ideas and constructions from the geometric Langlands program and using them to prove (phenomenal) arithmetic results. (Ngo's proof of the Fundamental Lemma was arguably the beginning of this trend.) The fundamental structures of the Langlands program already span across fields of definition in a natural way.

3. **David Ben-Zvi**
   August 22, 2014

   The most exciting thing around these parts though is the shockingly futuristic sounding course announcement (http://math.berkeley.edu/courses/fall-2014-math-274-001-lec) by Peter Scholze, who seems to be able to work with number fields as if they were function fields:

   Syllabus: Originally defined by Drinfel'd, and then used extensively by L. Lafforgue and V. Lafforgue, moduli spaces of shtukas have proved to be a powerful tool in the study of the Langlands correspondence over function fields. It is an important question whether something similar could work over number fields.
   In this course, we want to sketch a strategy to define moduli spaces of local shtukas over mixed-characteristic fields such as Qp (leaving open the problem of assembling these spaces for varying primes p). These spaces should generalize Rapoport-Zink spaces, as well as the conjectural theory of local Shimura varieties that has recently been suggested by Rapoport-Viehmann. Notably, the spaces of local shtukas should overcome the 'minuscule' condition inherent in the theory of Shimura varieties, so that they can be seen as very general p-adic period domains (which exist even in situations where Griffiths transversality is a nontrivial condition). We wll start by reviewing the theory of (local and global) shtukas over function fields. Next, we will define shtukas in mixed characteristic in an absolute setup; this is closely related to the notion of Breuil-Kisin modules, and has been the subject of recent investigations of Fargues, some of whose results we will recall.
   To set things into perspective, we will spend some time detailing the case of p-divisible groups, explaining the equivalence between p-divisible groups and certain shtukas (due to Breuil, Kisin, and Fargues). We will then use the joint work with Weinstein to identify Rapoport-Zink spaces with moduli spaces of shtukas.

We will then be able to define general spaces of shtukas. They will turn out to be somewhat esoteric objects, called ‘diamonds’, so quite a bit of time will be spent on explaining the definition of diamonds. In particular, we will explain how they overcome the problem that a general space of shtukas should live over ‘a product of several copies of Spa Qp’ (taken over some absolute base ‘F1’), by giving a highly nontrivial definition of ‘a product of several copies of Spa Qp’ in a way that makes Drinfel’d’s lemma true.
If time permits, we will try to (conjecturally) understand the étale cohomology of these spaces, and their relation to the local Langlands correspondence.defined by Drinfel’d, and then used extensively by L. Lafforgue and V. Lafforgue, moduli spaces of shtukas have proved to be a powerful tool in the study of the Langlands correspondence over function fields. It is an important question whether something similar could work over number fields.
In this course, we want to sketch a strategy to define moduli spaces of local shtukas over mixed-characteristic fields such as Qp (leaving open the problem of assembling these spaces for varying primes p).

4. **David Corfield**
August 23, 2014

I wonder if philosophy might be somewhat to blame. Or is this to take on to much of a role for my discipline? Perhaps if we had at least pressed mathematicians over the past, say, 60 years to try make clearer sense to us their conceptions of space, it might have stimulated some thinking along these lines.

It’s notable in this respect that Weyl’s gauge theory grew out of a deep reading of Husserl. And if Urs’s approach were to flourish, a philosophically-oriented mathematician, William Lawvere, will be in line for the credit of devising the notion of ‘cohesion’.

5. **Urs Schreiber**
August 23, 2014

I used to just believe the advertisement that the statement of geometric Langlands duality follows, at the moment , by more than educated guesswork. It was an eye-opener when Robert Langlands himself publically expressed doubts recently. In this vein it pays to look at page 4 of

* Dima Arinkin, Dennis Gaitsgory, “Singular support of coherent sheaves, and the geometric Langlands conjecture” (arXiv:1201.6343)

The usual statement of geometric Langlands duality, as found in the standard reviews, they call a “naive guess”, pointing out that V. Lafforgue had explicitly shown it to be wrong in general. Then they discuss the “heuristic reason” for this failure. Check out some sample text from this page 4 to see the educated guesswork in action:

> “So, in the geometric theory one has been faced with the challenge of how to modify the Galois side […] with the hint being that the solution should come from […]. The general feeling, shared by many people who have looked at this problem, was that the sought-for modification has to do with the fact that […]. I.e., we need to modify […]. The goal of the present paper is to provide such a modification, and to formulate the appropriately modified version of the “best hope.”

Needless to say that I don’t find fault with educated guesswork, and that I find the work by all people involved here admirable. But where it involves educated guesswork one should call it such, for the sake of the subject. Speaking to actual number theorists reveals that a derivation of geometric Langlands and its QFT incarnation not involving handwaving would be much appreciated.

My modest point is that if one had a systematic “inter-geometric” theory which would work both for complex analytic as well as for arithmetic gemetry, then this kind of problem of wrong guesses might not occur.

For instance one central part of the analogy is that automorphic representations on the arithmetic side are supposed to be analogous to Hitchin connections on bundles of conformal blocks over a moduli stack of fields of a gauged WZW model.

Now if one had a truly inter-geometric theory, then it might be possible to axiomatize what the Hitchin connection on the bundle of conformal blocks over the moduli of fields of the WZW model would be (indeed, that is what the “cohesive” axioms are aiming at, we are almost there), and then interpret these axioms systematically in arithmetic geometry, such that one would obtain systematically the desired number-theoretic analog, together with the guarantee that it has all the relevant properties.

In other words, with a genuine inter-geometric theory one might be able to systematically say what Yang-Mills/Chern-Simons/Wess-Zumino-Witten QFT is in arithmetic geometry (something like — but much more comprehensive than — what is currently found under the headline “p-adic string theory”) and then systematically work out what the bundle of conformal blocks is when interpreted over some global field. If the inter-geometric theory works well, then it would guarantee that the arithmetic-geometry incarnation of this quantum theory would satisfy the same kind of general properties (e.g. the relevant arithmetic version of S-duality) that its complex-analytic cousin does.

Such a theory would be an actual “unification of interactions in physics and number theory” as in the thread above. Whether or not my humble suggestion for how to go about this works out, I believe such a theory would be as desireable as it is clearly missing at present, all the excitement about undeniable progress nonwithstanding.

6. **uair01**
August 23, 2014

… the way the same mathematical structures appear in the representation theory point of view on quantum mechanics and in the modern point of view on number theory …

Is there any way an interested outsider can get a feel for what you’re doing here? It sounds fascinating and beautiful, but also frustratingly unreachable. As an engineer I have some grasp of mathematics but this is no mathematics “as we know it”.

7. **David Ben-Zvi**
August 23, 2014

As I understand them, the issues that Arinkin-Gaitsgory discuss don’t in any way reveal a shakiness of the analogy or an indication of guesswork (I haven’t understood Langlands’ notes so can’t comment). Part of the problem is that the words “geometric Langlands” stand for several layers of statements. The traditional one, formulated by Drinfeld, has to do with individual cuspidal Hecke eigensheaves corresponding to irreducible local systems. This statement is the one that’s easiest to see in analogy with number theory (matching Hecke eigenforms with Galois representations) though even here one has to take account of a basic failure of naive dictionaries: the geometric analog of a number field or function field in finite characteristic should not be a Riemann surface, but roughly a surface bundle over the circle. This explains the “categorification” (need for a function-sheaf dictionary, which is the weak part of the analogy) that takes place in passing from classical to geometric Langlands — if you study the corresponding QFT on such three-manifolds, you get structures much closer to those of the classical Langlands correspondence.

In any case, this form of the geometric Langlands correspondence is now a theorem for GL_n. The categorical form that people now mean by GLC is an attempt to understand something more subtle, namely the functional analysis aspect of Langlands: we want to decompose the geometric analog of L^2 of the adelic double quotient. So it is very natural to expect that functional analytic issues emerge, i.e., you have to be very careful about setting up the correct function space. This has been clear to experts from the start, with the stated versions of the categorical correspondence being a guideline rather than a statement to be taken literally. But remarkably, despite the extra categorifications, the functional analytic issues are precisely analogous to those that arise in number theory (in the Langlands decomposition and Arthur-Selberg trace formula), and that goes for Arinkin-Gaitsgory's work as well. In fact their work is for me further justification of the robust nature of the analogy between number theory and QFT since even at this greater resolution both sides give rise to the same structures.

If anything it seems that the two sides keep getting closer – for example Xinwen Zhu's striking recent version of geometric Satake in mixed characteristic. His story doesn't have a direct number field analogue of factorization, the main geometric structure to come out of the geometric Langlands program, but rumor has it Scholze does! Likewise classical Langlands doesn't seem to have much use for many of the categorical structures of geometric Langlands, but apparently the thriving p-adic Langlands program is finding many of the same issues and structures as well. None of which should take anything away from the inter-geometric theory Urs is developing, which sounds very exciting, just to say the analogies and bridges between the areas are stronger than ever (and to my mind were never questionable, just only recently starting to really live up to their potential).

Nature is Fundamentally Conformally Invariant

August 20, 2014
Categories: Favorite Old Posts, Quantum Mechanics

For a third slogan I've chosen:

> Nature is fundamentally conformally invariant.

Note the weasel-word "fundamentally". We know that nature is not conformally invariant, but the kind of thing I have in mind is pure QCD, where the underlying classical theory is conformally invariant, with quantization dynamically breaking conformal invariance in a specific way.

The group of conformal symmetries, its representations, and what this has to do with physics are topics I haven't written about in the notes I've been working on. This is because I suspect we still haven't gotten to the bottom of these topics, and properly dealing with what is known would require a separate volume. Part of the story is the twistor geometry of four dimensions, which Roger Penrose pioneered the study of, and which recently has found important applications in the calculation of scattering amplitudes.

As a more advanced topic, this slogan would normally have been put off until later, but I wanted to point to a new article by Natalie Wolchover in Quanta magazine which deals with exactly this topic. It describes several different efforts by physicists to rethink the usual story about the hierarchy problem, taking a conformally invariant model as fundamental. For the latest example along these lines, see this arXiv preprint. The whole article is well-worth reading, and it includes a quote from Michael Dine (whose work I've been critical of in the past) that I found heart-warming:

> "We're not in a position where we can afford to be particularly arrogant about our understanding of what the laws of nature must look like," said Michael Dine, a professor of physics at the University of California, Santa Cruz, who has been following the new work on scale symmetry. "Things that I might have been skeptical about before, I'm willing to entertain."

Perhaps particle theorists are beginning to realize that the landscape is just a dead-end, and what is needed is a re-examination of the conventional wisdom that led to it.

Comments

1. **vmarko**
   August 20, 2014

   Peter,

   "We know that nature is not conformally invariant, but the kind of thing I have in mind is pure QCD, where the underlying classical theory is conformally invariant, with quantization dynamically breaking conformal invariance in a specific way."

   I am amazed by the number of people who keep repeating this "pure QCD" effect of dynamical breaking of conformal symmetry, with none of them ever actually trying to do the math.

   I've already made a whole series of comments on one of your previous posts about this — in pure QCD, the symmetry breaking **is not** a consequence of quantum corrections. It is a boundary condition that one plugs into the theory by hand. One can equally well choose a different boundary condition, and keep conformal invariance at the quantum level, starting from the very same "pure QCD". So there is nothing "dynamical" in "generating the scale" from quantum corrections, because the boundary condition is not a consequence of dynamics.

   I do understand and appreciate the importance and beauty of conformal symmetry. But this symmetry is broken in nature (much like supersymmetry must be). And symmetry breaking is never a consequence of dynamics — be it spontaneous or through quantum corrections — it is always due to a boundary condition, independent of any dynamics.

   The fundamental property of nature is the existence of the scale, not lack thereof.

   Best, 🙂
   Marko

2. **Peter Woit**
   August 20, 2014

   Marko,
   I just completely disagree with you here, but there is no point in having the same argument as last time. To stick to undeniable facts, the pure QCD Lagrangian is conformally invariant, the spectrum of the quantized theory (as calculated e.g. in the standard fashion via lattice gauge theory), is not.
   By the way, there is a counterexample to your "none of them ever actually trying to do the math". I started my career doing this kind of QCD calculation…

   Whatever you want to call it, the point of the slogan is that the other interactions should get with it and try to behave as nicely as pure QCD.

3. **vmarko**
   August 20, 2014

   Peter,

   "the pure QCD Lagrangian is conformally invariant, the spectrum of the quantized theory […] is not."

   Of course, I don't have a problem with the facts. I just have the problem with spinning this as a "dynamically generated" thing. It is a property that you can choose for the theory to have or not have — the spectrum of the quantized pure QCD can also be conformally invariant, if you want it to. This is usually overlooked because it is an uninteresting scenario. But to claim that the conformal symmetry *must* be broken in quantized pure QCD is just wrong.

   "Whatever you want to call it, the point of the slogan is that the other interactions should get with it and try to behave as nicely as pure QCD."

   I can appreciate this way of looking at things. But in whatever way you formulate interactions, sooner or later you need to break the conformal symmetry. And there is nothing in the theory (classical or quantum) that requires you to do so — you need to **postulate** that conformal symmetry is being broken (for example, via quantum corrections). IMHO, this somehow this goes against the statement of the slogan.

Best, 🙂
Marko

Totally off subject, but really not:

https://www.southernnewengland.aaa.com/legacy/TravelDiscounts/discounts-details.php?PROD_ID=295

There's a new cruise liner in the Caribbean, Quantum of the Seas. No word if it sails through the Bermuda Triangle wormhole, or whatever it is.

Clearly, this quantum business is reaching new audiences.

5. **Nakanishi**
August 20, 2014

Pure QCD is badly infrared divergent; in contrast with QED, its infrared divergence survives even in the transition probability. Probably, it is impossible to avoid the appearance of infrared divergence without violating scale invariance. Indeed, in the 2-dimensional free massless scalar field theory, infrared divergence is very serious; scale invariance is spontaneously broken in the consistent quantization.

6. **Ramanujan**
August 21, 2014

QCD is classically conformally invariant. By asserting that it is fundamentally conformally invariant, you are claiming that classical physics is more fundamental than quantum physics. I do not agree.

7. **Aleksandar Mikovic**
August 21, 2014

Postulating conformal symmetry as a fundamental one (i.e. at short-distance scales) is the same idea as the fundamental supersymmetry: one wants to stabilize the quantum corrections to the Higgs mass or the cosmological constant by using the symmetry. However, in all these calculations the effect of quantum gravity is completely ignored, or it is assumed that it is not important. In a paper with M. Vojinovic (arxiv:1407.1394) we showed that the cosmological constant problem can be solved when a quantum gravity contributions are taken into account. I believe that the same could be done for the Higgs mass, so that one does not need fundamental supersymmetry or conformal symmetry. However, one needs a fundamental quantum gravity theory, and a good candidate is Regge quantum gravity (a modification of spin-foam models where the basic variables are the edge lengths and a spacetime triangulation).

8. **confused**
August 21, 2014

"Of course, I don't have a problem with the facts. I just have the problem with spinning this as a "dynamically generated" thing. It is a property that you can choose for the theory to have or not have — the spectrum of the quantized pure QCD can also be conformally invariant, if you want it to. This is usually overlooked because it is an uninteresting scenario. But to claim that the conformal symmetry *must* be broken in quantized pure QCD is just wrong."

I don't get that. The spectrum of pure QCD (SU(3) gauge fields only) consists of glueballs and you can compute their mass ratios in lattice QCD. I have done that. So there is no conformal symmetry in the quantum theory. What "property" of the theory can I choose to make these massive glueballs go away?

9. **vmarko**
August 21, 2014

"The spectrum of pure QCD (SU(3) gauge fields only) consists of glueballs and you can compute their mass ratios in lattice QCD."

Calculating mass ratios means nothing until you prove that at least one of those glueballs has nonzero mass. Otherwise all masses of all glueballs could be zero, and your mass ratios are satisfied trivially.

Btw, if you have managed to prove that a single glueball must have a nonzero mass, go claim the Millenium prize. 🙂

"What "property" of the theory can I choose to make these massive glueballs go away?"

Naively said, there is usually an implicit (and unproven!) assumption that at least one of the glueballs is massive, because only in that case calculating mass ratios is nontrivial.

More seriously, show me your calculation in full detail, and I'll probably be able to point you to such an a priori assumption. (Though it might be hard to find, if it is phrased in an obscure way or buried somewhere in the numerical calculations.)

Even more seriously, lattice QCD is an approximate rather than exact calculation method, and can introduce all sorts of artifacts (fermion doubling is the most popular example of this), some of which we may still not be aware of. These artifacts might lead you to a conformally broken result simply as a consequence of the approximation scheme, rather than being the property of the theory itself.

And really, in all these discussions one needs to pay special attention to distinguish the statement "mass gap *can* exist" from the statement "mass gap *must* exist", in every particular calculation. This can be done only by detailed step-by-step inspection on every paper that deals with conformal breaking in QCD. And it doesn't make sense to do this in blog comments.

I feel like I am going against the windmills with this. I've already stated my point as clearly as I can, and I see no point in further debate.

Best, 🙂
Marko

10. **confused**
August 21, 2014

"Calculating mass ratios means nothing until you prove that at least one of those glueballs has nonzero mass. Otherwise all masses of all glueballs could be zero, and your mass ratios are satisfied trivially."

That sounds a bit like demanding a proof that the International Prototype Kilogram has a non-zero mass.

11. **Peter Woit**
August 22, 2014

vmarko,
There is no fermion-doubling problem in pure QCD on the lattice. There is very strong numerical evidence for the conventional conjectures about the existence of a continuum limit of the lattice with a non-zero mass gap. Yes, there is no proof, and it's possible the usual conjectures are just wrong, but I know of no evidence pointing to that.

12. **vmarko**
August 22, 2014

Confused,

"That sounds a bit like demanding a proof that the International Prototype Kilogram has a non-zero mass."

Sigh… Are you trying to compare a glueball to a proton? One lives in pure QCD, while the other (arguably) lives in the Standard Model — where the conformal symmetry is explicitly broken by the Higgs mass, already at the classical level. Apples and oranges.

The proton mass can (in principle, ultimately) be expressed as the Higgs mass times a dimensionless coefficient. This coefficient is a complicated function of electroweak-, QCD- and Yukawa-couplings, some large and some small, combining into the renormalized grand-total of 1/125. While one can argue that the dominant contribution comes from QCD, it still ends up multiplying the Higgs mass (this is on purely dimensional grounds). On the other hand, in pure QCD there is no Higgs, and unless you *assume* the existence of some other nonzero mass parameter, the coefficient of 1/125 is multiplied by a zero, keeping all glueballs massless.

Peter,

"There is no fermion-doubling problem in pure QCD on the lattice."

Sure, but there might be other (unknown) artifacts of the lattice. Fermion doubling is just an example and a warning that such things may appear where you don't expect them a priori.

"There is very strong numerical evidence for the conventional conjectures about the existence of a continuum limit of the lattice with a non-zero mass gap. Yes, there is no proof, and it's possible the usual conjectures are just wrong, but I know of no evidence pointing to that."

That's because nobody is looking for such evidence — everyone is trying to calculate a nonzero mass gap. It's a social effect. Whenever I speak to QCD people, they always eventually say something on the lines of "Sure, you can keep conformal invariance, but why would you want that? It doesn't correspond to experiment.". And then people like Alessandro Strumia go on to claim that conformal invariance *must* be broken at the quantum level, because this effect was "proven" in QCD. But there is no proof. And there is no evidence to the contrary simply because QCD folks are just not interested in preserving conformal invariance, and they always implicitly discard that scenario as trivial.

That's why I have a problem with things like agravity and fundamental conformal invariance — they are blinded by a social effect, and have no solid basis.

Best, 🙂
Marko

13. **AlsoConfused**
August 22, 2014

Marko,
are you saying that in the end all mass is generated by the Higgs mechanism ?
But what if the Higgs mass is actually due to quantum corrections (Coleman-Weinberg mechanism) breaking the fundamental conformal symmetry of nature ?
http://arxiv.org/abs/1401.4185

14. **vmarko**
August 22, 2014

"are you saying that in the end all mass is generated by the Higgs mechanism ?"

Possibly. If not, you have to postulate other sources of mass. Mass is never automatically enforced by quantum corrections (or dynamics in general).

"But what if the Higgs mass is actually due to quantum corrections (Coleman-Weinberg mechanism) breaking the fundamental conformal symmetry of nature ?"

That always involves a postulate (a suitable boundary condition for the corresponding RGE). The CW mechanism does not *necessarily* break conformal symmetry — it does only if you choose appropriate boundary conditions. Alternatively, you can choose to keep the minimum of the Higgs potential at zero, with no spontaneous symmetry breaking at all.

Best, 🙂
Marko

15. **Peter Orland**
August 22, 2014

Marko,

1. It's not true that the mass of the proton mostly comes from the Higgs. It is the other way around – most of the mass comes from QCD. Most of the proton's mass is not from the quark masses (the latter does come from the Higgs, of course). Turning off the Higgs has little effect on the proton mass.

We used to call a fraction of the proton mass the "constituent" quark mass – but it is not really the quark mass – it comes from QCD.

2. "That's because nobody is looking for such evidence — everyone is trying to calculate a nonzero mass gap. It's a social effect." Not really. The numerical evidence has been done very carefully. As a matter of fact, it's been done carefully for decades.

There were serious analytic and numerical efforts by Patrasciou and Seiler to prove there was no confinement and gap, challenging the conventional wisdom. In the end, their program did not succeed, but they managed to do some interesting things in the attempt.

Also concerning 2.: there are a few people who do fool themselves into thinking they have demonstrated the existence of mass gap. They are generally not taken seriously (especially after the fiftieth paper). Most of us think that it will take a lot of creativity, hard work and (importantly) luck to understand the gap.

16. **Peter Orland**
August 22, 2014

Correction – almost all the constituent mass comes from QCD (flavor dependence comes from the Higgs).

17. **vmarko**
August 22, 2014

Peter Orland,

"Turning off the Higgs has little effect on the proton mass."

How can you know this? You can't turn it off in experiment, and you can't evaluate the proton mass analytically and take the limit, because we cannot solve SM QCD equations in the IR. Moreover, the argument that the two masses are proportional goes on purely dimensional grounds — besides the Higgs mass, there is no other fundamental dimensionful parameter in the SM that can be proportional to the proton mass. People often claim that effective QCD scale can serve for this purpose, but you should keep in mind that this scale is a phenomenological parameter, measured in the experiment, where the Higgs mass is always "turned on". So the QCD scale can also be considered proportional to the Higgs mass, and it can also go to zero if Higgs mass goes to zero.

As for numerical evidence, everything I ever saw were the calculations of mass ratios between hadrons. I've never seen an ab initio calculation from the fundamental SM parameters (if you know a reference for such an attempt, I'd like to see it). So numerical evidence basically says nothing about the nonzero-ness of hadron masses.

I am really frustrated by this being such an uphill struggle — everyone is just repeating the conventional wisdom, while nobody is able to provide serious proofs. And most often people assume that I don't know what I am talking about. I am really being tempted to write a serious paper with all the gory details of integrating beta-functions in various models, just to point out that a differential equation always comes with boundary conditions, and debunk the conventional wisdom about this.

Best, 🙂
Marko

18. **Hish**
August 22, 2014

Peter Orland, could you say a little more (or point to a reference) about the failure of Patrascioiu & Seiler's program? I only know a little of the story and that the question still appears to open on a (mathematically) rigorous level.

19. **MarkusM**
August 22, 2014

Peter,
"Nature is fundamentally conformally invariant."
Wouldn't that imply that "fundamentally" gravity is Weyl gravity (instead of Einstein gravity) as the Weyl tensor squared (more or less) uniquely leads to a conformally invariant gravitational action ? (Which wouldn't be all that far fetched, see http://www.ejtp.com/articles/ejtpv11i30p1.pdf)

20. **Peter Orland**
August 22, 2014

Hi Marko,

"How can you know this? You can't turn it off in experiment, and you can't evaluate the proton mass analytically and take the limit, because we cannot solve SM QCD equations in the IR. "

The experimental evidence is that the actual quark masses can be found through current algebra (pseudo-Goldstone Boson masses, for example). These are the masses given to the quarks by the Higgs. They are much smaller than the effective quark mass used to find other masses. You don't have to solve QCD to know this. This is fairly well-established physics. An experimentalist might laugh at our theories, but she/he takes this sort of thing very seriously.

Dimensional arguments don't work here. Any energy is proportional to any other energy. It doesn't mean both energies come from the same physics.

"I am really frustrated by this being such an uphill struggle — everyone is just repeating the conventional wisdom, while nobody is able to provide serious proofs. "

In the case, the conventional wisdom is clearly right. We really can say something about nature. The uphill struggle is due to QCD being a hard problem (hence no proofs), but it is wrong to say we don't know anything about it.

Hish,

I suggest you find P. and S.'s many papers at INSPIRE. There is far too much to summarize here.

Regards,
Peter O.

22. **Anonyrat**
August 22, 2014

I can have conformal invariance in QCD even with the scale anomaly?

23. **AlsoConfused**
August 22, 2014

Marko,
"That always involves a postulate (a suitable boundary condition for the corresponding RGE). The CW mechanism does not *necessarily* break conformal symmetry — it does only if you choose appropriate boundary conditions. "
Aren't these boundary conditions coming from experiments, namely that one measures and fixes the relevant parameters at some scale and then "runs the RGE equations". Now, as experiments tell us that scale symmetry is (obviously) broken, we can exclude the case of radiative corrections maintaining it. Isn't this a peculiar/"fine tuned" case anyway ?
Moreover, doesn't conformal symmetry imply that one is in a fixed point ?
(P.S. If these questions are naive, I apologize; I only have a quite superficial understanding of this topic).

"Alternatively, you can choose to keep the minimum of the Higgs potential at zero, with no spontaneous symmetry breaking at all."
Never heard of this kind of scenario. Is there a good reference where I can read about it ?

24. **Peter Orland**
August 23, 2014

AC,

I am also also confused by those remarks.

Generally (but not always) conformal-invariant actions lead to breaking of conformal invariance. The scale appears, not because of some special boundary condition, but because of the LACK of a special boundary condition. Generic boundary conditions have broken conformal invariance. There is a conformal limit, obtained by taking the scale to zero (which is the special bc).

Anyway it's the conformal-invariant limit which is non-generic. It's best not to learn such things from remarks on comment threads (including my own).

25. **confused**
August 23, 2014

vmarko: "As for numerical evidence, everything I ever saw were the calculations of mass ratios between hadrons. "

What I recall, and it has been almost 30 years since I worked on this, is that in pure SU(3) YM on the lattice you compute some glueball masses as well as another "mass" which is related to a "string tension". Everything depends singularly on the lattice spacing but only mass-ratios are meaningful quantities (in ANY theory) so we report the glueball masses in units of the string tension "mass". The latter is now the new "dimensional" free parameter, instead of the original dimensionless coupling constant g ("dimensional transmutation"). We can measure the string tension related "mass" Ms, which means really we can measure the ratio of this "mass" and that standard block of mass in France which we call 1 kg, so this allows you to come up with actual predictions for the glueball masses.

All you seem to be saying is that you can set Ms=0, which is true but as trivial as saying you can set g=0 in the SU(3) theory and get 8 massless particles instead of the usual QCD.

Obviously no theory without mass parameters can predict a particle mass in kg, if only because the laws of nature don't know anything about that object in France which we call kg.

26. **walkloud**
August 23, 2014

vmarko,

"Even more seriously, lattice QCD is an approximate rather than exact calculation method, and can introduce all sorts of artifacts (fermion doubling is the most popular example of this), some of which we may still not be aware of. These artifacts might lead you to a conformally broken result simply as a consequence of the approximation scheme, rather than being the property of the theory itself."

I do not intend to pick upon you, rather the above statement. This is a rather naive viewpoint, especially today. Aside from the lack of proof of lattice QCD calculations belonging to the same universality class (a proof which is not special to QCD, but to any theory requiring a non-perturbative regulator), all approximations made in numerical lattice QCD calculations are well understood, and systematically improvable, meaning these approximations can be removed with refined calculations to, in principle, any desired level of precision. Fermion doubling is not one of these approximations. Fermion doubling is a well understood consequence of the "naive" implementation of fermions. This problem has been resolved for decades, with the original solution by Wilson himself, with a technique now known as "Wilson fermions". There are several other solutions that are all employed in today's calculations.

The three big systematics are 1) the continuum limit, 2) the infinite volume limit and 3) the limit of physical quark masses. All three of these systematics can be cast into the language of Effective Field Theory and hence, order by order corrections due to being away from these limits can be systematically described and parameterized in a model independent way, and then these corrections can be extrapolated away. The order in perturbation theory needed to control this extrapolation depends upon the desired level of precision of the final result. State of the art lattice calculations are now performed with the light (up,down) and strange quark masses basically at their physical values. Three or more lattice spacings are used and several volumes are used.

These calculations have demonstrated, for example, that ~95% of the mass of the proton comes from glue – meaning the calculations were performed at several values of the current quark masses (and lattice spacings and volumes), and then the proton mass was extrapolated to the point where these quark masses are zero, with still ~900 MeV for the mass of the proton. This is not a pen-and-paper proof that the mass of the proton comes from QCD (and not the Higgs vev), but this is a numerical proof. Taken alone, you may have your doubts, but lattice QCD calculations have now been used to make several predictions (not post-dictions) that have all been experimentally confirmed. Most of these lie in the realm of heavy quark physics. There is an extreme preponderance of numerical evidence now that QCD is the correct theory describing the IR realm of strong interactions (hadronic and nuclear physics).

Since this is already a bit long – look at any of the proceedings of the annual international lattice conference in the last few years. To come up with an alternate theory that shows all the properties observed in nature, can reproduce all the results of lattice QCD, yet does not poses "dimensionful transmutation" would really require a "conspiracy theory".

Regards,
André

27. **walkloud**

August 23, 2014

confused:

“Obviously no theory without mass parameters can predict a particle mass in kg, if only because the laws of nature don’t know anything about that object in France which we call kg.”

In fact, this is precisely the point. The QCD Lagrangian with all quark masses=zero (pure QCD? or is pure QCD just Yang Mills – I am unfamiliar with this jargon), is conformally invariant. But the dynamics of the theory generate a mass scale, Lambda_QCD. This length scale is approximately the confinement scale of the theory, and all states of this theory will have a mass proportional to Lambda_QCD – hence the generation of a mass scale. In physics, this was coined “dimensional transmutation”, I believe by Sidney Coleman. This mechanism, as noted above, is how QCD solves its IR problem. Without confining the gluons, QCD would be IR divergent, and thus not a sensible theory.

Now, relating this mass to something in kg requires more subtle questions involving atomic physics and units. But the point is that a theory with a conformally invariant Lagrangian can have a mass scale and be used to predict the mass of states of the theory. These predictions may require the aid of a computer, but they can still be made.

Regards,
André

28. **vmarko**
August 23, 2014

Oh, wow, it appears that we are finally getting somewhere!

AC,

“Aren’t these boundary conditions coming from experiments, namely that one measures and fixes the relevant parameters at some scale and then “runs the RGE equations”. Now, as experiments tell us that scale symmetry is (obviously) broken, we can exclude the case of radiative corrections maintaining it. Isn’t this a peculiar/” fine tuned” case anyway ?”

YES! You are RIGHT! It is experimental data that provides us with the correct boundary conditions. My only point is that the theory itself *doesn’t*! The theory *allows* a maintained conformal symmetry, but this is not interesting (or, as you say, a peculiar case) because in the real world conformal symmetry is broken! The theory doesn’t say it must be broken, the experiment does! And this is in direct contradiction with agravity approach (and the like) which claims that breaking of conformal symmetry is required by the theory. It isn’t — you have to postulate the breaking (in the theory), because experiment says it is broken. And this is in direct contradiction with Peter’s slogan. Thanks for noticing!

Peter Orland,

“Generic boundary conditions have broken conformal invariance. There is a conformal limit, obtained by taking the scale to zero (which is the special bc).”

Thank you too! We agree that the conformal limit can exist, and that it is not excluded by the theory itself (but rather by experimental data). As I explained above, this is in contradiction with the agravity approach and Peter’s slogan.

Confused,

“All you seem to be saying is that you can set Ms=0, which is true but as trivial as saying you can set g=0 in the SU(3) theory and get 8 massless particles instead of the usual QCD.”

And thanks to you as well! That is indeed all I am saying! The theory allows for the case Ms=0. Trivial or not, the theory itself does not exclude this possibility. The fact that Ms is not zero in nature is therefore not a consequence of the theory, but comes from experiment. Therefore, to make theory match experiment, one needs a theoretical postulate that Ms is not zero. This contradicts agravity approach and Peter’s slogan.

Walkloud,

“But the dynamics of the theory generate a mass scale, Lambda_QCD. This length scale is approximately the confinement scale of the theory, and all states of this theory will have a mass proportional to Lambda_QCD – hence the generation of a mass scale.”

My statement is that the theory (the theory alone) allows for the case where Lambda_QCD iz zero. This would correspond to to strong coupling asymptotically flowing to one as we run it further and further into the IR regime. As unusual as it might seem, the only thing I want to say is that there is nothing in the theory that forbids this case. It is rather an *experimental* fact that the value of Lambda_QCD is nonzero, and consequently we have a mass scale via dimensional transmutation. And as I explained above several times already, this is in contradiction with the point of view of Strumia, Woit and others, who claim that nature is in fact conformally invariant, but that this symmetry must be broken because the theory dictates it. My whole point throughout this long discussion is that the theory *does not* dictate it, rather the experiment does. Hence the contradiction with Peter’s slogan.

I can see now a small glimmer of hope that I am actually getting my point through to people here… 🙂

Best, 🙂
Marko

29. **confused**
August 23, 2014

Marko, I think everyone is well aware of what you’re saying but considers it too trivial to mention every time. By analogy, when someone states that QED explains the Coulomb force people usually leave out the obvious caveat that the coupling alpha=1/137 is not predicted by the theory and there is no a-priori reason why it could not be zero with no Coulomb force.

But maybe I’m not understanding something subtle. For example I am reading in the statement of the millennium problem (http://www.claymath.org/sites/default/files/yangmills.pdf):

“Prove that for any compact simple gauge group G, a non-trivial quantum Yang–Mills theory exists on R^4 and has a mass gap $\Delta > 0$”

I don’t understand the question. In what units is \Delta supposed to be expressed?
The only computable quantities are mass (or energy) ratios.

30. **walkloud**
August 23, 2014

Hello Marko and confused,

"My statement is that the theory (the theory alone) allows for the case where Lambda_QCD iz zero. This would correspond to to strong coupling asymptotically flowing to one as we run it further and further into the IR regime. As unusual as it might seem, the only thing I want to say is that there is nothing in the theory that forbids this case. It is rather an *experimental* fact that the value of Lambda_QCD is nonzero, and consequently we have a mass scale via dimensional transmutation."

This is not correct. You DO NOT need experiment to be able to know if the theory develops a mass gap (is Lambda_QCD > 0). You need to be able to solve the theory in the IR, which is what no one knows how to do with pen-and-paper. All SU(N>1) gauge theories are known in perturbation theory to exhibit properties indicative of dimensional transmutation – ie their beta functions are all negative, indicating they do develop a mass gap (Lambda_QCD > 0). Of course, this is perturbation theory, so not a proof in the IR regime.

This is where (numerical) lattice field theory enters. The lattice calculations are of course performed in terms of dimensionless variables (to confused's question – you can only compute ratios of energy scales without further input). What lattice calculations unambiguously show is that the theory does develop a mass gap, with a highly non-trivial spectrum. Add quarks to the calculation, and the spectrum becomes significantly richer. The calculations show the spectrum does not become trivial as the systematics are removed. This does not require experimental input.

Experimental input is needed to fix the absolute scale, so that the resulting dimensionless spectrum determined with the computer can be converted into units we are familiar with. In case one is concerned that somewhere between the scale at which the calculations are performed, and the UV, there is a non-trivial fixed point where the theory becomes conformal, the calculations can be, and are performed at scales where perturbation theory is reliable, so that analytic perturbative results can be matched to the non-perturbative numerical calculations, thus providing a smooth transition between the UV and IR. Yang-Mills SU(N) gauge theories, including those with small-enough number of dynamical fermions (such as QCD), do not have non-trivial fixed points where they become conformal. There is, however, an active area of research where people are adding more fermions to the theory, to see if they become nearly conformal.

The theory (Yang-Mills + small enough number of mass-less fermions), defined as the Lagrangian, does not tell you if Lambda_QCD is zero or non-zero. However, the solution to the theory does tell you Lambda_QCD is non-zero.

Regards,

André

31. **Peter Woit**
August 23, 2014

Andre and others,
Thanks for trying to get this straight, but I don't think anyone is going to convince vmarko on this question of our understanding of QCD. So, no more about QCD's breaking of conformal symmetry, that topic has been beaten to death.

32. **ConformallyCyclic**
August 24, 2014

I lately read part of Penrose's new book "Cycles of Time" which is also concerned with conformal invariance.
There is one thing that troubles me, which he addresses in a in a footnote, namely the role of the conformal anomaly. He states:
"There can, however, be an issue with regard to what is referred to as a conformal anomaly, according to which a symmetry of the classical fields (here the strict conformal invariance) may not hold exactly true in the quantum context. This will not be of relevance at the extremely high energies that we are concerned with here, though it could perhaps be playing a role in the way that conformal invariance 'dies off' as rest-mass begins to be introduced."
Unfortunately I do not understand his argument which seems crucial for thee whole scenario to work. Can anybody help me ?

August 24, 2014

Astonished that Dilbert of Sunday Aug 24 has not received a mention yet.

Quick Links

August 25, 2014
Categories: Uncategorized

Now back from the West Coast, here's a list of things I've run across that may be of interest:

- One piece of news from Berkeley is that Peter Scholze will be there this fall, giving a course describing new techniques for dealing with Langlands conjectures for number fields in an analogous manner to ones successfully used in the function field case. The course announcement (described by David Ben-Zvi as "shockingly futuristic") is here.

  Since it's never too early for Fields Medal predictions, I'm predicting an award for Scholze at the next ICM, in Rio, August 2018.

- It also wouldn't surprise me if Scholze gets one of the $3 million Milner/Zuckerberg breakthrough prizes in mathematics before then. I'm pleased to see that last week there was an announcement that some of the winners of this year's math prize have banded together to fund graduate math fellowships in developing countries.
- On the physics front, rumor from Peter Coles is that:

  > I have it on very good authority that Planck's analysis of the Galactic foregrounds in the BICEP2 region will be published (on the arXiv) on or around September 1st 2014.

  so next week we may (or may not…) find out if BICEP2 was seeing primordial gravitational waves or just dust.

- In the meantime, this week there's COSMO 2014, a cosmology conference going on in Chicago. The conference organizers have decided to have their public event mix artists and scientists, brought together around the topic of Multiverse: Fact, Fictions and Fantasies.
- Also in the Chicago area, Fermilab last week hosted a Nature Guiding Theory workshop, considering the question of what to make of the failure of the LHC to find SUSY or other physics predicted by the "naturalness" paradigm. Some of the discussion was of the conventional SUSY or multiverse variety. For instance, see here, or Raman Sundrum's Super-Natural vs. Other-Worldly in Fundamental Physics, which ends up arguing that:

  > Naturalness, anthropic selection, Multiverse are *Meta-theories*. The collection of naturalness-related experiments – LHC, flavor, axion searches, tests of Inflation (e.g. BICEP2, …), Dark Matter search, form a *Meta-experiment*.

  I'm not sure what a "Meta-experiment" or "Meta-theory" is, other than that it's not the conventional sort of science where you have the usual notions of how to make scientific progress.

  Some talks dealt with dumping the "naturalness" argument in favor of ideas about fundamental conformal invariance that I mentioned here. See for example here and here. By the way, Natalie Wolchover's excellent article on these ideas has been given by Wired the title Radical New Theory Could Kill the Multiverse Hypothesis.

- Going on at the same time as the cosmology conference in the Chicago area this week is a Fermilab workshop on Next Steps in the Energy Frontier. Today there were talks on future plans from Fermilab, CERN and the Chinese. The Chinese now have a Center for Future High Energy Physics directed by Nima Arkani-Hamed and are talking about a huge new machine that would start off as an electron-positron Higgs factory in 2028, then become a 50-90 TeV proton-proton collider in 2042. CERN is discussing similar plans, although they will have the high-luminosity LHC keeping them busy through 2035.

  On Thursday Arkani-Hamed will end the conference with a talk at 12:15 entitled "Go Big or Go Home…" (the US I guess already has decided to go home, with no plans for a big new machine). He really is ubiquitous at fundamental physics conferences in a variety of areas, since at 9-9:45 that morning he'll be addressing COSMO 2014 up in Chicago on the topic of "Cosmological Collider Physics". This Tuesday night he'll be at the other public event there, a showing of the movie Particle Fever, which stars him discussing the multiverse.

- There seems to be little scientific news anymore about string theory, but it is everywhere in popular culture. This past weekend it made Dilbert, it's playing a big role in DC superhero comics, and a few weeks ago some peculiar British TV show designed to torment young "child geniuses" had string theorist Brian Wecht bringing an 11-year old to tears with questions on the subject.
- John Horgan has put online an interesting interview with Carlo Rovelli, following up on one with George Ellis. Both Ellis and Rovelli criticize physicists for knocking philosophy. On the whole I'm quite sympathetic to what both Ellis and Rovelli have to say, although I think the problem with string theory is not really the "philosophical superficiality" that Rovelli sees as the problem. Jerry Coyne has a blog posting criticizing Rovelli as an "accomodationist". Note that if you want to argue about religion, please do it at Coyne's blog, not here.
- For those interested in the metaphysical end of philosophy as applied to physics, Oxford is hosting a conference in October on The Metaphysics of Quantum Mechanics. It's organized by the Power Structuralism in Ancient Ontologies and Metaphysics of Entanglement Projects. The first of these is funded by the European Research Council, the second by the Templeton World Charity Foundation (which I've never heard of before, and wonder about its relationship to the Templeton Foundation). Entanglement is the hot topic in fundamental physics these days. The Metaphysics of Entanglement project promises to bring quantum mechanics and theology together bu (Jerry Coyne is going to hate this…)

  > bringing the research results of the above investigation to bear on our understanding of questions regarding the metaphysics of the incarnation and of the Trinity in philosophy of religion.

- Anyone interested in making some easy money might want to contact Gordon Kane. He has a letter to the editor in the latest Scientific American arguing that string/M-theory predicts superpartners visible at the LHC and complains that:

  > Predictions based on such theories should be taken seriously. I would like to bet that some superpartners will be found at the LHC, but I have trouble finding people who will bet against that prediction.

Update: One more. The New York Times today has a very good story about IMPA, the math institute in Rio de Janeiro.

   August 26, 2014

   It seems more accurate to say that Scholze is working with mixed-characteristic local fields as if they were characteristic-p objects, which after all is his speciality. Number fields don't really seem to be in the picture yet – though I don't disagree with Ben-Zvi's assessment!

6. **Bill**
August 26, 2014

Peter, you criticized the trend of giving all the attention to a few chosen stars and yet you do it here yourself with Scholtze. If you read his course syllabus, he is building upon the ideas of many other people, including recent ideas. He looks like the real thing though, so I wish him well. Let's wait and see.

7. **Peter Woit**
August 26, 2014

Bill,
My criticism of the academic star system is the same criticism I have of the US economy in general, a belief that having outsized rewards going to a small number of people is not healthy. This is something quite different than the question of how much attention I'd advise people to pay to certain people's work. Sure, Scholze is building on lots of other people's work, but he is doing so more successfully than others in his field. So, he should be getting a lot of attention. On the other hand, I don't think the $3 million check he's likely to get at some point is a particularly good idea, and, whatever department he ends up in, if he's paid vastly more than his colleagues, that won't be particularly healthy either (in the sense of causing him or anyone else to do better mathematics).

8. **David Roberts**
August 27, 2014

From the Quanta piece

>the new models require a calculation technique that some experts consider mathematically dubious,

anyone care to elaborate? I'm a mathematician, and I know path integrals are already mathematically dubious, though from a physics POV ok – is there some extra-dubiousness going on?

9. **David Ben-Zvi**
August 30, 2014

For those interested, MSRI has arranged to videotape Scholze's lectures (though they are taking place down at the University) and make them available on their webpage – you can find the listings here for example.

September 2, 2014

jd,
For a long time the story has been Planck data release on polarization in October, the conference in December to discuss. For a while now though there have been rumors of an earlier data release, of data about the BICEP2 patch. This keeps getting pushed back, and now it's September 2, with the rumored September 1 date past. Waiting for the supposed arXiv paper, or new rumors…

Use the Moment Map, not Noether's Theorem

August 28, 2014
Categories: Favorite Old Posts, Quantum Mechanics

For a fourth provocative slogan about quantum mechanics I've chosen:

> Use the moment map, not Noether's Theorem.

Pretty much every physics textbook these days explains the way symmetry principles work as:

- Start with an action functional, invariant under a Lie group G.
- Use Noether's theorem to get a conserved charge (for each element of the Lie algebra of G).

There's a short (slightly mystifying) calculation always given to derive this. I'd like to argue that this is really not the best way to think about the implications of having a Lie group act on a physical system, that for this it's better to take the Hamiltonian point of view. There the way symmetry principles work is:

- For a function on phase space (or on a general symplectic manifold) you get a vector field. This is just Hamilton's equations, giving the vector field for time evolution corresponding to any Hamiltonian function.
- The infinitesimal action of G on phase space gives a vector field for each element of the Lie algebra of G. The moment map takes an element of the Lie algebra to a function on phase space (the one corresponding to the vector field).

I'm ignoring some subtleties here having to do with the relation between vector fields and functions not being quite one-to-one.

All of the basic examples of conservation laws in physics come about this way. The action of time translation gives the Hamiltonian function, space translation the momentum, rotations give the angular momentum, and phase transformations give charge. You can get these either as moment maps, or using Noether's theorem.

The moment map however gives you much more, with phase space providing structure that is not visible just from the action. A simple example is the harmonic oscillator in 3 variables. SO(3) rotations act on the configuration variables, preserving the action, so Noether's theorem gives you 3 conserved quantities, the angular momentum variables. The moment map point of view however gives you much more. The phase space is 6 dimensional (3 positions + 3 momenta) and the Lie group Sp(6,**R**) of linear symplectic transformations acts on it, with a subgroup U(3) preserving the Hamiltonian. The U(3) includes the SO(3) rotations as a subgroup, but it is much larger (9 dimensions vs. 3), so the moment map gives you many more conserved quantities. After quantization, you learn that energy eigenstates are U(3) representations, telling you much more about them than what angular momentum tells you.

The moment map point of view also gives you quantities corresponding to the directions in Sp(6,**R**) that are not in U(3). In the quantum theory these act on the full state space (not preserving energy eigenstates) and your state space is a representation of (a double cover of) this group.

For the simplest possible harmonic oscillator, in one-dimension, Noether's theorem doesn't really tell you anything. The moment map point of view says that there is an Sp(2,**R**) acting on phase space, with a U(1) subgroup preserving the Hamiltonian. The moment map is just the Hamiltonian itself. In the quantum theory you find that the harmonic oscillator state space is a representation of (a double cover of) Sp(2,**R**), with the U(1) action on states characterized by integers, which correspond to the energy. This integrality is the essence of the "quantum" in "quantum mechanics", and it's quite invisible to Noether's theorem, but a basic fact of the moment map point of view.

In some sense this is an argument for the Hamiltonian vs. Lagrangian point of view in general. The relation between the two is that, given a Lagrangian, one constructs a symplectic structure on the space of solutions of the variational problem, and thus a Hamiltonian formalism. Noether's conserved quantities are then examples of moment maps. The problem is that typically this requires the use of constraints and the quite tricky constrained Hamiltonian formalism.

The positive argument for the Lagrangian point of view is that it comes into its own in the relativistic setting, making Lorentz invariance easy to handle by the Noether's theorem method. This is quite true, with the standard version of the Hamiltonian formalism distinguishing the time direction and breaking Lorentz invariance. There is however a less well-known "covariant phase space" point of view, where one tries to work with the space of solutions of the equations of motion as one's phase space. Only if one identifies a solution with its initial data at a fixed time does one distinguish the time direction. I've recently enjoyed reading Igor Khavkine's review article, which in particular does a great job of explaining the history of this line of thinking.

The Lagrangian also comes with the extremely seductive point of view on quantization of the path integral. This point of view works very well for dealing with Yang-Mills theory, and I spent much of my early career convinced that all there was to quantization was figuring out how to make sense of integrating over the exponential of the action. I'm now much more aware of the advantages of the Hamiltonian point of view, especially in terms of understanding quantum theory as representation theory. In some sense what one really wants is to understand quantization in a way that takes advantage of both points of view, but the relationship between them is quite non-trivial.

The discussion here has been far too wordy for most people to make sense of. If you want to understand any of this, you need equations. Luckily, I've provided lots of them and many details here, see chapters ~~12 and 13~~ for the moment map, ~~chapter 19-22~~ for the harmonic oscillator.

Comments

1. **Antonio (AKA "Un físico")**
   August 30, 2014

   Hi Peter, I have just discovered your blog.
   Question: assuming that quantum information is conserved, what (Noether's) symmetry would be related to that conservation?
   Can the moment map point of view help in answering this?

2. **Ioannes P.**
   August 30, 2014

   > "My hope is that this level of presentation will […] be useful to mathematics students trying to learn something about both quantum mechanics and representation theory."

   It is indeed! —at least to this Feynman-naïf, lowly mathematics student. Yours plus the quantum information approach are the only ones so far that have made any remotely *intuitive* sense to me, without leaving nearly as much of the usual (and inevitable) "shut up and calculate" aftertaste.

3. **Peter Woit**
   August 31, 2014

Antonio,
I don't know exactly what "quantum information" is, or the conditions under which it is conserved. From the little I know, I don't see how either the moment map or Noether's theorem have anything to do with it since these come into play when you are "quantizing" a classical system, and "quantum information" doesn't seem to involve that.

To the extent "quantum information" is counting something using integers, typically there's a U(1) group action around somewhere, explaining why you are seeing integers.

4. **João Esteves**
August 31, 2014

Hi,

Quite interesting your post. One may speculate and say that also Quantum Field Theory should be related to the representation of some group, in the same way that Quantum Mechanics is related with the representation of the Heisenberg group and that also some moment maps should give some conserved quantities. But now this representation space would most probably be the space of distributions or generalized functions and not the nice Hilbert space of L^2 functions (in fact it is its closure). And what kind of group would act on such a space? And would it be easer to define a measure on it that it is on a separable Hilbert space?

5. **João Esteves**
August 31, 2014

…just to say that I just got into this:

http://arxiv.org/pdf/hep-th/0206135v1.pdf

Very nice. It will be very helpful, as it has many intersections to what I'm interested in and working on at the moment.

6. **Peter Woit**
August 31, 2014

At least for free fields (and, more generally, linear fields in an unquantized background background) qft is based on the Heisenberg group. The difference in QFT is that the dimension of the group is infinite.

The issue of distributions vs. L^2 or some other function space arises long before you get to QFT. Even for a free particle in 1d in QM, momentum eigenstates are not in L^2, and position eigenstates are not functions at all, but distributions. One way I'd like to improve the current version of the manuscript is by doing a better job of dealing with this issue. The problem is that standard ways of doing this (e.g. rigged Hilbert spaces) introduce a lot of complexity even in the very simple basic examples I'm trying to explain.

The new problem in QFT is that the field operators depend on functions (whereas in the QM analog, the position and momentum operators only depend on a finite set of indices).

7. **João Esteves**
August 31, 2014

Yes, but in QM I suppose the use of distributions can be avoided. I even think this was the main motivation of von Neumann in writing his treatise "Mathematical Foundations of Quantum Mechanics" as an alternative, more to the ground of what was known at the time, to Dirac's description using delta functions. But in QFT as it is a theory of scattering observables have a continuous spectrum, in contrast to QM which is mostly a theory of bounded states, and in that case the commutation relations between conjugate fields are distributional. My intuition is that this must taken into account if one hopes to have a rigorous treatment of QFT.

8. **Peter Woit**
August 31, 2014

Joao,
In QM you can also just look at scattering, that's not really where QFT is different.

The problem in QFT is that your analog of an operator Q_j in QM is a field operator \phi(f), where instead of an index j, the operator depends on a function f. In QM you can multiply and manipulate operators without a huge amount of trouble (although there are problems due to operators being unbounded). In QFT you can do the same, but the problem arises because you want local interactions, so need for example to define not just an operator \phi(x) (the field operator for f a delta-function), but higher-order products of this. That's where the serious problems come from.

To bring this back to the topic of the posting (or series of postings), my point of view on this is that defining arbitrary local products of field operators is inherently difficult and ridden with ambiguities, with renormalization theory our best wisdom about how to deal with this. If one looks not at arbitrary products, but at ones that correspond to a representation of a Lie algebra, then one gets a much more rigid setup and can perhaps hope to uniquely define such products, or at least better understand exactly what the inescapable ambiguities are.

Unfortunately, this philosophy only now really works for quadratic products, which I try and work out in detail in the notes (the finite-dim versions are complete, still working on the qft part of the notes). Examples like the \phi^4 interacting QFT have no known interpretation of the interaction terms in terms of a representation theory problem. On a more positive note, the SM Hamiltonian (or Lagrangian) only involves quadratic powers of the fermion fields, so, before quantization of gauge fields and the Higgs, the problem doesn't come up. For pure gauge theory, you do get cubic and quartic terms in the non-abelian case, but there one can perhaps exploit gauge symmetry in some way. For the fully quantized theory of fermi fields coupled to the Higgs and gauge fields, you need some new idea…

9. **Antonio (AKA "Un físico")**
August 31, 2014

Thanks Peter, I have to think about the question I asked you.
I keep your email and in case those moment maps show something interesting, I might contact you again.

10. **Bill**
August 31, 2014

What you said reminded me of the issue of defining a product of distributions that Martin Hairer had to deal with in his theory which he applied to Φ^4_3 Euclidean quantum field theory. It also involves some form of renormalization.

11. **Peter Woit**

August 31, 2014

Bill,
Yes, I think this is essentially the same problem Hairer is dealing with. I see that in his paper he writes
"the mathematical analysis of QFT was one of the main inspirations in the development of the techniques and notations presented in Sections 8 and 10."

12. **João Esteves**
August 31, 2014

As far as I know the major successes of Quantum Mechanics in describing the real world are the exact solutions of the Hydrogen atom and the Harmonic Oscillator, which are bound states and as so have a phase space that is compact. And when you consider differential operators on a compact manifold you get a discrete spectrum and a countable base of eigenfunctions and so a separable Hilbert space is natural. Of course, formally you can consider the eigenvalue equation for the momentum operator on R and this gives plane waves for eigenfuntions and continuous eigenvalues, but does this describe anything in Quantum Mechanics beside a free particle?
Maybe you have a different perspective, but in my view this is one of the major differences between QFT and QM, the fact that in QFT generalized functions are unavoidable.

13. **Peter Woit**
August 31, 2014

Joao,
A large part of QM is scattering theory, and to do this you have to handle the continuous spectrum (and distributions are a good way to do it).
Again, if you look at the hard problems of QFT, they're due to the nature of interactions as local products of quantum fields. Yes, part of this story is that of problems with defining products of distributions, but it's best to understand what the fundamental nature of the problem is.

14. **Igor Khavkine**
August 31, 2014

Hi, Peter. I'm glad you enjoyed the little historical overview in my article of the ideas leading to a covariant view of phase space. As with many deep ideas, its history is a much tangled web, which I find fascinating. Thanks for the mention, btw!

15. **João Esteves**
August 31, 2014

OK, Peter, it has been an interesting discussion. Thank you for replying.
Regards.

16. **Hendrik**
September 1, 2014

Dear Peter, regarding the best mathematical framework for QFT, I favour the C*-algebra point of view, which includes the group perspective you take,
i.e. is more general, and has a well controlled representation theory.
(1) Regarding free bosons;- here one takes the Weyl C*-algebra which is a twisted discrete group algebra of the underlying symplectic space. It gives you those representations of the associated Heisenberg group where the central element maps to the identity, which is what physics wants. The "momentum eigenstates" you mention, correspond to certain states which are nonregular (i.e. they are discontinuous on the underlying Heisenberg group), but which are quite well-defined (see Verbeure on plane waves). So rigged Hilbert spaces are unnecessary. Other C*-algebras are also possible, e.g. the C*-algebra generated by the resolvents of the smeared fields.
(2) For free fermions, you need to take the CAR-algebra, which does not fit well into your group perspective, but it is a very well-behaved C*-algebra. If you have physical symmetry groups acting on the fermions, you will take appropriate crossed products, to get covariant representations.
(3) Renormalization (at least in lattice C*-models) can be understood as a procedure which moves you out of one representation into another, which is why the perturbation series cannot converge. But at the C*-level it makes sense.
(4) I agree that pointwise products of the fields (Wick products) are hard to understand – though have been rigorously constructed in the free field case. These currently do not fit well into the C*-algebra picture.
Regards

17. **Peter Woit**
September 1, 2014

Hendrik,
Thanks. The C* algebra point of view is deeply related to representation theory. For fermions I try to make clear in the notes that there is a perfect parallelism between the symplectic/Heisenberg story for bosons and the orthogonal/Clifford story for fermions. To the extent C* algebras don't equally well handle either case, that's a problem

18. **Peter Woit**
September 1, 2014

Thanks Igor, your paper was quite enlightening. The question of the relation of the Hamiltonian and Lagrangian viewpoints seems to me surprisingly still not completely satisfactorily understood.

19. **Johan**
September 2, 2014

Hi Peter,

In symplectic geometry, people often require moment maps to be equivariant (wrt the co-adjoint action), which is needed for things like Kirwan convexity to hold. Non-equivariant moment maps are nevertheless also useful in some contexts. Could you comment on the role equivariance plays for your purposes?

20. **Peter Woit**
September 2, 2014

Hi Johan,

I'm generally assuming that if possible the moment map (which is only defined up to a constant) is chosen to be equivariant, so you have a Lie algebra homomorphism from the Lie algebra to functions on phase space, which becomes a Lie algebra representation when you quantize.

When the Lie algebra has non-trivial central extensions (H^2 non-zero), then you will have non-equivariant moment maps that can't be made equivariant. This is what physicists call the "anomaly". It's usually thought of as a purely quantum effect, but you do actually see it this way even at the classical level.

The finite-dimensional groups I'm writing about in the notes all have vanishing H^2, so one can take the moment map to be equivariant. There are some comments there about the situation in infinite-dimensions, but that's mostly beyond the scope of what I'm trying to write about there.

Not sure if this addresses what you're thinking about. Quite likely you know about some interesting examples of use of non-equivariant moment maps that I'm just unaware of.

21. **Urs Schreiber**
    September 3, 2014

    The kind of anomaly given by obstructions against lifts from actions by Hamiltonian vector field to the Poisson bracket Lie algebra is typically called a classical anomaly (e.g. Arnold's book, appendix 5.A).

22. **Thomas Larsson**
    September 3, 2014

    Every finite-dimensional Lie algebra that can be embedded into gl(N) for some N can be realized as a function on phase space. Obviously, since E^i_j = q^i p_j generate gl(N) under the Poisson bracket. Classically the same is true in infinite dimensions, but quantization leads to infinitites and is problematic.

    What is perhaps not so well-known, but obvious once you think about it, is that most infinite-dimensional Lie algebras of interest in physics can also be realized as functions on a *finite*-dimensional phase space. Namely, the functions f^i(q) p_i generate the algebra vect(N) of vector fields, so every algebra that can be embedded into that can be realized as functions over phase space. Since the phase space is finite-dimensional, quantization is not a problem.

    This is a kind of first-quantized approach and not directly relevant to physics, but a slight variation of this theme actually yields interesting representations of infinite-dimensional Lie algebras.

23. **Igor Khavkine**
    September 3, 2014

    Famously, the momentum map for the action of the Galilean group *G* on the phase space of a non-relativistic particle (or N such particles) cannot be chosen to be equivariant, as long as the action of *G* on its dual Lie algebra *g** is the usual coadjoint action. On the other hand, a group cocycle of *G* with coefficients in the coadjoint representation can be used to modify the action of *G* on *g** and make it equivariant (as discussed, for instance in these slides by Charles-Michel Marle). The same cocycle (or rather its infinitesimal version) shows up in the fact that the the boost and translation generators cannot be chosen such that their Poisson bracket is zero (even though their Hamiltonian vector fields commute). Instead, their Poisson bracket is a constant proportional to the total mass of the N-particle system. This is indeed a famous example of a classical anomaly.

24. **Derek Teaney**
    September 6, 2014

    Peter,

    This is a quick not very well thought out reply.
    The symmetries of that you are talking about are manifest if one uses the
    Schwinger-Keldysh formulation where the fields are doubled. This is
    useful for discussing real time physics at finite temperature.

    For instance the action of the harmonic oscillator is

    S \sim \int dt (\dot x_1)^2 – x_1^2 – ((dot x_2)^2 – x_2^2)

    You might want want to think about it in these terms. The Keldysh
    setup is most useful close to the classical limit. See for example,

    hep-ph/0212198

SUSY Bets

September 3, 2014
Categories: Uncategorized

The LHC long shutdown (LS1) seems to be progressing on schedule, with physics collisions at 13 TeV planned for early April 2015. I'd guess the earliest 13 TeV results might appear at the summer 2015 conferences. The long term plan is to accumulate up to about 50 fb^{-1} of data per year for about 3 years of data-taking, ending in mid-2018. There will then be a year and a half shutdown (LS2), followed by data-taking at 14 TeV from 2020-2022. The plan is to end up with about 300 fb^{-1} before a long shutdown (LS3) starting in 2023.

Hopefully there will be much learned about the Higgs, and some unexpected discoveries. One of the main targets will continue to be SUSY searches, despite the negative results found so far at 8 TeV (and 25 fb^{-1}). Something to watch will be how long it takes theorists heavily-invested in TeV-scale SUSY to give up and concede that this idea doesn't work. For this, one thing to keep in mind is what precise bets theorists have made in the past.

There's a new one this week. After Gordon Kane complained that he couldn't find anyone willing to bet against SUSY, Marcelo Gleiser decided to take him up on it, with stakes a bottle of 15 year old Macallan (which goes for about $100). Marcelo seems to think he has a bet that will get him his Macallan if no SUSY is found in the run ending in 2018, but I fear he has been had. Kane specifies:

> To have a meaningful bet the LHC has to work at an appropriate energy and luminosity. It is expected to take integrated luminosity of order 300 fb^{-1} at a total energy near 13 TeV in the next run, in less than two years after turning on in early 2015. Assuming those results, signals for gluinos and/or light neutralinos and/or charginos are expected, and that's the appropriate bet.

The only problem with this is that the current LHC schedule foresees maybe 100 fb^{-1} two years after first physics in 2015, not 300 fb^{-1}. For 300 fb^{-1} the schedule says the wait is likely to be until 2023, so Marcelo is going to have a very long wait for his fine Scotch.

Here's the status of the other SUSY bets I know about, and I'd be curious to hear about any other known ones:

- Back in 2000 some theorists at a conference in Copenhagen bet (stakes $50 cognac) about SUSY being found at the LHC by mid-2010. The losers ~~welshed~~ reneged on that bet, to be fair partly because the LHC was delayed, and didn't really get going until 2010, at half design energy. A new version of the bet was made in 2011, with stakes raised to $100 cognac and a cutoff date in June 2016.
- David Gross here announced back in 2012 that he had taken bets on SUSY, paying off once 50 fb^{-1} of data have been analyzed. This would likely at the earliest be in mid-2016, same time frame as the Copenhagen bet.
- Garrett Lisi announced on Twitter back in 2009 that:

  > Frank Wilczek just bet me $1000 that superparticles will be detected by July 8, 2015. Max Tegmark will arbitrate.

  At this point it seems that Wilczek is likely out $1000, since this date will only be 3 months into the run with results available for only a small amount of data if any.

- Wilczek also has a 2013 bet with Tord Ekelof that gauginos will be found by end 2019. This one is just for some chocolate coins.
- Jacques Distler made a $750 bet with Tommaso Dorigo based on the first 10 fb^{-1} of LHC data. This was more general, Jacques would win if either SUSY was found, or something else unexpected. Jacques paid up last year, see here.
- Many theorists were highly skeptical of SUSY long before the LHC turned on. Back in 2008 Adam Falkowski assigned a probability of .1% to a SUSY discovery at the LHC, and gave Lubos Motl 100 to 1 odds for a bet about SUSY after 30 fb^{-1} of LHC data. Lubos still has his $100 since the LHC didn't quite get to 30 fb^{-1}, but he should be out the money probably sometime mid-next year.

If there are any others of these out there, let me know…

Comments

1. **Jan de Goor**
   September 4, 2014

   Peter,

   it is worth mentioning that Gordon Kane has his susy predictions in a preprint (http://arxiv.org/pdf/1408.1961.pdf). Kane has not yet answered on the following bet proposal by a good friend of mine:

   GK statement: Some superpartner will be found at the LHC.

   My friend's statement: No deviation from the standard model of particle physics or from general relativity will be found; no new elementary particle (including additional quarks, additional gauge bosons, additional Higgs particles, axions, WIMPs or superpartners) will be found; no new interaction (such as technicolor), no new fundamental parameters and no new symmetry (such as GUTs or supersymmetry) of nature will be discovered; no additional dimensions of space will be detected; no evidence against dark matter as a mixture of ordinary matter and black holes will appear; no experiment will measure values exceeding the Planck force, the Planck momentum, the Planck power or any other Planck limit; no evidence against a decrease of the cosmological constant with time will be found.

   Timing for decision: End of 2017 – or some other date of Kane's liking.

   Prize:
   If GK wins (meaning that superpartners are found at the LHC OR that any of the above statements are found to be wrong) my friend will wear a T-shirt of GK's design, with a photo exchanged as proof.
   If my friend wins (meaning that superpartners are not found at the LHC AND that all of the above statements remain valid), GK will wear a T-shirt of my friend's design, with a photo exchanged as proof.

   Such a bet between "susy or anything else new" and "nothing new" seems heavily weighed in Kane's favour. Being in the first camp, but fearing that the second is right, I am as curious as anybody else about how things will turn out. All the best to you and your blog! Jan

2. **M**
   September 4, 2014

Even if SUSY-like new physics will be seen, more likely LHC will not give enough data to establish if it is SUSY or something else.

3. **piscator**
   September 4, 2014

   Jan:

   Your friend has already lost his bet. From the CMB we already know that there is more dark matter than baryons, so the old idea that 'dark matter is just small black holes formed from baryons' is already dead. And the Planck momentum isn't very big, any macroscopic experiment can exceed it.

5. **Krzysztof**
   September 4, 2014

   Slightly off-topic:

   "If you have seen the movie Particle Fever about the discovery of the Higgs boson, you have heard the theorists saying that the only choices today are between Super-symmetry and the Landscape. Don't believe them (…) The Landscape surrenders to perpetual ignorance (…) Perhaps only the theory phenomenologists should be allowed to publish in general readership journals or to comment in movies."

   B. Richer, http://arxiv.org/pdf/1409.1196v1.pdf

6. **Peter Woit**
   September 4, 2014

   Clyde,
   Fixed.

   M,
   Good point. Any deviation from the SM at the LHC is likely to be greeted as evidence for SUSY.

   Krzysztof,
   Saw that last night, well worth reading, will likely discuss in a separate posting.

7. **Too Distinguished**
   September 4, 2014

   Adam Falkowski is hilarious.

8. **Anony**
   September 4, 2014

   Adam Falkowski's bet is very commendable — he really risked $10K for a mere $100, and that too while betting against SUSY, which is like the holy grail. He did this based on the 1% fine-tuning needed in SUSY as his blog says. I think the rest of the bets, some made by much more famous physicists, pale in comparison. The Jester-Lubos bet is surely THE SUSY bet to beat all bets.

9. **E**
   September 4, 2014

   Why are the bets so small? Why not some serious money like a month's salary or a year's salary?

10. **markusM**
    September 4, 2014

    E,
    right, my point.
    I guess most people are just lacking true physical instinct. (Except for Garrett Lisi of course -:)).
    As far as I can tell betting against supersymmetry is one of the most easy ways to earn money.
    Where are the bets in favour of large extra dimensions and microscopic black holes by the way ?

11. **Clyde Davies**
    September 4, 2014

    Peter: thank you.

12. **Clyde Davies**
    September 4, 2014

    Sorry, that should have been 'diolch yn fawr'. 😉

13. **Garrett**
    September 5, 2014

    I admire Frank Wilczek a great deal, and it was big of him to take the SUSY bet I proposed during a conference. Frank chose the amount and the decision date. It does now appear he chose a decision date that will come before we can get new discoveries from the second run of the LHC. To me, this seems not completely fair, but he did choose the date, and the Pacific Science Institute could use a nice $1k whiteboard. Once the first bet is settled and paid I would be happy to place another similar bet with a date further out.

14. **Anon**
    September 7, 2014

Reading through the comments, it looks like it may still be awhile before Motl is forced to pay up:

"On the other hand, you're the winner after 30 inverse femtobarns (at 14 TeV, or more than 12 TeV) if no "discovery paper" of this kind is in the waiting line."

Unless I'm mistaken, the LHC has been running well beneath 12 TeV, so no data relevant to the bet has been collected yet.

15. **tulpoeid**
September 19, 2014

I'm surprised to read that Kane thinks he can't find anyone to bet against. Actually, I was thinking recently that it's high time to search for a serious relevant bet, as one doesn't hear about these things as often anymore 😉
I wonder if he (or anyone else, for that matter) has set something up on his blog already and if he's willing to bet against non-famous physicists…

16. **John Baez**
October 1, 2014

For some reason the physicist David Ring bet me case of scotch against a check for a penny that there would be 'strong evidence' for supersymmetry by 2010. Like a true gentleman, he offered to pay up on January 2nd, 2011:

> Hello John,
>
> I believe I owe you a case of scotch. I knew they'd go over schedule at the LHC, but not by this much! (we could always double the stakes and give them another 10 years. 🙂
>
> If you are indeed in Singapore, then that makes things a bit difficult. The selection available for delivery is limited, and the prices are exorbitant!
>
> I can send a case of something nice to Riverside, but at Singapore prices I can only afford something cheap. Rather than send something you would not enjoy, I could send a single bottle of something nicer, like Johnnie Walker Blue Label or Chivas Regal Salute. If you prefer single malts I can afford 3 bottles of Macallan 12 year.
>
> Please let me know your preferences, and send delivery instructions.
>
> Cheers,
> Dave Ring

He wound up getting me a case of Laphroaig, and I still have one bottle left.

17. **Peter Woit**
October 1, 2014

Hi John,
Thanks for letting us know that story. It's interesting that there seems to be some correlation between high enthusiasm for SUSY and unreasonable expectations about the operations of accelerators. Kane's expectation that the LHC will produce 300 inverse femtobarns in the next run seems to be an extreme example.

Categories: Langlands

Well worth reading is High Energy Colliding Beams; What Is Their Future, by Burton Richter. Richter is one of the pioneers of designing and building colliders, and he starts off by recounting some of the history. About proposals for a 100 TeV collider he comments on the challenges of doing this at high luminosity and the danger that the cost will be prohibitive (one thing I haven't seen in these discussions is cost estimates), and asks why there is no large-scale program to develop low-cost high-Tc superconducting magnets.

He's critical of the film Particle Fever on the same grounds discussed here (its portrayal of the only possibilities as being SUSY or the multiverse). About the multiverse, he writes:

> There are two problems with the landscape idea. The first is a logic one. You cannot prove a negative, so you cannot say that there is no more to learn. The second is practical. If it is all random there is no point in funding theorists, experimenters, or accelerator builders. We don't have to wait until we are priced out of the market, there is no reason to go on.

For some mathematics news, first there's the announcement from the Flyspeck project of the completion of a formal proof version of the proof of the Kepler Conjecture by Thomas Hales. Hales is in Berkeley this week talking about something unrelated (the Langlands program) at an introductory workshop for this semester's MSRI program on geometric representation theory. I've been watching some of the videos of the workshop talks, all of which have been quite good.

Also in Berkeley this semester is Peter Scholze's course, with video of the first lecture here, notes here.

In yet more Berkeley news, in December they'll host a mathematical physics workshop on Mathematical Aspects of Six-Dimensional QFTs. Better understanding the 6d N=(2,0) superconformal theory and its implications for various lower-dimensional phenomena is the main target here, a topic that will also be discussed here in the spring (where the 6d theory is called "Theory X").

Comments

1. **HL-LHC or HE-LHC**
   September 5, 2014

   High Energy Colliding Beams; What Is Their Future, by Burton Richter – what is a better investment, HL-LHC or HE-LHC? upgrading injectors or upgrading the magnets?

2. **Peter Orland**
   September 5, 2014

   I'm sure Richter understands this much better than I do – but I don't see how high-T_c magnets would help. Isn't a huge cryogenic facility needed to pump the tunnel down to a good vacuum? I thought cooling the magnets was relatively insignificant. An accelerator physicist would certainly know the answer.

   I also thought that there were some fundamental problems with making powerful high-T_c magnets anyway (friction of vortices moving through in the material? ceramic machining?). Anybody out there know?

3. **Peter Woit**
   September 5, 2014

   HL-LHC or HE-LHC,

   It seems highly likely CERN will go ahead with HL-LHC. My impression is that the cost of that is much less than an HE-LHC project. The latter would require 27km worth of new superconducting high-field magnets, I'd assume this is very expensive. Not as expensive though as digging a 100km tunnel and equipping that with magnets, which is why Richter is worried that a 100 TeV machine may carry an impossibly high cost.

4. **Casey Leedom**
   September 6, 2014

   Thanks for the reference to Burton Richter's paper. It was wonderfully readable and enjoyable for its long-term take on the history and future of beam colliders. I wish more papers like this were written by the "old men & women of science."

5. **Martin**
   September 6, 2014

   @Peter Orland: if superconducting magnets can be run at the desired amperage without having to use liquid Helium, then this would obviously save a lot of money. High-Tc materials that superconduct at liquid nitrogen temperature (77 K) are known, but building strong and large magnets with them is still a challenge, due to a too low critical current.

6. **Peter Orland**
   September 6, 2014

   Martin,

   Hi Martin,

   Yes, liquid nitrogen costs the same as milk, so it would save money. But isn't that a small fraction of the cost of the liquid helium already needed to produce the vacuum? My impression was that most of the cryogenics is needed after preliminary pumping, to properly evacuate the tunnel. If that's true, perhaps more money would be saved inventing a better high-vacuum method (if such a thing is conceivable. I got nuthin').

   I recall something similar about the low critical current of high-T_c superconductors (due to dissipation of moving vortices? I am not sure), but I thought another problem was machining. The materials are ceramics, so making coils would also be a problem.

7. **anonimous**

September 6, 2014

From LHC insiders and people involved in data analysis, I heard that a lot of persons are not happy about the HL program, given the negative results of run 1 in terms of new particles. If the could, they would push for HE, but they cannot stop the train anymore. Accelerator physicists worked a lot on HL and now it is impossible or impractical to change to HE. In their dreams, a lot of analysts wish to have HE.

Moreover, HL means challenging backgrounds at the limit of the detectors, triggers and analysis techniques which risk to damage new particle searches. PP collisions are already dirty enough…

A discovery in Run 1 would have been much better for this program and as we stand now, HL might turn in a nightmere. Anyway, I do not know the future and maybe they turn on LHC@8TeV and new states pop out easily…
Let's wait and see, but HE would have been much better.

8. **rss**
September 6, 2014

In the interests of procrastination, I looked into Peter Orland's question. I think the short answer is, the beam line indeed has to be maintained partly at cryogenic temperatures, to achieve the ultra-low vacuum required. But the volume of the beam lines is "only" 150 cubic meters, whereas the volume of the insulating vacuum for the cryomagnets is 9000 cubic meters. So if high Tc superconductors could be made practical for this purpose, the cost savings could be significant.

http://www.lhc-closer.es/1/4/15/0

9. **Peter Orland**
September 6, 2014

rss,

Thanks for looking into it. It sounds like a sensible answer…

10. **Anonyrat**
September 7, 2014

Ha, seems like the next great accelerator will be built on Pluto! (33-55K surface temperature).

11. **HL-LHC or HE-LHC**
September 7, 2014

since there's no sign of SUSY or DM @ 8TEV, I would think HE-LHC would be the better ROI over HL-LHC with limited funds

12. **Peter Woit**
September 7, 2014

HL-LHC or HE-LHC,
I think the point is that with limited funds one can't afford HE-LHC, at least not anytime soon (but I haven't seen any cost estimate for HE-LHC, this is a guess).

13. **J.F. Moore**
September 8, 2014

Peter Orland,

There are many technologies to achieve the ultrahigh vacuum required to reduce scattering to a negligible level for LHC or future colliders. LHC for example uses ion pumps and non-evaporable getters in the 'warm' non-cryo sections. CLIC is one proposal for a linear collider that uses normal conducting RF, so no need for cryo facilities at all. Modern turbomolecular pumps are more than capable of reaching the required vacuum, its just a question of scale and expense and system maintainability.

14. **srp**
September 8, 2014

Nice to have Burton Richter supporting my-oft made and nearly always ignored point that the only rational course of action on the energy frontier is to put major effort into advanced accelerator concepts such as wakefields. Peter even managed to skip that primary takeaway in his summary, but here is Richter's bottom line:

"I am both more optimistic and more pessimistic about e+e- colliders. More optimistic because accelerating gradients of more than 50 GeV per meter (50 TeV per kilometer sounds even more exciting) have already been demonstrated in plasma- wakefield acceleration and of several GeV per meter in laser acceleration, though both have now poor 6-dimensional phase space; more pessimistic because I don't see a push to develop these technologies for use in real machines. The e+e- colliders have two advantages over the proton colliders. The cross sections of interest are all of comparable orders of magnitude. The background of 10 billion or more uninteresting events for each interesting one, the problem of proton colliders, does not really exist for the electron colliders. There is a low transverse momentum fizz that is confined to small angle, but the interesting events are much easier to get at. In addition the equivalent mass reach in the electron colliders only requires 10% to 20% of the energy of the proton collider with the same mass reach. The 100-TeV p-p collider is matched by a 10- to 20-TeV electron collider. My challenge to the electron accelerator community is to produce a cost effective system with an acceleration gradient of at least 1-GeV per meter with reasonable transverse phase space and an energy spread of no more than 10% to 20%. Because of the parton distribution in the proton, the effective energy spread in p-p collisions is more like 100%. You have about 15 years to do it since that is the time to when HL- LHC will start to operate."

15. **plm**
September 13, 2014

About the multiverse/anthropic principle/landscape:

The electroweak standard model has parameters just like vacua in the string landscape are. Yet it makes lots of predictions/postdictions.

Picking a vacuum assuming the anthropic principle (or not) still leaves alot of predictions from string theory, independent of vacuum-picking -which have so far proved wrong, for the nonpostdiction part.

Assuming the anthropic principle is really more of philosophical attitude, empty of consequences. It has probably very little effect on how research is conducted. People (will continue to) try to understand better string theory or whichever theory they like, hoping to constrain more their predictions. Any sensible researcher liking the anthropic principle will not give up his research because of this as far as I can tell -I may be wrong, if you have examples please share.

16. **Ray**
September 13, 2014

Hi Peter, off-topic question but I think one in which you take an enormous interest – do you have any idea when the Planck polarization results are going to be published? I had heard a rumour that they were going to be published around September 1.

17. **Peter Woit**
September 14, 2014

Ray,
I don't know about "enormous", if so I might have better sources of info about this… From what I've seen, what's publicly known is that this conference

http://www.cieffeerre.it/Eventi/eventi-in-programmazione-nel-2014/planck-2014-the-microwave-sky-in-temperature-and-polarization/PLANCK-2014

to discuss the results has been scheduled for a long time for December 1-5. In many places I've seen "late October" mentioned for the release of the data that would be discussed at that conference.

Frank Wilczek on twitter and Peter Coles on his blog had very definite rumors about an early release of data specific to the question of the BICEP2 patch of sky. It's now long past the dates claimed in those rumors, and getting to the point that it would not seem to make sense to have two closely spaced releases, so at the moment, my uninformed guess is that "late October" is when we'll hear something.

18. **Shantanu**
September 17, 2014

Peter, something OT.
are you planning to attend David Gross's colloquium at NYU this week?
http://physics.nyu.edu/events.php?EventsPage=
If you do, let me know how it was.
Thanks

19. **Bob**
September 17, 2014

Nice to see about the formal proof. I've always wondered why this hasn't been done more, after all who knows how much of mathematics has errors that have gone undetected, it would hardly be the first time …

20. **Peter Woit**
September 17, 2014

Shantanu,
I hadn't noticed that was happening. Unfortunately I'll be teaching at that time, can't attend. Maybe someone else will report.

21. **Franck Nadaud**
September 19, 2014

Dear Professor Woit, greetings from Paris, France !

Here is a paper about high energy particle accelerators and log-periodicity:

http://cybergeo.revues.org/14173

What is interesting are the figures about costs, but the paper is in french althrough an english version may have been published in a geography review.

The paper was presented at a seminar in France about "scale relativity theory" of the french astrophysician Laurent Notale.

However, the figures relate energy levels of past accelerators and costs in current dollars I guess.

All the best regards.

Franck

Various and Sundry

- The MacArthur Foundation today announced "Genius" grants of $625,000 to 21 people, including two mathematicians, Jacob Lurie and Yitang Zhang. While there was a time these awards often went to mathematicians and theoretical physicists (the 1987 winners included string theorists Dan Friedan, David Gross, John Schwarz and Steve Shenker as well as mathematicians Robert Coleman and David Mumford), that has been much less common in recent years.
  Zhang, now a professor at the University of New Hampshire, is a perfect candidate for the award, unrecognized by academia (he worked at a Subway for a while) while he was doing brilliant and important work in number theory. Lurie is undeniably a genius, but kind of the opposite of Zhang, someone whose talents and work have been very well-recognized and rewarded already. He's a Harvard professor and in November will be collecting a $3 million Milner-Zuckerberg Breakthrough Prize.
  The Wall Street Journal leads off their story about this with Lurie, characterizing him as "A mathematician offering his book free on the internet", implying that's what distinguished him for the award from the other possible genius candidates:

  > This year's winners span in age from 32 to 71 and include nine women and 12 men. A common thread: The winners reach their audiences in surprising places.
  >
  > "This year, we have several people who one might describe as being engaged to challenge the rest of us to be lifelong learners outside the traditional classroom," said Cecilia Conrad, who directs the fellows program as a vice president of the foundation. "It's new solutions to old problems."
  > …
  > Mathematician Jacob Lurie, who was honored for redefining models in algebraic geometry, negotiated with his publisher to make his book on math principles available for free download on his personal website. While academics sometimes place papers online free, putting a whole book online isn't yet standard practice, according to the 36-year-old Harvard University professor. "From my point of view, the benefit of writing a book is for people to look at it. I would like as many people as possible to look at it," he said.

  The book in question is the 2009 944 page Higher Topos Theory, available on Lurie's web-site here. He has just put up on his website an updated version of his second book, the 1178 page Higher Algebra. For those mathematicians worried that they might have trouble reading these because of a lack of physics background, Lurie himself reassures people here that

  > Since no knowledge of modern physics was required to write any of these books and papers, I can't imagine that you need any such knowledge to read them.

  In other Lurie news, he has also just put up on his web-site an important new paper, a first draft of joint work with Gaitsgory on the proof of Weil's Tamagawa number conjecture for function fields.

- Skepticism about string theory and the multiverse abounds these days. A wonderful New York Times profile of Peter Higgs ends with

  > This has led some theorists to propose that our universe is only one in an ensemble of universes, the multiverse, in which the value of things like the Higgs is random.
  >
  > Asked about that, Dr. Higgs lit up with a big grin. "I'm not a believer," he said.
  >
  > "It's hard enough to have a theory for one universe."

  In Scientific American, George Ellis has a piece entitled Why the Multiverse May Be the Most Dangerous Idea in Physics.

  Meanwhile, from a Templeton Foundation-financed conference on the Philosophy of Cosmology in the Canary Islands, Sean Carroll reports via Twitter that string theorist Tom Banks is arguing that "string theory has failed as a theory of our world."

- Commenter Shantanu pointed out something I hadn't realized, that David Gross will be here in New York this week, giving talks at NYU. Unfortunately I won't be able to attend, in particular I have to teach at the time of his colloquium on Tuesday. Perhaps someone who can attend will report what he has to say.
- In Grothendieck news, the English translation by Melissa Schneps of Winfried Scharlau's book on the later period of Grothendieck's life has started to appear, see some chapters here.

  A wonderful book of articles about Grothendieck's mathematics, Alexandre Grothendieck: A Mathematical Portrait, edited by Leila Schneps, has recently been published (with a version of the articles also available here).

Update: Vigorous back-tweeting (see here, here, here, here and here) now going on from Sean Carroll and Tom Banks. Admitting that string theory unification has failed is just not done. Revised and extended remarks from Tom Banks add praise for the greatness of string theory and avoid the word "failure":

> Without string theory we would never have been in a position to understand anything serious about quantum gravity, but without going beyond the present understanding of string theory we can make no further progress.

This still though reads as "string theory is at a dead end". Sean echoes the praise:

> conventional string theory has given us enormous guidance toward quantum gravity.

and dismisses the failure issue as something obvious and not worth mentioning:

> Need to go beyond is obvious.

I guess I should point out that it is not obvious that you need to go "beyond" string theory, in the sense of farther in the same direction. Might be that you need to abandon the direction that led you to a dead end, back-track, and try a different one.

Strange thing is that this discussion of a string theory dead end just seems to be about problems using string theory to do quantum gravity when there's a positive cosmological constant (otherwise, according to Carroll, "String theory is great"). The idea of string unification seems to be so dead it's not even worth mentioning.

Update: Shaun Hotchkiss has the latest news on Planck/BICEP2 and dust here. People are still scraping data off old Planck slides, with real Planck data on the BICEP2 patch rumored to be imminent for the past month or so:

> Any day now we are to expect Planck's paper revealing the non-conference-talk maps of the high frequency polarisation signal along BICEP2's line of sight. These will just be images though, not raw data. The word on the street/corridor is that a fully written draft exists and has clearance to be submitted and nobody I've spoken to knows why it hasn't been. The sort of phrases I've heard about what to expect from this is that "it will clarify a lot of things", but "it won't be conclusive".

Update: Two more. I've been avoiding writing about the AMS-02 announcement about the positron excess, waiting to hear something sensible about its significance. Resonaances is on the job, giving an interesting take on the data, and claiming this has nothing to do with dark matter.

There's a nice profile of Robbert Dijkgraaf here.

Comments

1. **george ellis**
   September 17, 2014

   Peter, you link to an article by me on multiverses that has appeared in SciAm with title "Why the Multiverse May Be the Most Dangerous Idea in Physics." This just shows the dangers of having subeditors assign titles to what you write, without consulting when they do so. I do not agree with that title, and disassociate myself from it. What is dangerous is weakening the criteria for what science is. Multiverses are only dangerous to science if they are used to motivate that move. String theory is of course another theory that has also been used to motivate that move. It is that move that is dangerous to science, not the theories that are defended in this way.

2. **Peter Woit**
   September 17, 2014

   George Ellis,
   Thanks for the clarification. My own version of this point would be that the problem with the multiverse is that it is being used to cheat, to evade having to acknowledge the failure of the idea of string theory unification.

3. **Jon Orloff**
   September 17, 2014

   I really dislike the term "genius awards," as the word genius is, I think, greatly overused. Aristotle was a genius. Newton was a genius. J.S. Bach was a genius. If you do something comparable to their work, you deserve to be called a genius.

4. **Michał Kotowski**
   September 17, 2014

   As for the Grothendieck news, I would like to stress that the fund-raising effort to collect money needed for the translation is still ongoing – see http://www.gofundme.com/7ldiwo (still almost $3000 to go…). Please contribute and spread the word!

5. **HL-LHC or HE-LHC**
   September 18, 2014

   "Sean Carroll reports via Twitter that string theorist Tom Banks is arguing that "string theory has failed as a theory of our world."

   can you clarify Tom Banks' view? is it that string theory is wrong, or is it not even wrong? what evidence or arguments persuade him? is he abandoning string theory for some other line of research? what is his preferred BSM and QG research?

6. **Casey Leedom**
   September 18, 2014

   George F. R. Ellis,

   Ignoring the editorial sub-title that was thrust upon your article, I'm confused about one sentence in it: "Astronomers are able to see out to a distance of about 42 billion light-years, our cosmic visual horizon." I thought we were only able to see backwards in time to about 13.7 billion years. Even if we double that for an edge-to-edge, 180° view we still only get 27.4 billion light years. Where's the "42" come from?

7. **S. Molnar**
   September 18, 2014

   Zhang recently gave a public lecture at IAS. I can't find the video on the IAS website, but here is a link on another website:
   http://video.ust.hk/Watch.aspx?Video=E05D054DB6D058F6

   Casey Leedom: I think we all know where the "42" comes from, but it's news to me that it has units of billions of light years.

8. **S. Molnar**
   September 18, 2014

   Correction: It must be a different IAS than the default, which confused me.

9. **Sesh Nadathur**
   September 18, 2014

   Casey: the distance we can see out to is not simply (age of the universe) x (speed of light). Perhaps this will help. (The precise numbers depend on the values of cosmological parameters, which have been updated since Planck though that page hasn't, hence the difference of 47 vs 42.)

10. **george ellis**
    September 18, 2014

    Casey Leedom: its basically because the expansion rate has not been constant over time. The universe was expanding faster at earlier times. You have to do an integral of 1/a(t) where a(t) is the scale factor to determine how far we can have seen. This gives a factor of about 3 extra over the present Hubble scale.

11. **george ellis**
    September 18, 2014

    The full details are here:
    http://www.scribd.com/doc/235971566/G-F-R-Ellis-T-Rothman-Lost-Horizons

12. **Peter Woit**
September 18, 2014

HL-LHC or HE-LHC,
Use of the "failure" word seems to have gotten Banks in trouble, see the update to the posting. Banks for a long time has had his own alternative to string theory "Holographic Space-Time", see for example
http://arxiv.org/abs/1109.2435

13. **HL-LHC or HE-LHC**
September 18, 2014

@Woit
yeah at the time of the comment i read the original post before the update.

It appears Tom Banks agrees with you on string theory unification.
I know this is outside your expertise, but is string theory a successful theory of QG, or has string theory provided us with a important insights into QG? Should string theory research continue on as a theory of QG – irrespective of its theory as GUT type unification?

14. **Geoff**
September 19, 2014

Is there some unspoken agreement that even the preface to a mathematical monograph has to begin with "Let…… " ?

15. **Peter Woit**
September 19, 2014

HL-LHC or HE-LHC,

My non-expert impression of string theory as QG research is that the last significant new idea was AdS/CFT 17 years ago, and that much of the work since then has been based on trying to figure out how to use gauge/gravity duality to think about QG. Both Banks and Carroll seem to be admitting that this doesn't work as hoped, at least for positive cosmological constant. The "firewall" business of recent years is based on the realization that it doesn't work to solve the black hole information paradox as hoped.

What's interesting about the Carroll tweets I think is that they show what happens when a realistic description of the situation slips out. This must quickly be remedied by larding it with hype.

People who have ideas about how to make progress on string theory as QG should do so. People who don't should consider working on something else.

16. **jd**
September 20, 2014

There is an article on AMS-02 on CNN. The publicity machine seems to be alive and well.

17. **Peter Woit**
September 20, 2014

jd,
Yes. Headlines like "AMS Space Experiment Sees Hints of Dark Matter Particles" can't be blamed on journalists. CERN put out a press release
http://press.web.cern.ch/press-releases/2014/09/latest-measurements-ams-experiment-unveil-new-territories-flux-cosmic-rays
claiming "tantalizingly consistent with dark matter particles with mass of the order of 1 TeV" and the APS summarizes the AMS-02 PRL as "More Dark Matter Hints from Cosmic Rays?"
http://physics.aps.org/synopsis-for/10.1103/PhysRevLett.113.121102

At Resonaances, Jester explains the actual situation:
"The dark matter explanation is unlikely for many reasons. On the theoretical side, the large annihilation cross section required is difficult to achieve, and it is difficult to produce a large flux of positrons without producing an excess of antiprotons at the same time. When theoretical obstacles are overcome by skillful model building, constraints from gamma ray and radio observations disfavor the relevant parameter space. Even if these constraints are dismissed due to large astrophysical uncertainties, the models poorly fit the shape the electron and positron spectrum observed by PAMELA, AMS, and FERMI (see the addendum of this paper for a recent discussion). "

Job Action at the Journal of K-theory

September 20, 2014
Categories: Uncategorized

Back in 2007 I wrote here several times (see for example here and here) about the story of the resignation of the editorial board of the Springer journal K-theory in favor of a journal published by Cambridge, called the Journal of K-theory. For a detailed history of this, see Eureka Journal Watch.

At first this story fit in with the narrative of a group of mathematicians banding together to do something about high journal prices, but the actual story was much murkier. There never seemed to be any evidence that anyone had tried to negotiate a lower price with Springer. The editorial board resigned in January 2007, but the managing editor Anthony Bak had stopped sending papers to Springer in April 2006, and the resignation wasn't made public until August 2007, a sequence of events that left some submitted and refereed papers in limbo.

The actual financial arrangements between Bak and Springer were never made public, and Bak was supposedly suing Springer for a significant amount of money, on grounds that also were never disclosed.

Wolfgang Lueck and Andrew Ranicki took over the task of dealing with the manuscripts in process at the Springer journal, and you can read Lueck's account of that here.

When the new "Journal of K-theory" was started, there was a statement from the editors that:

> The title of JKT is currently owned by a private company. This situation is only meant as a temporary solution to restart publication of K-Theory articles as soon as possible. It is the Board's intention to create a non-profit academic foundation and to transfer ownership of JKT to this foundation, as soon as possible, but no later than by the end of 2009, a delay justified by many practical considerations.

(a more detailed version is here).

The non-profit foundation did get created, it's the K-theory Foundation and one thing it does is sponsor conferences, and award every four years prizes for work by young mathematicians on K-theory, with the first two $1000 prizes awarded this year.

The latest news though is that there has been some sort of breakdown between management (the managing editor Bak), and the workers (much of the editorial board), leading to a strike (see news from Scott Morrison). The workers are demanding that the ownership of the means of production be transferred, as promised back in 2007, from Bak's company (ISOPP) to the K-theory Foundation.

Morrison has more details here, and in the comments quotes a claim that Bak's company has been been receiving 73-74,000 pounds per year, for services that Cambridge would normally pay 20-25,000 pounds per year for. So, this appears to not just be about the technicalities of ownership, but about significant sums of money coming in from publishing math papers. At Morrison's site, Andrew Ranicki advises "Follow the money."

It seems that removing control of the income thrown off by math journals from the clutches of Springer may not solve all problems. The editors on strike say that if Bak doesn't fold, they start yet another journal.

Update: The text of a recent talk by Tony Bak describing the history of the journal is here.

From Scott Morrison, news last week was that:

> As of a few hours ago, Tony Bak is no longer the President of the K-Theory Foundation, having been removed from the board by a unanimous (excepting abstentions) vote.
>
> Editors of the Journal of K-Theory have begun contacting the authors of submitted papers to give them the opportunity to withdraw their papers, or to wait and consider the option of transferring to a new journal.

Comments

   September 21, 2014

   I am reminded that Chandrasekhar almost single-handedly engineered the transfer of ownership of the *ApJ* to the AAS. *JKT* came in at just under 1200 pages in 2013. Unless there's some serious manuscript editing going on, including high-end LaTeX skills being brough to bear, that's barely an FTE.

   So, are they starting a new journal?

Quantum Field Theory: Past, Present and Future

September 21, 2014
Categories: Uncategorized

Video is now available of David Gross's colloquium this past week at NYU, which had the title Quantum Field Theory: Past, Present and Future. It's quite interesting to compare his current point of view to that of ten years ago. The earliest substantive post on this blog was this one, which reported on a similar sort of talk by Gross, of similar length, also here in New York.

If you look at that blog post, you'll see that I found myself in strong disagreement with many of the main arguments Gross was making back in 2004. Remarkably, ten years later, there's relatively little I would disagree with in his NYU talk on much the same topic. Back in 2004 he was predicting the imminent discovery of supersymmetry at the LHC, in the current talk supersymmetry was not mentioned at all. I think the negative LHC results have had a very real effect on his thinking.

His 2004 point of view on string theory was that it was a better, more fundamental replacement for QFT. His arguments for this weren't very good then (see the old blog posting), and he seems to now have wisely abandoned them. Instead, the first hour of his talk was all about the story of our increasing understanding of the power of QFT. From there, he argued that there's some larger framework that we don't understand, which includes our current understanding of QFT, as well as things like quantum states that look like strings. He likes to refer to this conjectural new framework as QFT/string theory. Interestingly, there was no reference at all to "M-theory".

Gross's current vision of the future comes down to something close to mine: some yet undiscovered new ideas will tell us something new about the QFT framework, and this will show us how to make progress on quantum gravity and unification. I'd add something more specific, that previous progress came from understanding new ways of exploiting symmetries in QFT, so future progress may very well be of that same general nature. He pointed out that the story of past QFT progress was often that people had decided that something dramatically different was needed, but ended up realizing that they just needed to solve some very technical issues, not move to something very different (e.g. proper handling of renormalization and of gauge symmetry was needed, not new degrees of freedom).

In the question and answer period Gross made clear his distaste for the string theory landscape. About all he would say about anthropics was "Oy-vey", and that it's nothing but a cop-out. He characterized the supposedly finite number of "string vacua" with stabilized moduli and positive CC as likely irrelevant, since you don't know what theory they are a solution to, and there's an infinity of other solutions to the kinds of equations you're considering.

All in all, I found watching this quite encouraging. Seeing one of the great elder statesmen of the field stop promoting failed ideas, challenge dubious received wisdom, and move on to a more promising take on where the field should be heading is cause for optimism. I hope younger theorists will pay attention.

   There is a brief mention to M-theory around 1:30:30.

2. **theon**
   September 22, 2014

   Yes, some are sick and tired of claims such as "Theory of Everything" (i.e. everything except the standard model), "multiverse" (a coverup for the failure to explain the Universe) and so on. More prudently, string theory can be seen as a framework that gives certain insights in quantum field theories.

3. **Hanna**
   September 23, 2014

   Peter,

   listening to the talk, I get an impression that differs from yours. My impression is that Gross is still a full believer in string theory, but that he acknowledges that critics have a point. It seems to me that his retreat is only tactical; he avoids the issues that are easily criticized, while still being convinced to be correct on the large picture. String theory is still what he wants and thinks correct. He still believes in supersymmetry and higher dimensions.

   On the other hand, maybe you are right, and there is hope for improvement.

4. **Nathalie**
   September 28, 2014

   Gross is a good speaker and fun to listen to. However, nature couldn't care less about his beliefs. They are no more than far fetched speculations involving huge extrapolations.

   He talked about Feynman diagrams but said nothing concrete. It would have been more useful if he, for example, had said something about "Amplituhedron". Is it really a breakthrough in quantum field theory, as it is advertised to be?

Planck: It's Just Dust

September 21, 2014
Categories: Uncategorized

The Planck paper with results on dust in the BICEP2 patch of sky is now out, see here. I'm sure experts will weigh in soon and I'll link to such discussions, but my non-expert take is that Planck is saying that what BICEP2 saw is likely just dust. See section 6 of the paper, especially figure 9 which appears to show that BICEP2's claimed value of r=.2 is just what you'd expect from dust.

Update: More details from Natalie Wolchover and Sean Carroll.

Looks like Scientific American will have to pulp this month's magazine, with its Lawrence Krauss cover story about how BICEP2 is experimental evidence for quantum gravity and the multiverse.

Update: For more press coverage, see Nature, New Scientist, BBC News, The Guardian, the Washington Post, the Daily Mail and the New York Times.

The best explanation for all this that I've seen of course is from a blogger, Sesh Nadathur at Blank on the Map.

Update: Jester has a sensible take on this fiasco here. It now seems that release of the full Planck polarization results has been pushed back from October to "late November", just before the early December conference planned long ago to discuss the results. The joint analysis of BICEP2/Planck data that will show if there's any evidence of something besides dust is supposed to be released at the same time.

   https://www.youtube.com/watch?v=tH2w6Oxx0kQ

   "Dust In The Wind"

   I close my eyes only for a moment, and inflation's gone
   My Nobel dreams pass before my eyes, a curiosity

   Dust in the wind, all inflation is is dust in the wind

   Same old song, just a drop of hype in the CMB
   Inflation crumbles to the ground, though we refuse to see

   Dust in the wind, all inflation is is dust in the wind

   Now, don't hang on, nothing lasts forever but the earth and sky
   It slips away, and all your money won't another primordial wave buy

   Dust in the Linde, all inflation is is dust in the wind (all inflation is is dust in the wind)
   Dust in the wind (inflation is dust in the Linde), inflation is dust in the wind (the wind)

3. **Avattoir**
   September 22, 2014

   Verbatim reader comment at Carroll's blog, under the reader name George Efstathiou [who looks to my eye to be either the biggest cheese at Planck or close to it]:

   "As a member of the Planck Science Team, I would urge caution concerning the interpretation. What we are saying is that polarised [sic] dust emission in the BICEP2 field is high. But it may be that there is something left in the BICEP2 signal that can be attributed to gravitational waves. We need to cross-correlated [sic] the Planck maps with the BICEP2 maps. This analysis is underway."

   BICEP2 was definitely way out of line on a) the meaning and value of the Planck slide, b) using Planck data before Planck itself was ready to publish, c) extrapolating from something they didn't understand, d) the intensity of its readings, and e) the reliability of its assertions, and that seems to me like an awful lot of basic stuff to be wrong on. But it'd be wrong as well to leap entirely in the opposite direction.

   This may well follow the members of the BICEP2 team thru the remainder of their careers (for some, still new), which means it'd be nice for accuracy.

4. **chris**
   September 22, 2014

   Avattoir,

   ATLAS and CMS hated the preliminaty combination of their Higgs search results by outsiders. They frequently told everyone not to buy any of this until the full, cross-correlated analysis was ready. and when it was, the result was virtually indistinguishable from the preliminary combinations.

   I'm quite sure it will be the same here. Just imagine: would Planck announce now that the BICEP2 signal is dead for sure, what would they tell the taxpayer why they are doing the crosscorelation analysis anyway?

5. **AdamT**
September 22, 2014

Since this was trumpeted as a prediction of inflation the failure to observe this prediction would deal a huge blow to the theory, right?

Or is that not how science works anymore?

I also remember this being trumpeted as a victory for the multiverse…

6. **Peter Woit**
September 22, 2014

Avattoir,
I think it's completely accurate at this point to say that BICEP2 has provided zero evidence for primordial gravitational waves, instead is seeing pretty much exactly the expected dust signal.

This may change in the future, based on Planck data, new BICEP2 data, and a joint analysis of the two data sets (although seeing a significant signal this way doesn't appear very likely), but that's a separate issue. I don't think it's fair to use this possibility to try and evade the implications of the bad science that BICEP2 has done, promoted by press conference, and gotten on the front pages of prominent newspapers and magazines.

This is a perfectly good example of normal science: a group makes claims, they are checked and found to be incorrect. What's not normal is a massive publicity campaign for an incorrect result, and the open question is what those responsible will now do to inform the public of what has happened. "Science communicators" often are very interested in communicating over-hyped news of a supposed great advance in science, much less interested in explaining that this was a mistake. Some questions about what happens next:

1. Will the New York Times match their front page story "Space Ripples Reveal Big Bang's Smoking Gun" with a new front page story "Sorry, these guys had it completely wrong?" Or will they bury it in the specialized "Science" section tomorrow with some sort of mealy-mouthed headline like the BBC's today that BICEP just "underestimated" a problem?

2. Will Scientific American in the next few months put out a magazine cover saying "Our October magazine cover was nonsense"?

3. Will the BICEP2 team withdraw their PRL paper?

4. Will Linde/Guth/Starobinsky return their May Kavli Prize, which was awarded with the explanation
"More evidence was provided earlier this year by an experiment at the South Pole called BICEP2 which, however, awaits confirmation by independent data. BICEP2 detected swirls in the polarisation of the CMB that are believed to be caused by the gravity waves spawned during inflation, as predicted by Alexei Starobinsky." see

http://www.kavlifoundation.org/2014-astrophysics-prize-explanatory-notes

5. etc….

Maybe things are different in the experimental world, but based on a long career of watching hype about strings, susy, extra dimensions never matched by public explanations of what went wrong, I'm not so optimistic.

7. **Jeff M**
September 22, 2014

So, I'm curious, has anyone done some sort of investigation of when "science by press conference" exploded? And why? Is it the money involved? There's always been pretty big money in physics, no? As a mathematician, it's not something I'm exposed to really, big NSF grants in math wouldn't even cover lunch in most physics grants. Off the top of my head, the first big press conference announcement of an incorrect result I can think of was the cold fusion thing, but there must be some before that, no? Particle physics always got pretty good press coverage that I remember, but you wouldn't see announcements until things had at least been accepted for publication that I remember, or close.

8. **Peter Woit**
September 22, 2014

Jeff M,
The difference with math I think is that there's just a lot more public interest in claims to have discovered a limitless source of energy, or seen back to the first gizillionth of a second of the Big Bang than there is in, for example, having proved that zeroes of a certain function lie on a certain line in the complex plane.

Unlike some other people, I don't actually have any problem with the idea of holding a press conference when you publicly release results for which there's a lot of public interest. You'll need to deal with the press, and that's one way to do it. Keeping such a result under wraps as it goes through a refereeing process is not so easily done, and putting out a preprint on the arXiv is a good way to allow your colleagues to evaluate your claims. But when you do this, you'll have to deal with press interest.

In the BICEP2 case, there would have been no problem at all if they put out a paper and press conference saying "we have a solid observation of non-zero B-mode polarization, have to wait on Planck to know if it's dust or not". Instead they convinced themselves they'd made a huge discovery and decided to throw long, making dramatic claims (5 sigma effect!) to the press. Question now is how the mess they created by doing this will get cleaned up (or will it?).

9. **Sesh Nadathur**
September 22, 2014

Peter, just on your point 3 above: the actual PRL version of the BICEP paper contains rather more careful statements about the possibility of foreground contamination and the need for follow-up checks than the gung-ho pre-print version from March.

Re the other points: concluding at this stage that a measurable gravitational wave signal does not exist would be to make a similar mistake as BICEP but in the opposite direction. Of course this does appear to be the more likely outcome, but it isn't certain yet.

10. **Grad Student**
September 22, 2014

Dear Sesh,

You write, "concluding at this stage that a measurable gravitational wave signal does not exist would be to make a similar mistake as BICEP but in the opposite direction."

Were Peter to host a major hour-long press conference and hire a film crew and visit Andre Linde's house to announce the news of the failed BICEP2 results to him, and then film him crying instead of celebrating, then, perhaps, Peter would be doing the same thing in the opposite direction, but only if he were also scraping data from a powerpoint presentation to justify the results.

11. **Winther**
September 22, 2014

Peter:
I toally agree that we need a discussion regarding how such discoveries should be communicated to the public and that scientist needs to be careful when presenting their findings. However, I think you being unfair in the rest of the critique you make. I have some comments regarding the retorical questions you presented in the comment above:
***
Point 2): "Will Scientific American in the next few months put out a magazine cover saying "Our October magazine cover was nonsense"?"
***
If you would take time to read the first line of article you would see in the first paragraph that the author talkes about what this *would imply* if it was true and not claiming that inflationary B-modes are a fact: " *If* the recent discovery of gravitational waves emanating from the early universe holds up under scrutiny, it will…". What can possibly be wrong with this?
***
Point 3) "Will the BICEP2 team withdraw their PRL paper?".
***
Why should they retract the paper? This shows little understanding about how the experimental science works. If you would take time to read the paper (and the critique of it) then you would find that the main part of their analysis has stood the test of time. They do find a B-mode signal (and Planck confirms this, but it turns out that it's likely to be dust). They also use the best availiable information about polarized dust availiable at the time and this seemed to suggest that it's small. However, I do think that they should be critiqued for claiming a too significant (7sigma) detection when the dust issue was as uncertain as it was, but this is not enough to merit retraction in my opinion.
***
Point 4): Again, Kavli says *awaits confirmation* and note that they do not get the prize just for the B modes, but for the idea of inflationary cosmology. It is still a strong consensus that inflation (or something like it) have happened and we do have other evidence for it. B modes is just the missing piece of the puzzle that would settle this for good. People coming up with an idea that has stood the test of time (40 years) and whose work has lead to a lot of development in the field deserves a prize (with or without B modes).

12. **Sesh Nadathur**
September 22, 2014

The BICEP team arguably made two different mistakes: one to do with the actual science (the over-optimistic interpretation of foreground models) and one to do with the presentation of their result to the press. I was referring to the first one rather than the second — and in any case, I'm not convinced that having the scientific process played out in spotlights actually does the reputation of science (as opposed to the reputations of some individual scientists) much harm.

13. **Jeff M**
September 22, 2014

Peter,

Really, there is NOTHING more interesting that whether the zeros of that function have real part 1/2 🙂

14. **Not a physicist**
September 22, 2014

I don't understand the technicalities at all, but can some clearer conclusions be obtained by repeating the experiment at multiple frequencies to try to separate the dust signal from a purported primordial signal?

Does this type of experiment at least have the potential to exclude (or confirm) some versions of inflation?

15. **Peter Woit**
September 22, 2014

Sesh (and Winther),
Upon better consideration, I agree that the BICEP2 PRL as published probably doesn't need retraction. I do think though that in this case the referees likely saved them from themselves, because their paper as submitted would be a much better candidate for retraction.

I don't think anyone is claiming that now we know a measurable primordial signal doesn't exist, and that such a thing is not contributing to the BICEP2 data. However, we do know that if it is in their data, they now have nothing at all that would justify such a claim. Maybe Planck will help them out to get some such evidence, but that's speculation about the future (and I suspect most people would now give long odds against it).

Winther,
The SciAm cover has nothing about "if this holds up under scrutiny". More seriously, I think publishing in September a cover story about this, even with the "if this holds up under scrutiny" caveat, was irresponsible, given that since May it had become widely known that this was NOT holding up under scrutiny. To be fair, since it's behind a paywall, I haven't read the whole piece. Perhaps later on it explains the dust issue as a serious concern.
Do you really think that the award of the Kavli prize this particular year was not influenced by the BICEP2 claims to have experimentally vindicated inflation?

16. **Peter Woit**
September 22, 2014

Not a physicist,
Yes, that's what many experimental groups are now trying to do.

As discussed here at various times, the problem with inflation is that it's only a rather general idea, which you can implement in many ways, and its seems you can get any value for r that you want, from BICEP2's .2 to hopelessly small. Steinhardt argues vigorously that because of this it's not science, but that argument is best left for another time.

17. **Curious Mayhem**
September 22, 2014

Yes, inflation models can predict “r” values over a wide range, depending on model details and basic assumptions. If it is all just dust in the interstellar wind, it means only that inflation with such large values of “r” has been ruled out, again.

And again, inflation does NOT imply a multiverse, which is just one type of inflationary model, the Linde eternal inflating universe, with nucleating bubbles (of which we are in one). And this is NOT the same as the string “multiverse,” which is multiple disjoint realities, or something along those lines.

Inflation is an idea historically prior to and logically independent of string theory. The two have nothing to do with each other.

18. **Peter Woit**
September 22, 2014

Sesh and Winther,

A New York Times story by Dennis Overbye on this is now out
http://www.nytimes.com/2014/09/23/science/space/study-confirms-criticism-of-big-bang-finding.html
He quotes Paul Steinhardt as saying that the BICEP2 PRL should be retracted.

19. **Not a physicist**
September 22, 2014

To be more concrete, is it anticipated that in the next few years, some values of r could be experimentally excluded, at least painting inflation into a corner (of parameter space).

20. **Peter Woit**
September 22, 2014

Not a physicist,
In some sense the BICEP2 result that they see what is expected from dust already provides a limit of r <.2 or something. The joint Planck/BICEP2 result in a few months will likely put a more stringent limit. Planned other experiments will take the limit down further, I don't know what the ultimate limits are. None of this though I think could be described as painting r into a corner, since an appropriate metric is probably in terms of the exponent: there are various versions of inflationary theories with very small predictions for r.

21. **Winther**
September 22, 2014

Peter, there is no doubt that the prize was influenced by the BICEP2 results, but the work they got the prize for has been so important for modern cosmology that it hardly matters: they would/should have gotten it anyway at some point. You can compare it to Higgs getting a prestigious prize before the Higgs was found – nobody would protest (and imo inflation is to cosmology what the Higgs is to particle physics : we know something like it has to be there, the question is just what exact form it takes). Importantly: it’s not the Nobel prize – that would be something I too would protest against.
–
This is still not over, but if it turns out to be just dust then I would still not agree that it is as damaging as you think. As you write yourself, this is a good example on how science is supposed to work and cases like this will also make sure that future experiments will be much more careful with what they claim (and how they present it to the media) which is a good thing.

22. **Shantanu**
September 22, 2014

Peter,
IIRC if the Bicep-2 results were correct, it kills Starobinsky’s 1980 model.
But I agree in general that he and Linde as well as Guth were awarded prizes for their pioneering contributons to inflation. Its somewhat unfortunate that Demos Kazanas never gets any recognition for his work (even though the Bicep-2 team is one of the few experimental groups to have cited his 1980 paper).
Shantanu

23. **Cormac O'Raifeartaigh**
September 22, 2014

Hi Peter, I had a quick look at Larry’s article in Sci Am, and I don’t think any pulping or revisions will be required. The piece is laced with phrases such as “The observation, if confirmed”….and other sensible caveats.
I think it’s important to emphasize that the Planck result goes some way towards suggesting that the BICEP 2 observation may be dust – this is not at all the same as establishing that the presence of primordial grav. waves in the CMB is ruled out!

24. **Neil**
September 22, 2014

The Krauss cover story does indeed contain caveats such as “…the result (or observation), if confirmed.” Normally, this sort of caveat means “if the result is replicated, or produced by some other experiment.” But given that the background noise is now shown to be sufficient to swamp any possible CMB signal, it seems to me that there is as yet no BICEP observation or result to be confirmed. Rather there is a claim, which is now shown to be unwarranted.

25. **Neil**
September 22, 2014

I meant foreground noise.

26. **jd**
September 22, 2014

When I finish an article with a hefty dose of caveats, I am most often angry because my time has been wasted. I have never written such and I ask what is the motivation of those who do. Well, such an article is another publication on one’s record and if it is in a well-read magazine then that is all the better. It adds to the fifteen minutes of fame.

27. **Avattoir**
September 22, 2014

Professor Woit’s questions, answered (some of them, anyway; two):

1. a) No. And b) No. Instead, the NY Times published a fairly meaty, non-mealy-mouthed Denis Overbye story that, per the usual Grey Lady etiquette, appeared on top of page 1 of the SCIENCE section, and has moved down during the day with subsequent editions (The headline itself still appears, but it's fading like a tropical sunset.)

2. If there's anyone in the blogosphere who can speak authoritatively to SciAm's historical position on the unraveling of string theory, it'd be you. Has SciAm EVER backed down on string? Or on any cover page article? If the answer to both is 'No', I should think the answer would apply here.

I agree with you citing Seth Nadathur for 'best explanation'; but also maybe funniest. His take on the paper (not to leave out the paper itself, pretty mealy-mouthed in its own right), that the sheer size of this galaxy neuters BICEP2 technology for use on even larger scales, sparks the image of potential practical application in the opposite direction: detecting unusually high accumulations of dust at very small scales – useful for cleaners of our largest, most byzantine and ornate mansions and other large buildings (tho likely beyond the pocketbook of most in the middle class, who, like the poors, unable to afford the tens of millions in money and dozens of volunteer experts, will continue to be stuck with eye-balling it on their own).

28. **Peter Woit**
September 22, 2014

Avattoir,
My questions were kind of rhetorical… As expected, Dennis Overbye of the NYT wrote a good survey of the situation, but yes, I'm guessing it will appear tomorrow not on the front page, but in an inside section. Someone much better informed than me about the ways of the publicity world recently told me that, despite things moving online, positioning in the print paper is still considered the final say on what is important and what isn't.

SciAm has had critical articles about string theory and SUSY over the years. I've never seen anything though like this current situation though: the highest profile result in years in the highest profile subject is dramatically announced, within a couple months it's clear there are problems with it, a few months later SciAm decides to put this on its cover anyway. I don't see how sprinkling in a few "if confirmed" helps the matter.

29. **Mike Black**
September 22, 2014

Let's all calm down for a second.
(1) Dust does not explain the entire shape of the curve that the BICEP2 and KECK experiments measured. If you look at Fig2 of the new Planck paper, the slope of the polarization vs. multipole for dust looks nothing like the curve for gravitational waves for low values of multipole.
http://bicepkeck.org/B2_2014_i_figs/speccomp-thumb.png
(2) The main, indirect evidence for inflation comes from the shape of the density fluctuations vs. wavelength in the universe. (see https://www.astro.virginia.edu/class/whittle/astr553/Topic16/t16_galaxy_power_spectrum.gif)
Inflation can explain the slope of the density fluctuations at long wavelength as well as their Gaussian nature. I know of no other model that can accurately explain the shape of the curve at long wavelengths and the Gaussian nature of the fluctuations.

The theory of inflation is no better or worse off today than it was before the new Planck paper.

30. **Peter Woit**
September 22, 2014

Mike Black,
I think it's more accurate to say that inflation is no better or worse off today than in early March, before the BICEP2 announcement. The argument by BICEP2 that there was too little dust to account for their observations, so it had to be primordial is killed off by the Planck paper, returning things to the pre-BICEP2 situation.

31. **chris**
September 23, 2014

Peter,

I'm sure you'll love this take on the story then…

http://www.gizmodo.com.au/2014/09/physicists-are-backing-away-from-the-biggest-discovery-of-the-century/

32. **cthulhu**
September 23, 2014

The extensive caveats that are described in the SciAm paper remind me of reading papers in my field, control systems theory, in the early '90s. They would start off by saying that "control design technique X is well suited to guarantee stability and performance metrics in the face of nonlinearities, noise, time delays, structured and unstructured model uncertainties, etc." The next sentence would be "In this paper, we will restrict our focus to linear, time invariant single-input-single-output systems with no noise, no time delays, perfect sensors, perfect actuation, and no unmodeled uncertainties." As somebody else said, if you've caveated everything, what's the point anymore?

33. **West**
September 24, 2014

Cormac,
As far as I can tell, no one is arguing that this set of measurements amounts to a refutation of inflation as a modeling framework. What this data seems to indicate is that the dust+backgrounds (noise-only) model is a better model for the B-mode polarization BICEP2 saw than GW+dust+backgrounds (signal+noise). Sesh delineates this chain of inference really nicely at the bottom of his post Peter links to in update2.

This doesn't mean there isn't a signal buried in there somewhere, just that the simpler model is better at matching the data with fewer free parameters. At some point the measurements will get so precise that either the signal is found or cosmologist will have use more complex theoretical models, but as has been said ad-nauseum, we aren't at there yet.

34. **Antonio (AKA "Un físico")**
September 24, 2014

My opinion is that Bicep2 manipulated their simulations to gain worldwide popularity and in my opinion Bicep2 should apologize. 7 sigma is the maximized significance level of r different from zero when setting the dust to zero but, why Bicep2 had to invent a fictitious scenario by setting that dust to zero and publiciting their results with worldwide propaganda?.
Planck's preliminary results say that the r = 0.2 could be explained only by dust. Planck must refine their analysis; so let's see how this story ends.

PS: I have been discussing with Lubos Motl about this issue: he believes that I am an incoherent conspiracy theorist that enjoys attacking science. But he cannot explain why: from the r diffrerent from zero at 7 sigmas with Bicep2, we are now talking of a confidence of only 2.5 sigmas with Planck (and we will see which is the confidence in future analysis).

35. **david**
September 24, 2014

Today the joint analysis of BICEP2/Planck dust was done by a Chinese group arXiv:1409.7025. They got a new stringent limit of r (0.083).

36. **Art**
September 25, 2014

Maybe SciAm has taken action. Since upgrading to ios8, their ipad app doesn't work…

37. **Art Brown**
October 8, 2014

As a follow-up, the new version of the SciAm iPad app works with ios8, so I've finally been able to read the Krauss article. It actually mentions the Planck results and includes a supporting figure:

"Alas, as of this writing, the situation remains unsettled."

"Recently the Planck satellite revealed that such dust could be more prevalent than previously thought."

"The BICEP2 team stands by its estimates – but it now admits that it cannot rule out a dust explanation."

Maybe Krauss (or SciAm?) got some insider info ahead of Planck publication? Anyway, the article ends up as an uneasy hybrid of theory and experiment, but maybe stands as a report from "the front lines".

38. **Peter Woit**
October 8, 2014

Art,
The problems with the BICEP2 result were known back in May, and I'd guess the SciAm reference is to other results about dust that came out earlier this year that reinforced evidence of a problem. What's surprising here is that SciAm still thought it a good idea to put this kind of thing on the cover, several months after it became clear there was a problem with it.

39. **Edward**
October 8, 2014

Does PRL lose its credit?

Now the value of r significantly drops down and is consistent with Planck. However, there are several papers in which some theoretical models were supposed to solve the tension of BICEP2 and Planck. How will PRL deal with these papers?

40. **Art Brown**
October 10, 2014

Re SciAm, I concede…

Will you be participating in Festival Albertine's "exploration of mathematical styles"?

41. **Peter Woit**
October 10, 2014

Art Brown,
I just read about that in the NYT this morning, hope to attend.

Horgan Interview With Witten

September 22, 2014
Categories: Uncategorized

Back in 1996 John Horgan's *The End of Science* appeared, which included material from a fascinating 1991 interview of Edward Witten. I had mixed feelings when reading this. On the one hand, Horgan was doing something truly remarkable, challenging Witten in a way that no one else dared. This was 7 years after the "First Superstring Revolution", and it was starting to become clear that string theory was not working out as hoped. No journalist other than Horgan though was talking about this, or willing to confront someone of Witten's stature with difficult questions. Pretty much every other story in the press stuck to the simple narrative that Witten was a genius, and superstring theory a great success. On the other hand, Horgan did use his author's freedom to edit and frame the interview to make Witten look bad (today he admits the Witten profile was "pretty snarky"), so he was landing some low blows, against a rather gracious opponent.

This year Witten won the Kyoto Prize, and I was shocked to hear that Horgan was the person chosen to interview him. Witten rarely gives interviews and I would have thought that Horgan would be the last person in the world he'd agree to an interview with, given his past experience. The interview is now available here.

This time around Horgan avoids the snark, and asks some straightforward questions about whether Witten's views have changed since 1991, and what he now thinks about string theory, the multiverse, anthropics, etc. I have to admit that I find Witten's answers depressing, in contrast to Witten's advisor David Gross's current take on these issues (discussed here). About anthropics, Witten's "I don't like it, but may be the way to go" contrasts with Gross's "cop-out", and his insistence on string theory as the way forward contrasts to Gross's emphasis on the fertility of quantum field theory.

Back in 1996, after the appearance of Horgan's book, Gross and Witten wrote in to the Wall Street Journal (reproduced here) to argue that Horgan was wrong, since string theory would be tested by finding SUSY at the Tevatron, or, failing that, definitely at the LHC. We all know how well that has worked out, and Gross seems to have learned a lesson from this. Witten on the other hand has moved on to even more dubious testability claims (e.g. that the string theory landscape can be tested by "seeing a signature of a prior phase transition in the CMB"). From the 1996 claim that vindication would come "in the next decade", he now is talking about "200 years from now". His one point of close agreement with Gross is that both agree that not knowing what string theory is when time-dependent effects are large is a big problem, one that has seen no progress.

By a couple years from now, the idea of making progress in our lifetime by seeing SUSY at the LHC, then going on to use this to learn about string theory should be finally finished off. Already Gross seems to have evolved from the 1991 point of view to a more promising one, perhaps Witten at some point will start to do the same.

Update: The AMS has something similar, a Mathematical Moment with Witten. Pretty much everything said about string theory is exactly the same as thirty years ago, only change is that the story used to be that string theory would get some vindication at the LHC, now it's:

> The verification of superstring theory is probably a long way off, but could be found here on Earth, using particle accelerators (possibly much more powerful than those of today)

consistent with the "200 years" estimate from the Horgan interview.

Comments

1. **RM**
   September 22, 2014

   I am not sure why John Horgan's views on science deserve publicity. Prior to his assertions about physics, he wrote a book claiming that mathematics was coming yo an end because proofs were becoming too hard. In the 20 years since the publication of his opinions, there is little doubt that major breakthroughs have occurred in mathematics. Similarly, we have gained hard data in physics on many fronts. We have not been as successful theoretically. Still, these are matters that should be judged by professional scientists rather than a journalist.

2. **Peter Woit**
   September 22, 2014

   RM,
   You're referring not to a book, but to an article he wrote for Scientific American ("The Death of Proof"). I haven't looked at that in years, but I do remember that I disagreed significantly with what he had to say there. How mathematics keeps making progress despite getting harder and harder is an interesting question. I'm not so convinced though that in the long term math may also not find itself having reached a sort of end-point, with all of its fundamental structures and their relations discovered and laid bare. We're still quite a ways away though…

   I think if you read Horgan's take on the state of physics in the mid-nineties in the End of Physics, it stands up very well now. He's not a physicist and didn't always get things right, but he saw the problems fundamental physics was running into, in a way that most professional theorists either didn't see, or if they did, refused to admit publicly. Like any science journalist he operates not as an expert, but as someone who talks to experts, asks questions, tries to get a handle on what is going on, and then communicate it to others. He has often been much more willing to challenge experts than is common among journalists. Experts don't necessarily like this, but it sometimes is really needed.

3. **RM**
   September 22, 2014

   Yes, it "Death of Proof" was an article and not a book. My apologies. I think my point remains – his book "The End of Science" was a sweeping generalization to *all* of science. Not just particle physics. But also every other kind of physics, chemistry and biology. Do you really believe these claims are justified for *all* science?

   For example, major advancements in biology seem possible with the advent of techniques to image the interior of the human body. In the late 1990s, we also discovered that there was a non-zero cosmological constant which has obviously influenced the way we think about physics.

   Even in particle physics, ideas such as supersymmetry could have been discovered. I am not aware of any argument that could have proven that the predicted supersymmetric particles would not be discovered at colliders. When Horgan wrote his book, he could not have possibly known that these discoveries would not have happened.

4. **Peter Woit**
   September 22, 2014

   RM,

I agree that there’s a criticism to be made of the book that he’s sometimes trying too hard to fit different sciences in very different states into the same framework.

As for supersymmetry, it was clear by the 1990s that this wasn’t an idea that was answering many questions that we didn’t understand about the standard model. Many people were highly skeptical of it for very good reason. If you had the choice to get your news from the many journalists who talked to Gross and Witten, took down uncritically what they said, then wrote articles about what glorious ideas susy and string theory were, or from Horgan who approached them skeptically, you’d have done a lot better in terms of understanding the real state of particle theory to go with Horgan.

Sure, his skepticism could have been mistaken, SUSY and string theory could have turned into great successes. But his skepticism turned out to be justified, to his credit. Sometimes the world really does need skeptics…

5. **Dave Miller in Sacramento**
September 22, 2014

RM,

I doubt that anyone, including Horgan himself, thinks that he has gotten everything right in everything that he has written. But, as illustrated in the discussion here, he has managed to get a lot of people thinking and talking about significant issues. Isn’t that good enough? After all, no one takes him as an expert, he does not control funding, etc.

There is a place for a gadfly, so long as a the gadfly does not have pretensions of divinity. Horgan does not seem full of himself.

After all, even many of us who do not agree with Peter on everything feel he is provided a real service to physics by raising questions that needed to be raised about string theory but that were just being ignored.

Dave

6. **RM**
September 22, 2014

I am all in favor of reasoned skepticism. Horgan did not have the evidence back in the 1990s to make the strong claims that he did – in many cases, he failed spectacularly. In one particular instance, his poorly reasoned skepticism happened to be right about one particular theory. I don’t think that one example does much to restore his credibility.

In the early 1990s, there were many reasons to think supersymmetry was the right path – starting with the fact that the gauge coupling measurements suggested unification. It is only after the discovery of the cosmological constant and the strong constraints on SUSY from LEP that the motivations for SUSY began slipping. But these occurred after Horgan’s book was published in 1996. If he had expressed skepticism about SUSY in 2001, I would not have complained.

To sum up, poorly reasoned skepticism is about as valuable as war hawks braying for a fight at every opportunity.

7. **PAC**
September 22, 2014

Gross was much more bullish on string theory during his recent lecture at the Kavli Institute than he was at NYU. (Starting around 1:01:00.)

http://www.youtube.com/watch?v=jhYzbX6qavc

8. **Peter Woit**
September 22, 2014

PAC,
Thanks. I think though that that’s also at NYU a few days ago, but a talk for the public as opposed to a talk for physicists like the colloquium talk a day earlier. To the public, Gross is giving much the same story as always, it seems to be when speaking to physicists that he’s evolving, perhaps realizing that the old arguments for string theory are no longer going over so well among his peers.

9. **Hanna**
September 23, 2014

Peter,

Thank you for the post. I was wondering for some time what Witten was thinking, now that experiment and theory speak loud and clear against supersymmetry. He did not publish for a while on arxiv. I was hoping that he changed his mind, or that at least he developed some doubts. Now we know that he did not. Reading the interview, he reminded me of an old dictum:

Errare humanum est, perseverare diabolicum.

10. **chris**
September 23, 2014

RM,

your reasoning is very peculiar. you say that in the mid ’90s a sober inspection of the evidence should have led a person to believing in SUSY. and that skepticism was not reasonable at that moment.

i think you do not quite grasp what skepticism means. as i understand it, it means not believing in any phenomenon that is not established by firm evidence. and there was as little firm evidence back in the mid ’90s than there is now.

now that the skeptics of back then turn out to be right (although some of them out of academia while some of the uncritical minds of the time hold professorships now) you suddenly say that they were mislead back then into holding the correct opinion?

that is a very queer take on history.

11. **S. Molnar**
September 23, 2014

So, is it fair to say that when addressing the public Gross and Witten give much the same take as always, but when addressing physicists Gross is not so sanguine? If so, is there really a difference between the two? What, if anything, is Witten saying to physicists about the project?

12. **Dom**
September 23, 2014

RM, I'll second the point about your take on scepticism, there is no onus of proof on the sceptic, the sceptic is the spokesperson for the Null Hypothesis.

13. **Shantanu**
September 23, 2014

Peter or anyone else: do you know if there was an upsurge in hype about string theory
when evidence for non-0 neutrino mass was found in 1998. This was before pre-blogging days, don't remember too well.
shantanu

14. **Peter Woit**
September 23, 2014

Shantanu,
I don't recall ever seeing much in the way of claims that non-zero neutrino masses had any significance for string theory one way or another.

15. **imho**
September 23, 2014

Perhaps the larger issue is that public/private versions of this story exists at all. Everyone understands the need to preserve funding, and in every other field on earth, it's almost mandatory that people "bend the truth" to protect their interests or create the appropriate public image… Unfortunately, that's just the way the world works… But hard science is different. One of the core strengths of science is that it's correct. No superstition, no opinions, just fact. The public trusts us because we're impartial and we don't lie to them… so why do some continue to obfuscate the truth???

There are fields like Medicine, or Chemistry, or Cond Matt that can probably afford to falsely hype results. These fields produce concrete real-world results that directly benefit society. Yet at times, it seems these fields are the most subdued. So why is it that Fundamental Physics, which is mostly disconnected from society, feels the need to exaggerate results…. or maybe I just answered my own question?

16. **Als**
September 23, 2014

"There are fields like Medicine, or Chemistry, or Cond Matt that can probably afford to falsely hype results. These fields produce concrete real-world results that directly benefit society. Yet at times, it seems these fields are the most subdued."

The situation in medical science is far worse than physics. False claims, outright fraud and massive overhyping are depressingly common.

17. **Guido**
September 23, 2014

Slightly, but just slightly off-topic:

"Brian Cox: 'Multiverse' makes sense"
at http://www.bbc.com/news/science-environment-29321771

18. **AdamT**
September 23, 2014

FYI, the context of that article above is Many World's interpretation of quantum mechanics measurement problem. As opposed to the string theory landscape or eternal inflation's multiverse.

19. **RandomName**
September 23, 2014

I am very disappointed Horgan got the interview as he is just not a good interviewer for this kind of thing. And a *science* journalist claiming that we have come to the end of science/math is pathetic and sad.

20. **Douglas Natelson**
September 23, 2014

As I had said on my blog relatively recently, I think Horgan is a provocateur who carefully defines his terms to suit his agenda:
http://nanoscale.blogspot.com/2014/04/john-horgan-same-old-same-old.html

21. **Roger**
September 24, 2014

According to Horgan, Bill Thurston sandbagged him on "The Death of Proof".

22. **Raisonator**
September 26, 2014

Apropos Witten interview, there is an old one on the web which may not be so well known:
https://www.youtube.com/watch?v=zsyF2BAHg2o

23. **NonaMe**
September 26, 2014

"string theory would be tested by finding SUSY at the Tevatron, or, failing that, definitely at the LHC. We all know how well that has worked out" Well, no we don't. As far as I know the LHC is not over yet: it is barely starting to scratch the surface.

24. **HL-LHC or HE-LHC**
September 26, 2014

"His one point of close agreement with Gross is that both agree that not knowing what string theory is when time-dependent effects are large is a big problem, one that has seen no progress."

Can someone explain what are time-dependent effects on string theory and why is it a big problem? Does string theory have problems reproducing gravitational time dilation in GR?

25. **Eduardo Lira**
September 28, 2014

Dave Miller in Sacramento: "Horgan does not seem full of himself."

Not full of himself? The following statement by Horgan paints a different picture to me: "I don't accept that the evidence for inflation is "vastly greater" now than in 1996."

Ed Witten may be wrong at the end concerning ST, but taking on him the way Horgan does reminds me of Salieri and Mozart. Except that Salieri was a music composer himself.

26. **Peter Woit**
September 28, 2014

Eduardo Lira,
An interesting question is whether Witten is right or wrong about the evidence for inflation being "vastly greater now than in 1996". I suspect Paul Steinhardt might disagree with him about this. Of the lists of evidence for inflation I've seen, the most convincing to me are pre-1996. But, I'm no expert, and I'd love to hear from an expert what they think of this.

Horgan now has a good track record in his skepticism about Witten's claims. Witten's 1991 story that string theory would be vindicated at the Tevatron or LHC has not worked out, and in general Horgan's 1991 skeptical point of view has held up a lot better than Witten's.

What do you suggest science journalists do when reporting comments from someone like Witten that they are skeptical about? Should they ever even have any skepticism about what someone like Witten has to say?

27. **Tim Howells**
October 3, 2014

> Roger says:
> According to Horgan, Bill Thurston sandbagged him on "The Death of Proof".
> http://blogs.scientificamerican.com/cross-check/2012/08/24/how-william-thurston-rip-helped-bring-about-the-death-of-proof/

Thanks for that very interesting and relevant link. Also note that in a postscript to that article Horgan links to this blog.

Thirtieth Anniversary of the First Superstring Revolution

September 25, 2014
Categories: Uncategorized

Today's about the date that I'd pick for the 30th anniversary of the First Superstring Revolution. Witten's paper Some Properties of O(32) Superstrings arrived at the journal Physics Letters on September 28,1984, so presumably was finished and sent out around September 25.

The effect of this paper on the field was a bombshell. Witten was at the time far and away the most influential person in the field, regularly producing staggeringly original work that was having a huge impact. The arrival that fall of a preprint from him announcing that he had stopped work on everything else, and now had what looked like a viable, consistent unified theory of everything, one that he claimed was determined by a single parameter and made predictions ("It predicts axions and stable Nielsen-Olesen vortex lines") was the true First Superstring Revolution.

I wrote about this in some detail ten years ago, for the 20th anniversary, so won't repeat what is here and here, supplemented by comments from Larry Yaffe. For something more recent along the same lines, see here.

Ten years ago the 20th anniversary of the First Superstring Revolution was celebrated with a symposium at Aspen, but as far as I know, no one has organized a 30th anniversary celebration. There are now many, many known ways of trying to get unification out of strings, with the original 1984 hope that anomaly cancellation gave a more or less unique possibility long gone. As for unification itself, thirty years later Witten remains a true believer in the vision that came to him in September 1984 (see here and here), although he now seems to see little hope for vindication during his lifetime.

Comments

1. **AdamT**
   September 25, 2014

   How had Witten become so influential before the first superstring revolution? What had he done or worked on up to that point that made him so influential?

2. **george ellis**
   September 25, 2014

   For his extraordinary citation record, see here:
   http://scholar.google.co.uk/citations?user=30JcgzcAAAAJ&hl=en&oi=ao

3. **Peter Woit**
   September 25, 2014

   AdamT,
   In my book I tried to explain some of this, it's a long story. One aspect is the relation to mathematics, a lot of that is in the book, and much of it happened after 1984, with the development of Chern-Simons theory (which got Witten the Fields Medal) and later all sorts of topological quantum field theory ideas, leading to things like Seiberg-Witten, which revolutionized 4d topology. From the purely physics point of view, some pre-84 high points were Witten's work on "current algebra", leading to an effective theory of mesons and Baryons, using the Wess-Zumino-Witten term, his work on WZW conformal field theory, work on analyzing in very general terms SUSY breaking, and much, much more. That period of the early 80s was quite remarkable, and he was doing things far beyond what anyone else could.

4. **Shantanu**
   September 26, 2014

   Just out of curiosity (since I am not familiar with most of Witten's HEP papers), has any high energy (or astroparticle) prediction/model made by Ed Witten been confirmed/verified by any accelerators? I am guessing no, but I maybe wrong.

5. **Bill**
   September 26, 2014

   I don't understand Witten's logic. When it comes to landscape interpretation, he says that "universe wasn't made for our convenience", but somehow universe cares about "wonder, incredible consistency, remarkable elegance and beauty" of string theory?

6. **anon.**
   September 26, 2014

   Does a free PDF of "Some properties of O(32) superstrings" exist anywhere, or is it being kept behind firewalls by Mr Witten?

7. **Peter Woit**
   September 26, 2014

   Shantanu,
   Actually, Witten's first paper, his Ph.D. thesis, was a calculation of QCD effects on photon-photon scattering which I believe were later experimentally tested. Wikipedia has this
   http://en.wikipedia.org/wiki/Photon_structure_function
   but I'm sure there are much better references elsewhere.
   The work on Skyrmions and the effective low-energy theory for mesons that I mentioned is just an approximation, so doesn't make sharp predictions, but quite possibly there are experimental results best understood this way.

   As for BSM physics, you can't blame Witten much for not producing anything experimentally testable, since no one else has either.

8. **M**
   September 26, 2014

   Actually nobody could have given a correct prediction different from the Standard Model, because all experiments so far confirmed the Standard Model.

   The problem is that, while acritically following the naive string dream, many theorists were driven away to speculations so disconnected from any possible experiment, that institutions that once had excellent theoretical groups have now disappeared from the map of fundamental physics.

9. **Justin**
September 26, 2014

Woit,

The anomaly cancellation that you are referring to in this paper by Witten was actually done by Schwartz and Green after Witten had wrongly concluded that such a thing wasn't possible. So, contrary to what you write, it was not Witten's brilliance that started the 1st superstring revolution. Rather, the work of Schwartz and Green influenced Witten.

Also, what I wrote above suffices to undermine what you wrote about Witten doing things far beyond anyone else. In particular, the work of Schwartz and Green was a critical development in string theory which Witten had failed to discover.

10. **Peter Woit**
September 26, 2014

anon,
The original preprint is available here
http://ccdb5fs.kek.jp/cgi-bin/img_index?198412280

Justin,
If you read any of the earlier discussion I linked to, you'd see that I'm well aware of that argument, just disagree with it, for reasons explained in detail. You might also want to learn how to spell John Schwarz's name correctly…

11. **anon.**
September 26, 2014

Peter: thanks for the link to Witten's 1984 preprint. He proves SU(5) can be obtained as a subgroup to an O(32) supersymmetry theory. But wasn't SU(5) disproved by the failure of proton decay?

12. **Peter Woit**
September 26, 2014

anon.,
Not supersymmetric SU(5), where the proton lifetime is much longer. Also, the significance of that paper is not any specific model, but the claim of existence of a class of testable TOEs with a single adjustable parameter, and that Witten was working on them. Very quickly attention turned to more promising specific models.

13. **HL-LHC or HE-LHC**
September 26, 2014

where do you see string theory 10 years from now when all the results of LHC will be in and analyzed?

14. **HL-LHC or HE-LHC**
September 26, 2014

Peter,
Ed Witten agrees with you on the importance of precise prediction

http://blogs.scientificamerican.com/cross-check/2014/09/22/physics-titan-edward-witten-still-thinks-string-theory-on-the-right-track/

Horgan: Do you agree with Sean Carroll that falsifiability is overrated as a criterion for distinguishing science from pseudo-science?

Witten: Scientists aim to get as reliable and precise an understanding of nature as we can. The gold standard is a precise prediction that can be tested in a precise way in a laboratory experiment. Experiments that disprove theories are an important part of the scientific process.
^

but Witten believes string theory is predictive.

"I asked Witten how he responded to the claims of critics that superstring theory is not testable and therefore is not really physics at all. Witten replied that the theory had predicted gravity. "Even though it is, properly speaking, a post-prediction, in the sense that the experiment was made before the theory, the fact that gravity is a consequence of string theory, to me, is one of the greatest theoretical insights ever."

Witten also claims black hole entropy as a success of string theory.

15. **Peter Woit**
September 26, 2014

HL-LHC or HE-LHC,
I think the LHC will conclusively not see supersymmetry, and this + another ten years of no progress towards getting physics out of the idea of string theory unification will continue the trend towards it being a dead idea.

As for arguments about predictivity like the "predicts gravity" one, they've been discussed hundreds of times here. About that one in particular though, I think the best response was Lisa Randall's : "sure, string theory predicts gravity, ten-dimensional gravity."

16. **JG**
September 26, 2014

the best response was Lisa Randall's : "sure, string theory predicts gravity, ten-dimensional gravity."

Oh come on, String Theory predicts gravity exactly as we observe it in 3+1-dimensional macroscopic spacetime according to Einstein's General Relativity.

THAT is amazing.

In fact it was pretty amazing when Feynman first started telling everyone back in the 60s that gravitons described the same equation as GR – but no one ever got gravitons out of a theory that also predicted SM particles – until String Theory.

So, please bear in mind this great achievement of String Theory that NO OTHER THEORY HAS COME CLOSE TO.

btw: If a SUSY particle is discovered will you still be anti-string?

17. **JG**
September 26, 2014

A nicely formatted version of Witten's 1983 paper Some Properties of O(32) Superstrings

18. **Peter Woit**
September 26, 2014

JG,
I'll let you argue that one with Lisa Randall.

And, you're seriously abusing the word "prediction". String theory does not "predict SM particles", and even if Randall is mistaken, that's called a "retrodiction", not a prediction.

19. **Tom**
September 27, 2014

@JG – you are wrong. In D=4, superstring theory does not predict Einstein gravity, but Brans-Dicke scalar-tensor theory with an equal mix of spin 2 and spin 0 mediated gravitational forces. Experimentally it is known, to a very high accuracy, that gravity is Einstein's pure spin 2. This is one of these rare cases when string theory makes a solid prediction — it is clear that most of the landscape has massless dilatons, so if you are a multiverse fan, you are very lucky to be here.

20. **JG**
September 27, 2014

Ok, let's be a little more precise, String Theory can describe Standard Model particles *and* gravitons. No other theory comes close to achieving this.

@Tom

Yeah, ok, but I'm talking about the macroscopic low energy limit that we can currently observe – *that's* predicted by String Theory. (A recent publication has claimed that, *mathematically*, Black-Holes should not form because of quantum effects (hawking) during star collapse, this may just be an isolated pure maths result, unrelated to real-world physics, but there should be quite severe contraints for predictions from QG theories once we get to the really strong-field regimes and high energies. (If not, then we really will have to give up on physics))

(btw I incorrectly referred to Witten's "famous" 1984 paper as from 1983 above)

21. **Jeff M**
September 27, 2014

@JG – interesting paper, and also the arxiv followup. Always did find GR more aesthetically pleasing than QFT. Anyway, what I'm curious about is how one might account for what, to cosmologists, seems to be plenty of evidence for black holes? Is there some other mechanism that could account for what is seen? The papers imply if a star wants to collapse it will end up exploding. Gets rid of the information paradox, but what about the giant black hole at the center of our galaxy?

22. **theon**
September 27, 2014

My teacher Veltman was speaking about the "desert" in the late seventies and what do we see now? I agree that ST is a framework within which certain interesting questions can be answered (after enough pleasant assumptions such as SUSY, extra dimensions and their compactifications have been made). Indeed, a theory of everything except the standard model AND of the solid state except high Tcs, has the smells of a framework. The multiverse just avoids to explain our Universe. The many words interpretation is a poor-man's-physics denying that one has to bother about the apparatus – don't tell Bohr. But workable models exist and in their solution "many worlds" do not show up, I would say: not to the least. But Einstein's ensemble interpretation gets to the point. Quantum gravity I would like to see in the QFT on the "boundary", I do not care about the bulk. Concerning Witten, may I recall: It is the task of physicist to explain Nature.

23. **JG**
September 27, 2014

@Jeff M

There is suprisingly little observational evidence to support GR in the strong-field regime, the "black-hole" at the centre of our galaxy could just be an incredibly dense object – we don't have experimental resolution to conclude an actual event-horizon exists.

But, it's not so bad, we do have concrete evidence that *some* of the strong-field regime in GR is correct, especially from twin pulsars. See the Experimental tests of gravitational theory section from the Particle Data Group

To tie this in with the thread's historical overview of String Theory, note that this very same review of experimental tests of gravitational theory has been published for many decades – and only last year did they remove the reference to String Theory as a "promising" theory, which existed at least since the turn of the millenium (eg the last sentence of the introduction section of the 2006 version says " Superstring theory offers a promising avenue toward solving this challenge"

24. **JG**
September 27, 2014

The link above to the 2006 version of Experimental tests of gravitational theory didn't appear

25. **Peter Woit**
September 27, 2014

Please, enough discussion of claims about GR that have nothing to do with the topic of this posting.

26. **Chris Oakley**
September 28, 2014

theon,

I am hoping that your "many words interpretation" above was not a typo.

27. **Wavefunction**
September 29, 2014

Did Witten actually say that he had stopped work on everything else?

28. **Peter Woit**
September 29, 2014

Wavefunction,
I guess the paper didn't say this explicitly, but it made clear that he all of a sudden thought he saw the way clear to a TOE. And people I know who talked to him at the time told me this is what he told them (as well as that they should drop everything and work on string theory too). Over the next couple years he wrote a very large number of papers, basically all about string theory.

29. **Bill**
September 30, 2014

Peter, are you again not going to make the Nobel Prize prediction?

30. **Peter Woit**
September 30, 2014

Bill,
I retired from the Nobel Prize prediction business after this
http://www.math.columbia.edu/~woit/wordpress/?p=84
No idea who they'll pick this year. If the Swedes change their mind and let groups get the prize, a Higgs prize for CERN + ATLAS + CMS would be a good idea…

31. **lun**
October 1, 2014

I am not sure if this was already posted, apologies if it was, but here is a video-discussion with Witten from around the times:
https://www.youtube.com/watch?v=AmUI2qf9uyo#t=1008
It is actually amazing how many of the subjects discussed are still discussed in just about the same way

32. **Martin S.**
October 3, 2014

>> *and even if Randall is mistaken, that's called a "retrodiction", not a prediction.*

@PW Did not A.E. get NP for "retrodiction" of the photoelectric effect? PS Am not stringy fan (and my gut feeling is the ST does not predict/retrodict anything), 'm just disliking extremisms.

33. **Peter Woit**
October 3, 2014

Martin S.,
Of course a good retrodiction can be very strong evidence for a theory. If string theory had a convincing calculation of any of the SM parameters, that would be very impressive and give it high credibility. It doesn't though retrodict four-dimensional gravity. My point was just terminological: the word "prediction" is often seriously abused in this kind of argument. No one says Einstein "predicted" the photo-electric effect…

Quick Links

October 1, 2014
Categories: Uncategorized

- This month's Physics Today has a long article by Wojciech Zurek, Quantum Darwinism, classical reality, and the randomness of quantum jumps. I'm not sure if there's anything new there, but it's a very clear exposition of what seems to me the most penetrating point of view on the measurement problem in quantum mechanics, one that gets far too little attention in the press.

  I'd like to know what this makes me in terms of various ideologies of the interpretation of QM. Am I a quantum Darwinist, or maybe a Zurekian?

- At another extreme, getting lots of media attention while not saying anything substantive, there's the multiverse of the Many Worlds interpretation. The media campaign to promote this is still in high gear. Recent examples include Brian Cox: 'Multiverse' makes sense at BBC News, this week's New Scientist, which has a bunch of things including Multiverse me: Should I care about my other selves?, and an upcoming program here in New York that tells us that:

  > We may live in a multiverse in which every possibility happens and with each new possibility the universe branches off into another of many worlds.

  The New Scientist article has Don Page pointing out that this explains the problem of evil. God likes the idea of everything possible happening all the time so much he'd rather not be bothered to stop bad things from happening:

  > "God has values," he says. "He wants us to enjoy life, but he also wants to create an elegant universe." To God the importance of elegance comes before that of suffering, which, Page infers, is why bad things happen. "God won't collapse the wave function to cure people of cancer, or prevent earthquakes or whatever, because that would make the universe much more inelegant."
  >
  > For Page, that is an intellectually satisfying solution to the problem of evil. And what's more, many worlds may even take care of free will. Page doesn't actually believe we have free will, because he feels we live in a reality in which God determines everything, so it is impossible for humans to act independently. But in the many-worlds interpretation every possible action is actually taken. "It doesn't mean that it's fixed that I do one particular course of action. In the multiverse, I'm doing all of them," says Page.

- On the math front, I just noticed that Pieter Belmans has a blog. One of the many nice things there is his "atlas" for Spec **Z**.
- Over at Persiflage, anyone interested in how NSF grant applications in mathematics are evaluated can find an extensive and well-informed discussion.
- Videos from last week's Heidelberg Laureate Forum (which features Fields Medalists and others) are available here.

Comments

1. **Matt Leifer**
   October 1, 2014

   "I'd like to know what this makes me in terms of various ideologies of the interpretation of QM. Am I a quantum Darwinist, or maybe a Zurekian?"

   It means you are a closet Everettian in denial. Zurek is explicit that his work is a development of the Everettian program, although he does not necessarily endorse many-worlds. Still, the only way I can really make sense of Zurek's work is within a many-worlds context. Zurek would likely disagree, but I think he is working with an unusual definition of "objective".

2. **Peter Woit**
   October 1, 2014

   Matt,
   I wouldn't really deny being an Everettian, although one suffering from not being quite sure what an Everettian is. Of the things I've seen purporting to describe what such a point of view is, they seem to me to range from sensible statements, clarifying a bit how to think about this, to the completely empty, heavily larded with silliness. Surely there's a terminology to keep straight which sort of Everettian one is.

3. **Als**
   October 1, 2014

   "Over at Persiflage, anyone interested in how NSF grant applications in mathematics are evaluated can find an extensive and well-informed discussion"

   It was a depressing read. I had no idea there was so much PC-bullshit going on behind the scene.

4. **Peter Woit**
   October 1, 2014

   Als,
   Funny, my reaction was the opposite. I would have thought there was MORE PC-bullshit going on behind the scenes…

5. **Alex**
   October 1, 2014

   The description of the NSF evaluation in mathematics sounds very much like how it works in astronomy, modulo some obvious differences. I'm stunned that 30% of NSF mathematics proposals get funded though! It was more like 10% in astronomy before the financial crisis, and is surely worse now.

6. **Yatima**
   October 1, 2014

   I came here to read about math and all I got was further erosion of my dwindling hope that human brains can actually generate meaningful statements.

   "It doesn't mean that it's fixed that I do one particular course of action. In the multiverse, I'm doing all of them"

   What the hell is this I don't even.

   I think it was Danielewski who wrote that the writings of Heidegger prove the existence of crack back in the early twentieth century. This surely reaches that kind of level.

7. **JG**
October 1, 2014

“I’d like to know what this makes me in terms of various ideologies of the interpretation of QM. Am I a quantum Darwinist, or maybe a Zurekian?”

The paywall interpretation of Quantum Mechanics

8. **Anon**
October 1, 2014

Alex–it is true that Astronomy gives out 10-15%, and Math about 30%, but in Astronomy they tend to give people roughly what they ask for, whereas Math cuts budget requests substantially. High Energy also is around 30% and cuts budgets substantially. One difference in High Energy is that they use external reviewers (3-4 per proposal, typically) and the panel then looks at those reviews before ranking the proposals.

9. **Don Jennings**
October 1, 2014

Is there a place where I can look up all the grants awarded by the NSF (or DOE) to a particular person? I think it would be rather interesting to see how much various papers have cost the public.

10. **abbyyorker**
October 1, 2014

darwin is behind a paywall… bummer

11. **Peter Woit**
October 1, 2014

JG/abbyyorker,
For something not paywalled, there’s
http://arxiv.org/abs/0903.5082

Don Jennings,
Much information about NSF awards is searchable here
http://www.nsf.gov/awardsearch/advancedSearch.jsp

12. **CPV**
October 1, 2014

What the solution to the measurement problem is depends in large part on what you think the problem is, if it even exists at all. Why do you think it exists at all? Thinking that classically emergent behavior can’t occur at scales many, many orders of magnitude larger than quantum behavior seems like a strange prior. Look at turbulent flow. Look at gravity (probably).

13. **GoletaBeach**
October 2, 2014

14. **Igor Khavkine**
October 2, 2014

I’d love to hear about the ERC (european) version of how the NSF grant review process works.

15. **Peter Woit**
October 2, 2014

Goleta Beach,
Thanks, very sorry to hear that news.

Perl had a blog, see
http://martinperl.com/

16. **nick herbert**
October 2, 2014

One of the reasons Giordano Bruno was burned at the stake was his doctrine of multiple worlds. Bruno argued that the Church-supported doctrine of One World constituted an unjustified limit to God’s omnipotence and glory.

17. **Jeff M**
October 2, 2014

I don’t see how Everett solves the measurement problem. He just says that the wave function doesn’t collapse, you still have a measurement which changes things somehow. As I remember reading Everett, Schrodinger’s cat is still both alive and dead until you open the door.

18. **piscator**
October 3, 2014

nick: not relevant and not correct

The ERC procedure is (partially) as follows. The proposal initially goes off to three external referees (this is the first stage). If successful in the first stage, the proposal goes to an additional four external referees and the candidate is invited to interview. Once the process closes you get to see all the referee reports. People getting to the interview stage have a 40-50% chance of getting it, the overall success rate I think is around 7 – 10%. The interview panel is large (around 16 people, most of whom are not even really close to your field). e.g PE2 which is the main panel for high-energy theory also serves not just all experimental and theoretical particle and nuclear physics, but also AMO/ tabletop atomic experiments. The interview is about 30 minutes.

19. **Don**
October 3, 2014

Dear Professor Woit

I am wondering if you have looked at a possible connection between Multiverse mania today and Cantor's set theory of ~ 100 years ago. I have been studying the status of Cantor in mathematics and it is even today contentious. There seem to be parallel sociological situations. In phyiscs, string theory and multiverse mania represent the institutional and media mainstream, and in mathematics the axiomatic method of Hilbert, and its foundations in Cantor's set theory, seem to be the mainstream.

The idea of transfinite numbers seems to have much in common with the idea of multiverses. But as I learn more about transfinite numbers, they seem more and more like fairy tales, or "castles in the sky", similar to multiverse ideas. I increasingly sympathize with people that advocate finite-ist mathematics.

Anyway, it seems there should be a connection, maybe even a lineage between the glib treatment of infinity in mathematics and the current glib treatment of infinity in the multiverse ideas.

I apologize in advance if you have written about this in the past and I am being redundant, and would appreciate links to your thoughts about the matter.

Thank you sincerely,

Don DeGracia

20. **Peter Woit**
October 3, 2014

Don,
Sorry, but my knowledge of set theory and trans-finite numbers is minimal. So, I don't see a lot of parallels with the multiverse, beyond the fact that both have potential problems of "glib treatment of infinity".

21. **Chris W.**
October 3, 2014

CPV,
Thinking—or even routinely observing—that classically emergent behavior *can* occur at scales many, many orders of magnitude larger than quantum behavior is not the same as understanding why it *does* occur, given that the world is fundamentally quantum mechanical. That is the issue that Zurek, et al, have been grappling with.

22. **Don**
October 4, 2014

Dear Peter

Thank you for the reply. That's too bad. I was hoping you might have some insights to shed on the issue. I will continue to study the issue, which seems to involve the split of math into the different camps of formalists, logicits and constructivist. Again, there seems to be a sociological dimension of comparison with current physics.

For example, formalists accept Cantor's ideas of "magnitudes of infinity" (e.g. transfinite "numbers"), but constructivists do not, because one cannot construct examples of such "numbers". This seems analogous to the situation in physics, where some physicists are constructing in-principle untestable theories, vs. those who demand a strong grounding in empirical facts.

Again, Sir, thank you for the input.

Best wishes,

Don

23. **BooToo**
October 4, 2014

Don-
As a working mathematician, I use the ideas of orders of infinity
(countable, uncountable) and even the ordinal numbers, first uncountable ordinal, all the time; these are very well understood on a "practical" level, meaning we can prove everything rigorously and also have a complete understanding at an intuitive level of what is going on. This is Cantor's beautiful universe and seems to me not at all comparable with physics, altough some try to make that stretch. For instance physicists use Quantum Mechanics to do calculations despite not understanding the measurement problem, but my impression is that there is some very basic and important level at which they (still) do not understand things. Hence all the discussion
e.g. by Peter.

Now though I am not in logic or set theory, I have taught "naive set theory" and can attest that everything there, including at first strange concepts like the Axiom of Choice, Russell's Paradox and ordinal numbers, also non-well-founded sets…makes perfect sense. (And is fascinating: it is, certainly, a triumph of human thought).

Even, say, the idea of having say different models for the real numbers, as in nonstandard analysis, seems not really objectionable. These are "models", that is they reflect actual properties of the reals, but carry additional structure, which one may or may not want to consider at any given moment. Perhaps an analogy is that a differentiable map "carries" a lot of hidden extra structure: it defines actions on other spaces (the tangent bundle; the space of continuous functions; spaces of paths; groups of matrices; the collection of differential forms; the collection of measures; on homology and cohomology; some push forward, some pull back…) So you choose which models, and which axioms, suit your immediate purposes, and there is no contradiction. All is rigorous.

The multiverse stuff (including the Many Worlds interpretation) seems to me to
to be in a completely different world, not at all analogous. First of all it seems (to this outsider) to be completely non-rigorous mathematically. Evidence for this is that there are so many disagreements among experts. That doesn't happen in math.
More evidence is the fear leading to depression among experts that years of their lives have been lost writing preprints (8000 citations of Witten????) which may prove completely useless.
Again, this can't happen in math, where things are actually proven and hence intrinsically, and practically, worthwhile.

More evidence is that, despite the potential mathematical difficulties of say string theory or quantum field theory being far beyond what many of us mathematicians encounter in our own small efforts, sometimes the techniques being attempted on these enormously difficult problems are ridiculous in their simple-mindedness (I saw a paper on the multiverse measure problem, which it is not AT ALL clear makes ANY sense at all, based on a simple Markov chain model as taught at an undergraduate level- please give me a break).

As to constructivism etcetera, again this iscan be viewed as an issue of how much structure you want to carry along with you- for instance if you want something to be computable or verifiable and so on, but it is not really an issue of what is "right" or "wrong". That is not the case in physics, where Nature (i.e. experiment) is the ultimate arbiter.

So, I would answer your question more or less as follows: "Is there a useful analogy? No, not really".

24. **Bill**
October 4, 2014

How come this doesn't get more attention…

25. **Bill**
October 4, 2014

Better link.

26. **Peter Woit**
October 4, 2014

Bill,
These are not elementary particles, but quasi-particle excitations in a condensed matter system. This is interesting condensed matter physics, but has nothing to do with fundamental particle physics, or possible Majorana neutrinos, dark matter etc. If you compare the article you linked to to the Princeton press release it is derived from, you'll see that the Princeton document does its best to hype this by bringing in neutrinos and dark matter:

"In addition to their potential practical uses, the pursuit of Majoranas has broad implications for other areas of physics. Scientists believe, for example, that another sub-atomic particle called neutrinos, which also interact very weakly and are very hard to detect, could be a type of Majorana—a neutrino and anti-neutrino being the same particle. In addition, scientists regard Majoranas as possible candidates for dark matter, the mysterious substance that is thought to account for most matter in the universe, but which has not been directly observed because it also does not directly interact with other particles."

The idea that this has "broad implications" for neutrino physics or dark matter is nonsense, and you can see why the writer was taken in by this. Great physics, but not a shining moment for the communication of science to the public by my alma mater…

27. **Bill**
October 4, 2014

Indeed, very misleading. Does this mean that this "particle" is its own "antiparticle" only by analogy?

28. **Peter Shor**
October 4, 2014

@Bill: the "quasi-particle" is its own "anti-quasi-particle" in a very real sense, but these quasi-particles are not elementary particles, but are collective excitations which behave like particles, much like phonons.

29. **Don**
October 4, 2014

Dear BooToo

Thank you for such a detailed reply. I do not know if Prof. Woit's blog is an appropriate place to further develop this conversation. I have included my website in this reply. If it is possible for you to email me, perhaps, if you have time and do not mind, I can ask you some further questions about your comments. It would be most informative to speak to someone who actually uses these ideas in their work. Again, very much thanks for taking the time to explain the above. Best wishes, Don.

30. **Another mathematician**
October 4, 2014

Sorry, Don, but I'll be more blunt and say that the idea of a "a possible connection between Multiverse mania today and Cantor's set theory of ~ 100 years ago" is a complete non-starter. It's just not worth pursuing.

31. **Florin Moldoveanu**
October 6, 2014

I am a Zurekian myself and I am not "a closet Everettian in denail" as Matt put it. I do take to heart Everett's message: "let quantum be quantum" but the world split idea of MWI is just a very cheap shot to solving the measurement problem. Quantum evolution is only unitary and it looks like a unitary description of the collapse is a contradiction in terms, but it is not so. The solution is to use Grothendieck group construction which introduces the inverse operation to the tensor product (understood as a commutative monoid). The inverse operation reduces the dimensionality of the Hilbert space and corresponds to wavefunction collapse. To get to Grothendieck group construction one needs an additional ingredient, an equivalence relationship. QM naturally has an equivalence relationship, and Zurek discovered it: it is envariance: "what the system evolves unitarily over here can be undone by the environment evolving unitarily over there". There is only one additional open problem: spontaneously break the Grothendieck group. In certain cases this was done rigurously, but what is lacking is a proof of the universality of the mechanism. When this is achieved it will lead to the complete solution to the measurement problem. Proving it requires advanced math.

32. **GoletaBeach**
October 6, 2014

12 hours until the physics Nobel.. no buzz? 51 years since the prize was given to a woman… an award to 3 all female would be great.

33. **Don**
October 6, 2014

Hi Another mathematician

Thank you for the reply. Even if the thesis is wrong, it is always nice to see exactly why it is wrong. BooToo's explanation is perfectly cogent and suggests the parallel between mutiverses and set theory is incorrect at some very basic levels. But this is a side issue with respect to the things I am wondering about math in general, for which BooToo's reply is also helpful, but also provocative.

I have been reading up on the old controversies from Brouwer and other critics (Weyl, Poincare) of the formalist approach (e.g. of Cantor, Hilbert, Zermelo, etc) to mathematics. Are these different philosophies of math a case of people agreeing to disagree? Do formalists have reasons for rejecting constructivists and intuitionists and vise versa? How can such seemingly incompatible approaches to math co-exist?

These are really the issues I am trying to sort out. It is hard to ignore Poincare, for example, when he criticizes Cantor. My initial impression from what I have read is that the respective approaches could be considered "progressive" (formalists) and "conservative" (constructivists).

If such thinking is not too far off base, the tie in with multiverse mania was an analog at this level: e.g. some one like Dr. Woit is "conservative", insisting on traditional criteria of scientific acceptability (something I easily accept, being a bench scientist), and the multiverse people are more "progressive" in that they are willing to trash traditional scientific values, similar to how Cantor trashed the centuries long prohibition on treating infinity as a mathematical object.

But again, my main concern is to understand, with at least as much depth as I can appreciate not being a professional in this area, the status of the situation in math.

Again, thank you for your input.

Best wishes,

Don

34. **Peter Woit**
October 6, 2014

Don etc.
Please, enough here about Cantor, this is just far off topic.

Goleta Beach,
No idea who will get the Nobel this morning. However I do predict that on Nov. 9 your neighbor Joe Polchinski will be $3 million richer….

35. **Bill**
October 7, 2014

They should just rename it a Nobel prize in engineering…

36. **NP**
October 7, 2014

Let's not make foolish value judgments. Marconi won for the wireless, Jack Kilby won for the integrated circuit (Robert Noyce was dead), Ernst Ruska won for the electron microscope, there was a prize a few years ago for giant magnetoresistance (don't remember the details) … all were good physics. Was it 'engineering' for Don Glaser to invent the bubble chamber?

37. **Michael Gogins**
October 7, 2014

Here is a link to a freely available Los Alamos publication on Quantum Darwinism and randomness: http://permalink.lanl.gov/object/tr?what=info:lanl-repo/lareport/LA-UR-14-24063

Regards,
Mike

38. **Hoyuna**
October 7, 2014

Progress in experimental HEP has slowed down considerably, so there's a good chance that other branches of physics (especially applied physics) have struck 'Nobel gold'. Depending on one's level of optimism, one might predict no end for this trend.

What do you think, Peter?

39. **tt**
October 7, 2014

engineering ?
the arrogance of particle theory never ceases to dissapoint.

40. **Bill**
October 7, 2014

Sure, it is a great engineering invention by three engineers, so create a Nobel prize in Engineering. Don't call it a Nobel Prize in Physics. I might be wrong though, I am not a physicist. Are LED lights used in physics besides lighting the offices and burning DVDs (although this is already outdated)?

41. **Peter Woit**
October 7, 2014

All,
I personally know zero about blue leds, and don't think arguing about what's engineering and what's physics is very interesting, enough of that.

Yes, progress in HEP physics is much slower than in the past, with implications for physics Nobel prizes. More relevant though may be that if the Swedish Academy sticks to refusing to award prizes to experimental groups, that may be what will shut off HEP physics prizes. That the experimental discovery of the Higgs was not prize-worthy, and maybe never will be, shows there's now a problem even if all of a sudden lots of great experimental discoveries are made at big colliders.

42. **GoletaBeach**

October 7, 2014

Blue LEDs are used throughout those particle physics experiments which use photomultiplier tubes, like, say, most of the large neutrino experiments. The emission spectrum from the Blue LEDs matches the sensitivity of most PMTs better than the old Green LEDs. The Blue LEDs are used for monitoring and calibration.

I recall condensed matter theorists telling me in the 1970's that Blue LEDs were impossible due to some limitation or another. Now Ultraviolet LEDs are available. Nakamura was unrelenting in his empirical pursuit of an idea that was quite unpopular at the time. Combine that with the practical applications and it seems like a good prize to me. Only worry is that maybe the invention of the first LED of any type might have gone unrewarded.

It remains embarrassing that the last Nobel shared by a woman was in 1963.

From Goleta Beach it is easier to see the College of Engineering at UCSB than the KITP. The Engineering buildings are taller, and they surround the KITP.

43. **Niclas**
October 8, 2014

Alfred Nobel was an inventor and engineer. I agree that he would have liked the blue LEDs. Given that 20-25 of the world's energy is used for light then this is significant as the world needs to stop excessive energy consumption. Here is the motivation: http://www.nobelprize.org/nobel_prizes/physics/laureates/2014/advanced-physicsprize2014.pdf

44. **NP**
October 8, 2014

The 2014 Chemistry Prize is for 'optical nanoscopy'. They figured out how to beat the Abbe diffraction limit. Who is to say this is 'chemistry' not 'physics'? And it is the development of a useful tool, as opposed to a specific discovery of a phenomenon. Who is to say that is not 'engineering'? It is every bit worth a Nobel Prize, be it in Chemistry not Physics.

45. **Curious Mayhem**
October 10, 2014

Sorry to hear about Marty Perl.

When I first heard of the "many worlds" interpretation of quantum mechanics, I was baffled as to why it was considered science. (It isn't, of course.) It sounded like speculative metaphysics. Anyway, later I heard about Zurek, and his work struck me as the right approach. The issue had moved from metaphysics to physics, and you can measure it in a laboratory.

Bruno did not champion "many worlds" in the multiverse or Everett approach. He simply (and correctly) guessed that the fixed stars (in the same universe as ours) were other suns and could have planets, including planets with life. This left him with a theological problem, assuming orthodox Christian beliefs. Had he been a Buddhist, it wouldn't have been a problem, as "many worlds, many bodhisattvas" is an acceptable, if not common, view in Buddhism. Don't know about Islam. In Judaism, it was a view entertained by the Kabbalists, but definitely not a standard view.

46. **B'Rat**
October 11, 2014

nick herbert, Curious Mayhem,
this is not what happened with Bruno.
He was burned at stake, a barbarous act, but for his insistence in negating catholic dogmas like Trinity and so on, not because of his "many words" speculation. In fact, such idea had already been suggested more than a century before by Nicholas of Cusa, a papal legate who was made cardinal whom Bruno cited. The Aristotelian notion that there cannot be more than one World had already been condemned by the Bishop of Paris in 1277 on the basis that it limited God's omnipotence.

Since I do not want to start an off-topic discussion, I suggest you to add any ulterior comment on the argument in the following link, which discuss many misconceptions about Bruno's history:
http://thonyc.wordpress.com/2014/03/17/cartoons-and-fables-how-cosmos-got-the-story-of-bruno-wrong/

47. **Michael Gogins**
October 13, 2014

Regarding einselection, which appears to be required for quantum Darwinism to be a physically viable theory, what about this? http://philsci-archive.pitt.edu/10757/

Regards,
Mike

October 14, 2014

Page's thought reminds me of the classical philosophy of occasionalism, perhaps most championed by Nicolas Malebranche, who though now widely disfavored was actually quite popular in his day.

Various News

October 15, 2014
Categories: Uncategorized

Various news about the usual topics:

- Natalie Wolchover at Quanta magazine keeps coming up with great, in-depth stories about interesting new topics in physics that are getting no attention elsewhere. Her latest is about the universality of the Tracy-Widom distribution.
- The LHC is cooling down, in preparation for a restart early next year. Nature has a good story about what is going on here. Latest status and plans are described here. The current plan is to start beam recommissioning next March, have 1 fb^{-1} by mid-June, in time to perhaps have some results to report at EPS-HEP2015 at the end of July. Another 10 fb^{-1} would be accumulated later on, before a heavy-ion run late in the year.

  In the long term, by 2023 there should be 300 fb^{-1} and many components of the machine and the experiments will start to become unusable due to radiation damage. Planning is going ahead for "Phase-II", or the HL-LHC, with Bertolucci's comment that "It is inconceivable under any reasonable scenario to stop the LHC program at that point".

- Nature has an editorial this week about What lessons can be learned from the presentation of the gravitational-waves story?, pointing to a planned discussion next week about Lessons in the communication of science from the BICEP2 story. I've already written extensively about this, but since the editorial refers to bloggers (and I know some people at Nature were unhappy with my blog entry about this, which was poorly worded), I'll take another opportunity to do so.

  From the purely scientific point of view, this is a pretty straightforward situation. The BICEP2 people fooled themselves into thinking that they had something much more exciting (primordial gravitational waves + evidence for inflation) than what they really had (a good measurement of B-mode polarization at one frequency). They then wrote a paper with over-optimistic claims, which later blew up in their face. This is perfectly normal science.

  What's not normal science is the behavior of a lot of theorists in response to the BICEP2 claims. The Stanford University Linde video and its 3 million downloads will live forever as an example of misguided PR for science. The comments from theorists about the significance of this for string theory that Nature quoted were an embarrassment for the field (why not just say that you could get any value of r out of string theory?), and even worse were the publicity campaigns from Linde, Guth and Carroll aiming to convince the public that this was evidence for the multiverse.

  What's the lesson for science journalists? Take a hard look at the behavior of some prominent theorists in this story, and draw the obvious conclusions for your future coverage of developments in this field of science.

- Just noticed that Sean Carroll is now trying to raise research funding online with a website devoted to attracting private funding. Will be interesting to see if that works, maybe it will become a model for how to fund this kind of research.
- One of the few things I'd change about my book written ten years ago would be the discussion of the philosophy of science "demarcation problem", that of deciding what is science and what isn't. Only after writing the book did I learn about the distinction between a "progressive" and "degenerating" research program due to Lakatos, which is a very good way of addressing the question of how to evaluate string theory. I also missed a paper that came out a few years ago by Johannson and Matsubara on String theory and general methodology. At one point they write that the string theory landscape business shows that:

  > String theory is a degenerative programme, according to Lakatos' criterion.

  There's a lot more in the paper, it's a good example of what I've seen too little of, philosophers of science engaging with the real issues here.

- For the latest on the string landscape, there was a conference last week on Fine-tuning, Anthropics and the String Landscape. See if you can find anything there like a plausible idea for how to get any testable physics, I couldn't. Alan Guth's introductory talk mainly explains why the measure problem means you can't predict anything, but then ends with a claim that physicists take the multiverse seriously anyway, quoting Weinberg from 2005 about Martin Rees's dog.
  Back in 2004-5, the expectation was that the string theory landscape could be used to predict whether SUSY breaking would take place at a high or low scale (see for instance here). That idea is long dead, and no other proposal for a prediction has replaced it. So, the string landscape is itself a degenerating research program. What do philosophers of science call it when a research program degenerates into something else, and that research program in turn degenerates. A (degenerating)^2 research program?
- The standard defence of string theory these days acknowledges that it can't explain particle physics, but claims it has had great success in quantum gravity. Next spring the KITP will have a program on quantum gravity foundations. The description of the program has a lot to say about "deep connections between quantum information theory and gravity", no mention of string theory. There seems to be a move away from string theory and a convergence between the KITP and the sort of alternative research favored by the Perimeter Institute.
- Speaking next month on Quantum Mechanics and Spacetime in the 21st Century at Perimeter will be Nima Arkani-Hamed, one of the organizers of the KITP program. Not clear what he'll be arguing for then, but he did just give a talk at an Oxford workshop on New geometric structures in scattering amplitudes, with the title "The Amplituhedron, Scattering Amplitudes, and the Wavefunction of the Universe". I'm curious to see how he gets the Wavefunction of the Universe, although I suppose one should keep in mind his comments here.
- Not announced yet what the price of tickets to Arkani-Hamed will be. For a real rock star of physics though, I think you want Brian Cox, who is on tour in Australia. Premium tickets there are about $175 US.

Update: The latest on the Journal of K-theory situation, from algtop-l

> Dear Colleagues,
>
> The time has come to advise your librarians to cancel the subscription to the Journal of K-Theory. The precious money could be better spent elsewhere.
>
> As you know the journal is going through a crisis. The most recent development is that the Bak family has written to Cambridge University Press informing them that they are under a contractual obligation to keep publishing the journal through the end of 2017, whether they like it or not. I haven't seen the contract in question, not have I seen the letter from the Bak family to Cambridge University Press, hence I cannot comment on the legal merits of the case. The Baks evidently feel confident, Tony Bak has accepted at least one paper for the 2015 edition of the journal without clearing it with any of the other editors.
>
> The Baks might be right, Cambridge University Press might have no choice but to continue publishing the journal. But the vast majority of the editors will be walking out and the scientific standards of the journal are bound to plummet. It would be a waste of money to continue subscribing.
>
> Yours, Amnon

Comments

1. **Sebastian Thaler**
   October 15, 2014

   Peter,

   Just curious if you've seen an advance copy of Lee Smolin's new book, being published next month by Cambridge. It sounds interesting and I'd love to hear your thoughts.

2. **Peter Woit**
   October 15, 2014

   Sebastian Thaler,
   I haven't seen the new book. From the synopsis, it sounds like it's largely along similar lines to Smolin's last book, which I disagreed a lot with, see here
   http://www.math.columbia.edu/~woit/wordpress/?p=5769
   He and I may agree about a lot of the problems with string theory, but we have completely different visions about how mathematics and physics relate to each other.

3. **Unemployed**
   October 16, 2014

   "…Sean Carroll is now trying to raise research funding online…"

   And I notice that his vehicle of choice, benefunder.org, says they'll take a flat 10% fee off all donations (or perhaps weaseled to >15% since they also claim researchers receive "nearly 85%".) Leaving aside the value of the actual research, doesn't a slapped-together website with 10% overheads seem like a bit of a scam?

4. **Shantanu**
   October 16, 2014

   Peter, I think PI is also gravitating more towards conventional physics in the last few years. You can get an idea by looking at their list of seminars and colloquia in the last few years compared to when they initially started.

5. **Peter Woit**
   October 16, 2014

   Shantanu,
   Will be funny if places like the KITP become the hosts for exotic speculation (eg. gravity is information), and PI becomes the place for staid, conventional research…

   Unemployed,
   My impression is that a 10-15% overhead expense for non-profit fundraising is not bad at all. And I thought the website (at least Carroll's part of it that I saw) was a well-put together professional effort.

   One danger of this kind of thing is not benefunder scamming the public, but the people advertising for funding doing it. When the NSF gives a scientist a grant, there are elaborate structures in place to make sure it is spent as intended, I wonder whether that's true in this set up. Is there really anything there to stop me from putting up a glitzy web-site advertising for funding for my investigations into the nature of reality and mathematics, but then using whatever comes in to finance my next vacation in Europe?

   This kind of funding raises a lot of interesting questions. Carroll's site makes all sorts of claims (just as a random example, that his "work is unique because he takes a big picture point of view that answers questions about the universe in the broadest possible terms") that would quickly get an NSF grant application put in the discard pile as not serious science. This is advertising aimed at the general public, something very different than making a scientific case to one's peers. The NSF is cutting back on support for HEP theory research, and a lot of new funding is coming in from private sources. So far, most of the private money has come from wealthy foundations, which often have a sophisticated staff to judge proposals and make sure the money is spent appropriately (as well as sometimes people like Jim Simons who can make scientifically informed judgements). That situation raises one set of issues, which I've discussed here often. Fundraising via direct advertising to the public, without oversight by foundation officers, is something I haven't seen before, I wonder how it will play out. What would theoretical physics look like 100 years from now if this becomes the model for how to fund it?

6. **Martin S.**
   October 16, 2014

   This kind of funding raises a lot of interesting questions. Carroll's site makes all sorts of claims …

   Hi, is something wrong about putting my own money directly to a research proposal, whatever vague it is? Does it mean that when a Joe gives a few bucks to Carroll, CERN looses some funding? According to my experience, research foundations tend to support current views and approaches with near and specific targets, thus effectively putting barriers on unbeknown ways. Any new source, especially when allowing more fundamental work (that usually needs a lot of relaxing), should be welcome, I would say.

7. **Peter Woit**
   October 16, 2014

   Martin S.,

   I'm not making any simplistic claims about what is bad or good. I just think that people should think about the significance of changes in how research is funded, not just assume that all new money is a good thing . At least in the US, it is a fact that government funding for theory research is being seriously cut back, and private funding is moving in to replace it.

   If the private model is a success, you'll likely see arguments made in Congress that this is a subject where government funding should be removed. You'll also see universities moving from hiring people who can get NSF grants to hiring people who can bring in money this way.

   The NSF peer-reviewed model for funding is not ideal, suffers from problems of favoring unambitious or conventional research. But there are also problems with funding research that makes grandiose claims about ambitiously revolutionizing the subject (I get a dozen of such claims in my email each week….). Is it better for people to have to convince their peers to fund them, or have to convince the general public/rich people (who don't actually understand anything about what they're funding). Both have problems…

8. **Baleen**
October 16, 2014

Doesn't the core of the anthropic argument, an "unnatural" lambda, basically render the entire landscape programme infeasible?

If lambda is unnatural then finding our vacuum state would involve working out a bunch of different quantities associated with some particular 10-dimensional CY manifold and then seeing if they all cancel each other to *120 decimal places*. No-one has even been able to use plain old lattice QCD in three dimensions to calculate the proton mass to *one* decimal place!

9. **Peter Woit**
October 16, 2014

Baleen,
Yes. And even if you could do that computation, there's this problem
http://arxiv.org/abs/hep-th/0602072

The whole string landscape business is very odd. There are all sorts of strong arguments that you can't get anywhere, have been for ten years. Everything people have done just makes clear these are insuperable problems, and yet, it somehow remains a subject people work on, and make claims to the media that this is a great insight into how physics works.

10. **Martin S.**
October 16, 2014

@PW: I understand that both of the approaches have issues, and that any change has two sides. Still, regarding peers: they are at conflict of interest, grouping into mafia structures, they (according to my experience) generally do *not* understand stuff slightly off their own work, and they tend to dislike anything that goes a different way than they do, and more it is relevant to their own work, more irrational they are. Thus I personally feel sympathies to this new public approach.

PS Is not your fear alike Anderson's fear about SSC?

11. **Peter Woit**
October 16, 2014

Martin S.,
Anderson was worrying about the allocation of money between fields of physics, I think this is kind of different.

Maybe one source of my worry about this has to do with seeing how US universities have changed during my lifetime. They're now a lot more market-driven and PR-driven, and this is not necessarily a good thing for scholarship. And, for whatever reason, I seem to have an aversion to PR as opposed to serious discussion.

12. **Martin S.**
October 16, 2014

@PW
I seem to have an aversion to PR as opposed to serious discussion.
That's the point: one day you can discuss with the public on a blog, the other day you can try to convince your peers within academia. Or it can actually go like: today a nonsensical PR, tomorrow a power abuse within the institution. Thus it seems to be about the general approach, not about a currently followed path.

Whatever way it will go I wish you good luck. And I guess that this blog puts you into a good position regarding a reasonable communication with the public.

13. **Daniel Fischer**
October 16, 2014

Re. BICEP2 Lawrence Krauss made an interesting case today – in a talk called "Cosmology for Philosophers" at Bonn University in Germany – that there could well be a cosmological signal in the data after all (with a lesser r, I suppose, but good enough to test inflation). And that we should all wait until the end of this year when the *joint* BICEP/Planck paper will come out. So I will.

14. **Peter Woit**
October 16, 2014

Daniel Fischer,

Sure, there could be an observable non-dust signal, we don't know yet, but back in March all BICEP2 had was an observation of B-modes at a level consistent with that expected from dust. Claiming a "five sigma" observation of primordial gravitational waves was just completely wrong and unjustified.

Any real evidence of such a signal will be based on joint work of the two experiments, or maybe on Planck's all-sky results on their own. Supposedly we'll know end of next month. Whatever happens, doesn't change the fact that the March headlines and PR were an embarrassment and a fiasco, a good example to various people of how not to behave.

15. **Ramanujan**
October 17, 2014

In the Linde video, the experimentalists showed up at his door unannounced, and claimed a discovery that was not supported by the evidence. How do you transmute this into a statement about "the behavior of theorists" ?

16. **Lee Smolin**
October 17, 2014

Dear Sebastian Thaler and Peter,

My new book, The Singular Universe and the Reality of Time is written with Roberto Mangabeira Unger, a Brazilian philosopher who is Professor of Law at Harvard, and is thus a very different kind of book than my previous books. I hope you will find more to agree with in it, or at least take it as a challenge to argue with. It supports the conclusions of Time Reborn, but it is more radical and goes deeper.

In the end, you and I may disagree about the nature of mathematics and its proper role in physics (about which there is much more in the new book) but I suspect we agree that what really matters is to develop theories that make testable predictions for doable experiments. The new book lays out a program for doing that and presents some early steps.

Best wishes,

Lee

17. **Peter Woit**
October 17, 2014

Lee,
Thanks, I look forward to seeing it.

Ramanujan,
Yes, you're right, the experimentalists have most of the blame for that video. Linde's claims about "a smoking gun" were in the Stanford press release, not that video, see
http://www.math.columbia.edu/~woit/wordpress/?p=6958

Linde could have pointed out to the guy who showed up at his door that while r=.2 was all well, and good, he had versions of inflation for any value of r.

From Alan Guth's presentation:

> * For every real Alan Guth, there will be an infinite number of BB[]s who will think they are Alan Guth, sharing exactly all my memories and all my thought processes.
>
> * With overwhelming probability, the BB[]s who share my memories will see the world rapidly disappear, since for them it never existed. Thus, with overwhelming probability, beings who think they are me will see the world rapidly disappear.
>
> * Conclusion: our continued observation of a coherent world gives overwhelming evidence that we do *not* live in a world with an infinite (or huge) ratio of BB[]s to normal observers. Hence a naive measure based on our own pocket universe is unacceptable.

I'm no physicist or expert of any kind, but doesn't point 1 completely undercut the conclusion reached in point 3 here? At any given point in time, Alan Guth's observation that he has continued to observe a coherent world over the previous five seconds, or two weeks, or 62+ years, can only be based on what he can recall of that stretch of past time. But if what he remembers, or thinks he remembers, is a function only of what his present brain-state is … and if (by point 1) that brain-state is (barring some extra constraint) more likely a product of fluke than the kind of environment and life history which his brain state tells him that he has … then what reason does he have to trust his recollection of experiencing a normal world over the past however-long? His recollection doesn't let him conclude a suitable extra constraint exists, because his recollection itself requires the existence of such an extra constraint to be a reliable witness to that effect (or to almost any effect).
And it obviously doesn't work for him to say "aha, I'll settle this through experiment, by waiting five seconds to see if I still exist and life continues as normal during that time". At the beginning of the five seconds the results of the experiment are of course not in yet. At the *end* of the five seconds, the results may be in but now he's facing the equally uncertain question of whether his last several seconds of remembered past, including the decision to test his Boltzmann-brainness by waiting five seconds, were fictitious or not!

22. **Peter Woit**
October 20, 2014

anonymist,
The "Boltzmann brain" business was a hot topic in certain circles six years ago, see for instance
http://www.math.columbia.edu/~woit/wordpress/?p=836

I don't think anything worthwhile ever came out of that debate, and it seems to have died out for very good reason. I have no idea why Guth is reviving it.

All: please don't try and revive this debate here. The probability of anyone having anything interesting to say about it at this point seems to me to be about the same as that of a Boltzmann brain popping into existence.

Thank you PW.
I have enjoyed very much over the last several days (1) delving into where the Natalie Wolchove Tracey-Widom article have lead me and (2) reading of Lakatos' ideas in philososphy of science (was pretty much ignorant of them before this).

Yet More News

October 24, 2014
Categories: Uncategorized

- Charlie Munger, the billionaire business associate of Warren Buffett, has donated $65 million to the KITP at UCSB for the construction of a residence for visitors. For more on this, see a UCSB story, a New York Times article, and for some background, 90-year old Munger's explanation that "I won't need it where I'm going".
- On the other coast, today and tomorrow at Princeton there will be a workshop on string cosmology and inflation. They have a list of questions to be addressed, including

  > Are there any plausible alternatives to string/M-theory as a fundamental theory of physics?
  > …
  > Does string theory make any cosmological predictions? Does it exclude anything?

  As far as I can tell, there's an odd consensus set of answers to these two questions among string theorists. No, string theory makes no predictions about cosmology, but also no, there are no alternatives.

- For an interesting discussion of the problems raised by this sort of "no possible predictions, but no alternatives" situation, see this debate involving John Horgan, David Tong and Tara Shears. Horgan does a good job of pointing out the problem. Tong's defense of string theory relies heavily on claiming that it is highly mathematically rigid, so mathematical consistency is what can give us faith in it. One problem with this is that the whole string theory landscape picture is an extremely ill-defined conjectural framework, the opposite of mathematically rigid. Yes, there are parts of string theory that seem to be mathematically consistent and lead to interesting results. The problem is that those have nothing to do with what is observed about fundamental physics.
- Jim Gates has an article about Sticking with SUSY, despite no evidence from the LHC. He explains that the thing he finds most convincing about SUSY is the cancellation in divergent vacuum energies between fermions and bosons (or at least that's how I interpret his comments). I'm actually somewhat in sympathy with this. One thing I've been writing about in my quantum mechanics notes is the beautiful parallelism between "bosonic" and "fermionic" quantization. A fundamental theory needs both, and likely has some super-algebra of symmetries acting on it. I just don't though see a good argument for the realization of this general idea in terms of the standard kinds of extensions of the Poincaré algebra to a superalgebra. These don't appear to tell us anything about physics we know about, and predict physics we don't see.
- I was hoping to have time last Sunday to see a discussion at the French Embassy between John Nash and Cedric Villani, part of their Festival Albertine. Unfortunately I ran out of time to do this, but luckily for you and me, video is available here.

Comments

1. **Lee Smolin**
   October 24, 2014

   Dear Peter,

   If the conferees want an answer to the question "Are there any plausible alternatives to string/M-theory as a fundamental theory of physics?" they ought to invite some of the people contributing to the development of such alternatives and have an honest examination of the question. They have plenty to choose from, they could start with the speakers at Loops 13, which 200 people attended: http://www.pirsa.org/C13029.

   Fifteen or twenty years ago it was possible to say that string theory was more promising than its alternatives, and indeed 15 years ago I switched my research from LQG to M theory. But I think that any objective evaluation of the evidence has to credit much more substantial progress has taken place since concerning the alternatives; especially spin foam models, but also other background independent approaches including shape dynamics, CDT, group field theory and tensor models, etc.

   To support this I would point to the fact that much more is known from spin foam models about the challenges it faced 15 years ago, including substantial recent results on the emergence of GR in the semiclassical limit, the entropy and temperature of generic black holes, the elimination of cosmological and black hole singularities, finiteness, etc.

   So, I would urge my string theory friends who think they know the answer to the question to have another look. There is a whole generation of brilliant young theorists working on alternatives to string theory you should meet!

   Thanks,

   Lee

2. **Marty Tysanner**
   October 24, 2014

   The Horgan/Shears/Tong debate was interesting, but I found the some of the reasoning (especially by Tong) to be wanting. A few examples:

   1. Mathematical consistency as a pillar of science (experiment being the other): Tong argued the internal consistency of string theory should be taken as significant evidence for it even without experimental evidence. The obvious problem he ignored is that mathematical/logical inference is only useful in physics if the starting *physical* assumptions are correct. Even if string theory were completely consistent mathematically, to justify his argument Tong would need to show that its underlying assumptions are uniquely implied by observations, a task that isn't humanly possible. (One can't exhaust all possible alternatives — that requires unlimited creativity and time to propose and carefully work out all possible theories and their consequences.) Experimental evidence of deduced consequences of his favored theory is *mandatory* to help validate its initial assumptions — "pure thought" doesn't cut it.

   2. Tong argues for the proposal of atoms in the 18th century as an example of "pure thought" that only later was shown true experimentally. Atoms were proposed as a possible way of explaining concrete observations — the idea was driven by unexplained observations, not "pure thought." Is Tong suggesting that any newly proposed model that attempts to explain new phenomena, but only later is supported observationally, supports a conjecture that his favorite quantum gravity theory will someday have concrete observational evidence specific to that theory?

   3. Dark energy. The moderator tried to point out the distinction between excellent *observational* evidence of accelerated expansion of the Universe, and the *theoretical* nature of conclusions that it is due to dark energy. Tong insisted the acceleration must be caused by dark energy because GR predicts the acceleration if dark energy is inserted (i.e., as a cosmological constant in Einstein's equations); therefore "dark energy" is not just a theoretical conclusion. He overlooks that, while observations are *consistent* with a c.c., they don't demonstrate (yet, at least) that the acceleration is uniform everywhere and that therefore dark energy is the *only* plausible cause. The Lambda-CDM "concordance model" hasn't yet attained an observational status that makes it unassailable…

3. **Art Brown**
   October 24, 2014

Thanks much for the link to the Festival Albertine video. I had hoped that the topic of “style” might form a bridge across the chasm between hi-level math and the rest of us, but that organizing principle damped out in the first half hour or so (to re-emerge, it is true, in the final question on the math “lab” vs solo work).

I was surprised that Dr. Villani appeared to downplay the role of intuition in guiding his work; I had thought that quite important, and look forward to his book to learn more. (I suppose that also qualifies as “style”, so maybe the topic was more successful that I at first thought.)

Two trivial notes:
1) Was that a large spider lapel pin I glimpsed from time to time on Dr. Villani’s jacket?
2) Microphone technology seems stuck in the 20th century: if you aren’t within licking distance, it’s useless.

Unrelated and Classical: In the area of “Amazingly Correct Pop Science”, Kip Thorne has been tasked by Warner Brothers to come up with a visually correct Black Hole. Disregard the default “the feels” music:

Interstellar – Building A Black Hole – Official Warner Bros.

5. **amused**
October 25, 2014

I expect that alchemy had a good degree of `mathematical consistency’ too, back in the day when heavyweights such as Isaac Newton and Robert Boyle were working intensely on it.

6. **David**
October 25, 2014

Dear Peter,

Can we find the slides or videos of the workshop of string cosmology and inflation at Princeton?

7. **Peter Woit**
October 25, 2014

David,
Sometimes someone posts slides and/or videos of talks at these PCTS workshops after they’re over, sometimes not. It’s still going on, so, wait and see. Most likely they would be posted at the workshop website
http://pcts.princeton.edu/pcts/StringOpen2014/StringOpen2014.html

8. **Jesper**
October 25, 2014

Dear Lee

could you provide links/references to the recent results you mention on emergence of GR in a semi-classical limit?

Thanks

9. **Lee Smolin**
October 25, 2014

Dear Jester,

There are many papers which discuss the emergence of GR from spin foam models; here is a small selection of them, in no particular order.

http://arxiv.org/abs/1108.2258, http://arxiv.org/abs/1304.5626, http://arxiv.org/abs/1109.6538, http://arxiv.org/abs/1308.4063, http://arxiv.org/abs/0809.2280, http://arxiv.org/abs/0902.1170

Thanks, Lee

10. **vmarko**
October 26, 2014

Jesper, Lee,

Just for completeness, there are also some criticisms regarding the way GR emerges from spin foam models (and ways to get around that). See for example

arXiv:1307.5352, arXiv:1104.1384, arXiv:1111.2865, arXiv:1201.2187.

11. **Bob**
October 26, 2014

Dear Lee,

Thanks for those paper references. They look interesting. I have a question for you. LQG, spin foams, etc., are characterized as a quantum theory of pure gravity, without matter and matter interactions. Can you discuss the ways in which Loop Quantum Gravity addresses the criticisms that quantum gravity needs to unify gravity with the other interactions because gravity cannot be decoupled at Planck scales from all other interactions (if there are any) at Standard Model, and higher, energy scales? Thanks very much!

12. **Oregonator**
October 26, 2014

I can’t make sense out of Nash’s 4th order gravity equation. The Lagrangian is that of conformal gravity except that he has replaced the 1/3 by a 1/2. Why ?

13. **Lee Smolin**

October 26, 2014

Dear Bob,

Actually there is a moderate sized literature on matter coupling and unification within LQG. To summarize, let me emphasize that there are several different questions.

1) It is just not true that "LQG, spin foams, etc., are characterized as a quantum theory of pure gravity, without matter and matter interactions." From very early in its development, it was worked out in detail how to include gauge fields, fermions and scalars in LQG. For example, see Thomas Thiemann's book.

2) Extension to supergravity is also straightforward, at least for N=1, including D=11. See papers by Yi Ling and myself as well as recent papers by Thiemann and collaborators,

3) Hence, even if LQG doesn't constrain the matter or gauge field content of what it is coupled to, LQG provides a framework in which matter gauge fields and gravity are all coupled together.

4) There are issues that need to be addressed with fermion doubling which are the subject of work in progress with Jacob Barnett.

5) You can ask in addition whether, "quantum gravity needs to unify gravity with the other interactions". This from a LQG point of view is an open question.

6) But you can ask if LQG gives a compelling framework for unifying the different interactions? Here the answer appears to be yes. The simplest possible extension of the theory, gotten by extending the gauge group of gravity, which is the Lorentz group, to a larger group, G, yields a natural extension of Einstein-Yang Mills. This comes about from a built in spontaneous breaking of the gauge group G to the product of the Lorentz group with a compact factor H, which becomes the Yang-Mills gauge group. See arXiv:0712.0977, older papers by Peldan and later papers by Krasnov et al. See also arXiv:1212.5246 which explores implications for a unification of the electroweak interactions with gravity.

7) Going beyond all these solid results are indications that the chiral fermions of the standard model may emerge from topological excitations of spin network states, arXiv:hep-th/0603022.

Clearly there is much still to do in this direction, but these are sufficient to assure us that LQG provides a framework within which to describe matter and gauge fields coupled to quantum gravity which can suggest hypotheses as to further unification.

Lee

14. **Noboru Nakanishi**
October 26, 2014

Dear Peter,

SUSY is an unnatural symmetry when gravity is taken into account, because the local version of translation group already include Lorentz group. Indeed, in the Einstein gravity, the local Lorentz group is completely disconnected from general coordinate transformation group. This situation cannot be resolved by considering supergravity, in which the Poincare symmetry becomes internal symmetry and therefore quantum supergravity necessarily becomes inconsistent with SUSY in the sense that the anticommutator between two supersymmetry generators cannot yield the translation generator.
I think it more natural to supersymmetrize the local Lorentz symmetry alone. Since its Lie algebra is sl(2, C), its natural "super"extension is the orthosymplectic superalgebra osp(N,2; C).

15. **Marc**
October 27, 2014

Kaku still keeps on spreading the message (to the public, unfortunately) that string theory is the only game in town.
https://www.youtube.com/watch?v=fV1eAAvAQVc (4:50)

16. **Aleksandar Mikovic**
October 27, 2014

Dear all,
The exact statement regarding the classical limit of a spin-foam model is that it is given by the area-Regge theory (see arxiv:1104.1384) whose geometry is different from the the usual Regge discretization of General Relativity (these geometries are known as the twisted geometries, see arxiv:1308.0040). A natural way to solve this problem, as well as the problem of coupling of fermionic matter to a spin-foam model, is to introduce explicitly the edge lengths into a spin-foam model, which can be done generalizing spin-foam models by replacing the symmetry group (Lorentz group) with a 2-group (Poincare 2-group), see arxiv:1110.4694 and arxiv:1302.5564.

    Thanks Hendrik,
    That required its own blog posting…

Breakthrough Prize Ceremony

October 29, 2014
Categories: Uncategorized

There's a story in Variety this afternoon announcing that Seth MacFarlane will be the host this year for the ceremony in Silicon Valley announcing the 2015 Breakthrough Prizes. MacFarlane was the host of the 2013 Oscars. Other celebrities there to award prizes will include Kate Beckinsale, Benedict Cumberbatch, Cameron Diaz, Jon Hamm and Eddie Redmayne. The ceremony will be televised, not live, but November 15 at 6pm on the Discovery Channel.

The announcements that evening will include awards of up to 6 $3 million prizes in the life sciences. The physics prizes this year, funded by Yuri Milner, will include a $3 million prize and one or more $100,000 prizes for young researchers. The past practice of awarding $300,000 to semi-finalists for the $3 million seems to have been stopped, after Joe Polchinski collected a couple of these. Polchinski seems to be the odds-on favorite for the $3 million this year. Another possibility would be Strominger and Vafa, also semi-finalists last year. I suppose there's an outside chance that the committee making the choice, which is dominated by string theorists, will decide that a non-string theorist is worth recognizing.

The Mathematics prize is funded by Milner and Mark Zuckerberg. The winners there are already known, see here.

The next day there is an announced symposium scheduled to be held at Stanford to honor the prize winners in the life sciences (see here). Last year there was a similar symposium in physics right after the ceremony, so one could guess that such things might be planned for physics and math as well.

Update: There will be separate math and physics symposia on Monday, and an evening lecture from the Physics winner. A little more detail here. The math symposium will be at Stanford, live-streamed to Berkeley, Stanford details and RSVP here.

Comments

1. **Per**
   October 29, 2014

   These prices are such nonsense. Why give it to some dinosaur who's been faculty for well over a decade and already won a bunch of prices? Better to focus on the young and upcoming and help them focus solely on research without any economic concerns.

2. **Michael Hutchings**
   October 29, 2014

   There will be a math symposium at Stanford on Nov 10. However I can't find a website for it.

3. **abbyyorker**
   October 29, 2014

   Quite a break from the past. The 1938 Breakthrough prizes were hosted by Seth Niedermayer.

   October 29, 2014

   I'll never complain (much) about scientists getting more money, but I can't for the life of me understand how larding up the event with a bunch of celebrity eye candy is supposed to draw the kind of public interest anyone would want.

5. **martenvandijk**
   October 30, 2014

   Breakthrough Prize 2015? Breakthrough Credit 2015 if you ask me.

6. **Yaakov Baruch**
   October 30, 2014

   Sorry – I don't want to hijack the thread with this totally unrelated link:
   http://www.realclearscience.com/blog/2014/10/lhc_outdone_by_tabletop_electron_experiment_108918.html
   I'm only posting it in the hope that Peter, and others, may comment on this subject at some future time within an appropriate post.

7. **Peter Woit**
   October 30, 2014

   Yaakov,
   That's not really news, so I don't want to start a discussion of it here. Note that the graphic in that story shows that "naive SUSY" was already ruled out by this kind of experiment back in 2002, long before the LHC. The fact that these kind of precision experiments rule out popular SUSY models has always been ignored by SUSY enthusiasts, and I suspect will continue to be ignored by them, no matter how good the bounds get.

8. **Als**
   October 30, 2014

   Tao is going to appear on Colbert according to this article in the Atlantic : http://www.theatlantic.com/education/archive/2014/10/when-your-teacher-is-a-celebrity/382029/

9. **CPV**
   October 30, 2014

   What would have a higher effect – 3 mm to one awardee, or 100k to 30? I think very, very few people who make large contributions to math and science go in it for the money. These prizes aren't going to improve the level theoretical science occurs at. Progress hasn't stalled because theorists aren't working hard enough or there aren't enough of them or they can't make 3mm a year. It might be nice to boost salaries to 100k /yr for postdocs but I bet that wouldn't make much difference either. Progress has stalled because of scale ratios like 10^30.

10. **Jim**
    October 31, 2014

    Seems an odd choice of celebrities. I could understand a Natalie Portman (with a finite Erdos number) or even a James Franco as a presenter but I can’t understand what Cameron Diaz has to do with science.

11. **Simple biologist**
    October 31, 2014

    @Jim

    Cameron Diaz was at least one of the quests on that evangelical science+atheism film about Lawrence Krauss & Richard Dawkins. Quick googling also reveals that she describes herself as ‘science nerd’.

    Propably easy picking (as far celebrities are concerned) for the organisers.

12. **Jonathan Miller**
    October 31, 2014

    I work about 20 hours less per week than I would prefer, in part due to low pay. I expect that there are others like me, more pay being available for young physicists might improve physics productivity.

News, Interesting and Otherwise

November 3, 2014
Categories: Experimental HEP News, Multiverse Mania, Uncategorized

On the side of interesting good news, I just heard that yet another Fields Medalist has a blog. This time it's David Mumford, who is blogging here, with his latest posting about path integrals.

His website contains a wealth of other very worthwhile material, including copies of pretty much all of his papers, some of which had been quite hard to find. Much of Mumford's career has been in the field of algebraic geometry, where he is a towering figure for mathematicians working during the past few decades. This is not just due to his ideas, but also to his expository talents, which have made many of his monographs and papers the standard place young mathematicians have gone to learn parts of the subject.

Michael Schmitt's Collider Blog is not new, but it's great to see that after a period of relative quiet he's been very active there. His postings from the last couple months give some great detailed explanations of recent news from HEP experimental analyses.

The news from Mochizuki is that there will be a workshop in March on his work, with proceedings to be published. Go Yamashita will be giving two weeks of lectures there. One can hope that this is good news, in that it promises the possibility of an exposition of Mochizuki's claimed proof of the abc conjecture that will allow other mathematicians to finally understand it well enough to evaluate it.

On the much less interesting news front, multiverse mania continues. Much of this mania seems to have to do with people's fascination with the idea of different copies of themselves doing somewhat different things an infinite number of times elsewhere. I fear that in my case the multiverse is just causing me to do the same thing an infinite number of times in this universe, which is really tedious. In any case, latest developments are:

- Nathalie Wolchover and Peter Byrne have a new piece at Quanta: In a Multiverse, What Are the Odds?, which leads with the news that "the multiverse camp is growing", while headlining the obvious "measure" problem that you can't calculate anything with the idea. Paul Steinhardt is quoted as saying

  > The multiverse idea is baroque, unnatural, untestable and, in the end, dangerous to science and society.

  which is about right, but the rest of the article is mostly dubious claims from the multiverse promotion crowd. More to come next week, looks like the usual bubble collision business.

- Ars Technica has a report on last week's debate in Brooklyn about the multiverse. Tegmark was on the pro-multiverse side, Wilczek on the anti-side, Janna Levin in the middle. According to the reporter

  > Overall, Wilczek seemed to get the better of this part of the debate.

  Much of the debate seemed to be about the "Many Worlds" interpretation, with Wilczek describing this as an empty idea: "metaphysical baggage added on", and Tegmark rather enthusiastic about this kind of thing. On the cosmological multiverse, I gather Wilczek's attitude wasn't so much negative as that it was too speculative to be interesting.

- What started this multiverse obsession among prominent theorists was the work by KKLT and others supposedly showing that you could get the right cosmological constant in string theory, but that when you did so you ended up with an exponentially large number of possibilities and a likely loss of any predictivity. At the time I thought that was the end of that line of thought in string theory, but instead it turned out to be the beginning of the bizarre period of multiverse mania we now live in.
  The latest news is that KKLT doesn't actually work, that you can't get stable string vacua that way. I don't think though that this will have any effect on multiverse mania and its use as an excuse for the failure of string theory unification. It seems to me that we're now ten years down the road from the point when discussion revolved around actual models and people thought maybe they could calculate something. As far as this stuff goes, we're now not only at John Horgan's "End of Science", but gone past it already and deep into something different.

Comments

1. **Amused**
   November 3, 2014

   "The latest news is that KKLT doesn?t actually work, that you can?t get stable string vacua that way."

   Are the results of that paper generic, or do they only apply to a specific set of models? Just reading the abstract makes it seem like it's the latter, though I'm definitely no expert on this stuff.

2. **Amused**
   November 4, 2014

   Peter,
   "I don't know" is an acceptable answer.

3. **Peter Woit**
   November 4, 2014

   Amused,
   Sure, I'm no expert and don't know. But I mentioned this because I heard from someone much better informed than me about it, and they believed it was significant (i.e. it's not that there are other known ways of doing this). I'm hoping someone better informed will comment here about this. One reason I haven't looked into this more is that it seems to me that virtually no string theorists any longer care about the technical issue involved. Maybe some commenters will show up to prove me wrong…

4. **Peter Woit**
   November 4, 2014

   Amused,
   If you want something amusing about this, see Lubos's blog, where he picked this up from me. An expert on the problems with KKLT has written in to complain about "the lack of scientific attitude of some members of the string pheno community". It seems that string theorists trying to examine the problems of KKLT get something like the response to anyone pointing out problems with string theory. In this subject now, as I suspected, it's all about the politics of defending an ideology, no longer about

science.

5. **lazyman**
   November 4, 2014

   "The latest news is that KKLT doesn't actually work, that you can't get stable string vacua that way."
   Well, not in this universe, but there are infinitely many other universes where it does work! 😉

6. **Curious Mayhem**
   November 4, 2014

   The multiverse idea is baroque, unnatural, untestable and, in the end, dangerous to science and society.

   It may also rot your teeth. Being unnatural, it's undoubtedly outlawed in some states.

7. **bombom**
   November 5, 2014

   A side benefit of "multiverse mania" is that the ironic phrase "In what universe?" seems to have entered the lexicon. (Thanks, perhaps, to Sheldon??)

   Peter, I think the real reason for the popularity of the multiverse is for people to imagine that in at least one of them, string theory is right.

   (And that in at least one other, "they" received the Milner prize…)

This Week’s Hype

November 3, 2014
Categories: Quantum Mechanics, This Week's Hype

From commenter Hendrik, there’s the news that USC has put out a press release claiming that String Theory Could Be the Foundation of Quantum Mechanics. These claims are based on this paper, which argues that finding the Heisenberg commutation relations in a string field theory calculation means string field theory can be the foundation of quantum mechanics.

In my quantum mechanics course this semester, I’m now up to around chapter 13 or so of the notes available here. Last class I was pointing out that one already sees the Heisenberg commutation relations in classical Hamiltonian mechanics. The functions on phase space are a Lie algebra, satisfying commutation relations given by the Poisson bracket. These relations are determined by knowing what happens on linear functions, together with the Leibniz rule. On linear functions, the commutation relations are Heisenberg’s.

So, I think the discovery out of USC is an even greater one: string field theory can explain not only quantum mechanics, but classical mechanics too.

Update: I should have realized that this thing already had one wave of hype earlier this year, courtesy of Tom Siegfried, which I wrote about here. This new wave comes courtesy of Physics Letters, which thought this worth publishing, and USC, which thought a press release was a good idea.

Comments

1. **Bob Jones**
   November 3, 2014

   You know, string theory actually is quite important for understanding the (mathematical) foundations of quantum mechanics:

   http://arxiv.org/abs/0809.0305

   http://arxiv.org/abs/q-alg/9709040

   It’s a shame that serious ideas like this hardly ever get discussed on this blog.

2. **Peter Woit**
   November 3, 2014

   Bob Jones,
   There has been some blogging here about the mathematical foundations of quantum mechanics. I’ve been teaching and writing about the topic, expect more blogging, this spring a finished draft of a book, and more to come after that. Sorry, but claiming that those two papers you reference show that string theory is important for understanding the foundations of QM is utter hype. I don’t believe the authors of those papers would agree with that claim.

3. **Bob Jones**
   November 4, 2014

   Peter,

   I’m glad to hear that more serious content is on the way.

   Regarding the papers I mentioned, the formality theorem proved in the second one is really one of the most fundamental results in the mathematical theory of quantization. I don’t think I’m exaggerating when I say that string theory is important here; in the second paragraph, Kontsevich himself writes, “The solution presented here uses, in an essential way, ideas of string theory”.

4. **Peter Woit**
   November 4, 2014

   Bob Jones,
   Actually, it seems to me that all Kontsevich is really saying is that in order to prove a certain technical conjecture, he used calculational techniques developed in studying topological string theory (which has nothing to do with physical string theory). He then writes the proof without using any string theory. Quite interesting work and great mathematics, but, sorry, “string theory actually is quite important for understanding the (mathematical) foundations of quantum mechanics” is just hype.

5. **Bob Jones**
   November 4, 2014

   Ah, so mathematical work on two-dimensional sigma models and topological string theory doesn’t count as string theory. Got it.

Last Week’s Hype

November 3, 2014
Categories: This Week's Hype

When looking at the nonsense spread around the media by this week’s university press-release-driven hype about string field theory “explaining quantum mechanics”, I realized that maybe I shouldn’t have ignored last week’s university press-release-driven hype, which was about the multiverse “explaining quantum mechanics”. For that one the press release is [New quantum theory is out of this parallel world] and the paper is [here]. It has generated all sorts of press stories, with a typical example [Parallel Universes Exist – And Could Explain All Physics, Says Griffith University Study].

Sharing the credit or blame for this with the Griffith University press office is the APS and its Physical Review X, which published the paper [here]. The APS Editor in Chief explains [here] that

> In recent years, however, we have seen a strong need of some researchers to have their best scientific contributions published in highly selective and small journals that can disseminate those contributions broadly and offer them high visibility.

The idea seems to be that if you want “high visibility”, and you’ve got $1700 to pay for it, Physical Review X is there to get you into the media. They seem to have realized though that maybe the “parallel worlds explain quantum mechanics” might be seen as going too far, so have put out an [editorial justifying its publication].

Comments

1. **Matt Leifer**
   November 3, 2014

   Your criticism of PRX seems a little bit harsh to me. The APS have decided to adopt PRL-like standards for PRX. This has resulted in PRX getting a higher impact factor than PRL in the last couple of years. The 2014 numbers are:

   PRX: 8.385
   PRL: 7.728

   To me, it can only be a good thing that the top ranked journal in physics is no longer one with a ridiculous page limit. Hopefully, the most important papers in physics will now be easier to read and better explained.

   Of course, the APS does media promotion for articles published in all of its journals, and it should be no surprise that they put more effort into this for their top titles like PRX and PRL. Science journalists are also aware that these are the top journals, so they pay more attention to stuff that appears in them. It should also be no surprise that they are liable to pick up on anything that mentions parallel words or the multiverse. You can’t blame the APS for the fact that this paper got more attention than other things that appeared in the same journal.

   PRX is not a journal that the APS have set up just to be a fast track into the media for a fee. It is simply a that adopts PRL-like standards, and hence gets more media attention, that also happens to be gold open-access. We can argue about the merits of gold, author-pays, open access, and we can argue about whether this particular paper ought to have been published in PRX. We might even find ourselves agreeing on these issues to some extent, but to lambast PRX over this one paper seems a bit of a stretch. The impace factors speak for themselves. Physicists are paying attention to what appears in this journal, and I don’t think they are being swayed by what gets media attention.

2. **Peter Woit**
   November 3, 2014

   Matt,
   Thanks. Perhaps you’re right that I’m being somewhat unfair. I do think though this shows the danger of where you can end up if you emphasize “high visibility” and have an “institution pays” model. If I were an author who publishes in PRX I’d be kind of unhappy to see this stunt, and I wonder if the editor is hearing about it.

3. **Neil**
   November 4, 2014

   I love that they are invoking Feynman. I can well imagine what he would think of this.

4. **Maurice Carid**
   November 4, 2014

   Hi Peter,
   implicitly you call their paper “nonsense”,
   can u tell us why u think so?
   You yourself expressed unease with the
   foundations of QM, so what’s wrong when these guys
   make a proposal to clarify them on the level
   of new physics rather than philosophy?
   I found the paper’s arguments quite sound
   on a technical level, and
   their theory clearly can be tested
   against experiment (for a finite
   number of worlds). Also, what exactly
   is wrong on a technical level with the press
   releases? To me it seems that they give
   a fair popular account of the paper and make
   no other exaggerated claims.
   cheers Maurice

5. **Bernd**
   November 4, 2014

I’ve heard that PRX is burning money at a crazy rate because they’re not publishing enough papers to meet their costs, so expanding their mission to fringier stuff might be a step to generate more income.

And if the editorial tells us anything, it’s that they’re not following PRL standards as PRL would not publish a manuscript that merely contained “new ways of looking at things”.

6. **Als**
November 4, 2014

I think you’re being unfair. The press misleading titles are annoying, but the article itself is fine.

7. **Peter Woit**
November 4, 2014

Maurice/Als,
I’ve already wasted more time on this than is wise.

8. **Shantanu**
November 4, 2014

I am afraid standards of PRL have also gone down. I don’t understand
why PRL still publishes upper limit papers (for experimental papers).

9. **Narad**
November 4, 2014

> I’ve heard that PRX is burning money at a crazy rate because they’re not publishing enough papers to meet their costs, so expanding their mission to fringier stuff might be a step to generate more income.

It is unclear to me how well such a strategy would advance the stated goal of “diversify[ing] the Journals’ revenue stream” in the long run.

10. **upper limit**
November 4, 2014

Why shouldn’t PRL publish papers establishing upper limits, for example for the neutron electric dipole moment?

11. **Peter Woit**
November 5, 2014

Narad,
That document makes clear the issue here. It points out
“APS rejects ~18,000 articles each year. At $1500 each, this is a tempting potential revenue stream of $27,000,000”
It goes to on to emphasize commitment to high standards. The problem is though that from the APS point of view accepting rejected papers and collecting $1500 for them IS tempting, and the collision of hard cash and intellectual standards isn’t always going to leave intellectual standards coming out on top.

12. **Narad**
November 6, 2014

> The problem is though that from the APS point of view accepting rejected papers and collecting $1500 for them IS tempting, and the collision of hard cash and intellectual standards isn’t always going to leave intellectual standards coming out on top.

Sure, but I don’t think that turning into, say, *Medical Hypotheses* would work in the long run, especially with a shiny 8.463 IF at stake. It doesn’t even seem to be a case of the “portable peer review” that Springer was using to auto-shunt rejections into its OA operation, even if that was an idea for *PRX* in the early stage (as well as perhaps competing with *NJP*, an idea I’ve seen floated).

Then again, there’s no accepted date on Hall et al. (and that $1700 isn’t buying competent typesetting, given Eq. [25] in the PDF, but perhaps *PRL* is just as bad). There *is* the October 9 “PRX Takes on a New Role” announcement, though. Time will tell.

13. **srp**
November 6, 2014

The strategy problem for an author-pays journal with high initial prestige is analogous to that facing luxury product brands such as Hermes or Fendi. Such a brand is usually prestigious partly because it is somewhat exclusive. But a successful brand of this type always faces the temptation to make a short-term killing by surging production and reaping large margins on those sales until the market realizes that exclusivity has disappeared. After making this killing, though, the brand’s prestige drops very low and it may have to lie fallow for a long time before it can be rebuilt. That’s pretty much the story of Cartier. (Actually this can happen in the mid-market, too. In the late 1970s and early 1980s Izod became a cultural phenomenon with the publication of The Preppy Handbook, and they responded by putting that crocodile logo on a flood of product that cascaded into down-market channels.)

Could APS play this game?

Hollywood Theoretical Physics Week

November 5, 2014
Categories: Film Reviews

Just got back from an opening night showing of the new sci-fi film Interstellar at the Ziegfeld theater here in New York. If you want some idea of what the film is about, trailers are here and here. Warning: spoilers in next paragraph, skip that if you care.

To me the big plot surprise was that the human race is saved by the theoretical physicist. An elderly theoretical physicist has been trying to solve some equation for gravity his entire career. If he solves it this will somehow save the human race (which has just about ruined its planet). Turns out, he wasn't being honest, he knew how to solve the equation, but to save the planet, you need to reconcile quantum theory and gravity. Only way to do this is to go into a black hole and get the "quantum data". Dad (Matthew McConaughey) does this, then manages to transmit the "quantum data" via Morse code to his daughter, a theoretical physicist who has taken over from the old guy, who has died. She uses the "quantum data" to write something on the blackboard that flashes by (maybe a 10d gravitational action), this somehow saves the human race. Before we get to this point, lots of plot involving going through a wormhole (looks kind of like what going through a wormhole always looks like), and various time spent on exotic planets orbiting a black hole.

The black hole portrayal is one that great effort went into on the accuracy front, with Kip Thorne involved. He and the film's director have a book coming out Friday, The Science of Interstellar, and there's a TV documentary about the science behind the movie. Evidently this film has been in the works for a while: John Preskill tells the story here of a 2006 meeting with Steven Spielberg to discuss the film, also attended by Andrei Linde, Lisa Randall, Savas Dimopoulos, Mark Wise and Thorne.

Anyway, I enjoyed the film, even though I'm not usually a big fan of sci-fi films.

Opening in a few days is another major Hollywood effort centered around theoretical physics, quantum gravity and black holes: the Hawking biopic, The Theory of Everything. A trailer is here. I'll probably see that this weekend and will report back.

For yet a third Hollywood-type event opening this week and featuring a theoretical physicist, quantum gravity and black holes, see this trailer. You can watch this Thursday night, more info here.

Finally, it's not really Hollywood unless you have an awards ceremony featuring Hollywood stars. This Sunday night, some lucky string theorist will get a $3 million check for his work on quantum gravity and black holes. Seth MacFarlane is hosting, more details here. From what I recall, the argument for setting up this huge prize for theoretical physicists was that they don't get enough public attention…

Update: I hadn't noticed that there's another film opening this week featuring theoretical physicists, The Principle, with trailer here. I wrote a bit about this early this year here.

Update: Phil Plait really doesn't like the film, finding much of the plot scientifically implausible. Of course he's right about that, but it makes one wonder if he has seen many sci-fi films. From my limited experience, this one is about average on the implausibility meter.

Comments

1. **Tim Howells**
   November 5, 2014

   Re Realism and black holes: I was struck by a question made to Leonard Susskind after his talk on the great "Black Hole War" he had with Hawking.

   http://www.youtube.com/watch?v=KR3Msi1YeXQ

   Susskind had elaborated at length on information theoretic properties of black holes – how all the information within a BH is projected as a holographic representation onto its spherical outer surface; How a paradoxical interpretation allows that somehow information both can and cannot escape from a BH (or something like that). etc etc etc.

   Then someone asked "How confident are you that black holes exist?" Great Question! Susskind hemmed and hawed and finally said, "Well most great physicists believe they exist, and very few do not believe, so It would be really surprising to find out that they did not exist …".

   My interested layman's take-away was that this is just more madness.

2. **dr. kansas**
   November 5, 2014

   perhaps the most remarkable thing of the film was not one mention of string theory not the multiverse nor inflation.

   i guess they wanted to make it as plausible as possible, and thus the filmmakers were operating under greater constraints than academics.

3. **Grad Student**
   November 5, 2014

   yes indeed. imagine if one of the characters would have invoked the multiverse or the stringy landscape or parallel worlds or the many-worlds theory.

   Matthew McConaughhey: The world is going to end.

   Anne Hathaway: Do not worry, as it is just our world. There are infinitely more worlds that are not going to end, in which the crops are doing just fine. For you see, everybody splits into multiple independent worlds with every decision.

   Matthew McConaughhey: Oh OK.

   THE END

   Thus while, the movie would have ended there, in our world the multiverse movie has no end in sight.

4. **Yatima**
   November 5, 2014

It’s 2014, but then!

“How confident are you that black holes exist?”

This is on the same level as “How confident are you that the world is not 3000 years old” or “How confident are you that P is not NP?” though.

Pretty confident.

Classical GR never lets you down.

If there was any hemming and hawing, it was because of the scientist’s customary bashfulness. An individual with Neil Armstrong tendencies would just have facepunched the questioner, then gone on to the next question.

5. **CFT**
November 5, 2014

Once upon a time fissile nuclear radiation was the rage. It caused ants and angry women to grow fifty feet tall, and nonplussed fifty story tall lizards to eat Tokyo, and gave nerds glowing eyes and superpowers in comic books and b-rated movies.
*
Now we have black holes and worm holes. They allow cosmic space babies to pop out of creepy dark monoliths, empower red satanic floating cyclopean robots to go crazy, and provide nerds with FTL interstellar travel in comic books and b-rated movies.
*
While the special effects and CGI eye candy for the plot devices have improved dramatically,
The scientific aspects of the stories are as tenuous and mediocre as ever.

6. **Oldster**
November 5, 2014

Yatima: I realize it’s a trivial point, but wasn’t it Buzz Aldrin who facepunched somebody, not Neil Armstrong?

7. **Grad Student**
November 5, 2014

Serious question here.

Has a black hole every been directly observed? I am fairy certain a wormhole has never been directly observed.

I just googled “black hole observation” and found numerous press releases and PR claiming their existence and direct observation thereof.

I also read the recent news that a UNC Professor has proven that black holes cannot exist, which also got a lot of press.

Well, if they have been observed for sure, as thousands of sites state, then how can thousands of other sites state that a UNC Professor has proven that they do not exist?

Does anyone have any more insight on this?

Have black holes been observed?

Are there photos from the hubble?

8. **Peter Woit**
November 5, 2014

Grad Student,

It seems to be uncontroversial that there’s a black hole at the center of the galaxy. You can observe orbits of objects nearby, and there’s something there exerting a gravitational force of million of solar masses, while at the same time not itself radiating, so if that’s not a black hole, it’s something very much like one. To the extent there are controversies over black holes, I think it would be more accurate to describe the controversy as about exactly what their properties are.

As for believing something because internet sites quote a professor saying it, surely you know better…

9. **Igor Khavkine**
November 5, 2014

Clearly, the new biopic about Hawking spans a larger time period than this older one from BBC, as well as having a much larger budget. I wonder if it will do anything much differently. The BBC one actually contained some math and physics, in a decently correct way. On the other hand, I doubt that either one nails all the personalities involved.

10. **Gus Bici**
November 5, 2014

I’m looking forward to seeing Larry & Max & Michio in this movie:
http://pressreleases.religionnews.com/2014/10/30/highly-anticipated-documentary-principle-opens-chicago-multiple-sold-screenings/

Cool trailer, Larry with eerie green backlighting.

11. **Peter Woit**
November 5, 2014

Gus,
Thanks for the news, I’ll add that one to the list for this exciting week. Hope it will make it to NYC…

12. **vmarko**
November 5, 2014

Peter,

I'm curious about some more spoiler details, if you care to share. Namely, one of the talking points about the movie was that it aimed at scientific accuracy more than usual, in particular wrt. to wormholes etc.

So my question is — which of these do you think has been depicted in the movie:

(a) the Schwarzschild BH solution — which does not feature a wormhole, or
(b) the Einstein-Rosen solution — which does not feature a traversable wormhole since it is inside the BH horizon, or
(c) the Morris-Thorne solution with exotic matter — which does feature a traversable wormhole but doesn't have any properties that even remotely resemble a black hole (nothing black, no horizon, etc.)?

I mean, one cannot just draw pretty pictures of an ordinary black hole, simultaneously claim that there's a traversable wormhole inside it, and then go on to say that all this can be scientifically accurate. There was an interesting discussion regarding this over at Sean Carroll's blog, so I'm just wondering now what actually happened in the movie? 🙂

13. **Peter Woit**
November 5, 2014

(Spoiler alert, you may not want to read…)
vmarko,
In the plot, the wormhole and black hole are two different things. The wormhole is small, near Saturn. The black hole is big, it's what the planetary systems in another galaxy rotate around. The wormhole is pretty much a black spot, and when they enter it, it's exactly the same graphics as always: you're rushing down a tube-like region, random stuff going by fast on the sides, then you come out to regular space.

It's the black hole the planets rotate around that is what is supposedly more accurate than usual. Basically though, it's the picture you see here
http://www.wired.com/2014/10/astrophysics-interstellar-black-hole/
I gather this is the image that is supposed to be scientifically accurate. When our hero goes into the black hole to get the "quantum data", then it's back to the usual visual silliness, flying through various collections of luminous stuff in the dark.

14. **vmarko**
November 5, 2014

Peter,

Thanks for the info, now the whole thing makes more sense. Btw, the rendering of the black hole's accretion disc is actually not fully accurate — they have dropped the (very prominent) Doppler effects [1], because they make the resulting image too confusing for the audience. I guess that the actual realistic black hole is not what can be seen in the movie, after all. 🙂

[1] See Jean-Pierre Luminet's comments (and a fully realistic rendering of a black hole) here: https://www.facebook.com/sabine.hossenfelder/posts/10152939381329574

15. **Chris Oakley**
November 5, 2014

Re: the original topic (Interstellar), Christopher Nolan always gets my vote. I will look forward to seeing it. And if he forbade mentions of String Theory and multiple universes, it was probably on the grounds of lack of scientific evidence. What kind of crazy world are we living in when a film director takes more trouble about such things than many leading scientists?

16. **Gus Bici**
November 5, 2014

Peter, in your review of "The Principle" trailer you wrote:

"As near as I can tell from all this, without having yet seen the full film, it appears that what probably happened is the following. Sungenis decided that the anthropic principle business in cosmology supported his views, so he went and got physicists like Kaku, Krauss and Tegmark to say silly things on camera, then edited this to suit his case. Maybe the trailer is misleading, and these people actually make a cogent case against Sungenis's nonsense and for solid science, we'll see…"

Is the Earth's supposed alignment with the CMB radiation really anthropic? I mean it does not HAVE to sit on this "axis of evil". If this alignment does exist, there will have to be a non-anthropic explanation. I think "coincidence" is the current explanation?

17. **Peter Woit**
November 5, 2014

Gus,
My interest in discussing the details of the scientific arguments in "The Principle" is about the same as in discussing the details of what the stuff on the side of the tube of the wormhole in Interstellar was. Before saying more, I'll wait till I actually see "The Principle". From the trailer it looks like a hoot.

18. **martibal**
November 5, 2014

Honor to the precursor !
Black Hole in Hollywood is an old story. Anybody remembers the Disney movie "The Black Hole" in 79 ? Was quite impressive at the time
http://en.wikipedia.org/wiki/The_Black_Hole

19. **Gus Bici**
November 5, 2014

Point taken, Peter. I'll go back now to happy lurker on your fine blog:)

20. **Jeff M**
November 5, 2014

RE the science in "Interstellar" you might want to check out http://www.theguardian.com/film/filmblog/2014/nov/05/interstellar-astrophysics-does-space-science-work-out

21. **CFT**
November 5, 2014

martibal,
My comment above mentioning how black holes now "empower red satanic floating cyclopean robots to go crazy, " is homage to Maximillian, the big red floating evil robot with meat grinder arms and one uni-brow eye in Disney's movie "The Black Hole". It goes crazy, kills a bunch of people, and then literally goes to hell, flames, pitchforks, screaming souls and all, no joke. No one believes me how over the top strange this robot character actually is until they see the movie. The creative director of the movie was definitely on something psychotropic at the time.

22. **MB**
November 6, 2014

The link to your earlier article on The Princple is broken. There's just got an extra "http://www.math.colum" at the beginning.

23. **Peter Woit**
November 6, 2014

MB,
Thanks, fixed.

24. **Narad**
November 6, 2014

Martibal, the NBC "Special Treat" (similar to the better remembered ABC "Afterschool Special") did *The Day after Tomorrow* back in 1975. The traversing-the-black-hole effects, as I recall, were of the crew moving in slow motion in skewed and stretched video frames.

25. **Wavefunction**
November 6, 2014

There's also "The Imitation Game", the movie about Turing based on Andrew Hodges's biography that's coming out later this month. This year's turning out to be a good year for science-based movies.

26. **martibal**
November 6, 2014

Narad: cannot remember to have heard about it, maybe it did not cross the Channel. Looks funny.

CFT: I should have recognized the terrible description of Maximilian, indeed !

27. **martibal**
November 7, 2014

A nerd post (sorry):

Which one would be next ? String theory awakes, Susy awakes, gauge theory awakes ? I would prefer noncommutative geometry awakes, but not sure Disney would buy it 🙂

28. **Narad**
November 7, 2014

It turns out that there *is* a multiverse movie.

29. **Patrick Harris**
November 8, 2014

Just saw Interstellar and really enjoyed it (I'm a big sci-fi fan). Didn't have too many eye-rolling lines as these type of films can have and the quality portrayal of the other planets and space scenes was appreciated.

Glad to hear The Principle is coming out, hopefully my eyes won't roll too much that they fall out ;). Looking forward to your comments!

30. **cl7281**
November 10, 2014

Just seen (and enjoyed) it, and while I agree no multiverse musings I'm not so sure string theory didn't creep in by the back door. There was much talk of extra dimensions and gravity leaking across them. Admittedly this was 5d not 10d so maybe Chris Nolan is a big Kaluza-Klein fan…

Quantum Mechanics and Spacetime in the 21st Century

November 6, 2014
Categories: Uncategorized

This evening's Hollywood-style entertainment came from the Perimeter Institute, where they had a big public event, live-streamed to the world, featuring Nima Arkani-Hamed speaking on Quantum Mechanics and Spacetime in the 21st Century. You should be able to watch the thing soon from the Perimeter site, should be posted at some point here.

The talk was pretty much the same as many other such Arkani-Hamed talks, quite close to the one at the IAS nearly four years ago, discussed here. In this format he can't go on forever, was cut off by around an hour and a half, so said he couldn't get to the third part of the talk, which might have been the 21st century part (amplituhedron?). As in the IAS talk, what he did cover was first mostly the 1960s sort of arguments that Weinberg describes in the first volume of his textbook about the constraints on consistent relativistic QFTs. Then an advertisement for the Veneziano model and string theory. The last part of the talk was a long advertisement for SUSY, ending with an acknowledgement that it wasn't showing up at the LHC. He's now giving 2018 as the date for when we'll know about LHC-scale SUSY, which is moved up from the 2020 of the IAS talk of 2011, but still very different than the "year or so after LHC startup" he was saying in 2005. The current plan is for maybe 10 inverse-fb next year, 50 in 2016. If nothing shows up then, I don't see that the next 50-100 supposedly coming by 2018 have any real chance of finding SUSY.

One thing that struck me about the talk was its odd combination of over-the-top enthusiasm ("this is the greatest time ever!") and intense defensiveness. He kept emphasizing the claim that theorists, even without experiment to keep them honest, were working with highly constrained rules, that it was very hard to do anything not obviously wrong. He denied sociology had to do with what unsuccessful ideas people decide to pursue. He didn't address at all the "not even wrong" problem: what about the things like the landscape, baroque constructions that evade being wrong by being empty? I like a lot this picture and quote from Perimeter:

> If you manage to find one idea that's not obviously wrong, it's a big accomplishment. Now, that's not to say it's right. But not obviously being wrong is already a huge accomplishment in this field.

I think the defensiveness here that's coming through is very personal. He's gotten a $3 million award and a reputation as a leader of the field for ideas that haven't worked out, but which he can defend as "not obviously wrong" and thus a "huge accomplishment".

All in all, the talk was very backward looking, recapitulating the SUSY/string theory ideology that has led us to where we are. It looks like he's planning on hanging in until 2018 with the same story, only then maybe admitting failure (and possibly going for "the multiverse did it, we never had a chance" cop-out). He did end with an upbeat claim that the SUSY picture being all wrong would be very exciting, opening up the field by showing we need something completely new. The obvious question for him is "you pretty clearly wouldn't now bet $10 on SUSY at the LHC, so why wait?" Why not stop giving promotional talks about SUSY? One thing he could have done that would have generated some excitement in the field would be to have pitched out the two-thirds of the talk he did give, publicly saying these ideas aren't working, and talked about something from this century, amplitudes or whatever, the part of the talk he never got to.

Well, maybe in 2018…

Update: You can watch the talk here, along with some online commentary in a chat box that was rolling during the talk.

Update: There was also a more technical talk at Perimeter by Arkani-Hamed, earlier in the day, on Cosmological Collider Physics. The video doesn't seem to be available yet though.

Comments

1. **Neville**
   November 7, 2014

   Off topic: For a real hoot, listen to Barry Simon's story starting at 1:05:41 of http://www.youtube.com/watch?v=GIQXE_2a3KI

   The punch line is at 1:07:02.

2. **blue**
   November 7, 2014

   I have a PhD in mathematical physics and I am desperately looking for a postdoc position of around K$40/y with NO hope, and he just won a M$3 prize for "not obviously being wrong"!!! Tyrion Lannister: "If you want justice, you've come to the wrong place".

3. **manfred Requardt**
   November 7, 2014

   Dear Peter, I am always fond of reading your commentaries about such strange kind of physics talk. Such talks always get a lot of attention but there is almost no physical progress being conveyed.

4. **Hamish**
   November 7, 2014

   "Not obviously wrong"…sounds like a good name for a physics blog!

5. **Dimitrelis**
   November 7, 2014

   @Peter:
   By negation of the statement "not obviously wrong" one gets "obviously not wrong", i.e. "obviously right"…
   You have to be obviously right, in order not be considered obviously wrong.
   So what does he mean with "Now, that's not to say it's right"?

   …hmmm, I must be "obviously" wrong.

6. **Shantanu**
   November 7, 2014

Peter at some point the problem also lies with the hosts . I am pretty sure they must have been aware of similar hype he must have mentioned in other talks(many of which can be easily found from the web). Were there hard questions(similar in spirit to what you wrote in this article)? Its somewhat sad that people like blue and others are having
a hard time finding jobs and here …

7. **Peter Woit**
November 7, 2014

The Arkani-Hamed show really is quite a performance. His colleagues and the public do seem to just eat it up uncritically. In this case, since he went on so long, they had no time for questions.

8. **Shantanu**
November 7, 2014

Peter, the technical talk is now available.

9. **Peter Woit**
November 7, 2014

Shantanu,
I'm still getting an error message if I try to play the video. Audio and a pdf of images is available.

10. **Shantanu**
November 7, 2014

Peter you may need to contact the help desk (assuming you haven't tried other web browsers etc). I had a technical problem in viewing
many PI talks recently(not this one) and I contacted them, and since then I don't see a problem. (although I don't know what was the problem and what was the fix done by PI folks)

11. **Grad Student**
November 7, 2014

Listening to Arkani-Hamed speak, I am reminded of the famous poem by W.B. Yeats:

"The best lack all conviction, while the worst
Are full of passionate intensity."
– http://en.wikipedia.org/wiki/The_Second_Coming_(poem)

12. **First Last**
November 7, 2014

Hi Peter, if I understand Arkani-Hamed correctly, the only graviton-graviton scattering amplitude consistent with relativity and qm (unitarity) that has been found is the Veneziano amplitude. Is that correct? That would seem to be a strong indication it is the one to pursue, isn't it?

13. **Peter Woit**
November 7, 2014

First Last,
Sure, that's the main motivation for string theory. But Arkani-Hamed neglects to mention that to get a consistent amplitude, you need to be in flat space-time 10d, which is, well, obviously wrong. To get the 4d Veneziano amplitude he was advertising, you have to get to get rid of 6 dimensions, and that is why the program has failed.

Another point that struck me is that he's convinced space-time is "doomed", and if so, amplitudes at short distances are irrelevant, since there is no space-time at these distances. There's a huge inconsistency between "we must do string theory because it has well-behaved amplitudes at short distances" and "we know there is no space-time at short distances".

14. **Nobody**
November 8, 2014

"Not obviously wrong" approaches "not even wrong".

Progress!

15. **NEOW**
November 8, 2014

But now there's an even lower rung:
"not even obviously wrong"

16. **Peter Woit**
November 8, 2014

All,
If you have something interesting to say about the Arkani-Hamed talk, please do. On the other hand, if you just want to repeat content-free slogans about quantum gravity, please do that elsewhere.

17. **Gus Bici**
November 11, 2014

Listening to the "more technical talk" (MP3) by Arkani-Hamed and it ended abruptly before Nima could finish "what really bothered him". He said it might not bother others, but it really really bothered him. Can anyone summarize Nima's bother?

Short Items

November 7, 2014
Categories: Uncategorized

- On Monday there will be symposia at Stanford featuring the Breakthrough Prize winners, with streaming video available. For the morning program, with dignitaries and such, see here. The Mathematics symposium will run 11-5, the program is here, streaming video here. The Physics symposium is also 11-5, no program yet, but streaming video will be here. If you're in Berkeley they have an event to watch the videos at International House, see here.
- Tomorrow in Paris will be the Seminaire Bourbaki, supposedly you can watch the talks online here.
- Latest news on the Journal of K-theory front (for background, see here) is that the Editorial Board has resigned and is starting up a new journal, to be called Annals of K-theory and published by MSP. The story seems to be that the Journal of K-theory was very profitable, but the profits were going personally to the managing editor, Anthony Bak. Evidently he refused to agree to demands to change this arrangement, so was removed from the K-theory Foundation set up to use funds from the journal, and the other editors (except one) resigned. They are encouraging university libraries to consider canceling subscriptions to the Journal of K-theory, but it's not clear this is possible, since such subscriptions are now often part of bundles.
- If you'd like to see what the theory group at CERN is up to, take a look at presentations at their retreat, which ends today.

Update: The program for Monday's Breakthrough Prize physics symposium is available. It reveals that there will be 3 joint winners of this year's $3 million. I'm betting Polchinski and two others, most likely Strominger and Vafa. The physics speakers get 15 minutes to give a talk, 5 minutes for questions. Mathematicians get twice as long, a total of 40 minutes/talk.

Update: It looks like mathematicians too are getting in on the Hollywood thing. Next week, sandwiched in between Diane von Furstenberg and Jennifer Lawrence, Terry Tao will appear on the Colbert show.

Update: The Terry Tao Colbert show segment is here.

   November 9, 2014

   Interesting. Does this indicate that Mr. Milner is coming around to the not uncommon sentiment that doling out $3m per already-quite-wealthy-physicist is perhaps not the smartest way to spend money?

5. **David Roberts**
   November 10, 2014

   Amusingly, the Colbert Report profile neglects to mention the Fields Medal, probably the most impressive prize Terry has received.

6. **Whoops**
   November 13, 2014

   David- it was mentioned at 0:30, check again (and called the "Nobel of Math").

7. **David Roberts**
   November 13, 2014

   @Whoops

   I can't watch the video clip from my Vegemite-munching country, but the Fields was and still is missing from the long list of prizes here:

The Theory of Everything

November 8, 2014
Categories: Uncategorized

Hollywood theoretical physics week, focusing on quantum gravity and black holes, continues with the opening this weekend of The Theory of Everything, a Stephen Hawking biopic. It's quite good, although a bit too heart-warming for my taste. The focus is on the relationship between Hawking and his wife Jane, and there's quite a bit more emphasis on religion than can really be justified. I wouldn't be at all surprised if Eddie Redmayne gets an Oscar for his portrayal of Hawking. It's very impressively well-done, and the sort of inspirational material the Academy Awards people love.

There are things you could complain about in the film's portrayal of the science (and Dennis Overbye does so here), but this was handled better than I expected, with some reasonable relationship to reality, given the constraints of this kind of movie. In every way, a better film than Interstellar, the other Hollywood theoretical physics movie of the week.

Watching the film did remind me of days long past. When I was a graduate student in Princeton I remember Hawking coming there to give a talk (or talks?), this would have been around 1980. He was talking about Euclidean quantum gravity, and at the time was still able to speak, but his speech was so indistinct that someone who worked with him translated, repeating what he said so everyone could understand. At the time, the general feeling was something like "great physicist, too bad the guy only has a year or two to live" (he did come close to passing away in 1985). I'm absolutely sure that no one then would have believed it possible that he'd go on to become a huge celebrity, make it through two failed marriages, sell 10 million books about physics, and still be with us and active deep into retirement age. Personally I thought a lot of his last book was misguided (see here) but his is an amazing story and he's got a lot better excuse than his able-bodied colleagues for giving up and going for the multiverse.

Comments

1. **Spelling**
   November 9, 2014

   "Stephen" rather than "Steven"?

2. **Katy**
   November 9, 2014

   "….but his is an amazing story and he's got a lot better excuse than his able-bodied colleagues for giving up and going for the multiverse."

   Not a fan multiverse fan, thankful for this blog, disappointed with this concluding sentence. What on earth doe Hawking's disabilities have to do with his belief in the multiverse?

3. **Katy**
   November 9, 2014

   Seriously, if Hawking believes in the multiverse, it's not because he "gave up." Say what you will about the man- his disability has never caused him to lose interest in scientific advancement.

4. **Known As Drew**
   November 9, 2014

   Don't know if you've seen the 2004 BBC biopic "Hawking" starring a young(er) Benedict Cumberbatch. Managed to avoid being sentimental or mawkish. Recommended.

5. **Peter Woit**
   November 9, 2014

   Spelling,
   Thanks. Fixed. I always make that mistake. I blame it on my brother, Steve.

   Katy,
   Sorry, but I do think that the M-theory/multiverse argument is very much what people do who are giving up on really understanding unification (and the movie paints Hawking's main early scientific motivation as understanding unification). "The Grand Design" really is a book that does serious damage to science, by blithely claiming that the M-theory multiverse is a solution to the unification problem. Hawking should know better, just like a lot of other prominent theorists should know better.

6. **Jon**
   November 10, 2014

   I, too, was disappointed to read the last sentence of this post. Sure, you can say he gave up, but your response to Katy does nothing to clear up why you conflate his physical condition with his position on these theoretical issues. Total cheap shot.

7. **Peter Woit**
   November 10, 2014

   Jon,
   I didn't conflate his physical condition with his position on the multiverse. My comment was more a cheap shot at a long list of his colleagues, who don't have the excuse of having to work under extremely challenging conditions to explain why they have taken the easy way out and given up. I don't claim that Hawking's disability is why he has chosen to give up, just point out that at least he has an excuse for doing so, unlike others.

   But, make no mistake about it: Hawking, like others, has chosen to give up. This is a great shame, given his huge influence.

8. **disgruntled**
   November 10, 2014

   Peter – non-scientist, read your blog, find it hugely interesting.

I’ve always thought your arguments carry far more weight and are more likely to influence when they are devoid of sly comments, blithe ‘humour’, cheap shots or the like. This is a case in point.
Your last sentence is very mis-guided, and your responses to Jon and Katy actually make the situation worse – you actually seem to suggest that you used Hawking’s physical condition to make a cheap shot at others……..

9. **Cosmonut**
November 10, 2014

IMO, Hawking’s huge influence is mainly due to his physical condition and his grandiose claims about wanting “complete understanding of the Universe”, “knowing the mind of God” and so on.
His big discovery about black hole radiation happened 40 years ago and while certainly excellent work, it doesn’t really merit comparison to Einstein (whom the media love to compare Hawking to).

But while media hype is one thing, what annoys me is that Hawking does disingenuous PR for himself as in his “Grand Design” book where he claims that the Theory of Everything has already been discovered and hence, he has already achieved his goal of “understanding it all”, which is quite false.

Even worse is his recent autobiography where he presents his highly speculative hypotheses as established scientific facts. For example, he explicitly claims that “the No Boundary Principle is the reason why anything exists at all”.

This is not just hype, its outright dishonesty to boost his own image.

10. **Peter Woit**
November 10, 2014

disgruntled,
Sorry, but this blog is chock-full of sly comments and blithe “humour” that not everyone finds funny. Always has been and always will be. I do try and keep the cheap shots to a minimum, the reference to my making them here was in the blithe humor category.

A certain amount of humor in confronting the massive PR campaign by Hawking, Susskind, Linde, Guth, Polchinski, Arkani-Hamed, Carroll and a raft of others to promote pseudo-science seems to me a healthy way to deal with an otherwise thoroughly depressing and intellectually empty subject. I intend to keep at it.

11. **jd**
November 11, 2014

Amen, Peter Woit. I find that my sense of humor, dark though it is, maintains my sanity. You hang in there.

12. **Jim**
November 12, 2014

I will join the chorus saying the last line is pretty bad and if you are worried PR then you ought to remove it (as well as this comment when you’re done).

The point is that it reads more or less as “Hawking’s in a wheelchair, so we don’t have to expect too much from him. These other guys aren’t, what’s their excuse?!” A bit mean-spirited, wouldn’t you say? And that’s only if we accept your premise that accepting the multiverse is tantamount to giving up. We are therefore left with the conclusion that either accepting the multiverse (as such and so famous physicists do) is NOT giving up or the opponents of the multiverse are arguing from a mean-spirited position. Or both. Whatever the case, it’s not a good look.

13. **Peter Woit**
November 12, 2014

Jim,
I’ve repeatedly clarified exactly what I meant, and I actually don’t think there was anything at all unclear about what I originally wrote. If you or others just ignore that and want to argue about something else, I don’t see why that’s a good reason for me to delete things because of PR concerns.

One additional perhaps clarifying remark: there is no humor here, this is about two tragedies. The first is Hawking’s medical condition, which has forced him to try and survive and work under an awful set of constraints. The second is the tragedy of the descent of a subject with a great history into pseudo-science, led on this path by Hawking and many others. Why each of these scientists have given up on the tough job that initially inspired them is a complex issue that will keep historians of science busy in the future. One aspect of this issue is a moral one, and all I’m pointing out is that Hawking’s situation on that front is different than that of others.

14. **Katy**
November 25, 2014

If you believe that Hawking has given up intellectually, fine, but don’t tie his disabilities into that decision. (You are, ultimately, speculating why he has bought into the multiverse nonsense). Read up on ableism and how language, conflation and projection have real ramifications on disabled people. It’s not a matter of what you meant, it’s what you said.

2015 Breakthrough Prize in Fundamental Physics

November 9, 2014
Categories: Uncategorized

The prize was awarded (by the actor who played Stephen Hawking), in a Hollywood-style awards ceremony (see here) to the 51 members of the two teams responsible for the supernova data showing that the universe is accelerating, with the 2011 Nobel Prize Winners (Perlmutter, Schmidt and Riess) specifically cited as the leaders. I gather the 51 people split the $3 million, so each get around $60K. This is interestingly different than the previous prizes, which mostly went to a small number of string theorists for research that hasn't worked out very well (my prediction of an award to Polchinski, the runner-up for the past two years, was quite wrong). I'm quite curious what caused the change of policy here. The only previous prize for experimental work in physics was a special award for the Higgs discovery, and that went to the experiment spokespersons, not to all the physicists involved (which was controversial at the time).

Anyway, quite interesting and surprising, kind of an about face from theory to experiment, and from rewarding just leaders to recognizing full collaborations.

Update: More here. It seems that the $3 million is not split equally among everyone involved, but that half goes to each of the two teams, and for each team, one third of their winnings goes to their leaders (all to Perlmutter in one case, split equally by Riess and Schmidt in the other).

Video from the ceremony here.

Update: For more details about the ceremony, there's Vanity Fair. I had heard that relatively few actual scientists were getting invited (and no one really wanted to hear from the mathematicians…). It does seem that a big motivation here is to bring Silicon Valley guys and Hollywood/music biz women together for a party:

> Christina Aguilera, who performed during the event, also noticed a difference between tech types and her entertainment-industry colleagues: "Through Yuri, I've been hanging out with the Google guys, Facebook guys. I find them all to be so down to earth. It's really refreshing."
>
> Unlikely duos chatted over a dinner of lasagna and chicken by the French Laundry's Thomas Keller. Aguilera conversed with Twitter C.E.O. Dick Costolo. Elon Musk and Kate Beckinsale were instantly alight in each other's company.

Comments

1. **Navneeth**
   November 10, 2014

   Typo in the title.

2. **Peter Woit**
   November 10, 2014

   Navneeth,
   Thanks, fixed. I hope the topics in 2105 will be different.

3. **Bernhard**
   November 10, 2014

   Since the prize was not split between the collaboration, in what sense has the prize been given to "to the 51 members of the two teams"? It seems to be the same BS of awarding the spokespersons, just as the Nobel.

4. **Peter Woit**
   November 10, 2014

   Bernhard,
   My understanding is that all the members of the two teams are officially recipients and do get a share of the money (each team splits whatever is left of half, after a third goes to their leaders). Only the three leaders though I think get to dress up and meet the Hollywood stars who hand out the prize.

5. **Bernhard**
   November 10, 2014

   Hi Peter,

   Ah OK, I jumped the gun. So, around 40k each. Not bad.

6. **Kuas**
   November 10, 2014

   I wonder how the vote associated with the prize will be split up. Obviously having 51 experimentalist laureates voting on the next winner could cause some problems if they were not de-weighted.

7. **Peter Woit**
   November 10, 2014

   Kuas,
   Already if you look at the Selection Committee for this year, of the 7 LHC experimentalists given a prize last year, only three are now on the selection committee, so there's already some selection effect against experimentalists. In this case, I assume they just allow the three leaders to be on the committee, the rest don't qualify.

   I'm quite curious though what caused the big change in policy this year in the type of award. Seems unlikely it was just the 3/15 experimentalists, but who knows. It seems quite possible that either Milner or the string theorists themselves finally realized that a prize of this kind always going to string theorists was not good for its credibility. Whoever you are, if you're giving out prizes, you want to award prizes to people who will increase your own credibility, not reduce it…

8. **Don Jennings**
   November 10, 2014

Just speculating, but I've been pretty surprised that the $3m recipients seem to have used only a negligible fraction of their new wealth to support anybody else doing physics. Perhaps if Milner too had been expecting to see some secondary philanthropy, he's now decided to just cut out the disappointingly greedy middle-men.

9. **Bernhard**
November 10, 2014

Don Jennings,

Yes, and we should specially quote some spokespersons who said would their money to finance the poor postdocs and students but never did. I guess in the end mortgage is more important than the Higgs.

10. **Bernhard**
November 10, 2014

that would use their money

11. **JD M**
November 10, 2014

On an unrelated piece of news, George Zweig won this year's J. J. Sakurai prize:
<a href="http://www.aps.org/programs/honors/prizes/prizerecipient.cfm?last_nm=Zweig&first_nm=George&year=2015&quot; title="2015 J.J. Sakurai Prize for Theoretical Particle Physics Recipient"

12. **mateo**
November 11, 2014

Eagerly awaiting your take on the latest Higgs hubbub!

13. **Curious**
November 11, 2014

Can you elaborate on "and no one really wanted to hear from the mathematicians…"?

14. **Peter Woit**
November 11, 2014

mateo,
Best ignored, seems to be non-news. Maybe someday there will be exciting news about the Higgs if the LHC measurements of its properties show something unexpected. Unfortunately, that hasn't happened.

15. **Eric Weinstein**
November 11, 2014

Well, I can assure you that even mathematicians in the heart of Silicon Valley are not on the radar. I wouldn't read too much into that. Give it time and see what happens. They are finding their way. This is a particular crowd (so far), but they are trying to do some good. It would be very surprising if they got it nailed down straight out of the gate.

16. **Nicholas Suntzeff**
November 11, 2014

Although the teams were officially recognized in the Breakthrough Award, we were not invited to the ceremony. In the case of the Gruber Prize, the team was generically awarded but our names were not listed individually (except for Saul and Brian). However, we were invited to a simple and elegant ceremony hosted by Martin Rees at Trinity College Cambridge, which was wonderful for the teams. For the Breakthrough Prize, our names are listed but we were not invited. I know that Brian Schmidt made a number of appeals to the organizers that it is wrong not to have the teams there, but they did not agree. It is not as if there was not space – it was in a blimp hanger after all!

Brian and I co-founded the High Z Team in 1994, after the Calan/Tololo Survey had proven that Type Ia supernovae could be calibrated to 6% distances. He and I made two rules: (1) each six months a new subgroup based on university or observatory location of us would get the recent data, and the whole group would work in support of that subgroup, and (2) the person who was the intellectual force behind any particular paper would be first author. With those rules we had no problems of authorship and responsibility, and not surprisingly almost all the papers were first authored by a grad student or postdoc. So the University of Washington (Stubbs, Reiss, and Diercks) had the data the semester before UC Berkeley with Riess and Filippenko got new data.

What these prizes don't seem to understand that most science is done by teams, and at least in astronomy, the teams are often creative anarchies. Brian was elected our leader after one year of both of us co-leading, and deserves to be recognized as our leader. Adam was first author on the discovery paper, and without his dedication and brilliant work, our paper would not have been published in time with the SCP. But, if you took away many of the single members of our team, we would not have made this discovery as quickly as we did, if at all. Thus, the team needs to recognized as a team. Both the Gruber and the Breakthrough Prize went partially in this direction, but not completely.

My hope is that as the Breakthrough Prize evolves, the idea of a team of equals with different talents working together, becomes more understood by those who have no idea of what doing science is.

17. **CPV**
November 11, 2014

Rich people generally believe that, upon reflection, what made them rich is their own unique gift. Team prizes don't fit that narrative. When they give back it's almost always in a reflected glory sense. There are exceptions, but not many. So, the giving will be in ways to find or assist those with unique gifts like their own. I think you could argue that people with immense gifts don't really need anyone's help on average, and that one should look down the ladder for people to help. Gates has done a good job with this, mostly.

18. **emkajot**
November 12, 2014

@CPV
I very much recommend reading Gladwell's "The Outliers" for a completely different perspective on how some people with immense gifts succeed (and many others

don’t). Gates is actually discussed as an example.

19. **vzn**
November 12, 2014

lol “nobody wanted to hear from the mathematicians”…. :'(
you gave a link for the televised stanford event featuring the mathematicians.
wonder if that is archived anywhere? really hope it is. has anyone seen it?
more commentary on breakthrough prizes 2014 (last yr)

20. **Peter Woit**
November 12, 2014

vzn,
While I saw some of the streamed talks, it looks like they are not now available. Presumably they will at some point appear on the breakthroughprize.org site. When that happens I’ll probably take a look at some of what I missed, and link to them from here.

21. **Bernhard**
November 15, 2014

Nicholas Suntzeff,

I very much agree with you. What is troubling about these prizes is that they are supposed to be a channel to make scientists be recognized by the rest of the society. People working in big science are very much aware how a huge collaborative work each paper is, but outside this bubble this is alien culture. What these prizes do when crowning the leaders is to actually diminish the group’s efforts even more, IMO. People will acknowledge what they can see – if they see the leaders these are the one’s who will get ALL the attention from the outside world no matter how many footnotes people write saying the work was actually a collaborative effort,

22. **Davide Castelvecchi**
November 16, 2014

This whole thing reminds me of the party at Peter Gregory’s mansion in the Silicon Valley sitcom 🙂

Alexander Grothendieck 1928-2014

November 13, 2014
Categories: Obituaries

I just heard that Alexander Grothendieck passed away today, at the age of 86, in Saint-Girons. For a French news story, see here.

Grothendieck's story was one of the great romantic stories of modern mathematics, and many would consider him the greatest mathematician of the twentieth century. For some blog entries about him here, see for example this and this. I'll add other links as I see them or think of them.

Update: For some blog entries about Grothendieck's recent life, you could start here.

One of the best places to learn about Grothendieck is from his friend Pierre Cartier, in an article that can be found here, among other places.

Le Monde now has an obituary.

Steve Landsburg has a blog post.

Update: The news about Grothendieck came out in the French press a day ago, but at this point the only things I've seen in the English-language press are an AP wire story, and this at the Independent. Come on science journalists, if any story about mathematics and mathematicians is worth writing about, this one is.

Update: There are now obituaries at the New York Times and the Telegraph. The IHES has a page at their website.

Comments

   November 13, 2014

   A great mathematician and a great man. Too sad.

2. **Felipe Zaldivar**
   November 13, 2014

   Adieu Shourik!

3. **Ryszard Kostecki**
   November 13, 2014

   This are sad news. He had very unique personality, and was a great master of structure, intuition, poetry, and anarchy. But maybe his death and surrounding publicity can, ironically, stimulate translation of his works to English? In particular of *Recoltes et semailles* (only some small part of it was translated). There is an ongoing crowdfunding project of translation of his biography from German to English: http://www.gofundme.com/7ldiwo. Maybe a translation of Recoltes could be organised in the same way?

4. **SusanA**
   November 14, 2014

   One of the greatest–if not the greatest–mathematicians of the 20th century has died, yet the English media has not picked up on it.

5. **Winfried Scharlau**
   November 14, 2014

   Grothendieck has passed away, a great man and a great human being. I think it is a matter of respect and a matter of honesty to be very careful with statements about him. The internet is full with wrong, half-true, incomplete, sensational and misleading information about him. Do not believe everyting you read and check everything carefully.

   Winfried Scharlau

6. **CIP**
   November 14, 2014

   Thanks for this nice post Peter.

   Note though, that, as Cartier mentions, Grothendieck insisted on the spelling "Alexander" for his first name. A bit of political rebellion against the oppressively intrusive French State?

7. **Peter Woit**
   November 14, 2014

   CIP,
   Thanks. Given Cartier's comment, I did change the spelling.

   I was somewhat tempted to leave the French version though, since it's quite sad to see that so far virtually the only new coverage of his death is coming from the French press, where it's a big story.

8. **XXM2212**
   November 14, 2014

   The point is that only a few mathematicians can really connect to his work .
   He was the purest form of mathematicians ,the best mathematician in the 20th century no doubt about it .
   It would take world leading mathematicians to talk about his maths,for every mathematician it would be the same as some child talking about seashells ,fantasmagoric divination.

The truth is that what distinguishes him is that he answers the Why questions , mathematicians live in a universe which is bounded in the same manner the physical world at some era ,R.Feynman talked about this impossibility in physics. But in maths it is possible … the why is generally untouchable
His maths reflect the universe .

9. **laboussoleermonpays**
November 14, 2014

The last forty years of Grothendieck's life were a long goodbye to mathematics but his "broken dream […] to develop a theory of motives" (to quote P. Cartier in his famous article "A mad day's work…") seems to me a silent hello to physics thanks to the works of Kontsevitch and Connes…

And here is his forecast about a unification theory :
<blockquote cite=
[…] Toujours est-il que de trouver un modèle "satisfaisant" […], que celui-ci soit "continu", "discret" ou de nature "mixte" — un tel travail mettra en jeu sûrement une grande imagination conceptuelle, et un art consommé pour appréhender et mettre à jour des structures mathématiques de type nouveau. Ce genre d'imagination ou de "flair" me semble chose rare, non seulement parmi les physiciens […], mais même parmi les mathématiciens (et là je parle en pleine connaissance de cause). Pour résumer, *je prévois que le renouvellement attendu (s'il doit encore venir…) viendra plutôt d'un mathématicien dans l'âme ; bien informé des grands problèmes de la physique, que d'un physicien* . Mais surtout, il y faudra un homme ayant "l'ouverture philosophique" pour saisir le nœud du problème. Celui-ci n'est nullement de nature technique, mais bien un problème fondamental de "philosophie de la nature
in *Récoltes et semailles*
(Chapitre 2. Promenade à travers une œuvre ou l'Enfant et la Mère. § 2.20. Coup d'œil chez les voisins d'en face, p. 80 (transcription d'Yves Pocchiola))

10. **laboussoleermonpays**
November 14, 2014

English translation* of the last Grothendieck's quote from "Harvests and Seeds"
<blockquote cite=
It nevertheless remains true that the finding of a 'satisfactory' model […] – whether this model was 'continuous', 'discrete' or of a 'mixed' nature – would require a great conceptual imagination, and a consummate art for apprehending and updating mathematical structures of a new type. This kind of imagination or 'flair' is rare indeed, not only amongst physicists (Einstein and Schrödinger seem to be notable exceptions), but even amongst mathematicians (and there I am speaking in full knowledge of the facts).
To sum up, I predict that the long-awaited renewal (if it is still coming…) will come from a born mathematician well-informed about the big questions of physics rather than from a physicist. But above all, we will need a man with the kind of 'philosophical openness' necessary to take hold of the heart of the problem. This problem is by no means a technical one, but is rather a fundamental question of 'natural philosophy'.

20. **Reza**
November 15, 2014

Dear Als

Thanks for putting the address of this video in your comment.
Grothendieck wanted to be alone and I think he recived his gift.

21. **Thomas**
November 15, 2014

Peter, unsolicited advice: why don't you contribute to cover this yourself in the US media, by writing a piece, for e.g. the Wall Street Journal ?

22. **David Appell**
November 15, 2014

It is not so easy trying to explain modern mathematics to the public. Several years ago I tried to cover the 2002 Field Medals for Salon.com. I was so frustrated I ended up taking a completely different angle:

"Math = beauty + truth / (really hard)," Salon, September 5, 2002.
http://www.salon.com/2002/09/05/math_prizes/

Several people have told me they like it, including an editor at Forbes, and one persobn saying it was the best article about mathematics she'd ever read. (But she wasn't a mathematician.)

23. **Richard**
November 15, 2014

Grothendieck

Brilliance and bizarrerie —
Inextricably intertwined:
No subject that he plumbed
Took the measure of his mind.
A soul forever questing
For the Great Beyond —
A heart forever testing
The limits of despond.

24. **suzanna**
November 15, 2014

I was surprsied that the BBC did not pick up on this and still hasn't! The only English press that has finally covered this is the Telegraph on 14th Nov. I myself only heard of Alexander Grothendiek through one of Peter Woit's recent blogs (i work in a completely different scientific field). I got intrigued by the fact that a genius can abandon his amazing career. it became clear to me that this guy was not only a pure mathematecian but also carried his purity of reasoning to other areas of life from scientific funding issues to the environment and the human condition. ok, maybe some describe his reaction to scientific corruption and social injustices as insanity but actually it's totally admirable and inspiring to all kinds of scientists.

Are there any mathematical notes or manuscripts that can now become available to be examined by experts?

Breakthrough Prize on TV

November 15, 2014
Categories: Uncategorized

You can watch the recent Breakthrough Prize awards ceremony on TV tonight, 6 pm on the Science and Discovery channels. The Science Channel has a [site with videos of highlights of the evening](), the complete list of which is:

- Christina Aguilera singing "Beautiful".
- Larry Page of Google talking about himself and Google.
- Mark Zuckerberg talking about the universe and the "masters of string theory", which is "our best hope for one explanation of reality".
- Michael C. Hall talking about his own cancer, then bringing on Jimmy Wales to talk about a cancer researcher.
- Sergey Brin of Google talking about himself.
- Sergey Brin's wife Anne Wojicki talking about herself, and about her husband's DNA (which supposedly indicates an increased risk for Parkinson's, so research on curing that is important).
- Lana Del Rey singing "Video Games".

I've heard a rumor that one mathematician was actually allowed to say something, for 30 seconds. Will have to wait for the show tonight to see if that was true…

Update: Just saw the show. There was a nice video shown of the mathematicians saying some things about math in general. Unlike the rest of the scientists, they weren't given their award by a star or starlet, but were brought on stage together already holding their awards, and Richard Taylor said something for 20-25 seconds on everyone's behalf. I also hadn't realized that a sizable part of the show was two promotional segments for Hollywood movies (the ones about Hawking and Turing).

   November 15, 2014

   Science and Propaganda* Channel Presents!

   *Propaganda is a form of communication aimed towards influencing the attitude of a population toward some cause or position

2. **David Appell**
   November 15, 2014

   How many explanations of reality does Mark Zuckerberg need?

3. **Peter Woit**
   November 15, 2014

   amirpouyan,
   The Science channel does carry a lot of propaganda for science, and that's not necessarily such a bad thing. The Breakthrough Prize business does fit into that, one of its themes is that science is valuable, deserves more recognition. Another theme though is that Silicon Valley billionaires belong up there with Hollywood and music-world celebrities on TV. They're paying for it, so I guess they should get what they want.

4. **Bernhard**
   November 15, 2014

   This is great material for a South Park episode.

5. **Nobody**
   November 16, 2014

   Peter,

   "… not necessarily such a bad thing."

   Are you sure? Where would the multiverse and other such corruptions be without all the money associated without the publicity? The politicized nature of show biz is powerful. Look at what politics did to climate science. I'd say that physics is playing Russian roulette with this 'star' business. Some money might be generated, but you're losing your soul.

   Run the publicity seekers out of the business and turn down the big star prize money (if you can resist the corrupting lure).

6. **Nobody**
   November 16, 2014

   "without the publicity"

   Cut and paste error: "with the publicity"

7. **Peter Woit**
   November 16, 2014

   Nobody,

   I don't really think that money has much to do with what's causing the multiverse problem (and its predecessor, the string theory unification problem). In general, I don't think the people driving this are doing it for the money. They're doing this because doing something real is hard and frustrating, while this is much easier, and it's easy to fool oneself. As always, the people you see on TV are going to be the ones who are most interested in being on TV. But in a world with no TV science channels, no large book advances, and no billionaires giving prizes, I think we'd have the same problem (although the public would be less aware of it).

   What traditionally keeps a lid on this kind of nonsense is that other scientists, especially ones in your own department, will stop taking you seriously if you start doing this kind of thing, start ignoring your opinions about who to hire, start discouraging students from working with you, etc. The real money danger here is that a colleague spouting pseudo-science is one thing, a colleague spouting pseudo-science who has just won a respected $3 million prize, has a large grant from the Templeton Foundation, is bringing large donors to the university, and attracts students because of his/her TV appearances is a more challenging problem. And even if your colleagues know not to take you seriously, that may be less true for university administrators.

8. **anon.**
   November 18, 2014

   Peter. Are multiverse TV adverts simply a symptom of the problem that alternative ideas are *less interesting* to viewers? In other words, there are people talking about multiverse ideas to lay persons in an exciting way, but the guys with really interesting work don't go on TV to issue adverts, partly because they're busy actually doing stuff, and partly because it's not trivial but requires complex math to explain.

Advertisements for the Multiverse

November 15, 2014
Categories: Multiverse Mania, Uncategorized

After watching the Breakthrough Prize awards tonight, tomorrow night on the Science Channel you can watch a program that actually features physicists rather than Hollywood/Silicon Valley celebrities. There's an hour long infomercial for the Multiverse, entitled "Which Universe Are We In?". You get to hear from

- Max Tegmark starting and ending the show with a generic promotional spiel about how wonderful the multiverse is.
- Seth Lloyd about how weird QM is, and that it and cosmology provide strong experimental support for the multiverse.
- Anthony Aguirre explaining about seeing collisions of other universes in the sky, and about how evidence for the multiverse has now been seen (BICEP2), providing a huge leap forward for the multiverse.
- Laura Mersini-Houghton about the string landscape and how she has used it to make predictions, which are now becoming accepted.

The program ends kind of like a car commercial, with beautiful scenery and swelling music. A voice over mentions un-named fuddy-duddy critics, mainly to say that BICEP2's "great support for the theory of the multiverse" has "given then something to think about". It suggests that the answer to the question raised by all these different kinds of multiverse ("which one is true?") can be answered by believing all multiverse models at once, no need to choose.

No mention of tedious things like dust. This multiverse is all new and shiny, slices, dices, provides every reality you could possibly want.

On a somewhat higher level, Quanta magazine followed up last week's multiverse piece with a new one this past week, Multiverse Collisions May Dot the Sky from Jennifer Ouellette. Aguirre appears here too, working with collaborators on analyzing possibly observable consequences of bubble collisions. One of them is Hiranya Peiris, who explains that multiverse theory is like the theory of evolution:

> Peiris acknowledges that this argument has its critics. "It can predict anything, and therefore it's not valid," Peiris said of the reasoning typically used to dismiss the notion of a multiverse as a tautology, rather than a true scientific theory. "But I think that's the wrong way to think about it." The theory of evolution, Peiris argues, also resembles a tautology in certain respects — "an organism exists because it survived" — yet it holds tremendous explanatory power. It is a simple model that requires little initial input to produce the vast diversity of species we see today.
>
> A multiverse model tied to eternal inflation could have the same kind of explanatory power. In this case, the bubble universes function much like speciation. Those universes that happen to have the right laws of physics will eventually "succeed" — that is, they will become home to conscious observers like ourselves. If our universe is one of many in a much larger multiverse, our existence seems less unlikely.

The problem of course with bubble collision "predictions" are that they're not falsifiable. As far as they're concerned, you can only win: seeing nothing doesn't disprove the multiverse. The most recent attempt to look for evidence in the CMB that I'm aware of is this, which found nothing in the WMAP-7 data. I haven't seen anything using Planck data released so far. Presumably when new data is released later this month some kind of search for bubble collision evidence will be done, and Quanta magazine isn't likely to report the likely outcome.

The Quanta piece isn't an infomercial like the TV program, it does explain some of the problems with this whole endeavor, including this from Erick Weinberg:

> "My own feeling is you need to adjust the numbers rather finely to get it to work," Weinberg said. The rate of formation of the bubble universes is key. If they had formed slowly, collisions would not have been possible because space would have expanded and driven the bubbles apart long before any collision could take place. Alternatively, if the bubbles had formed too quickly, they would have merged before space could expand sufficiently to form disconnected pockets. Somewhere in between is the Goldilocks rate, the "just right" rate at which the bubbles would have had to form for a collision to be possible.
>
> Researchers also worry about finding a false positive. Even if such a collision did happen and evidence was imprinted on the CMB, spotting the telltale pattern would not necessarily constitute evidence of a multiverse. "You can get an effect and say it will be consistent with the calculated predictions for these collisions," Weinberg said. "But it might well be consistent with lots of other things." For instance, a distorted CMB might be evidence of theoretical entities called cosmic strings. These are like the cracks that form in the ice when a lake freezes over, except here the ice is the fabric of space-time. Magnetic monopoles are another hypothetical defect that could affect the CMB, as could knots or twists in space-time called textures.
>
> Weinberg isn't sure it would even be possible to tell the difference between these different possibilities, especially because many models of eternal inflation exist. Without knowing the precise details of the theory, trying to make a positive identification of the multiverse would be like trying to distinguish between the composition of two meteorites that hit the roof of a house solely by the sound of the impacts, without knowing how the house is constructed and with what materials.

There's also the problem that even if you did see something, it really would tell you pretty much nothing about the supposed other universe:

> Should a signature for a bubble collision be confirmed, Peiris doesn't see a way to study another bubble universe any further because by now it would be entirely out of causal contact with ours. But it would be a stunning validation that the notion of a multiverse deserves a seat at the testable physics table.

Update: One problem with arguing that the multiverse is like the theory of evolution that physicists should keep in mind: creationists love it.

Comments

1. **Phil Fogle**
   November 15, 2014

   Peter, after following your blog for several years, I finally got round to reading your book, thank you – an exhilarating read!

   I can't help thinking of Copernicus adding epicycles to his heliocentric model of the solar system to avoid the 'paradigm shift' of Keplerian orbits.

   Multiverse -> epicycles?

2. **Peter Woit**
   November 15, 2014

   Phil Fogle,

   Not sure it's such a good analogy, with epicycles you at least have a rather well-defined, testable framework. Part of the problem with the multiverse is that you don't even have a well-defined theory you can calculate anything with.

Glad you enjoyed the book!

3. **tulpoeid**
November 15, 2014

If I can put a name on what concerns me with "this kind" of theories (strings, multiverse, parallel universes *inter alia*) is their theism.

Their fans glorify the Impossibility of Knowing, and they bask in it.

They are glad that the scientific method has finally found the position such a slut deserves (back to the kitchen) and they feast on the infidels.

Have we already past the point where enough is enough and their marks are already left on science for a couple of centuries? I don't know. But hopefully in the end what will be remembered won't be the silence of the friends.

4. **Michael**
November 15, 2014

Peter,
Is there any chance of sanity and the scientific method coming back to physics? With billionaires giving away money to theorists who have no testable results, it doesnt seem as though there is any feedback to prevent this thing from spiraling out of control. Any ideas how we might see theoretical physics become a science again?

5. **Andrew Foland**
November 15, 2014

On falsifiability: "Fossil rabbits in the Precambrian."

6. **Peter Woit**
November 15, 2014

Michael,
The problem isn't billionaires. The choices of mathematicians were perfectly reasonable, and this year the physics prize went to an important experimental result, which I think had to do with a realization that the physics prize choices of theorists were becoming an embarrassment.

Many parts of theoretical physics are perfectly healthy, but the multiverse mania problem really is just getting worse, and it's a problem generated by physicists themselves, not by the press and not by the billionaires. I have no idea what might slow it down or reverse the trend, keep thinking people will just get tired of listening to the same nonsense. Doesn't seem to be happening though.

7. **Robert Arnold**
November 16, 2014

It is more than evident to any fair minded observer that this pop science multiverse mania harms fundamental progress in physics. It reminds me of the attitude of the of the faculty of the university I attended in the seventies that deterred me from continuing to be a math major.

8. **Martin**
November 16, 2014

This comparison with evolution theory is nonsense. From the fossil record (e.g. the faunal succession) and DNA it is evident that the biological species have not all come into existence at the same time as the Genesis fairy tale would have it, but in temporal succession. And that the fittest (in terms of adaptation to the environment) survive is seen all the time. To suggest that evolutionary theory is a tautology is BS. The theory of evolution is not at all like this multiverse nonsense for which there is no evidence at all. Peiris must be desperate to come with this "comparison".

9. **Low Math, Meekly Interacting**
November 16, 2014

I suppose I must accept some of the blame myself. Subjects like unification and universal origins are intrinsically fascinating to me, and I keep going back to those subjects again and again in hopes of learning about the true answers to the deepest questions. This is in spite of the fact that there's virtually no hope of any relevant prediction making contact with experiment.

Meanwhile robust and vital physics is being done in areas like calculating QCD phenomena from first principles, untangling the mysteries of high-temperature superconductivity, using quantum mechanics to speed up computation without worrying about all the dead cat nonsense. I.e. doing research that is constantly confronted with the unforgiving standard of nature as we know it exists. Such work is old, somewhat prosaic, fiendishly difficult, tends to yield only incremental progress over the span of careers and does almost nothing to satisfy the primeval desire to somehow understand "what it all means".

Unfortunately, the multiverse is the only realm in which such spiritually satisfying pursuits are likely to flourish while I am alive. Maybe a bit like a habitual parishioner finally losing his faith completely, and facing the loss of the sense of certainty and wonder that faith once promised, I'm mourning. I used to love reading these gripping stories about strings and loops quantum proliferation. But it's dead to me now, and the storytellers are not sages; they're human just smarter-than-average beings who went far down the wrong path in pursuit of some standard of beauty they'll never realize, and likely doesn't even exist.

I'll look forward to the LHC telling us a bit more about things like QCD matter and the properties of the Higgs. I'll try to be more appreciative of the real science being done, and give the time and consideration people doing such difficult and important work are due. I'll once-and-for-all tell multiversalists where they can shove it.

10. **Simple biologist**
November 16, 2014

The comment about evolution is so ignorant that I can't even be bothered to de-construct it. Just about the only good thing left to say about these stringy multiuniversalists is that they serve as an example and warning of the pathology that happens to the natural sciences when they get separated from nature and observation.

I just wish that they wouldn't try take to take biology, chemistry, condensed matter physics and other forms of science still following scientific method down to their path into pseudo-science and metaphysics.

11. **Peter Woit**
November 16, 2014

LMMI,

I don’t think it’s at all necessary to only pay attention to ideas that are experimentally testable. Actually, testability in itself is not the real problem with the multiverse. The problem with the multiverse is that it’s inherently an empty idea, devoid of explanatory power, being invoked as an excuse for failure. In fundamental physics, there are a small number of questions we don’t understand, and there’s nothing wrong with speculative work with a long-term goal of understanding those, but now far away from useful contact with experiment. As an example: there’s a huge amount we don’t understand about QFT, and trying to improve that situation is very worthwhile, even if dealing with questions about QFT not relevant to experimental tests.

The problem is that this kind of hard work has trouble competing with hucksters who claim that they already have the answers. Such hucksters are always going to get on TV shows, the disturbing trend is that they’re now starting to get real traction in the scientific community itself. Dealing with this I fear is not a problem for the public, but a problem for scientists themselves.

12. **Steven**
November 16, 2014

Thr multiverse interpretation I think is a primary example of an empty or bad explanation like the Ancient Greek Myth of Persephone as an explanation for the seasons. It was specific/testable, but not truly falsifiable because you could ways move the goalpost or alter something without questioning the main idea.

13. **Neil**
November 16, 2014

Actually, Persephone was falsifiable, with a trip to the southern hemisphere where it is summer in january. The multiverse has lots of explanatory power. It can “explain” everything, and therefore nothing.

14. **chris**
November 17, 2014

Peiris’ take on evolutionary theory serves to show exactly two things: his utter ignorance and arrogance. unfortunately, physicists are derided as arrogant by many of the practitioners of the so-percieved “less hard sciences” and this is a perfect example why.

I wonder whether she realizes how much harm she does to the credibility of science with statements like these. Or if she even cares, for that matter.

15. **Visitor**
November 17, 2014

The tautology that Hiranya Peiris has in mind is “the survival of the fittest”. I.e. “they survived because they were fit and we know that they were fit because they survived”. In the context of evolution that is a tautology but it is not quite the same as Peiris’ garbled “an organism exists because it survived” .

“One problem with arguing that the multiverse is like the theory of evolution that physicists should keep in mind: creationists love it. ”

Let’s just keep them out of the argument. Saying that this or that theory is unacceptable because creationists like it is no better than saying that the multiverse is true because is supports atheism (which is Susskind’s position.)

See http://en.wikipedia.org/wiki/Association_fallacy

16. **Mike Sharples**
November 17, 2014

The “epicycles” analogy is an interesting one. However I think it is an analogy that applies to the Standard Model rather than the Multiverse. The arbitrary terms of the SM could be considered similarly to planetary epicycles, motivating one to look for a deeper model underneath which may explain why the terms are what they are.

Unfortunately the Multiverse says you can have any “epicycles” you like. No further explanation necessary!

17. **Stuart**
November 17, 2014

There is only one hope out of this multiverse/dimensions mania. Let the real falsifiable quantum theory of gravity show up.

18. **Mike Sharples**
November 17, 2014

“Let’s just keep them out of the argument. Saying that this or that theory is unacceptable because creationists like it is no better than saying that the multiverse is true because is supports atheism”

I am not so sure I agree. I think it is very important to understand why creationists like the Multiverse so much. It is not that they believe in it, they like it because it so seriously discredits the anthropic principle.

19. **Peter Woit**
November 17, 2014

Mike Sharples,
It’s not that creationists like the multiverse or care about the anthropic principle. What they (or at least some of them) do like is when prominent physicists announce that the theory of evolution and an obviously pseudo-scientific theory have the same status.

20. **B'Rat**
November 17, 2014

Just wondering… who exactly is investing the big money on such infomercials?

21. **Peter Woit**
November 17, 2014

B’Rat,
I don’t think filming a physicist talking in an exotic location and throwing in a few special effects is really all that expensive. So, this infomercial probably didn’t cost a lot

to produce, and it's being shown repeatedly on cable channels, funded by commercials and your cable fees. So, no big money needed, it's just the usual sort of project that TV production companies do all the time.

22. **Jeff M**
November 17, 2014

Actually the "tautology" argument really is just silly, and shows up Peiris as at best completely uninformed. Biologists have of course known about that from the beginning, Stephen Gould talks about it quite a lot. "Survival of the fittest" is a tautology, but that's not what evolutionary biologists talk about. They talk about natural selection, and how it operates on various traits. Simple Biologist would no doubt be able to give a much better explanation than I can, as a lowly mathematician, but it's very clear that evolutionary biologists don't use any sort of tautological arguments. It's depressing that a high end physicist thinks they do.

23. **Nobody**
November 17, 2014

Jeff M,

To me. the TOE _is_ tautological in the sense that it is so good that, if it were not true, that fact would require an explanation – that is, in the absence of experimental evidence directed for or against the TOE, one would expect it to be true. This would not, of course, be a true tautology but rather, it seems to be a prediction or consequence of already known science. The amazing discovery would be that the TOE was _not_ true, and we would have to search for an explanation.

OTOH, the falsity of the multiverse would require no explanation. One does not expect it to be true on the basis of uncontroversial science,

This would make the TOE completely dissimilar to the "gee whiz" multiverse, which is just an escape from the hard problem of understanding and explaining, in a verifiable way, the particulars of this physical reality which we have come to know and love, and for which we have more concrete evidence than that we can imagine it.

24. **Peter Orland**
November 17, 2014

"To me. the TOE _is_ tautological in the sense that it is so good that, if it were not true, that fact would require an explanation – that is, in the absence of experimental evidence directed for or against the TOE, one would expect it to be true."

You must be joking. This is not a scientific argument. It reminds me of arguments for the existence of god – or communism – or scientology.

25. **Peter Woit**
November 17, 2014

All,
Not much point in arguing about the possibility of a self-evidently true TOE, all that's clear now is that no one has a candidate for such a thing. And if there were such a thing, I don't think it would be "tautological", but rather some sort of opposite of tautological, not telling us nothing new, but telling us everything.

26. **Supernaut**
November 17, 2014

"I haven't seen anything using Planck data released so far." Lloyd Knox of UC Davis gave a popular talk last week about the Cosmic Microwave Background as observed by the Planck spacecraft. At the end of the talk someone asked him about this (multiverse collisions) and he stated that they had seen no evidence to support this.

27. **Theo Nieuwenhuizen**
November 17, 2014

Dear Peter, this multiverse nonsense is more than I can bear. How can serious people throw our trade in the garbage bin on selling nonsensical emptiness? They also make me look like a fool, I am in the same trade, called physics.
But one thing is clear already: the many worlds idea about quantum mechanics is a mistaken, nonsensical issue. I spent 15 years on studying what goes on in quantum measurements, the only point of contact between the quantum framework and the reality of tests in detectors. We have good results and a good picture of what goes on. What is very clear: the many worlds idea comes in nowhere and it has nothings to to with the whole subject. It is a lot of talking about a misconceived structure of the theory. You better adopt the ensemble interpretation, and for those who don't like that, let me add: Einstein worked on it, even in his last year.

28. **David**
November 17, 2014

Mike Sharples,
"Unfortunately the Multiverse says you can have any "epicycles" you like. No further explanation necessary!"
In a sense this is true. But I'm guessing the folks in favor of the multiverse argue that what makes the multiverse explanations for things possible is string theory with its myriad of ways the extra dimensions can compactify. Presumable, string theorists are hoping that eventually we will understand string theory much better, and be able to understand the mechanism by which a multiverse is generated as well as what makes each "universe" take on the specific set of laws it takes on.

But perhaps in the distant future, some theory (be it string theory, or something completely different) will come along and do a superb job at explaining everything we see around us, unifying gravity and quantum mechanics, and all the particles and interactions. Perhaps it will be validated by many experiments. But if it predicts a multiverse, then that would be very strong (indirect) evidence in favor of a multiverse. Perhaps this theory will rely on the multiverse explanation for at least one parameter that we observe (eg, dark energy). If the multiverse exists, then I suppose that's the closest we can come to showing it exists.

29. **Peter Woit**
November 17, 2014

David,
Sure, if you have a well-tested theory that implies a multiverse, that would be a good reason to believe it. With string theory though, this is being used the other way around, with the multiverse given as the reason for not being able to test it.

Theo,
I pretty much agree with you about the many worlds interpretation. But I hope people who want to argue about that will wait for a post where it's the topic, which I'll get around to some day…

30. **Nobody**
November 17, 2014

Peter Orland,

“You must be joking. This is not a scientific argument. It reminds me of arguments for the existence of god – or communism – or scientology.”

It’s not a scientific argument for what?

I said that one would *expect* the TOE to be true and that if it turned out not to be (obviously implying experiments) one would need to know why. That is not an argument either …

Wait a minute, I know what’s wrong. I used “the TOE” to mean “theory of evolution” and you (and Peter W) took it to mean “the theory of everything”.

(slapping forehead)

I was trying to outline a substantial difference between the type of theory that was the theory of evolution, before it was established through research, and these theories of everything that are making physics look like a carnival side show. The reason I am doing it is that the comparison was made in the article referenced above.

31. **Peter Orland**
November 17, 2014

Sorry about the misunderstanding, Nobody.

32. **Peter Woit**
November 18, 2014

Nobody,

Funny. I thought the particle physicist’s had a trademark on “TOE”…

33. **nb**
November 18, 2014

“One problem with arguing that the multiverse is like the theory of evolution that physicists should keep in mind: creationists love it.”

Not just they love it. The cited argument is the so called ‘tautology argument’.

http://www.talkorigins.org/faqs/evolphil/tautology.html

Can’t find the right words.

34. **Tammie Lee de Cortez Haynes**
November 18, 2014

Dear Dr Woit
.
You really shouldn’t tell us what Creationists think.
Unless you like telling us stuff that’s wrong.
.
I’m a Creationist.
I like the multiverse for this reason:
If the multiverse is the best case that Atheists can offer, Creationism is in the catbird seat.

35. **scottrileywilson**
November 18, 2014

Peter,
As bad as you think these “theorists” are I don’t even think you fully realize the negative impact they have and are making. Science has become religion. Peer review has become the new authority…etc

36. **Curious Mayhem**
November 18, 2014

Umm … there’s no evidence for any multiverse in the BICEP2 data.

If they mean evidence for inflation, inflation doesn’t require a multiverse. Even the Linde eternal inflation idea is not the modern multiverse concept, which comes from trying to save string theory from itself.

Meanwhile, while there’s no string cosmology, “string-inspired” cosmology has a hard time predicting inflation. If the next round of precision CMB measurements do confirm anything like what BICEP2 reported, string theory will have suffered another mortal blow.

How this is related to Darwin’s natural and other mechanisms of selection and evolution is beyond me. Unobservable multiverses, mutually disconnected, don’t “compete” in the same ecosystem and have nothing to adapt to. From a mathematical point of view, there’s no defined space of possibilities, or measure on that space. How do you compute probabilities?

I know, I know — I just don’t appreciate the poetry of it.

37. **Monty**
November 19, 2014

Peter, you wrote: “The problem of course with bubble collision “predictions” are that they’re not falsifiable. As far as they’re concerned, you can only win: seeing nothing doesn’t disprove the multiverse.” There’s not really anything wrong with this kind of search for corroborating evidence though, really. I mean, what’s the difference between that and, say, someone hunting for exoplanets in 1960? It was theorized that other stars should have planets, and until we had better equipment no one would have suggested in 1960 that not finding any was proof that there were none out there. But if there *happened* to be one big enough and near enough that a telescope in the 60s could see it, well great. The hypothesis that there were exoplanets was not falsifiable in 1960, but someone could have proved it if they’d got lucky. By analogy, some people think we live in a bubble universe that could in the past have intersected with another bubble, leaving a trace. If we find such a trace, that will be a pretty good data point. If we don't–well you're right, we don't learn anything from that, because maybe the hypothesis is wrong, or maybe the traces are too far in our past, or maybe we're not looking right, or maybe our bubble is still a "virgin". But does that really mean no one should be allowed to look for the traces in the first place? There are probably better examples than exoplanets… counterexamples to the Riemann hypothesis? If we look and don't find one, we haven't learned anything. Should we not bother looking, then, because it's a search that can only result in winning or stalemate, but never losing? Or SETI signals–no one will ever be convinced no one else is out there just because SETI doesn't find any signals. Does that mean they shouldn't even look? etc. etc.

I mean I agree there's no evidence at all to believe that our bubble ever intersected another, or even that there were ever any other bubbles coexisting with ours in the first place. But you can't also blame people exploring these ideas for actually going and looking for evidence – surely that can't be a bad thing?

38. **anon.**
November 19, 2014

Monty: a better analogy is philosopher Auguste Comte (1798-1857) who (prior to the discovery of emission and absorption line spectra from various elements in sunlight) claimed it impossible to ever know the composition of the sun, because it's too hot to visit and sample. This is typical of defective "no go theorems," which only get "accepted" without scrutiny because nobody has the time or inclination to argue over them. Woit and others are not, however, claiming to disprove and discredit all research on certain topics that are currently unproductive; rather they are trying to deflate the hype from populist speculations that are way overblown in the media.

39. **Dom**
November 19, 2014

Monty. As I understand it, the problem is not speculation and trying to find things out, it is partly presenting science fiction as science fact and partly suggesting that anything we don't have an answer for is "Because Multiverse".

40. **Nobody**
November 19, 2014

"There's not really anything wrong with this kind of search for corroborating evidence though, really."

There's nothing wrong with looking to see what's there – in fact it's necessary, but since you put it that way ("corroborating evidence"), what is it that you are trying to "corroborate"? Do you have any falsifiable predictions about the signal or is it "anything surprising will do"? If you can't make a falsifiable prediction then you can't use unpredicted results as a "corroboration" of an existing scientific theory.

So what is the theory and what observations does it predict?

How would an unexpected, unpredicted, structure in the sky "corroborate" an existing theory that makes no predictions any more than the existence of specific constants in our familiar world, which constants have never been derived from an over-arching theory that survives Occam's razor, "corroborates" the multiverse? How would your multiverse theory without predictions be any better than "God set it up that way"?

A large scale, unpredicted, structure is nothing. Were such a thing found, you would have to write a theory simpler than the result and then verify it through its predictions. You aren't at the first step of that. You haven't even begun. You haven't found something unknown to explain.

You multiverse lovers are already involved in overwrought promotion of fantasy as fact in the popular press. I dread the impact of an actual discovery on that existing, shameless performance, but _I_ predict that, should that happen, there will be an overnight cobbling up of some BS theory which would magically be much easier for our geniuses to arrive at than a theory explaining the parameters of our known laws, especially since multiverses are so fascinating to the gullible. Thinking will come later.

Oh wait, I forgot – the parameters of our laws have already been explained by the multiverse theory, as a consequence of its 3rd law – "whatever is, is".

Kaku's a good at this TV stuff. Perhaps you can arrange, beforehand, for him to explain how the multiverse is proven the very evening after something unknown is discovered or even better, he could explain it the day before as he already is.

As for exoplanets, their existence is a straightforward expectation from known theory. The form of an exoplanet's signal was predictable and easily separable from spurious results. The discovery of their signal confirmed what was predicted and is providing fine tuning detail.

41. **Peter Woit**
November 19, 2014

Monty,
Of course I'm not arguing one shouldn't look, but just pointing out this is not a falsifiable test of the theory, and when, as everyone expects, nothing is found, no one will report on this or pay any attention.

42. **Fred P**
November 19, 2014

"The theory of evolution, Peiris argues, also resembles a tautology in certain respects — "an organism exists because it survived" — yet it holds tremendous explanatory power."

"an organism exists because it survived" is an observation, not a theory. It is an inaccurate re-statement of survival of the fittest (inaccurate in part because survival of the fittest works on populations over generations – it doesn't describe an individual organism), which is a somewhat misleading phrase describing the process of natural selection. Natural selection is quite testable and verifiable, even if the biochemical mechanisms behind natural selection were not known for a long time after On The Origin of Species was published; indeed, On The Origin of Species itself has a lot of evidence for natural selection. On The Origin of Species, 1st edition 5th edition, with a definition of "Survival of the Fittest"

Finally, natural selection itself is only a subset of the modern theory of evolution. Mutation bias (some mutations are biochemically more likely to occur than others), as one example, is also part of the theory of evolution which is not part of natural selection. Sample source on Mutation bias)

So Peiris is arguing using an inaccurate re-statement of a misleading description of a portion of the theory he's claiming that he's describing to attempt to buttress a particular theory.

43. **Katy**
November 25, 2014

I personally never found the concept of the multiverse to be beautiful, though I was willing to accept it as a grim reality. We should be relieved if the multiverse were universally accepted as bunk. There is plenty left to ponder and strive for without chalking up every event as "bound to happen somewhere in the multiverse."

Planck News?

November 19, 2014
Categories: Uncategorized

The timing for release of long-awaited Planck polarization data keeps getting pushed back. At one point it was supposed to be earlier this year, most recently it was supposed to be this month, with that timing forced by a conference devoted to discussion of the results planned for December 1-5. The website for that conference now says:

> The 2014 Planck public release of data products and papers will actually take place a few weeks after this conference. This conference is therefore the first occasion to preview the Planck 2014 data products and discuss their scientific impact. The presentations will be videocast online. After the conference, the presentation slides will be made available.

Another conference scheduled assuming the data will have been released is this one in Paris December 15-19.

The Planck website now reports:

> – The data products and scientific results will be presented at a public conference in Ferrara. The presentations will be videocast during the conference and slides will be made available after the end of the conference.
>
> – It is planned to release all major data products and scientific papers to the public before the end of 2014. A few of the derived products (e.g. the Likelihood code) will need a little more time to be readied for release, but will be made public within the month of January 2015.

David Spergel on Twitter reports December 22 as the date for release of papers and data.

It will be interesting to see how the cosmology community deals with the situation of no papers or data, just videocast and slides, from December 1 on. From similar situations in the past, some people have highly developed technology for scraping data off slides, presumably that will be in high demand.

Comments

1. **piscator**
   November 19, 2014

   Given that one informally hears from people in the collaboration that it is a desperate rush to get these papers written in time, the question arises as to how trustworthy and nailed-on the results will be. e.g even the WMAP-9 paper, with much more time on a well-understood instrument, had in its original version a significant error in the headline numbers in the abstract.

2. **JG**
   November 19, 2014

   Oh dear, so it looks like the 700 million euro Planck project won’t be able to rule out BICEP2’s conclusions after all. Christmas time release of disappointing news is an old trick.

3. **West**
   November 20, 2014

   Everyone expects there to be a mad dash for whatever sort of data that can be gleamed from presentation slides. I am more curious what the Planck collaboration is doing to try to manage the free-for-all.

   With seemingly reliable techniques to estimate the uncertainties inherent in screen-scraped maps, I hope we won’t see a replay of previous silliness. If Planck doesn’t come out with its own preliminary parameter estimates, someone else definitely will (poorly done or not) using their now public data. So I expect some actual numbers from the first December conference and not just a flashing of maps on the screen for a second or two.

   Or the entire presentation could be devoid of images, which would be a hilarious tease to the model building theorists.

4. **Ben Gold**
   November 20, 2014

   I think with Planck’s high resolution screen-scraping is less valuable, and the current excitement is around B-modes which you will never get in any believable way by screen-scraping a polarization map. I imagine the main delay of releasing maps is precisely because they know full well that the instant they’re out people will be running their own analysis code and publishing power spectra and cosmological parameter estimation.

   In any case, it sounds like their plan is to release the maps and basic parameter results at the same time. Likelihood code gets released a little later mostly because that’s a pretty big chunk of software & data that has to be cleaned up once the analysis chain has settled down.

5. **Sesh Nadathur**
   November 24, 2014

   Ben Gold: it doesn’t seem to make much sense releasing parameter results and model constraints if the likelihood code is not settled. Probably only those non-controversial results will be released where a later change in the likelihood code is unlikely to result in a significant change to parameter fits. Which means there won’t be much new to learn from Ferrara.

6. **Ben Gold**
   November 25, 2014

   Sesh: I meant more that the likelihood code release usually happens after running -all- chains, including the weird stuff like simultaneously allowing tensor running, variable neutrino number, isocurvature modes, etc. Some of those chains can take a long time to converge, and sometimes involve changes to the code which are insignificant unless you’re one of the three people worldwide interested in that particular model. But they’re totally unnecessary for a “basic results” paper.

   That doesn’t mean only non-controversial stuff can be released before then, since there could be something new that’s demonstrably robust against other weird parameters (say, n_S running) without requiring lengthy chains of every possible parameter combination.

7. **Martin**
   November 28, 2014

   Peter, as always thank you very much for the comprehensive coverage! Interestingly, the following statement is now missing on the conference page: “The presentations will be videocast online. After the conference, the presentation slides will be made available.”
   Maybe they changed their mind to prevent the problems you alluded to (screen-scraping etc) ??

The Imitation Game

November 19, 2014
Categories: Film Reviews

This season's Hollywood math/physics extravaganza is starting to come to an end. For coverage of the Breakthrough Prize ceremony, I enthusiastically recommend Michael Harris's new piece at Slate which just appeared.

The final high profile production, one promoted at the Silicon Valley ceremony, should be The Imitation Game, a film based on the life of Alan Turing, to be released on November 28th. I had the chance to attend a preview screening last night, featuring a Q and A with the film's screenwriter. The short version of a review is: go to see this is you like watching Benedict Cumberbatch and Keira Knightley perform, but if you want to know anything about Turing, avoid the film and spend your money instead on a copy of the new edition of Alan Turing: The Enigma by Andrew Hodges.

Turing's story was little known until 1983, when Hodges published his biography, which is just fantastically good. Hodges (see his web-site here) is a mathematical physicist who began working with Penrose back in the 1970s on twistor diagrams, work that has recently played a prominent role in the hot topic of new methods for computing scattering amplitudes. The Hodges book made Turing a famous figure, partly for his code-breaking role, partly as a martyr for gay rights given the horrific story of the way he was treated because of his sexual orientation. By 1986 the biography had inspired a play, Breaking the Code, that ran in London and New York, and then became a 1996 movie. There have been other film treatments of the story since, including the 2011 Codebreaker.

Other than a few general facts, the part of the film set at Bletchley Park has little relationship to reality, with almost none of what is portrayed actually having happened. As just one example of the sort of thing that was made up out of whole cloth, the film has Turing discovering a Soviet spy, who uses his homosexuality to blackmail him into silence. Cumberbatch plays a compelling character, but one much like his Sherlock Holmes on TV, not like the Turing of the Hodges book, or like any other mathematically talented person I've ever known.

It often mystifies me why people who make movies based on fascinating real stories sometimes just ignore what really happened and instead make up a much less interesting plot. In this case, hearing from the screenwriter after the film made the problem clear. He seems convinced that Turing is a little known figure, and that it is his job to reveal this unknown story to the public, unaware that this was done much better back when he was in pre-school. From his comments, he never bothered to understand anything about what Turing actually did during the war, in particular he is convinced that Turing's big breakthrough was to realize that to break codes it was helpful to know some phrases that were likely to be in the message (e.g. "Heil Hitler"). He explained that he was sure that Turing saw himself as a figure in a thriller, and that informed how he wrote the film. All in all, he had a very simplistic agenda (to reveal the unknown fact that a gay man had won World War II) which completely overwhelmed any interest in the details of what actually happened.

The contrast with the recent Stephen Hawking biopic is striking. That film took some dramatic license, and simplified some complex people and situations, but it didn't just completely make things up, and the star's portrayal of Hawking was convincingly true to life. The memory of Alan Turing would have been much better served by a similar degree of respect for reality.

Update: The Guardian has a review, which explains some of what the film gets wrong. For something with more detail, see this.

Comments

1. **S**
   November 19, 2014

   This is very discouraging to hear. "Breaking the Code" is a fine play — it's too bad, even mystifying, that they didn't trace that back to its source (which would have been easy).

   I second your mystification point. Years ago, I was involved in a society devoted to the work of a writer (who had an exceptionally interesting life) and we were contacted by a group of filmmakers who were making a fairly high-profile film about him and wanted help locating an example of his handwriting so that they could get every detail perfect. We obliged, of course, but imagine our surprise when they had completely substituted his life with far less interesting Hollywood boilerplate in the film.

   Some things never change I guess.

2. **Jeff M**
   November 19, 2014

   Peter,

   Not to pick nits, but describing Turing as "mathematically talented" is kind of like saying that Micky Mantle was a pretty good ballplayer. 🙂

   I am not a logician, nor do I play one on television, but Turing's proof of Godel's theorem is one of the most beautiful things I've ever seen. And he did much much much more than that.

3. **Peter Woit**
   November 19, 2014

   S,
   The Hodges book is credited as "inspiration" for the film, and some of what's in the early part of the book about Turing's experiences in school and his first love for another boy is used in the film. I suspect though that once the story moved to Turing's actual career and the work done during the war, this became technical material the screenwriter had no understanding of or interest in. From then on, supposedly more dramatic fiction replaces non-fiction.

   The Soviet spy business is a weird example, since it's not only a fantasy the writer dreamed up, but exactly the fantasy that later motivated Turing's homophobic persecutors (i.e. that his homosexuality made him someone the Soviets could blackmail).

4. **bugannoyer**
   November 19, 2014

   In case you want to read a more entertaining fantasy involving imagined Turing activities during WW II, I recommend Neal Stephenson's "Cryptonomicon". Turing is a secondary character.

5. **Sammy**

November 19, 2014

If anyone has any doubts about reading the Hodges biography, then I should pass on that in 1983 I loaned my copy of the 1st edition to a couple who had actually worked with Turing. They both said it was very faithful to the man they knew.

6. **Yatima**
November 19, 2014

Seconding "buannoyer" on "Cryptonomicon". It's a fun but sometimes overly loquacious story. A notable book of 1999.

It is an interesting twist of history that Alan Turing, inventor of the concept of the Universal Turing Machine, designed the specialized "Bombe" to break the Enigma cipher in Hut 8, while the world's first fully programmable electronic digital computer, the Colossus, was designed by Tommy Flowers just a hut or two away to break the Lorenz cipher.

P.S. @Jeff M.: "Turing's proof of Godel's theorem". I suppose you are talking about the negative answer to Hilbert's "Entscheidungsproblem": Given a formula in First-Order Logic, is there a procedure that can say whether the formula is a tautology or not? Gödel's completeness theorem proves that if the answer is "yes", this will eventually be proved (which practically may take longer than the universe's lifetime though). Turing showed that if the answer is "no", the procedure may well never find out. Alonzo Church proved the same a bit earlier using a different approach.

7. **Jeff M**
November 19, 2014

@Yatima,

Yes, but I was keeping it simple for the physics types 🙂

8. **anon.**
November 20, 2014

There's a nice extract from Turing's popular article, "Solvable and Unsolvable Problems", published by Science News in 1954, here:
http://www.ens.fr/IMG/file/internationale/2009/Sciences/Sujets_commentaire_SIS09_en.pdf

9. **Em Comments**
November 20, 2014

"Turing's story was little known until 1983"

Yes exactly. That's why the Turing Award (http://en.wikipedia.org/wiki/Turing_Award) which is described as 'the "highest distinction in Computer science" and "Nobel Prize of computing"' was created in 1966 as he was unknown until 17 years later.

10. **dpb**
November 20, 2014

@em comments

Turing was known as a pioneering computer scientist and mathematician in the 50s and 60s, but very few people had any idea what he was up to during the war. People from Bletchley Park tended not to talk.

11. **Visitor**
November 21, 2014

No one else seems to care but I am profoundly offended by the idea that Turing "won the war".

12. **Dom**
November 21, 2014

Visitor, you may be British and I may have the wrong idea, I don't know but speaking as a British person, the oft-repeated snippet from the trailer where the character says something about "Breaking an unbreakable code and winning the war" is to my ears typical British humour where we will matter of factly put together two difficult and possibly unrelated things as if it was a formality.
Having said this and having read Hodges book when it was first published as my late father had a great interest in Enigma, the film looks like a missed opportunity.

13. **srp**
November 21, 2014

Turing's work gets what sounds like better treatment than John Nash's did in A Beautiful Mind. How hard would it have been to get the Nash equilibrium concept right instead of mangling it completely? It's not that abstruse an idea.

14. **Michael Shain**
November 21, 2014

Our local cinema, The Phoenix, in East Finchley, London had a special showing of The Imitation Game followed by a question and answer session with a panel a member of which included a very lively Ruth Bourne well into her eighties.
Ruth was a Royal Navy Servicewoman who was a Bombe operator and was asked about war time romances at Bletchley Park. The entire cinema audience collapsed when she said "the odds were good but the goods were odd".
There is a wonderful interview on YouTube recorded in 1992 "From Code Breaking to Computing: Remembrances of Bletchley Park 50 Years Later"
http://www.youtube.com/watch?v=6p3mhkNgRXs
where Jack Good, who worked with Turing, and Donald Michie are interview by David Kahn. To quote from the blurb:
"In this 1992 interview Jack Good and Donald Michie discuss their cryptanalytical work during World War II at Britain's Bletchley Park. The technical aspects of Germany's Enigma and Lorenz Geheimschreiber, the code-breaking Bombe, Heath Robinson, and Colossus machines, and the personal contributions of Max Newman, Alan Turing, and Tommy Flowers are explored. Donald Michie, in the final part of the interview, offers some details on the origins of artificial intelligence research."

15. **Dom**
November 21, 2014

Bill Tutte and his reverse engineering of the Lorenz machine configuration just from the ciphertext always deserves a mention I think.
Bill Tutte Wikipedia

16. **Visitor**
November 22, 2014

"The contrast with the recent Stephen Hawking biopic is striking. "

…along with a few other striking contrasts. For example, Hawking is still alive whereas Turing is dead and couldn't object to anything that the film makers wanted to do. There is no doubt that had Hawking died before the picture about him was made, the contrast between it and the Turing picture would be rather less striking…

Remember: a story "based on a true story" is false story.

17. **Joe Prokop**
November 22, 2014

Hi,
This link was posted on a film review website for the Imitation Game,
http://en.wikipedia.org/wiki/Marian_Rejewski.
It would appear that a joint effort by Polish and French Mathematicians including Unercover activities broke the Enigma Cipher in 1932. Mathematical Techniques developed by Prof. Rejewski and colleagues solved the Cipher. It is interesting how this has never been recognized in the popular accounts about code breaking during WW II.

18. **Chris W.**
November 22, 2014

Michael Shain mentioned Tommy Flowers. See this article, published about a week ago on IDGConnect.com:

> As contemporaries explained in a short film made by Google, once war was over the orders were to smash everything to pieces. According to these testimonials some Colossus machines were even dumped down coal mines. This was extremely galling for the people who had worked hard, for years, creating and nurturing these machines.
>
> It also pushed back the development of computing. "Tommy Flowers held various master documents in a safe concerned with Colossus and he had been instructed that these were to be destroyed," described one individual. "And he went down to the workshop and destroyed them. Put them on the fire. That was the end of them."

19. **dom**
November 23, 2014

The Poles have been given credit for their work in the detailed accounts I have read.

20. **Dom**
November 24, 2014

As a follow-up to my comment about the Poles, here is a timely bit of correspondence in The Guardian Engineers, linguists and other heroes

21. **Peter Shor**
November 29, 2014

@Joe Prokop: As I understand it, the Poles and the French broke the 1932 Enigma cipher and got the techniques to the British. But by 1939, the Germans had changed the Enigma machines and made the cipher harder to break. So Turing and Bletchley Park actually needed to do more than just use the Polish techniques.

22. **R.K.**
December 1, 2014

"not like the Turing of the Hodges book, or like any other mathematically talented person I've ever known"

one could remark that it is usually interesting to see how (male) mathematicians and physicists tend to define 'themselves' by certain 'habits', certain behavioural traits that they obviously think they somehow learned already during infancy, or even before and not while conformizing each other during the eras of shapening their career. Instead of taking the above dicscussed film, I didn't see it and will not ever make any attempt to see it, as a starting point to discuss stereotyping of and *among* mathematicians and how these patterns could maybe possibly be overcome in the distant future, one takes the 'mis-match' of the film with a possible stereotype as a further proof that 'it doesn't show reality'. To remind the reader also of that: art is not about reproducing reality, even if a film or a piece of 'art' (I don't know if I wouldn't call this film art, but it could be close) is based on real characters or events it is usually judged as a poor endeavour for any artist to merely reproduce 'reality' that i.e. the cinema misleadingly often tries to imitate. Instead, such films possibly have to be viewed as documents how society deals with science and/or mathematics and such endeavours can be shallow, but they will always lead to interesting insights, if more on a meta-level (i.e. discussions like these here).

23. **Curious Mayhem**
December 3, 2014

One of the striking things about the real story of Turing is that it is unlikely that he died a suicide. His mother, for one thing, emphatically denied it. It seems that Turing had a penchant for experiments with poisonous chemicals, which is probably what led to that deadly apple bite. See *Turing: Pioneer of the information age*, by B. Jack Copeland.

For Your Viewing Pleasure

November 29, 2014
Categories: Uncategorized

If you've already seen the various new math/physics films coming out of Hollywood, this week you might be interested in watching some of the real thing, including the following:

- The hot ticket this week will be Monday's Planck session at the conference in Ferrara. They've now edited their website to remove references to a promised webcast and slides. So, the only way to get images suitable for scraping may be to get yourself into the lecture hall at Ferrara and bring a camera. Press release here, conference program here.
- Also on Monday, if you're in Cambridge (MA), there's Steven Weinberg's Lee Historical Lecture in Physics, topic Glimpses of a World Within. The only blurb is

  > "Since the 1970s the evidence has accumulated that the structures appearing in the laws of nature at a really fundamental level are vastly smaller than anything we encounter in our high energy laboratories."

  which I don't think I'd personally agree with, quite curious to see what case he makes. These lectures often are later made available here.

- For another historical lecture, there will be a webcast of this event at CERN on Tuesday. It features film of interviews with Roy Glauber, characterized as "the last living scientist from the Theory Division of the Manhattan Project". Glauber taught the first quantum field theory course I ever took, at Harvard in 1976-77, almost forty years ago (I thought he was pretty ancient at the time). The year earlier I had taken quantum mechanics with Norman Ramsey, here shown signing Fat Man. At the time it seemed perfectly normal that all my instructors had gotten their start designing weapons.
- If you're in Berkeley this week, you could attend a Langlands-related conference at MSRI, which in addition is honoring Michael Harris. Program is here, videos to appear soon after the talks.
- Recently concluded at MSRI was a workshop on geometric representation theory, with lots of interesting talks, videos available here.

Update: There is supposed to be video from Ferrara here, but not working. A press conference was held, but the only thing I see from Planck online is in French here. Nothing about primordial gravitational waves, just confirmation of the standard cosmological model and of 3 neutrinos.

Update: No public release of any numbers from Planck that I can see, although they are being discussed in Ferrara. People are pointing out that the authoritative source for the best values of cosmological parameters at the moment is Twitter.

Update: Peter Coles has this take on the Ferrara Planck results: "a bit of a farce." Among the many oddities here, it seems that only the French component of Planck is putting out any news to the public.

Update: Adrian Cho at Science has a report about the latest Planck results here. Speculation is that Planck data alone and their joint analysis with BICEP2 will not see a gravitational wave signal, just set an upper limit. Planck is supposed to release papers Dec. 22, unclear if this will include the analysis with BICEP2.

Comments

1. **Arkadaş**
   November 29, 2014

   On the Loeb & Lee Lectures page that you link to, there is also a link to a talk by Glauber titled Recollections of Los Alamos and the Nuclear Era.

2. **David Appell**
   November 29, 2014

   Hi Peter. I'm just curious — how much did you learn in your first QFT course by Glauber, compared to what you know today?

3. **Peter Woit**
   November 29, 2014

   David,
   Not very much, for one thing the class was way above my head (I was a sophomore…) so while I learned a lot in it, I missed even more. Given Glauber's interests, the course was aimed not at the hot topics of that moment (gauge theory, the standard model), but at other applications of qft, including condensed matter and quantum optics. I then went on to take QFT courses from Coleman and Weinberg, learning about Yang-Mills theory and the path integral method. It seemed to me that the lesson of the Standard Model was that path integrals were the way to go, much simpler conceptually than canonical field theory methods that Glauber was using (just pick a Lagrangian and start turning the crank…). I think I kind of dismissed much of the material of Glauber's course as old-fashioned and unnecessary.

   I've kept learning more and more about QFT over the years, and I've in recent years grown to appreciate canonical methods, that's mostly what's in the course I'm teaching. These provide a connection to representation theory that is much harder to see in the path integral. Nowadays my point of view is that we don't truly understand QFT, with the standard story in all the textbooks just one slice of much wider topic.

   So, taking Glauber's course was just a first step, there's a huge amount to learn from what we do about QFT, far beyond what is in typical courses and textbooks, and a huge amount we still don't know.

4. **Mark Hillery**
   November 30, 2014

   I never took a course from Roy Glauber, but, since I have worked in quantum optics, I have made extensive use of the techniques he developed. He is one of the founders of the field, and by determining which quantum states of the electromagnetic field correspond to its classical description, he was able to show when distinctly quantum effects come into play. His papers are masterpieces. Just this last summer at a conference three of us, Pierre Meystre, the editor of Physical Review Letters, Carl Caves, who has made numerous highly significant contributions to quantum optics and quantum information, and I were discussing how elegant Roy's papers are and how they can serve as models for younger physicists. Those of us who have worked in the field were delighted when Roy's contributions were recognized by his sharing the 2005 Nobel Prize in Physics.

5. **Doug McDonald**
   November 30, 2014

I have no idea if Glauber was at Harvard when I was (1966-1970) (in the Chem. dept) but I did meet Ramsey a couple of times and visited his lab. My housemate worked for Klemperer, who did molecular beam electric resonance while Ramsey was a magnetic beam resonance type. The big deal (i.e. envy) was that Ramsey had a PDP-8 before Klemperer got an HP machine, and only slighter later did I get a PDP8-e for our beam scattering experiments. All those computers would be big big ticket memorabilia today.

But the physics story was that I sat in on (alone among chemists!) Schwinger's quantum mechanics class (not field theory). He delivered exceptionally lucid lectures that I, even from the start, even as a chemist (but I had already had the corresponding chemistry class, once at Rice, once at Harvard), had detected to be the "Chinese Lunch" of exposition. He could make you think, from the reasoning he delivered, that if YOU had been there 1920-1940, YOU could have replaced Schrodinger or Dirac (not so much Heisenberg) … in class … but five minutes later and little bit of thought, it all fell apart. The physicists actually taking the class eventually realized this too.

I'd love to find out if any people who later became famous were in that room.

A tidbit question: what did Glashow's license plate read?

6. **Brathmore**
   November 30, 2014

   Peter,

   You took QFT as a sophomore, and QM as a freshman (along, presumably, with Math 55)? I'm astounded. I suppose you must have taken several college level courses while in high school to pull that off! Wow.

7. **Peter Woit**
   November 30, 2014

   Brathmore,
   I'd studied multivariable calculus and physics on my own in high school, so QM and Math 55 were courses I was prepared for (and did fine in). Taking QFT as a sophomore was something a responsible advisor would probably have stopped me from doing. Luckily I was assigned Glashow…
   But, for just about anybody, I'd argue two QFT classes at least are what it takes to get any handle at all on the subject.

8. **Aaron**
   December 1, 2014

   Do you remember what text you used for the multivariable calculus?

9. **Peter Woit**
   December 1, 2014

   Aaron,
   Funny, but I realized I still have that book, it is a Calculus book by Hocking
   http://www.amazon.com/Calculus-introduction-linear-algebra-Hocking/dp/0030779103
   I don't remember how I got it, I don't think there was any good reason for that book in particular, and I don't recommend it, there are lots of similar and better books. Looking at it now I see it doesn't include some vector calculus (e.g. Stokes theorem), which I guess I must have learned elsewhere (E and M?).

10. **paddy**
    December 1, 2014

    Peter,
    As best as I can remember, I must have had Coleman 75-76 ish for QFT immediately before Glauber took over for your years. I do appreciate your point: at that young age the more times I was exposed to the same subject alternately constructed the more I learned.

11. **Bob**
    December 2, 2014

    Does anyone know if Roy Glauber is related to Robert Glauber, currently at Harvard's Kennedy School?

12. **Bernhard**
    December 4, 2014

    The video session (which was really good) with Roy Glauber is now available here:

    https://cdsweb.cern.ch/record/1973615

    I actually managed to download to a mp4 file (no link available, but if you know how to do it for youtube, it's the same principle here).

13. **Surjit Singh**
    December 8, 2014

    Does anyone here have any opinion on this controversy here?
    http://en.wikipedia.org/wiki/E._C._George_Sudarshan#Controversy_regarding_Nobel_Prize

14. **Shantanu**
    December 9, 2014

    Surjit: Sudarshan's case was discussed on this blog a while back.
    http://www.math.columbia.edu/~woit/wordpress/?p=311&cpage=2
    Not sure what became afterwards of these petitions etc. There are very few people who read this blog who have expertise in this field to confirm or refute this.

The Multiverse in a Nutshell

December 1, 2014
Categories: Multiverse Mania

The Guardian has a podcast up today featuring Robert Trotta and David Wallace called The Multiverse in a Nutshell. It's largely more of the usual uncritical multiverse hype that has been flooding the public expositions of fundamental physics for years now. Trotta gives the usual promotion of the cosmological multiverse, with no indication there is any problem with it. He assures us that this is being tested (by looking for "bruises" in CMB collisions). As far as I can tell, the Planck results released today, like all CMB data, show no evidence for anything like this. It appears that the Planck people don't even think this is worth mentioning. The public channels used for this hype will never report the fact that there's nothing there, instead they will just endlessly talk about this as something "scientists are looking for."

Wallace talks about something completely different, many-worlds, with nobody telling listeners that this has nothing at all to do with the cosmological material. Instead we're told that it's all related, because "most theories" "tell us there must be a multiverse". When challenged about the splitting universe business in QM, Wallace admits that at the fundamental level there is no splitting, there's just one theory and one universe, that "many worlds" is just a way of talking about the emergent behavior of the classical approximation. His book about this, The Emergent Multiverse, is quite good and makes clear what the "Multiverse" there really is. It's a real shame that he chooses to involve himself in this kind of attempt to muddy the waters and promote pseudo-science to the public.

Thankfully at least the physics community has one physicist trying to do something about this nonsense: Paul Steinhardt. In an interview with John Horgan, here's his "Multiverse in a Nutshell":

> Unfortunately, what has happened since is that all attempts to resolve the multiverse problem have failed and, in the process, it has become clear that the problem is much stickier than originally imagined. In fact, at this point, some proponents of inflation have suggested that there can be no solution. We should cease bothering to look for one. Instead, we should simply take inflation and the multiverse as fact and accept the notion that the features of the observable universe are accidental: consequences of living in this particular region of the multiverse rather than another.
>
> To me, the accidental universe idea is scientifically meaningless because it explains nothing and predicts nothing. Also, it misses the most salient fact we have learned about large-scale structure of the universe: its extraordinary simplicity when averaged over large scales. In order to explain the one simple universe we can see, the inflationary multiverse and accidental universe hypotheses posit an infinite variety of universes with arbitrary amounts of complexity that we cannot see. Variations on the accidental universe, such as those employing the anthropic principle, do nothing to help the situation.
>
> Scientific ideas should be simple, explanatory, predictive. The inflationary multiverse as currently understood appears to have none of those properties.

Comments

1. **Travis**
   December 1, 2014

   I don't understand this type of objection to the multiverse. It's entirely plausible that many features of the universe are in fact accidental, in exactly the same way that many features of earth and our solar system are accidental. Imagine for a moment that our solar system were completely surrounded by dust which made it completely impossible to see any other stars (for the purpose of this thought experiment, the dust is some kind of super dust which is opaque to all wavelengths). Would we be warranted, based on our knowledge of physics, in concluding that it is extremely likely that there are other stars out there, with planets arranged around them in different orbits from those in our solar system? Or would we say that such a model of the universe "explains nothing and predicts nothing" and keep searching for some deep reason why the orbits of the planets in our solar system are exactly the way that they are? The reason we would go with the "many stars" model of the universe is that theories which makes testable predictions, like the theories of gravity and nuclear reactions, also predict that similar processes should happen elsewhere in the universe. Analogously, inflationary theory which makes testable predictions like B modes in the CMB also predicts that similar processes should happen elsewhere in the larger universe. Even if inflationary theory in particular turns out to be wrong, the idea that many features of our universe are accidental is no more unscientific than the idea that the exact positions of the planetary orbits are accidental.

2. **Peter Woit**
   December 1, 2014

   Travis,
   Sure, it's plausible that some features of what we think of as fundamental physics are historical accidents. It's also plausible that these are not accidents but choices of an all-powerful deity. Neither conjecture is science though until you come up with a conventional scientific test of the idea. Until then, no matter how much hype proponents put out, Steinhardt is right that the "idea is scientifically meaningless because it explains nothing and predicts nothing".

3. **Katya**
   December 1, 2014

   Peter-
   You wondered if Paul Steinhardt agreed with Edward Witten about the "vast amount of evidence for inflation in the last 20 years." Now you have your answer:

   "…none of the magnificent observations made over the last 30 years can be viewed as supporting inflation."
   and…
   "As just explained, it is not possible to find evidence to support or refute inflation because an inflationary multiverse includes patches with cosmic gravitational waves and without them."

   No one more credible on this topic.

4. **Justin**
   December 1, 2014

   Woit,

   If I'm not mistaken, don't you consider yourself a believer in the many worlds interpretation of quantum mechanics. If you really believe that the universe splits off into undetectable many worlds when a quantum measurement takes place, how are multiverse ideas more nonsensical?

5. **Peter Woit**
   December 1, 2014

Justin,
No, I'm not a believer in many worlds. I've written a bit about QM interpretations, someday should write more about many worlds. As I tried to refer to in the posting, I think I mostly agree with Wallace: fundamentally there's only one world, no splitting, and quantum mechanics is exact. Classical behavior emerges in some limits from quantum, and if you try and say what is happening in classical terms you can do this using the "many worlds" language if you want. But this is in many ways a misleading thing to do, it just completely ignores the actual problem (how is classical behavior emerging from quantum mechanics?). If you try and take it seriously you get all sorts of problems.

So, I'm just not particularly opposed to people using "many worlds" language if they want for some purposes, but they need to make clear what they're doing when they do this, that there really is just one universe and fundamentally no splitting. Unfortunately many worlds fans mislead people about this, and then, even worse, go on to promote this misleading version of many worlds as related to empty pseudo-science about the string landscape, etc.

6. **Justin**
December 1, 2014

@ Woit,

Thanks for clarifying your viewpoint on quantum mechanics. Indeed the "language" of many worlds can get confusing. I highly recommend you take a look at the book Consistent Quantum Theory by Robert Griffiths. It's available for free in pdf format easily found online. It's very much in tune with your views on quantum mechanics.

Keep up the good work on this multiverse nonsense!

7. **GM**
December 1, 2014

@ Travis

That analogy is not really very good. The features of a particular planetary system may be "accidental", but they are not completely random, they are what they are because of simple and understood laws of physics, even if the process is extremely complicated . And it's worth remembering that historically we actually made a lot of progress towards understanding those laws by studying such accidents.

8. **amirpouyan**
December 2, 2014

I have two questions about many-worlds interpretation:

1)when one uses an ensemble of a system to study it in statistical mechanics, there are two ways he can interpret his work:

a) he can claim that every single picture in the ensemble(with millions of different scenarios) actually exists, or
b) he can say that the different scenarios in ensemble only exists in "his mind"

I think the question of importance is that is there any "experimental" distinction between these two views? (somehow i guess that the -b- interpretation sounds better!)

2) doesn't path integral formulation of QM support the idea that the different universes are somehow real? (because it seems that they interfere with each other in the integration process!)

I also found the "many-worlds interpretation" section of this post by R. F. Streater very interesting,

9. **David Metzler**
December 2, 2014

I second Justin's comment about Griffiths' book. Not wanting to push you too hard, Peter, to explain in depth your views on interpretation of QM, but I would be curious about your take on the Consistent Histories approach. I find it intriguing.

10. **howie**
December 2, 2014

The problem Steinhardt has i think is that he needs to construct an alternative to inflation if his attack is going to be fruitful.
But his alternatives are basically cyclic universes, in the case of the Ekpyrotic model embeded in a higher dimensional space. so its hard to see how they are not just multiverses in time rather than in space.
Interestingly other string cosmologies seem like they might be simpler, have you seen them discussed in this video? some claims of potential tests as well:

http://www.youtube.com/watch?v=Do4HGjmjobw

11. **Mr MonoPole**
December 2, 2014

"Science and hypothesis", by Henri Poincare, foreword by Larmor. Some good definitions of what science is and what is not. As one may expect – common sense and relation to the doable experiments characterize Poincare views. He does not mention universe at all.

12. **Peter Woit**
December 2, 2014

David,
I haven't paid much attention to the "Consistent Histories" business. From the time I've spent thinking about this, the whole "interpretation" issue increasingly seems to me besides the point. The interesting question is that of really understanding what happens in a "measurement", how classical emerges from quantum, and what the limitations of that approximation (classical, isolated system) are. Without engaging with those questions I don't see how one addresses the question of what is really paradoxical (as opposed to an artifact of one's over-simplified model for measurement, one's insistence on trying to isolate a system from apparatus and environment), and what if anything is missing from the standard formalism of states and unitary time evolution in order to understand measurements.

13. **Neil Bates**
December 2, 2014

Peter, first let's try to get MWI proponents' point right, then I'll say why I don't agree with them. They say that the wave equation continues to evolve. That means, literally no reduction to exclusive outcomes. Yes they say *that* all "happens in one world", but we can only see the events relative to our own entangled branch. In that sense, the unobserved possible outcomes are literally “other worlds”. Yet the branching structure of the continued superpositions contradicts the observed Born probabilities. The attempts to get actual correct frequentist proportions of events to fit the BPs, are basically circular or contrived arguments. IMHO it just doesn’t work. (See the many critical comments at e.g. Sean Carroll’s blog posts on the subject.)

OTOH if we reject that, we are stuck with a special “collapse” happening to the wavefunction. I myself think that interactions can make that happen, it’s not about “observers”, but no one can really resolve that yet. The “quantum measurement paradox” is still unsolved.

14. **Unemployed**
December 2, 2014

@DavidMetzler, @Justin:
I was about to follow your recommendations and download Griffiths’ book, but then I saw he’s also written stuff about QM&Theology. Unfortunately, time is finite, and I don’t want to waste it on god talk. Is his book that you recommended pure science, or is there any religious stuff hidden in it?
Thanks.

15. **David**
December 2, 2014

Unemployed,
It’s always possible that Griffiths’ book has stuff in there that you won’t agree with (some kind of philosophy you won’t agree with, or some kind of religious stuff you won’t agree with), but just skip over it. What’s wrong with that? Are you worried that you won’t be able to tell what’s science and what’s religion or “god talk”? It’s a free pdf, so just skip over the stuff you don’t like.

16. **Tim May**
December 3, 2014

Unemployed,
There’s nothing mystical or religious in the Griffiths book. The philosophy mentioned is not central and is mostly of the nature of mathematical theories versus actual physical reality. (Think of the point that planets and people don’t move by computing differential equations, yet Nature does indeed follow the results quite closely. Then extend this point to Hilbert spaces, tensor projections, and all that stuff. Griffiths does conclude that just as Newtonian mechanics appears to be much closer to reality than pre-Newtonian mechanics and the quantum mechanics is even closer to reality, from vast numbers of experiments carried out to very high precision.

Griffiths does a good job of gathering together the arguments of many in this area.

No religion that I could find, except for one line thanking his parents.

BTW, very little said about Many Worlds, and what there was was uncontroversial.

–Tim May

17. **David Metzler**
December 3, 2014

Peter, I agree with you on what the main problem is. However I do think that some interpretations of QM (e.g., for me, the Copenhagen interpretation) make it harder, psychologically, to think in productive ways about measurement, decoherence, etc. So I see an alternative interpretation as a psychological device that may possibly help get to the bottom of the key problem you mention, namely how classical emerges from quantum. The Consistent Histories approach seems particularly well suited for that purpose in some ways. (For me, MWI does not help at all, though likely that’s my problem.)

Unemployed, as Tim May says, there’s no religious material in Griffiths’ book. And if you skim some of the detailed examples on first reading, you can get a sense of the CH approach pretty quickly.

18. **Curious Mayhem**
December 3, 2014

We should be grateful to the all-powerful deity–or whatever arranged things to be just so–for Paul Steinhardt and the few others like him, like Peter.

If primordial gravitational waves are detected–and they could be soon–then inflationary theories move into firmly scientific territory. But the multiverse proper will remain a fever swamp of insanity.

19. **al**
December 3, 2014

Opening the new Smolin-Unger book, on finds it on page2 of the preface, in a nutshell:
” There is only one universe at a time, with the qualifications that we discuss. The most important thing about the natural world is that it is what it is and not something else. This idea contradicts the notion of a multiverse – of a plurality of simultaneously existing universes – which has sometimes been used to disguise certain explanatory failures of contemporary physics as explanatory successes.”

20. **Mark Thomas**
December 3, 2014

Marco Gleiser has a short commetary titled ‘A Quest for the Unattainable Unification of Knowledge” on E. O. Wilson’s new book “The Meaning of Human Existence” see link http://radio.wpsu.org/post/quest-unattainable-unification-knowledge
It is good to know that there are some who still believe in the faith of Einstein that there are Unities of knowledge and explanatory power in such unifications (in the Sciences). I hope we do not look at the likes of E. O. Wilson someday and say he was a relic of the 20th century and what he has to say was or is wishful thinking and that such is quaint. By God I hope it does not come to that.

21. **Katya**
December 5, 2014

Curious Mayhem-
Re detection of primordial gravitational waves; Professor Steinhardt’s comments are beautifully simple:

“…it is not possible to find evidence to support or refute inflation because an inflationary multiverse includes patches with cosmic gravitational waves and without them.”
and therefore,

"…even if we detect primordial gravitational waves, we should not rush to the conclusion that they are due to inflation. Better theories may come along that avoid the pitfalls of inflation and that nevertheless predict gravitational waves."

22. **amirpouyan**
December 6, 2014

"A different way of conceiving of this unimaginably immense proliferation (Multiverse idea) is to locate it as happening not externally to the cosmos but internally to the mind/brain states of observers. Making that move is a turn from a manyworlds interpretation to a many-minds interpretation, but this scarcely serves to mitigate the prodigality of the proposal … for many of us it still remains a metaphysical steam hammer brought in to crack an admittedly tough quantum nut" John Polkinghorne, Quantum Theory: A Very Short Introduction,p:53,

note that the book is highly praised by Chris Isham ,

23. **Andrew**
December 6, 2014

Katya

Steinhardt criticizes inflation, because if this theory is confirmed, then his own work on the cyclic universe will remain useless. It looks like a conflict of interest.

24. **Tom**
December 6, 2014

@Andrew,
When the initial Bicep2 (now apparently faulty) results were released, I recall some interview w/ Steinhardt where he seeemed very accepting of the possibility that his cyclic universe hypothesis could have been falsified. He wasnt trying to handwave and make a torturous, convoluted defense.
While he probably feels vindicated in light of Bicep2 non-results, had the Bicep2 results been corroborated, I didnt sense that he would go to his grave trying to defend cyclic cosmologies.

I dont know the detailed chronological sequence, but was Steinhardt critical of inflation before he started advocating cyclic cosmology?

25. **S**
December 7, 2014

Correct me if I'm wrong, but Steinhardt might well stand to win a Nobel prize if inflation is verified. Before he became a major critic of it, he helped develop the theory.

In any event, it doesn't seem fair to me to call it a "conflict of interest" when a scientist with one theory critiques a competing theory. Presumably his criticisms might be part of what motivated him to develop another theory in the first place. Conflicts might arise in refereeing or the like, but I don't think the accusation should be raised just for simple public criticism.

26. **Andrew**
December 7, 2014

No, if inflation is confirmed (I'm pretty sure) Steinhardt did not receive the Nobel Prize. I mean, Steinhardt and Turok gloatingly respond to failure of Bicep2 team. It's No Good. P.S. Sorry for my English.

27. **howie**
December 8, 2014

The Nobel is limited to three persons.
If inflation were to be recognised , Guth is the stand out name. But you are right the theory was developed by others as well. Linde, Starobinsky, Albrecht and Steinhardt would be the next in line to be considered.
Steinhardt would be just as entitled to share the prize as any of the others but given his vocal opposition its unlikely he would be picked , although it would be very amusing.
However without a red tilted gravity wave spectrum i doubt inflaiton will be handed any nobels.
Steinhardt developed the cyclic cosmology as an alternative to inflation as I understand becuase he was not happy with the implications of inflation (i.e a multiverse). i dont think that's a conflict of interest, scientists have to follow what they think is the most promising leads.

28. **Abraham**
December 8, 2014

This week's Guardian Science has a decent counterpoint and discussion by Ungar and Smolin:

http://www.theguardian.com/science/audio/2014/dec/08/cosmology-robert-mangabeira-unger-universe-time

29. **Curious Mayhem**
December 17, 2014

Katya,

The point you make about there being other explanations for cosmic gravitational waves is a good one. Their detection alone doesn't prove inflation.

But they are a distinctive predictive of inflation, and along with the classic problems that inflation solves, their detection would be strong evidence in favor of it.

Very Short Items

December 9, 2014
Categories: Uncategorized

- Long-awaited results from the Planck experiment were unveiled last week, with a new model for how to do this: hold a conference with no videos, no slides released, no wifi in the lecture hall, and put out a press release in French. They did release an amazing image that looks like a Van Gogh, but if you want numbers, you have to search Twitter. Stories at Nature and the New York Times indicate not much new, data relevant to primordial gravitational waves still to come (Dec. 22?, next year?).
- News from MIT is that, after an investigation of charges of sexual harassment of one or more students online, the university has revoked physics professor Walter Lewin's emeritus status and is removing his lecture videos and course material from their online course sites.
- Today's Wall Street Journal has a sensible piece by Ira Rothstein on The Perils of Romanticizing Physics.
- I took a look at Kip Thorne's *The Science of Interstellar* in a local bookstore. It gives a detailed explanation of the "science" behind the film, explaining what a lot of the highly confusing later plot of the film was supposedly about. It seems it's all based on the "large extra dimension" business of 15 years ago, the dimensions that were supposed to show up at the LHC. If you want to see all the equations, go here and look for the pictures of the blackboards.
- The LHC magnets are now getting trained for 6.5 TeV operation, as well as inspiring fashion designers.
- I mentioned last year's Gelfand Centennial conference at MIT here, thought that there were no videos. Luckily I was wrong, quite a few talks well worth watching are now available here.
- Videos from the Breakthrough Prize symposia recently held at Stanford are now available. For the physics talks, see here. For the math talks, see here, here, here, here, here and here.
- If you need a change of pace, and can't get enough of the string theory/LQG debate, this is for you.
- For talks about the implications of not seeing new physics at the LHC, there's Naturalness 2014. Nima Arkani-Hamed kicked it off with "Hopefully My Last Ever Talk On This!" (seems unlikely…). He argues for the idea that it's the Multiverse that did it, and we should keep looking for Split SUSY, disses "conformality" approaches. Matt Strassler on the other hand points out that Arkani-Hamed's use of the multiverse explanation doesn't make sense (there's no anthropic reason for the highly non-generic SM).
- There's a workshop this week at Caltech on scattering amplitudes and the Grassmanian.
- Finally, a HEPAP meeting this week. Budget news for HEP theory doesn't look good, but on the other hand the US now seems to be functioning without a budget, so it's kind of hard to be sure…

Update: Slides from the Planck conference are now available.

It seems the US does have a budget now, some info here. DOE HEP and Cosmic Frontier $766 Million, down very slightly from last year's $775 million, higher than the White House requeset of $744 million.

Update: Scott Aaronson on Walter Lewin here.

Comments

1. **Too Distinguished**
   December 9, 2014

   Peter,
   Can you unpack Matt Strassler's argument a bit?
   Thanks.

2. **Peter Woit**
   December 9, 2014

   Too distinguished,
   I'm referring to the last few slides of the set that I linked to, which are Strassler's. I don't want to do more to put words in his mouth, but he explicitly refers to Arkani-Hamed (and Dimopoulos), and seems to just be making the obvious argument that the SM is highly non-generic, in all sorts of ways that have nothing to do with the possibility of life. So, it seems to me that arguing that the Multiverse solves the naturalness problem is nonsense since that argument says that we live in some generic universe, just constrained by anthropics, and that isn't the case.

3. **Too Distinguished**
   December 9, 2014

   Thanks Peter. It seems like there are two ways to think about this. In one picture of the multiverse, the Higgs mass is the only tunable parameter in an otherwise fixed symmetric structure (our non-generic Standard Model), whereas in the picture Strassler seems to be considering, literally anything could happen. Is that a fair assessment, and if so, do you know of any good arguments made by NAH or anyone else in favor of the first picture?

4. **Peter Woit**
   December 9, 2014

   Too distinguished,
   I don't know of any arguments from Arkani-Hamed or anyone else that would justify starting by assuming that the multiverse gives a highly non-generic thing like the SM. You can do this, but it seems to me (and I think this is Strassler's point) that this is just internally inconsistent.

5. **martibal**
   December 9, 2014

   What's wrong with a press release in french ? 🙂
   Actually there is at least one number, an upper bound on the sum of the masses of the neutrinos: 0,23eV

6. **Peter Woit**
   December 9, 2014

   martibal,
   Who said there was anything wrong with just putting out press releases in French? Not me.

7. **Ivan**
December 9, 2014

“The LHC magnets are now getting trained for 6.5 GeV operation”.
Isn’t it TeV?

8. **Peter Woit**
December 9, 2014

Ivan,
Thanks. Fixed.

9. **Yatima**
December 10, 2014

News from MIT is that, after an investigation of charges of sexual harassment of one or more students online, the university has revoked physics professor Walter Lewin’s emeritus status and is removing his lecture videos and course material from their online course sites.

I can’t think of many regions in the Multiverse parameter space where such a reaction makes any sense, except the ones affected with dangerously high masses of Policial Correctness and Nether Regional Covering. As the press release says, “[Lewin] last taught an online MITx course in fall 2013.” Are the videos going to harass students all by themselves? Will the course material morph into sexually explicit material, burning the minds of the young ones forever? Sadly, MIT has not been very great in the backbone department this decade.

10. **Wayne**
December 10, 2014

Yatima — one presumes that the OCW videos and associated course material (textbook readings, problem assignments and solutions, and so forth) contained well-hidden subliminal messages of evil intent, only now discovered.

Were that not been the case it would be impossible to conceive of a justification MIT could have used as a basis to purge everything associated with Walter Lewin’s immensely popular 8.01, 8.02 and 8.03 courses — the first of which was recorded in 1999! — on elementary physics.

I suppose we should be relieved that high-school and college students, and legions of adult learners will now be protected from .. well, it’s hard to imagine from *what* exactly, but no doubt MIT should be encouraged in its campaign to make Lewin not merely a non-emeritus former professor, but a non-person as well.

11. **Too Distinguished**
December 10, 2014

Peter,
One more question if you would be so kind.

It seems to me that a critic of the multiverse idea would want to argue that the SM is generic, in the sense that it “couldn’t be any other way.” If it could be other ways — if there is nothing fundamental or inevitable about its symmetries — then one is led inexorably to the question of why it is this way, and from there, to anthropic selection in a landscape. By calling the SM non-generic, doesn’t a multiverse opponent get him- or herself in a bind?

Thanks again.

12. **Peter Woit**
December 10, 2014

Too Distinguished,
By “generic” one usually means indistinguishable from others, the opposite of “it couldn’t be any other way.
Yes, one is led inexorably to the question of why the SM is the way it is, but “because anthropics” is a non-answer.

13. **Shantanu**
December 11, 2014

Peter, something OT.
Watched this CFA talk on fast radio bursts by AVi Loeb
https://www.youtube.com/watch?v=aHVx6FCHsCg
and towards 1:10:43 (near the end) he shows an email from Freeman Dyson.
shantanu

14. **Peter Woit**
December 11, 2014

Thanks Shantanu,
To save others some trouble, here’s a quote from the e-mail from Dyson that Loeb was showing:
“I was lucky to grow up at a time when students had no respect for elder statesmen. The elder statesmen at that time, Heisenberg and Dirac and Born and Schrodinger and Yukawa and Einstein, were all pursuing fantasies that were obviously going nowhere. So we ignored the elder statesmen and went ahead using our own judgment. The students today should be doing that too.”

Maybe off-topic here, on-topic for the next posting…

15. **Arthur Reader**
December 21, 2014

The treatment of Walter Lewin by MIT is an academic disgrace and a clear assault on basic freedoms. No opportunity was afforded Lewin to defend himself in court before a judge and jury and no opportunity was given to face his accuser or cross-examine.

With spinelessness like that, who will dare teach women STEM knowing full well that any personal comment in any context misinterpreted by anonymous women with borderline personalities will be grounds for peremptory dismissal, removal of all titles and your teaching career consigned to the memory hole?

Weinberg on the Desert, Seiberg on QFT

December 9, 2014
Categories: Uncategorized

Last week Steven Weinberg gave a Lee Historical Lecture at Harvard, entitled Glimpses of a World Within. There's a report on the talk at the Harvard Gazette.

In essence, Weinberg argues in the talk for an idea that first started to dominate thinking among HEP theorists nearly forty years ago, one that is sometimes called the "Desert Hypothesis". The idea is that by looking at what we know of the SM and gravity, you can find indications that the next level of unification takes place around the Planck scale, with no new physics over the many orders of magnitude between the scales we can observe and that scale, at least no new physics that will affect running of coupling constants for instance. The evidence Weinberg gives for this is three-fold (and very old by now):

- He describes listening to Politzer's first talk on asymptotic freedom in 1973, and quickly realizing that if the strong coupling decreases at short distances, at some scale it would become similar to the coupling for the other fundamental forces. In a 1974 paper with Georgi and Quinn this was made explicit, and he argues this is evidence for a GUT scale a bit below or around the Planck scale.
- He explains about the Planck scale, where gravity should be of similar strength to the other interactions. This idea is even older, well-known in the fifties I would guess.
- He refers to arguments (which he attributes to himself, Wilczek and Zee in 1977) for a Majorana neutrino mass that invoke a non-renormalizable term in the Lagrangian that would come from the GUT scale.

Weinberg sees these three hints as "strongly suggesting" that there is a fundamental GUT/Planck scale, and that's what will explain unification. Personally though, I don't see how three weak arguments add up to anything other than a weak argument. GUTs are now a forty-year old idea that never explained very much to start with, with their best feature that they were testable since they generally predicted observable proton decay (which we haven't seen). We know nothing at all about the source of particle masses and mixing angles, or the reason for their very different scales, and there seems to be zero evidence for the mechanism Weinberg likes for getting small neutrino masses (including zero evidence that the masses are even Majorana). As for quantum gravity and the Planck scale, again, we really have no evidence at all. I just don't think he has any significant evidence for a desert up to a Planck unification scale, and this is now a very old idea, one that has been unfruitful in the extreme.

Weinberg ended his talk with another very old idea, that cosmology will somehow give us evidence about unification and GUT-scale physics. That also hasn't worked out, but Weinberg quotes the BICEP2 value of r as providing yet more evidence for the GUT scale (he gives it a 50/50 chance of being correct). Again though, one more weak piece of evidence, even if it holds up (which I'd give less than 50/50 odds for at this point…), is still weak evidence.

For a much more encouraging vision talk, I recommend listening to Nati Seiberg at the recent Breakthrough Prize symposium. Seiberg's talk was entitled What is QFT?, and to the claim that QFT is something understood, he responds "I really, really disagree". His point of view is that we are missing some fundamental insights into the subject, that QFT likely needs to be reformulated, that there exists some better and more insightful way of thinking about it than our current conventional wisdom. In particular, there seems to be more to QFT than just picking a Lagrangian and applying standard techniques (for one thing, there are QFTs with no known Lagrangian). Seiberg takes the fact that mathematicians (who he describes a "much smarter than most quantum field theorists"…) have not been able to come up with a satisfactory rigorous version of QFT to indicate not that this is a boring technical problem, but that we don't have the right definition to work with.

To make things more specific, he describes joint recent work (for another version of this see here) on "Generalized Global Symmetries" that works with global symmetries associated to higher co-dimension spaces than the usual codimension one case of Noether symmetries and Lagrangian field theory. Evidently there's a forthcoming paper with more details. I'm in complete agreement with him that there must be better ways of thinking about QFT, and I think these will involve some deeper insights into the role of symmetries in the subject.

Update: The paper Seiberg mentions is now available here.

Comments

1. **West**
   December 9, 2014

   I continue to be amazed at the comments of those who hope-beyond-hope that the BICEP2 claim of r=0.2 will somehow survive the full results from Planck. I'd gladly take those 1:1 betting odds. It really requires some serious prior confidence in "large r" being true to get that odds in the face of a serious galactic dust problem.

   Or maybe 50/50 is just a "pull a ratio out of the air to still seem confident/hopeful but not overly so." Maybe someone should ask where that conjectured odds comes from next time.

2. **Nobody**
   December 9, 2014

   " Maybe someone should ask where that conjectured odds comes from next time."

   50/50 means the same thing as "I haven't got a clue".

3. **Peter Morgan**
   December 9, 2014

   I don't see any discussion of regularization/renormalization in Seiberg's talk, the Strings14 powerpoint of his that you link to, nor in the one paper I've looked at, arXiv:1401.0740v2 [hep-th] (cited on the first page of the powerpoint). Is there some magic way to use his methods to construct a mathematically well-defined interacting QFT that is so obvious that renormalization doesn't need to be discussed?

4. **Peter Woit**
   December 9, 2014

   Peter Morgan,
   Seiberg isn't claiming to solve the problem of rigorously constructing interacting QFTs. My take is he's making the claim that physicists understand less about QFTs than they think. One aspect of this is his suggestion that the reason for not having a rigorous construction of 4d interacting QFTs is that we're missing some important understanding of the problem. But you should take his general claims about QFT as an argument about our ignorance, that we don't know what QFT is, not as a claim that he knows what it is while others don't. These general arguments are given just as a motivation for the very specific research program he then describes, investigating new ideas about symmetries.

5. **West**

December 9, 2014

Nobody,
At least in probability theory, one does not quantify the large uncertainty in a parameter r ∈ [0, ∞) with the invocation of a coin flip. Thats what posterior distributions and credible intervals are for. But if we want to compare nested models with an odds ratio, you still need to specify your chosen prior odds ratio and compute a ratio of marginal likelihoods.

So if a physicist has no clue what a reasonable estimate of the true value for a parameter is, he or she should just say so in colloquial language. On the other hand, if that person wishes to invoke a probability or an odds ratio as a meaningful probabilistic statement, I think demanding the reasoning as to how that value was reached is perfectly acceptable.

6. **Nobody**
December 10, 2014

"What are the chances that the BICEP2 value of r is correct?"

"50/50"

You can't get any more uncertain than that.

It is colloquial language. It just sounds slightly better than "I don't know", invoking a sense of calculation "to still seem confident/hopeful but not overly so" (as you put it).

You don't think he calculated it do you? Was a range specified? If not, it's meaningless, except as a big "I don't know".

7. **Peter Woit**
December 10, 2014

Enough about Weinberg's "50/50". Listened to in context, he wasn't saying "no idea", but indicating a reasonable chance that BICEP2 was seeing something other than just dust, r some sizable fraction of the .2 initially claimed. He would like to claim this as yet more evidence for the GUT scale. We'll see what Planck says.

One thing I do know though: if BICEP2 is all dust, Weinberg won't count that as evidence against a GUT scale…

8. **Flavio**
December 10, 2014

Peter,

in your post you seem to make several different, but related points:

1) There is no evidence for a desert up to a high (GUT/Planck) scale.
2) There is no evidence that unification takes place at the GUT scale, and such a scale probably does not exist, because GUTs disagree with experiments.
3) There is no evidence that unification takes place at the Planck scale.
4) There is no evidence that there is a Planck scale at all.

Did I summarize your view correctly ? If not, which points do you disagree with?

9. **vmarko**
December 10, 2014

Flavio,

"4) There is no evidence that there is a Planck scale at all."

I'd say this is a misnomer. Planck scale exists by definition (Planck length, time, mass, etc.). What you probably wanted to say is something like "that there is no evidence for any scale where gravity has strength comparable to other forces", a hypothetical scale which may or may not coincide with the Planck scale.

HTH, 🙂
Marko

10. **Ru**
December 10, 2014

On thing I've never quite understood – why should the fact that coupling constants are of similar strength in a certain regime be anything more than coincidence? particularly as, as I understand it, with the unadorned SM the constants don't all cross over at the same point.

11. **chris**
December 10, 2014

Ru,

if there is an underlying symmetry group that is broken at a certain scale, then the remnants start out with the same coupling at that scale.

and the crossing becomes more precise if you have TeV scale superpartners (not that i am advocating them – just stating the standard rationale).

12. **Shantanu**
December 10, 2014

Peter, did someone in the audience ask the obvious questions you alluded to such as how come no proton decay has been seen and so on?
Or are people so brainwashed that they cannot see the emperor is not wearing clothes?

13. **Peter Morgan**
December 10, 2014

Peter, *if* one takes the ill-definedness as a starting point, as Seiberg seems to, then what about the Wightman axioms and/or the Haag-Kastler axioms might reasonably and usefully be changed seems IMO the question to ask, not the deep dive into more-exotic-but-apparently-just-ill-defined. It seems as if Seiberg is not really starting from where he thinks he is. Hey ho.

14. **Peter Woit**
December 10, 2014

Flavio,
Change all the "There is no evidence" to "There is only very weak to weak evidence" and I'd agree with all those statements. The problem here isn't that Weinberg has no argument or evidence, it's that the arguments are quite tenuous and weak. Given the lack of good ideas to pursue, it's reasonable to pursue weak arguments and see where they lead. The problem is that people have been doing this for forty years now with no success, which is a good reason to be suspicious of the arguments and well aware of why they are weak, instead of trying to push them the way Weinberg is doing, implying that they are stronger than they really are.

One problem with tenuous arguments is that it's then easy to explain away any failure of their predictions. While claiming vindication from BICEP2, if its result disappears, that's no problem. Another tenuous argument that Weinberg might have brought up 5 years ago if he was giving the same talk would have been that GUTs + no proton decay are evidence for SUSY (this is how Weinberg could have answered Shantanu's question if it had been asked), and that plus the "naturalness argument" implies LHC-scale SUSY breaking. Now that that hasn't worked out, this isn't considered a serious problem for the whole scenario, because the argument was always tenuous.

15. **Peter Woit**
December 10, 2014

Peter Morgan,
We've known for a long time that axiom sets like Wightman or Haag/Kastler aren't good enough (gauge symmetry, gravity, etc, etc). The problem is what is the right thing to replace them, and I think it's highly likely new ideas are needed.

16. **David**
December 10, 2014

Peter,

If, at a certain energy scale, the forces (except gravity) all have the same coupling strength, does it necessarily follow that they are all "unified" under one mathematical theory, as in the electroweak theory? Is there some kind of proof of this idea? Or is it possible that they can all have the same strength, yet still exist separately as the strong and electroweak forces? Is this discussed in QFT textbooks?
Thanks!

17. **Peter Woit**
December 10, 2014

David,
The fact that running coupling constants have the same strength at some energy in and of itself says nothing about unification. The argument is that it's evidence for unification, because in some GUT unification schemes you break the symmetry with Higgs fields, and the way this is done, there is an energy at which this breaking occurs and at which the coupling constants need to be the same. This actually depends on a mass of details, including how you define the coupling, how the Higgs breaking takes place, whether you choose a supersymmetric theory, what the scale of SUSY breaking is, other threshold effects, etc. etc. I wrote a little bit about this question in my book "Not Even Wrong". If you want to know exactly what is going on, you have to get into the details of how SUSY GUTs work.

This is one of the two main pieces of evidence for SUSY GUTs (the other is that the particles in a generation fit well into the spinor rep of SO(10)). Again, the problem is just that it's a weak piece of evidence.

18. **Flavio**
December 10, 2014

Peter,

thank you for your clarifications, which makes your point of view very interesting and different from many others. What then is your present opinion about the following statements:

5) Unification surely occurs between LHC scales and at the latest some distance scale larger / some energy scale lower than the Planck scale.

6) Something about our present understanding of QFT has to change between LHC scales and some distance scale larger / some energy scale lower than the Planck scale.

7) Speaking about distance scales smaller than the Planck scale (or about energy scales for single particles higher than the Planck scale) makes no sense.

Do you tend to agree or disagree?

19. **Peter Morgan**
December 10, 2014

> We've known for a long time that axiom sets like Wightman or Haag/Kastler aren't good enough (gauge symmetry, gravity, etc, etc). The problem is what is the right thing to replace them, and I think it's highly likely new ideas are needed.

I agree that we need some new idea(s), but there are many possible weakenings either of Wightman or of Haag/Kastler. We can consider relinquishing microcausality or Lorentz invariance (both often relinquished at small scales, including for string theory and noncommutative geometry approaches, but fairly constrained), introduce non-associativity (limited C*-algebraic/Hilbert space structure, problematic for interpretation, I can't see how it can work but maybe it's not impossible if there's non-associativity only at time-like separation), or introduce nonlinear structure instead of using distributions (for Haag/Kastler, no weak additivity, which is fairly often relinquished, but it's new insofar as it's not been concretely considered in the Wightman context, AFAIK, no definite constraints yet), or some other new modification. Do you just mean not a field theory and not an algebra of observables, which more-or-less cuts Wightman and Haag/Kastler off at their roots?

20. **Peter Woit**
December 10, 2014

Flavio,
I don't agree with any of those statements, because I don't agree with "surely occurs", "has to change", "makes no sense". All one can solidly say about these issues is that we don't actually have any solid arguments or evidence, so should keep an open mind and not convince ourselves that our weak arguments imply that we must follow their

logic.

21. **Peter Woit**
December 10, 2014

Peter Morgan,
I don't have specific alternate axioms in mind and I doubt Seiberg does either. I wish I did. If you want some vague personal speculation, a major motivation for the book I've been writing about QM (and some free QFT) is to see how far I can get recasting QM and QFT in terms of representation theory (for instance taking the enveloping algebra of a Lie algebra as one's algebra of operators). It's very clear though that this is insufficient, not capturing a lot of the mathematical structure one wants. It's very unclear what the right general framework is to capture the structures one finds in the Standard Model. So, to me at least, better axioms are a long range goal, not something for the near future. Before worrying about axioms I think you first need to find a deeper understanding of the mathematics behind the Standard Model, and that question still holds many mysteries.

22. **Flavio**
December 10, 2014

Peter,

thank you for your answer. I am intrigued that you do not agree with the statements 5, 6, and 7, as I have rarely heard about people not agreeing with them. Disagreeing with them means that you are open for the existence of scales smaller than the Planck length. Maybe that is indeed the way to go, advancing against the flow of the more usual arguments. All the best for your endeavours, and please let us know about your progress!

23. **guest123**
December 10, 2014

"there must be better ways of thinking about QFT" I agree. Someone compared QFT to a Rube Goldberg machine. One promising approach is the Amplituhedron. Scattering amplitudes are volumes of a geometric figure.

24. **Minimal action**
December 10, 2014

WHat exactly is a "QFT without a lagrangian"?
It is true that under certain symmetries (like conformal symmetry) and boundary conditions, you can calculate some or even all correlators without any lagrangian being necessary.

That said, if it also turns out that, whatever lagrangian you try in the classical level with this symmetry, the symmetry is broken by quantum corrections (CFT again!), it is not clear that you are talking about a "theory without a lagrangian" rather than "a symmetry impossible to realize in a quantum theory".

I guess one has to wait until the paper, but Some of the discussion around QFT seems a little bit vacuus.

25. **Peter Woit**
December 10, 2014

Minimal action,
The 6d N=(2,0) superconformal theory that is a hot topic this days is often given as an example of a theory with no Lagrangian.

26. **A String Theorist**
December 10, 2014

Minimal action,

Any "isolated" quantum field theory—that means, one with no continuous parameters—cannot admit a Lagrangian description. To understand why, look at the converse statement: any time you have a QFT with Lagrangian L, meaning that the correlation functions may be computed by the path integral of exp(i L), then nothing stops you from considering the correlation functions computed by exp(2 i L), or exp(g i L) more generally. Doing so will give you a family of correlation functions depending on the parameter g (except in the trivial case when L is free; then g can be trivially absorbed into the path integral measure and has no relevance). The (2,0) theory, and many other QFTs, have no continuous parameters, so their correlation functions cannot possibly be computed by the path integral of any Lagrangian.

27. **Martin**
December 11, 2014

Physicists like theories that work. That is hard enough. Mathematical rigor comes second, and is often useless anyway. E.g. sloppy use of Dirac delta functions often works well enough. You only improve the math if the theory does not work well enough, which is why AQFT is of no interest to most physicists. That is just pragmatism. Data are needed to show that current QFT theories are not good enough, only then progress may be made. Speculating about the Planck scale without having relevant data is for retired physicists.

28. **tristes_tigres**
December 11, 2014

What is the state of understanding of far less advanced theory – QED ? It was a long time ago that I took the class on it, and it may not have been very up-to-date at that time, so my question may be obsolete. But isn't renormalization in QED a bit of a crutch to compensate for lack of consistent theory?

29. **Thomas Larsson**
December 11, 2014

A String Theorist:
Is this correct? To me, a quantum theory (not necessarily a field theory) is fully defined by its set of all correlation functions, but couldn't there be a Lagrangian formulation anyway. E.g., the Ising model, i.e. the CFT with c=1/2, is an isolated theory, since the closest theories have c=0 or c=7/10. Nevertheless, it has a lattice formulation with a Hamiltonian (the real Ising model that Ising thought about), and can also be reached with epsilon expansion from phi^4 theory in 4D.

30. **A String Theorist**
December 11, 2014

Thomas,

The Ising model is isolated only as a CFT, not as a QFT. You can perturb the theory by adding an operator to the Lagrangian. It will no longer be a CFT, but its a fine QFT. And voila, the coefficient of that operator you've added is the continuous parameter.

31. **minimal action**
December 11, 2014

More to T.Larrsonś comment, if you know the topology and all correlation functions, you should be able to reconstruct Ln(Z), and hence the lagrangian.
The issue is, not all symmetries "imposed" are stable against quantum correction.
Naively I would say the same applies to the remark by `string theorist` about "isolated"theories, if any lagrangian changes the parameters continuisly, why do you talk about a "theory without a lagrangian" rather than just an inconsistent theory?

32. **Thomas Larsson**
December 11, 2014

String Theorist,
Now I feel stupid. The Ising model at a non-critical temperature is of course related to phi^4 theory without being conformal.

33. **Giotis**
December 11, 2014

You can find a strong reason why the 6d (2,0) SCFT cannot have an action, on the first two paragraphs of page 10 of the following paper by Witten:

http://arxiv.org/abs/0712.0157

There are also no go theorems saying that you can't have a deformation of a free Abelian 2-form gauge theory to a non Abelian one but the assumption is that you have a local action

See e.g.

http://arxiv.org/abs/hep-th/9909094

34. **GBrown**
December 13, 2014

"It's very unclear what the right general framework is to capture the structures one finds in the Standard Model."
Doesn't Connes' noncommutative geometry capture the structures satisfactorily ?

35. **Yatima**
December 13, 2014

@Martin

Physicists like theories that work. That is hard enough. Mathematical rigor comes second, and is often useless anyway.

I agree that rigor comes second, but it being useless is an inflammatory statement in the class of "I don't know what's going on but I can fib my way through, and I don't really care whether any of this makes sense."

Working on a mathematical object that is shown to imply ⊥ after a decade or so in a footnote that no-one reads? I'm against that. That is not a theory that "works" in any sense, shape or form.

36. **Peter Woit**
December 13, 2014

GBrown,
No. Noncommutative geometry ideas have been used to give a different formulation of QFT, but I don't think the results at this point convincingly explain any of the things we don't understand about the standard model.

See a later comment for more about this.

37. **Martin**
December 13, 2014

@Yatima: OK, I withdraw "useless". Sorry.

I meant: if a theory is approximate (effective) then mathematical rigor does not make it any better. See e.g. algebraic QFT – did this yield anything of use for actual particle physics? I have nothing against math, honest.

38. **Peter Woit**
December 13, 2014

Martin,
Seiberg's point was not that rigor matters, but that the failure of mathematicians to develop rigorous versions is a hint that something is missing, something that could lead to important new insights if you found it.

One thing you learn when doing mathematics is that sometimes when you can't find a proof of a statement that you think you understand well and has to be true, it's not because you're not clever enough to find the proof, it's because you were misunderstanding the situation, and the statement was actually not true.

39. **Martin**
December 13, 2014

Yes, Peter, I see that.

On the other hand, mathematical rigor does not imply physical correctness. I think that in some areas of theoretical physics (not in all!) math has overtaken physics, which is a sign of a crisis, at least from the physics point of view.

40. **Martin S.**
December 14, 2014

"*One thing you learn when doing mathematics …*"

@Peter: I seem to have a different experience (being a mathematician myself), at least when dealing with structures where you already have found an amount of stuff. When in such cases I encounter a situation of not being able to find a proof, I usually have to dig more deep into those structures. And then one reveals more precise properties of the studied structures, usually along with that searched proof (and why the proof could not have been found without taking into account those more precise properties).

41. **Martin S.**
December 14, 2014

"*I think that in some areas of theoretical physics (not in all!) math has overtaken physics, which is a sign of a crisis, at least from the physics point of view.*"

@Martin: Physics is, for sure, ultimately ruled by experiments. Still (if mathematics does exist underneath as I strongly expect), you want to have some theory that either directly describes the physical stuff, or at least it approximates that stuff. And you want to understand that math too, to not get lost in translation (as it apparently happened to those overtaken by the parts of mathematics that are irrelevant to physics).

42. **Peter Woit**
December 14, 2014

To expand a bit on my perhaps overly dismissive comment about NCG approaches to QFT and the Standard Model, a better way to describe my impression of the subject is that I'm intrigued, but not convinced. I should make clear that this is an "impression", based upon periodic attempts to learn a bit about the subject, which have not at all gone far enough to really understand what is going on. Such efforts have taken me just far enough to see what look like some interesting ideas, while not seeing something that, to me, convincingly explains what seem to me the big mysteries of unification.

Among the many things I haven't had a chance to look at, it has been pointed out to me that there are new papers out by Connes and Collaborators, see
http://arxiv.org/abs/1409.2471
and
http://arxiv.org/abs/1411.0977
as well as a blog posting about this by Connes here
http://noncommutativegeometry.blogspot.com/2014/11/particles-in-quantum-gravity.html
which anyone interested in the subject should take a look at.

I should also point out that while I'm not convinced by this, I'm quite convinced that standard GUT approaches don't work, better alternatives are few and far between, so this is one that deserves to be taken seriously.

43. **Lee Smolin**
December 14, 2014

Dear Peter,

You might look at a recent reformulation of the NCG formulation of the standard model by Boyle and Farnsworth: http://arxiv.org/abs/1408.5367.

Thanks,

Lee

44. **Peter Shor**
December 14, 2014

You say *"zero evidence that the [neutrino] masses are even Majorana"*. There's also zero evidence that the masses are Dirac. The only real evidence we have that the neutrino masses are Dirac is that the other fermions we've seen are Dirac.

And (since I don't think you can count the different generations as separate pieces of evidence) we've seen exactly three elementary Dirac fermions: the electron, the up quark, and the down quark. I don't think this is strong evidence that the neutrino isn't Majorana.

45. **martibal**
December 15, 2014

"Noncommutative geometry ideas have been used to give a different formulation of QFT, but I don't think the results at this point convincingly explain any of the things we don't understand about the standard model."

I would have rather permuted "QFT" and "Standard Model" in the above sentence:

NCG (in Connes sense) does not explain so much about QFT, in the sense that once obtained the Lagrangian of the Standard Model, in order to do physics one uses the usual tools of QFT (in particular the equation of the renormalization group, coming from usual approach to the SM). On the contrary, it gives explanations on several aspects of the SM that are rather ad-hoc otherwise:
– the Lagrangian, with the correct representations of particles;

– the need for a scalar field (which comes out on the same footing as the other gauge fields, as the "noncommutative" part of the connection 1-form);

– a constraint on the number of particles per generation (which should be 2 x (2 x n)^2 for n integer. The SM is n=2, that is (6 colored quarks + electron + neutrino) x 2 (left, right) x 2 (antiparticles) = 32;

– a relation between masses.

The gauge group itself has been "almost" derived from geometrical principle, up to an ad-hoc symplectic hypothesis. And it seems that in the last work of Connes and al you mention, this ad-hoc hypothesis can be removed.

46. **martibal**

December 15, 2014

One may say think this does not explain anything and this is just a way to rewrite in a complicated mathematics language things that one already knows. But one could say the same about GR (Weinberg does it in his book, at least an older version of it): “all the tensors with their funny way of transforming under Lorentz transformation can be given a geometrical interpretation, like curvature, but this is not relevant for physics”. [the quote is not exactly Weinberg, but there is a chapter in his book which says something like that].

In my opinion all the interest of GR is precisely its geometrical interpretation, which makes it much more that just a collection of rules of tensor transformations. If NCG manages to turn the SM into a geometrical theory, I would say it is quite relevant for physics.

Of course, there are other aspects of the SM one should explain which are not addressed in NCG, or not in a sufficiently convincing way. Peter, could you be more explicit on that point: in your opinion, what are the most important things we do not understand about the standard model ?

47. **Peter Woit**
December 15, 2014

martibal,
I wrote a chapter in my book (chapter 8) specifically about this, don’t want to reproduce it here, in any case it’s pretty obvious to anyone who spends much time studying QFT and the Standard Model what the list is of things it doesn’t explain.

As for why I don’t find the list you give of answers provided by NCG convincing, part of the problem is that these are post-dictions, so that raises the bar for how compelling they need to be.

48. **Jesper**
December 15, 2014

“… I think you first need to find a deeper understanding of the mathematics behind the Standard Model… ”

“As for why I don’t find the list you give of answers provided by NCG convincing, part of the problem is that these are post-dictions … ”

Well, if you find a deep mathematical understanding of the standard model it will by default be in the form of post-dictions.

49. **anon.**
December 15, 2014

“Well, if you find a deep mathematical understanding of the standard model it will by default be in the form of post-dictions.”

That’s like vacuously arguing that Schwinger’s prediction of the electron’s magnetic moment was a post-diction, because it had already been measured. A better mathematical understanding of the SM might allow a precise prediction of neutrino masses, the strong coupling, the Weinberg mixing angle, or the CKM weak interaction mixing angles matrix. Thus it could be a prediction fully testable by future inprovements in SM parameter measurements, not just an ad hoc post-diction.

50. **Peter Woit**
December 15, 2014

Jesper,
Sure. Nothing wrong with a good postdiction, they can be very convincing. But the bar is higher for such claims.

51. **Will**
December 15, 2014

I know nothing at all about non-commutative geometry, but martibal’s post seems to imply at least one prediction, which is the existence of three right-handed neutrinos. If the “relation between masses” include predictions of the neutrino masses (sterile or active), that would be even better. Does it make these predictions?

52. **Nobody**
December 15, 2014

If the new mathematics does not simplify, I would not call it “deep”, but “obtuse”. If the mathematics simplifies, it should postdict everything the old theory did, but why would it need to predict anything new to be considered a step in the right direction?

53. **martibal**
December 15, 2014

@Will: there was an older version of the model with massless neutrinos. NCG seems to be dead when neutrinos were discovered to have a mass. Some years after, it came out that some flexibility can be introduced by making the distinction between two notions of dimensions (the metric dimension, and the so called KO-dimension). In the commutative case, i.e. for a Riemannian manifold, both notions coincide with the usual dimension of the manifold. It was implicitly assumed that the same should be true in the noncommutative case.

At the same time, Connes and Barrett noticed independently that there was no reason to identify these two dimensions in the noncommutative case. By fixing the KO-dimension (which can take value from 0 to 7) to 6, one solves at the same time two problems: 1. The number of particles/generation is 2(2 x a)^2, hence the possibility to incorporate a massive neutrino; 2. One solves a problem of over-counting degrees of freedom in the fermonic action (“fermion doubling”).

The point is that NCG does not say anything about the number of generations. So with some contorsion one might built a model where the three generations do not have the same KO-dimension, meaning that one could have massless neutrinos (i.e. KO-dimension 0, as in the older version) for some generations, and massive neutrinos for other (i.e KO-dimension 6) for others. However I do not know if such weird possibilities have been checked.

54. **martibal**
December 15, 2014

The relation is between the sum of the mass of the fermions ans the mass of the W. Since the top is much heavier than the other fermions, in pratical the relation is between the mass of the top and the W.

55. **martibal**
December 15, 2014

Peter & Anon: a postdiction that the gauge group of the SM is U(1) x SU(2) x SU(3) would be a high level postdiction, or there already exists some justification to it ?

56. **Peter Woit**
December 16, 2014

Martibal,
SU(3)xSU(2)xU(1) is already a very simple mathematical structure. If you predicted this before it was known in terms of some other simple mathematical structure, that would be compelling. If you start already knowing this, claiming to derive it from some other "simpler" structure is going to be convincing only if the simpler structure is quite a bit simpler, and what I have understood of the NCG explanations doesn't to me convincingly do that. In any case, the real test I think is whether you can explain the more complicated aspects of the standard model in terms of the simpler structure you are advocating, it is that which would be convincing.

57. **martibal**
December 16, 2014

Peter,

to push a little bit the argument: the U(1) x SU(2) x SU(3) structure is simple, but in usual QFT nothing explains (or am I wrong ?) why it should stop here: why not … x SU(4) x SU(5) x… ?

The whole point of NCG is that (Euclidean) GR + SM are obtained from one single action, which is geometrical. In other terms the SM is viewed as "gravity" on the noncommutative part of space (time). So a postdiction would be that – assuming the geometrical structure of space(time) is not a manifold, but a manifold x noncommutative part – then there are only four interactions: gravity on the commutative part, the SM which has to be a U(1) x SU(2) x SU(3) gauge theory on the noncommutative part. But I agree this is not the most highly convincing postdiction.

Before I stop monopolizing the discussion: I do not think anybody working in the field is pretending that this is fully convincing. But as you said earlier, none of the other approaches to unification or quantum gravity seems much more convincing. Looking at the ratio produced results/attention received, I think NCG scores not too bad.

58. **Hans-Peter**
December 16, 2014

Martibal,

some months ago I have searched through arxiv, google scholar and the SCI about this topic; I found just one postdiction of U(1)xSU(2)xSU(3) from a simpler structure. And that postdiction is not taken seriously by anybody in the high energy physics community. Many have tried to relate the three gauge groups to the complex numbers, for U(1), the quaternions, for SU(2) and the octonions, for SU(3), but without success. Many other attempts failed and were not even published – ask your favourite high energy physicist. So the present situation is: There is no justification, as you call it, of the interaction gauge groups from a simpler structure.

Many are trying to deduce them uniquely from other, more general structures, dropping the requirement of simplicity, but still without success. (Uniqueness is the key here, of course.) Also Peter's work can be seen as an attempt in this direction, I guess. But no such postdiction or justification is available yet. Finding a postdiction seems to be easy at first sight, since the result is known, but in fact it is a surprisingly hard problem.

59. **Peter Woit**
December 16, 2014

martibal,

I definitely agree that NCG ideas are worthy of attention, especially because of the lack of good ideas about unification.

In your description though of unification by NCG, the problem is with the claim of deriving SU(3)xSU(2)xU(1) by just doing geometry on the "non-commutative part". The danger is that among many possibilities for the "non-commutative part", you have just picked the one that gives SU(3)xSU(2)xU(1). When I've been trying to read the NCG literature, this is a point at which I've found things unconvincing. Possibly I'm not reading the right explanation…

60. **David**
December 16, 2014

Didn't I read somewhere that NCG predicted the wrong mass for the Higgs? Did they do something about that?

61. **martibal**
December 17, 2014

Peter, well the hope is that precisely, on the noncommutative part, one does not have so much way to do geometry but the one that gives you the standard model. All depends on what you call "doing geometry" of course.

The starting point is the observation that all the information of a compact spin manifold M is encoded within a triple given by the commutative algebra C^infty(M) of smooth functions on M, the Hilbert space of spinors and the Dirac operator. Conversely, Connes worked out the conditions that must satisfy a commutative algebra A, an Hilbert space H and an operator D such that – given any triple (A, H, D) with A commutative – then there exists a spin manifold such that A = C^infty(M). Then one drops out the commutativity requirement, and define a "noncommutative geometry" as a spectral triple (A, H, D) where A does not need to be commutative.
Now the result is, assuming three things:
– the algebra is the product of C^infty(M) by a finite dimensional algebra A_F,
– the KO-dimension (see a post above) of the finite dimensional part is 6,
– there is an ad-hoc "symplectic hypothesis" to define a real form on A_F,
then A_F = C + H + M_3(C) (complex, quaternion, 3×3 matrices), which is precisely the algebra the spectral triple of the SM is built on. All this is in the paper "Why the standard model" by Chamseddine and Connes (arXiv: 0706.3688 [hep-th]). In their most recent work you have already mentionned, it seems they can get rid of the ad-hoc symplectic hypothesis.

So once you buy the definition of a spectral triple (which has a strong justification, since in the commutative case this is equivalent to the definition of a Riemannian spin manifold) one basically deduces the gauge group of the SM from the first two assumptions above.

62. **martibal**
December 17, 2014

Hans-Peter: thanks for the information.

David: from the beginning of the model (early 90′) there was a prediction for the Higgs mass around 170GeV. It has been ruled out in 2008 by Tevatron. After the discovery of the Higgs, Chamseddine and Connes noticed that if one takes into account an extra-scalar field (proposed in a completely different context by particle physicist to avoid the instability of the electroweak vacuum due to the “low mass” of the Higgs), then one can obtain the correct Higgs mass.

The question is then: why this extra field was not present before, since the claim is that the SM is almost uniquely derived from the NCG principles ?

It turns out that to justify this new field inside the NCG framework, one has to allow a little but of flexibility, regarding one of the conditions that defines a spectral triple (namely the one that tells you the operator D is a first-order differential operator). The present state of the art is that the extra-field (which violates the first-order condition) can be viewed as a small excitation around a vacuum (which does satisfies the first-order condition).

63. **Hans-Peter**
December 17, 2014

Martibal,

the key assumption in what you write about NCG is the KO-dimension 6 of the finite dimensional part. It indeed implies the three gauge groups – but does not imply them uniquely: if you took 7 or 8 or 9 as an assumption, the argument dissolves. Besides, the assumption is not simpler than the result, as required; it is just a hidden way to introduce the result in the argument right from the start. So it should not be counted as a justification of the standard model.

64. **Curious Mayhem**
December 17, 2014

Seiberg’s argument is very interesting and deserves closer attention. We don’t understand QFT and only have a “practical” or pragmatic understanding of how to calculate with it in certain cases. That’s not satisfactory. The situation becomes acute when gravity is brought into the picture and the spacetime background moves to the front of the stage and becomes part of the show. We need something background-independent — indeed, spacetime-independent — to make progress. Higher groups? Maybe. My pet cause is starting with field fluxes as fundamental. You can do that already, although it’s merely a curiosity in QFT as we know it now.

65. **martibal**
December 17, 2014

Hans Peter: as I said in a precedent post, the KO-dimension 6 also has a justification regarding the fermonic action. In fact it is justified in this way in Connes and al paper. Then one “noticed” that it allows to have massive neutrino. In Barret paper the KO-dimension 6 is justified because it corresponds to the Dirac operator with Minkovski signature. So the choice is far from arbitrary.

Even if you consider it as a free parameter, that one single parameter with only 8 possible values (from 0 to 7), fixes the gauge group of the SM, the number of particles per generation, their representation, the form of the Bosonic Lagrangian – including the Higgs – obtained together with Einstein-Hilbert action… well, I would say this is quite an interesting step towards an understanding of the mathematical structure of the SM.

66. **Hans-Peter**
December 21, 2014

Martibal,

Connes indeed achieved an interesting step. He discovered a structure that allows to tie the gauge groups together in a different way from that of GUTs. He showed that the three gauge groups are deeply related somehow. On the other hand, he also states that these ideas do not explain most parameters of the standard model, nor the number of generations. So we have to take the truth in these ideas and continue the search. But in which direction …?

67. **martibal**
December 21, 2014

Well, recently there have been several works by various groups on a new scalar field who comes out by relaxing the first-order condition (see a precedent post). This opens some possibility towards some Pati-Salam models, whose SM would be the vacuum. Hopefully some phenomenology could be done there.

At more fundamental level, there is also the idea to get rid of the assumption that space (time) is described by the product of a manifold by a finite dimensional space. In Connes and all last work there are very interesting things in that direction. The idea would be NOT to postulate from the beginning that there is a manifold (or say differently, NOT to start with an algebra with an infinite dimensional center and only a finite dimensional noncommutative part) but to be able to reconstruct everything from some “abstract” noncommutative relations.

The problem is not to find research projects, the problem is to have the possibility to work on them with a little bit of stability (meaning contracts longer than 1 or 2 years). But that is another story.

Defend the Integrity of Physics

December 17, 2014
Categories: Multiverse Mania

This week's Nature features a call to arms from George Ellis and Joe Silk, entitled [Scientific method: Defend the integrity of physics](). I'm very glad to see well-known physicists highlighting the serious problem for the credibility of science raised by the string theory multiverse and the associated ongoing campaign to justify the failures of string theory by attacking the scientific method. Acknowledging evidence that an idea you cherished doesn't work is at the core of what science is and physics now has a major problem with prominent theorists refusing to abide by this principle. Ellis and Silk do a great job of identifying and characterizing an important challenge the scientific community is facing.

The issue is however complicated, and while the Nature piece carefully and clearly addresses some of the complexities, there are places where things get over-simplified. In particular, the introduction frames the issue as whether a theory being "sufficiently elegant and explanatory" allows it to not need experimental testing. The problem with the string theory multiverse though is not this, since such a theory is the antithesis of "elegant and explanatory". There's just about nothing in science as inelegant as the various attempts (e.g. the KKLT mechanism) to make string theory fit with known physics, and "the multiverse did it" is no more an actual explanation of anything than "a big omnipotent turtle did it".

Trying to cut through the complexities, Ellis and Silk write:

> In our view, the issue boils down to clarifying one question: what potential observational or experimental evidence is there that would persuade you that the theory is wrong and lead you to abandoning it? If there is none, it is not a scientific theory.

This is at the heart of the matter, but there are subtleties. A common recent move among some prominent string theorists has been to argue that string theory is falsifiable: it is based on quantum mechanics, so if experiments falsify quantum mechanics, they falsify string theory. This just makes clear that the question of falsifiability can be slippery. Philosophers of science are experts at the intricacies of such questions and Ellis and Silk are right to call for help from them.

They also make the interesting call for the convening of a conference to address these issues. How such a thing would work and how it might be helpful seem well worth thinking about. As for one of their other recommendations though:

> In the meantime, journal editors and publishers could assign speculative work to other research categories — such as mathematical rather than physical cosmology — according to its potential testability.

I'm leery of the impulse among physicists to solve their problem of how to deal with bad physics by calling it mathematics. Yes, there is good mathematics that has come out of untestable ideas about string theory, but no, this doesn't include the string landscape/multiverse cop-out, which physicists need to face up to themselves.

For the specific arguments from Sean Carroll and Richard Dawid that Ellis and Silk address, I've written about them elsewhere, see for instance [here](), where I discussed in some detail Dawid's arguments.

Update: Sabine Hossenfelder has commentary on this [here]().

Update: Taking the opposite side of the argument in January's Smithsonian magazine is by colleague Brian Greene, with an article entitled [Is String Theory About to Unravel?](). As you might expect, Brian's answer is "No", and he gives a good account of the point of view Ellis and Silk are warning against. He mentions the possibility of encouraging news for string theory from the next LHC run, but says that "I now hold only modest hope that the theory will confront data during my lifetime."

Update: Sean Carroll responds to the criticism from Ellis and Silk with [a tweet]() characterizing them as belonging to the "falsifiability police":

> My real problem with the falsifiability police is: we don't get to demand ahead of time what kind of theory correctly describes the world.

Update: Gordon Kane joins the fight in a [comment at Nature](), claiming that, before the LHC, string theory predicted a gluino mass of 1.5 TeV.

> The literature contains clear and easily understood predictions published before LHC from compactified string theories that gluinos, for example, should have been too heavy to find in Run 1 but will be found in Run 2 (gluino mass of about 1.5 TeV).

As far as I can tell, this is utter nonsense, with Kane publicly claiming string theory predictions of a gluino mass of around 600 GeV (see page 22 of [this]()) back in 2011, then moving the "prediction" up as Run 1 data falsified his earlier predictions. Kane at least makes falsifiable predictions, the problem with him only comes when they get falsified…

Update: Chad Orzel has his take [here]().

Update: Adam Frank has an essay on this [here]().

Comments

1. **Bee**
   December 17, 2014

   I quite like the idea to rename it, this is an important issue when it comes to funding. It would make it abundantly clear what this is an what it isn't. This really is my biggest frustration when it comes to high energy theory, cosmology and quantum gravity today, that in my book much of it simply isn't physics. Jeez, have you recently looked at the hep-th arxiv? Most of it is in the best case mathematical physics, in the worst case philosophy, or maybe art. I kinda wish it was at least science fiction, then it would be more interesting.

   If you think that the mathematicians or philosophers don't want it either, then call it something else, but please don't let them block money and jobs that funding agencies mistakenly believe go into theoretical physics. (Yes, that's right, what I actually mean is give me a job and boot some string theorists.)

   Needless to say, I have made myself very unpopular among my colleagues with this opinion 😉

   I don't want anybody who really wants to work on string theory to stop – if it makes them happy, please. But don't sell it as something it is not. And I say this as somebody who has a paper in physics.hist-ph, so don't get me wrong, I do think philosophy is relevant and we'd even be better off paying more attention to what the philosophers are trying to tell us – sometimes at least.

2. **Peter Morgan**
   December 17, 2014

As always, thanks for the link and for your discussion. I commented there.

3. **Peter Woit**
December 17, 2014

Bee,
One of the odd sociological things I've noticed about the arxiv hep-th category is that it increasingly has large numbers of papers about quantum gravity/inflation/cosmology. What's odd is that I would have thought that the "Quantum Cosmology" in gr-qc was precisely intended to provide the right home for this topic. One interpretation is that people coming out of a string theory background don't want to be associated with those coming out a GR background…

4. **Douglas Sweetser**
December 17, 2014

I make it a practice to always refer to "work on strings" instead of the far, far more common label. One of the greatest disservices to the scientific community was the wide use of Theory label. The word Theory should be reserved for only be used for the best science has to offer: Newtonian mechanics, special relativity, general relativity, quantum mechanics, and the standard model are all physics theories. They each are logically coherent and make many predictions. I think we may have to replace some of these theories with better theories, but any upgrade must be coherent and have predictions.

Same number of characters, one more space: "work on strings" is my small way to defend the integrity of physics, and science in general.

5. **Bee**
December 17, 2014

Peter: Not sure about this. Annoyingly, almost all of these topics are cross-linked now. It's annoying because more often than not I have the same paper 3 times in my feed. At this point I myself am so confused which arxiv category to best post in, that I normally do the same – after somebody once asked me why I post in qg-qc "which nobody reads".

In any case, I have a longer comment on the Nature piece at Starts With A Bang. Thinking that maybe it's of interest for some of your readers, the link is here:

https://medium.com/starts-with-a-bang/does-the-scientific-method-need-revision-d7514e2598f3

6. **Bee**
December 17, 2014

gr-qc I meant, sorry.

7. **Peter Woit**
December 17, 2014

Bee,
Thanks for the link, I'll add that to the text of the posting.

I am looking at arXiv postings at the arXiv site, so the cross-posted ones come later. I do mean that what's odd is that articles on inflation, string cosmology, etc. are getting posted with hep-th as the primary category, cross-posted to gr-qc, not the reverse, which is what one would have naively expected.

8. **Martin**
December 17, 2014

"A common recent move among some prominent string theorists has been to argue that string theory is falsifiable: it is based on quantum mechanics, so if experiments falsify quantum mechanics, they falsify string theory".

This is not how science works. In real life there must be a reason to take a theory or model seriously, in particular non-trivial (good enough) confirmation by experiment. Science is about inferencing in the Bayesian way. The 1930 theme was that some statements cannot be verified whereas they can (in principle) be falsified. E.g. a statement like "there are no pink elefants" is not confirmed by never seeing one, it can be falsified by seeing one. That sort of logic.

In normal physics a theory is never deemed credible merely because it is potentially falsifiable. That may be a necessary quality of a theory, but it obviously has nothing to do with making the theory credible. A credible theory is a theory that WORKS. Why don't these "theorists" understand this? We could discuss what is meant with "work", but to pretend that everyting is fine as long as the possibility of falsifiability cannot be proved to be identically zero is a joke. I have never seen this type of argument in real physics such as solid state physics and theory, or in relativity theory, or in quantum mechanics. Why was quantum mechanics with the probability interpretation accepted? Because it worked. Why was special relativity accepted? Because it worked. Why does physics work with theories that are evidently not totally correct – but only approximate or effective? Because these theories work. In real physics nobody presents a theory without showing that it has at least some correspondance with experiment or observation. I do not understand why so many seem to believe that a mere theoretical possibility of falsification should make a theory credible to a reasonable extent. Falsifiability is merely a negative criterion: a model that cannot possibly be falsified cannot be scientific. Turning it into a positive criterion makes no sense.

String theory does not work. That is all. People come with "theoretical falsifiability" only because they have nothing else.

9. **Martin S.**
December 17, 2014

@Bee: I guess that the original source of one of the images at your commentary is AbstruseGoose. Sorry for putting it here, I am not social enough to leave message there.

10. **amirpouyan**
December 17, 2014

In his "The Road to Reality" , Penrose argues that supersymmetry has an unfalsifiable(un-Popperian) character because you can always argue that the superpartners can be detected with higher energies, then he asks:
"Does the 'un-Popperian' character of such models (like supersymmetry) make them unacceptable as scientific theories? I think that such a stringent Popperian judgement would be definitely too harsh. For an intriguing example, recall Dirac's argument that the mere existence of a single magnetic monople somewhere in the cosmos could provide an explanation for the fact that each particle in the universe has an electric charge that is an integral multiple of some fixed value (as is indeed observed). The theory which asserts that such a monopole exists somewhere is distinctly un-Popperian. That theory could be established by the discovery of such a particle, but it appears not to be refutable, as Popper's criterion would require; for, if the theory is wrong, no matter how long experimenters search in vain, their inability to find a monopole would not disprove the theory! Yet the theory is certainly a scientific one, well worthy of serious consideration."
R.Penrose, The Road To reality, ch:34,

I have added “(like supersymmetry)” to the text because Penrose has mentioned it as an example of un-Popperian idea a few lines earlier,

As you see, being falsifiable is not necessary for the basic assumptions of a scientific theory (like existence of a magnetic monopole somewhere in universe), but it is necessary for the predictions of such theory (like the fact that electric charge is an integral multiple of some fixed value). In other words, we may have a theory based on some unfalsifiable assumptions, but the theory can be scientific if it makes falsifiable predictions. And it can become “credible” if the predictions are verified.

A more complete version of what martin said, can be:”a model that its predictions cannot possibly be falsified cannot be scientific. Turning it into a positive criterion makes no sense.”

In the string theory case, it seems that neither the basic assumptions (like replacing particles with tiny strings) nor the predictions (if any!) are falsifiable and it makes the situation very difficult.

11. **Mesa**
December 17, 2014

Maybe these things can take a page from mathematics and be described as conjectures instead of theories. IE string conjecture, multiverse conjecture, inflation conjecture, quantum gravity conjecture. Maybe the burdens on conjectures are less stringent. Along the road to theories from conjectures might lie testable hypotheses.

12. **Bee**
December 18, 2014

Hi Peter,

I see. I just don’t notice this in my reader – I have hep-th, hep-ph and gr-qc in the same feed and (that includes all the cross-links), so I often don’t even know which category a paper is posted in.

Anyway, I think the main reason people post papers in one arxiv and not in another is not the name of the arxiv but the people who they know read it. Another issue with the arxiv categories is of course all the AdS/CFT stuff, much of which goes under high energy physics, though there really isn’t much high energy physics in it.

A simple way to avoid these issues would be to allow people to tag their papers with certain keywords.

13. **Bee**
December 18, 2014

Martin,

Thanks for this. I vaguely recalled that I had seen this elsewhere before, but couldn’t recall where. I’ll update the reference.

14. **Chris Oakley**
December 18, 2014

Brian Greene writes well as always, but I cannot help feeling that he would have been better off switching fields as advised in the autumn of 1984. I cannot say that the unification of General Relativity and Quantum Field Theory was high on my own list of priorities, though I was aware of the messianic zeal of those, like him, who latched on to the new band wagon in the succeeding months. My problem was, and is, that there is no point in trying to unify anything with Quantum Field Theory until we actually have one.

15. **David Bailey**
December 18, 2014

I feel that theoretical physics is not unique in science in having been infected with non-science of a variety of forms. I daren’t quote any examples because I’d be off topic, but the causes are not restricted to this area – people trying to publish as much as possible, the relentless push of money, and the way the media will hype very preliminary research reports that don’t need to be right, just exciting.

I don’t know what the answer is, but it might help if people from different disciplines realised how widespread these problems are.

16. **Simeon Every**
December 18, 2014

Penrose’s monopole example is I think only unfalsifiable if the existence of a single monopole produces “… the fact that each particle in the universe has an electric charge that is an integral multiple of some fixed value…” but also has no other consequences that are not more easily falsified by observation than the detection of the single monopole. Also, the theory would need to specify that there was in fact only one monopole, or some other practically undetectable number of them.

17. **Jerzy Kowalski-Glikman**
December 18, 2014

I think that the utilitarian character of science (predictions of the results of experiments and the background on which engineering can be developed), physics in particular, to which indeed Popperian argument applies, is only one side of the coin. The second, and not less important is to tell a story about the world. Such story might be full of dragons, fairies and multiverses -nothing wrong with it. Whats might be wrong would be to say that your story is the only one, but I do not think even hard core string theorists say that nowadays.

18. **Chris W.**
December 18, 2014

Jerzy,

The predictions of the results of experiments is not simply part of the utilitarian character of science, because the experiments themselves generally lack a utilitarian motivation. Rather, they are designed and performed specifically to *test theories*. There may or may not be a utilitarian interest in those theories’ predictions, and in any case that interest is largely beside the point.

People have been telling a stories about the world for millennia. What matters about science is its specific, focused and serious efforts to find out whether or not those stories are false, or by elimination *might* be true. The only reason we can seriously contemplate in science that there might only be one true story about the world is because of the objective elimination of candidates through such a process of elimination, leaving just a few standing. Of course we can never know for sure that we have found that one true story, even when “a few” becomes one.

For these reasons the testability of theories is of critical importance. Sean Carroll deplores demanding “ahead of time what kind of theory correctly describes the world.” Nevertheless we have no alternative but to require—ahead of time—that scientific theories be testable. This may very well be a non-trivial constraint on what the world can be like, but we’ve always known that this is implicit in the effort to do science. A world that is sufficiently capricious—a world in which reproducible results can never be sustained—would not be a world in which science can be done. It would be strictly the domain of gods, demons, and fairies, or something even more chaotic. Indeed, for most of human history the world appeared to most people to be more or less just this.

(PS: The use of the word “story” in this context is problematic, but I’ll have to leave that alone for now.)

19. **Bernhard**
December 18, 2014

I really had a big laugh with Gordon Kane. I wonder if anybody still takes him seriously, it’s so ridiculous.

20. **Flavio**
December 18, 2014

The discussion mixes up two arguments.

(1) The string idea does not work.
(2) The string idea is not falsifiable.

Argument 1 is tested by checking with experiment. For example, we can check whether supersymmetry exists. Discussing argument 2 is not smart. The argument would imply that the whole string approach is nonsense. Therefore all string workers get angry when falsifiability is discussed; they know that they are not doing nonsense. A fair and honorable discussion should only focus on argument 1; the rest is gratuitous hostility and leads to hostile reactions.

Stating that an idea is wrong is different from stating that it is nonsense. Also Ellis and Silk mix up the two arguments, and thus elicit a lot of hostile reactions. As expected.

This situation leads to my personal point of view on unification research:

(a) The unified theory we are all so desperately looking for has not yet been found because feedback, criticism, responses from reviewers and responses from funding agencies always slip from argument 1 to argument 2, thus discouraging anybody attempting to work on the issue.

(b) The unified theory will only be found by a researcher with no need for funding and who works in hiding. (Like for Fermat’s last theorem.)

Let us create a climate free of hostility – a climate that allows loners to work on their own. Then unification will appear.

I am currently reading Hermann Weyl. Since its a real book and not a PDF, I can’t find the exact quote and am only paraphrasing from memory, but he says something to the effect: Philosophers wish to think a thought and immediately get the truth, but science takes a very long time and philosophers are just impatient.

Increasingly, as I become familiar with this whole debate, Weyl’s sentiment seems a wise attitude to take.

Thanks,

Don

Chris W.,

I probably should write “utilitarian”, by which I mean “to be able to develop a technology i.e., to produce artifacts (not only material, but also, say, medical procedures) that behave according to the designer’s plans”. As for the story, I precisely said what I meant, and therefore I do not agree with you. In my view, the only requirement is that the story is consistent, in particular consistent with other stories that we consider “correct”

December 19, 2014

I finally got around to reading the *Nature* article, and came across this line:

> In our opinion, this is moving the goalposts. Instead of belief in a scientific theory increasing when observational evidence arises to support it, he suggests that theoretical discoveries bolster belief.

This is clearly taking things too far in the opposite direction. The theoretical discovery of color confinement and asymptotic freedom clearly increased belief in the quark model, and there was even a Nobel Prize given out in connection with it.

But that’s because this theoretical discovery improved the alignment of theory and experiment, which is the test that theories need to pass.

I think the work of Gerald Holton is helpful in this context of what is science and what not (Thematic Origins of Scientific Thought). It shows how important mental dispositions are.

25. **Kevin Henderson**
December 19, 2014

As an experimentalist, having physicists making claims that are, in principle, not falsifiable does not appear bad. You can think of it like this:

I have just thought of something and I think it explains some physical phenomena. If it never gets published (arXiv) no one will know about it. It might have a flaw that others can point out. It may be useful in peripheral ways that help others connect ideas of their own. It may, of course, be of no benefit to anyone, but what harm has come?

In my field, the reverse tends to be true. People do not publish enough of their mistakes to let others know not to try a specific method that is doomed to fail. Science is becoming more about not doing, but deciding what not to do. I think we all have to get used to that.

26. **Nobody**
December 20, 2014

"It may, of course, be of no benefit to anyone, but what harm has come?"

You'd be right if funding was unlimited. Since it isn't, there has to be fights over whether or not various lines of thought are crap.

27. **arsenic&lace**
December 20, 2014

It makes perfect sense to describe modern string theory as a form of mathematics. Mathematicians may not view their work as speculative* but that's really what it is; conjuring rules to describe an imaginary system, and then deducing the consequences of these rules. String theorists are only different in that they sometimes eschew the levels of rigor employed by mathematicians.

At any rate, this whole debacle is just what is guaranteed to occur when experiment, which is the driving force behind physics and all science, atrophies due to lack of reasonable targets. Abandoning string theory won't save HEP; the only thing that can do that is some actual experimental results.

*Some mathematicians view their work as an investigation on equal footing with say, chemistry: much as the chemist investigates the properties of an object found in reality, so too does the mathematician. Different algebras are as real to them as different polymers, but this is a ludicrous position. Mathematicians just don't hope necessarily that their work has actual relevance to reality.

28. **Peter Woit**
December 20, 2014

I think that virtually no mathematician would say that "string theory is mathematics" and that people claiming this are not mathematicians (Ellis and Silk certainly aren't). What mathematicians do is work to create new mathematics. Applying known mathematics doesn't make you a mathematician any more than my using the laptop I'm typing into makes me a computer scientist. "String theory" now covers a wide variety of different things, some of which try to use mathematics that is not well-understood, and can very well lead to new mathematics. Some of that activity certainly can be seen as mathematics research (a lot of Witten's work falls into this area for instance). Other parts of string theory, for instance those trying to put together complicated models of "string phenomenology" or "string cosmology", are just using well-known mathematical techniques and are in no sense mathematics research. They're straightforwardly physics, sometimes using mathematics that just doesn't happen to be part of the usual physics curriculum. The failure to connect successfully to reality doesn't make this work mathematics, it makes it failed physics.

29. **Colin**
December 20, 2014

The pure mathematician's view on string theorists seems to be roughly: "They believe in a lot of conjectures, some of which turn out to be very insightful, but their confidence in these beliefs is difficult to comprehend, as is their obsessive focus in certain specific classes of examples." Genuine and interesting new mathematics, such as 'monstrous moonshine', has been inspired by developments in theoretical physics, even if we don't trust what the physicists claim as 'theorems'. It's reminiscent of the story of the Italian school of algebraic geometry in the early 20th century: some people working in this area became increasingly cavalier with standards of rigour, and for a long time 'got away with it', in that they obtained a number of important results that were ultimately proved correct by more rigorous standards, but eventually the contradictions started to pile up and nobody had any confidence any more about which results were correct.

30. **tulpoeid**
December 21, 2014

"It is based on quantum mechanics, so if experiments falsify quantum mechanics, they falsify string theory. This just makes clear that the question of falsifiability can be slippery."

No, excuse me, this is not some deep smart logical paradox, don't let these people lower everybody's standards. It's a failure to grasp ridiculously basic logical concepts to a degree horrifying for someone who gets public funds (directly, instead of as a pupil or a patient). "Send someone to fetch a child of five."

31. **Hilton Ratcliffe**
December 22, 2014

I recently retired after 40 years in astrophysics, during which time I succeeded in making of myself something of a pariah, although all I wanted to do was practice physics, physically. I am South African, partially educated at the University of Cape Town, George Ellis's academic home. At this stage of my life I can say what I like without jeopardising my meagre pension. And what I say is this: thank heavens for George Ellis, Peter Woit, the late Geoff Burbidge, and those few others who had the courage of their convictions and stood up to the corruption of science. My swansong, and indeed also my magnum opus, is my third book, Stephen Hawking Smoked My Socks, a treatment of the influence of belief in the formulation of our opinions, scientific or otherwise. In it, I acknowledge the courage of Ellis, Burbidge, and you, Peter. I salute you, Sir.

32. **Hontas Farmer**
December 22, 2014

A point of view which is quite interesting was published here by Johannes Koelman which states that string theory, M-Theory and other quantum gravity models can claim a degree of verification by post-diction. M-Theory in particular reproduces the Standard Model of particle Physics (many of them actually) and General Relativity. By predicting the same low energy behavior as those models theories gain their verification.

What is your take on such an argument?

Personally while I find this line of thought interesting I am not totally convinced. Postdiction of known physics only means a model is plausible. What needs verification are the unique features of a hypothesis. *What needs verification are the predictions that go beyond known physics*.

> I'm leery of the impulse among physicists to solve their problem of how to deal with bad physics by calling it mathematics. Yes, there is good mathematics that has come out of untestable ideas about string theory, but no, this doesn't include the string landscape/multiverse cop-out, which physicists need to face up to themselves.

Let us hope this kind of thinking does not gain traction. Who would they have make that call? What "wonderful group" would get to decide that this model which deals with physical phenomena is physics and this other model over there isn't?

33. **Nobody**
December 22, 2014

“Who would they have make that call? What “wonderful group” would get to decide that this model which deals with physical phenomena is physics and this other model over there isn’t?”

Nobody can stop anybody from claiming that some idea is physics. But people do make decisions about what research will be funded, who will be hired, and what papers will be published in reputable journals.

It is how the world works.

34. **Curious Mayhem**
December 23, 2014

@Douglas Sweetser – I like this “work on strings.” The overuse of “theory” was perhaps lifted from the follies of the humanities of recent decades.

As for “predicting quantum mechanics,” this is as absurd as “predicting the Standard Model.” In both cases, the theories in question pre-existed “work on strings” — as did supersymmetry, higher dimensions, and inflation — and depend in no way on “work on strings.”

What amazes me is how long this desperation has lasted and how many who might have done some science have been driven from the field by the “work on strings” monomania.

Categories: Uncategorized

- The Planck data release has been delayed yet again. December 22, is now off the table, the latest plan is "before the end of January 15", see here. Some peeks at their results are in slides from the Ferrara conference, available here. The fact that the slides for the "Planck low-ell CMB power spectra" talk are unavailable correlates with the rumor I've heard that they have recently found serious problems with that part of their data analysis, which would explain why the data release keeps getting pushed back.

  This week there's a conference in Paris, no slides yet. Streaming video has been available, which I took a look at for a while. Just managed to catch the tail end of questions about what the state of their analysis is relevant to the crucial B-mode business. Not enough to get the bottom line of what the state of affairs is. Perhaps someone who was there or who watched the whole thing can report. About the best source of information on cosmology these days seems to be Twitter, hashtag #planck2014. Something else of interest at the Paris conference was a debate about inflation featuring Steinhardt, Mukhanov, Linde and Brandenberger. Maybe video will be available someday, along with the slides.

- Scott Aaronson has more here about the problems with the recent movie about Turing that I mentioned here. Despite (or maybe because of…) having little relation to reality, the screenplay of the film has been nominated for a Golden Globe award.
- David Mumford and John Tate wrote a biographical sketch of Grothendieck for Nature. Unfortunately it seems that it won't be published there because of being too technical. It is however available at Mumford's blog.
- There's an interesting interview with Nikita Nekrasov at the artist Marina Abramovic's MAI site.

Update: Shantanu points out that the Paris talk videos are available here. Looking a bit, I didn't see anything from the Planck people about when they will release direct B-mode polarization results (next month? later?). Steinhardt gave a powerful talk arguing in detail that inflation does not predict anything, and that the usual claims for it are untenable. For the Steinhardt, Mukhanov, Linde, Brandenberger debate, see here.

Update: For yet another explanation of the problems with the Turing movie, set this at the New York Review of Books.

4. **Katya**
   December 21, 2014

   Peter – Thanks for the link. I also enjoyed Slava Mukhanov, who gave a rollicking presentation. He pointedly disagreed with Alan Guth, who now claims that science does not depend upon falsifiability, but instead progresses in an "arena of competing ideas." Mukhanov slammed that as theology or philosophy, but not physics. He was also dismissive of the multiverse, because if he cannot check to see if it's there or not, "who cares." Science is built on experimentation, not theoretical arguments. "If something cannot be ruled out, it is not science." Bravo.

Dualities

December 19, 2014
Categories: Multiverse Mania

There's a very interesting new paper on the arXiv by Joe Polchinski, a survey article for Studies in History and Philosophy of Modern Physics, entitled just Dualities. It's an unusually lucid summary of the story of dualities in quantum field theory and string theory. This is a very complex subject which has been a central one in theoretical physics for the last few decades, but most expository writing on the subject has tended to be either superficial promotional material or mired in technical detail obscuring fundamental issues.

One reason for this is that, as Polchinski does an admirable job of making clear, in a very real sense we still do not understand at all the fundamental issues raised by these dualities. He notes that "we are still missing some big idea", and points to the same comments from Nati Seiberg last month that I blogged about here. For most of the dualities at issue, our current standard technology for dealing with QFTs (the Lagrangian and the path integral over classical fields) is capable of capturing the two QFTs that are in some sense "dual", but we lack a viable larger framework that would give the two QFTs in two different limits and explain the duality relationship.

For an example of the problem, probably the oldest and most well-studied case where we are missing something is Montonen-Olive duality, a non-abelian duality between electric and magnetic charges and fields. A currently popular idea is to find the explanation of this in "Theory X", a 6d superconformal QFT, with duality coming from compactifying the theory on a torus (for more about this, see talks last week in Berkeley). The problem with this is that we don't have a definition of the "Theory X".

Polchinski places this problem in the context of a conjectural "M-theory" with various string theory limits. This has been the dominant idea in the subject for nearly 20 years now, but we seem no closer now to finding an actual realization of this conjectural picture than we were back in the mid-90s. Twenty years and thousands of papers have just given better understanding that various possible ideas about this don't work.

One place where I think Polchinski's survey is weak is in the treatment of this conjecture, where at times he takes as solid result something highly conjectural. For instance he starts off at one point with:

> String-string dualities imply that there is a unique string/M-theory.

and moves on to the conjecture that

> In this sense it may be that every QFT can be understood as a vacuum state of string/M-theory.

The problem here is that he's built a speculative view of the unification of physics, constructed on an assumption about a "unique" theory, when we don't know at all that such a thing exists. One basic lesson of mathematical research is that you need to keep very clear the distinction between what you really understand and what is speculation, because your speculation is often wrong and if so will lead you in the wrong direction. I think particle theory of recent decades likely suffers from people forgetting that some ideas are speculative, not firmly grounded, and may be pointing in the wrong direction.

One wrong direction this takes Polchinski is to the non-predictive, pseudo-scientific landscape of supposed string theory solutions and the multiverse, which he blithely invokes as our best fundamental explanation of physics. Tellingly, unlike the clear explanations of other topics, here he makes no attempt to describe these ideas other than to note that

> they rest on multiple approximations and no exact theory.

In a final section, Polchinski addresses the question of what all this tells us about what is "fundamental" and what is the role of symmetries. This is the crucial question, and I'd argue that our lack of understanding of where these dualities come from likely is due to our missing some understanding of how symmetries are realized in QFT or string theory. This has been the lesson of history, with the Standard Model only coming into being when people better understood how symmetries, especially gauge symmetries, could act in QFT. Polchinski largely takes the opposite point of view, arguing that the fundamental theory maybe has no symmetries, local or global. He quotes Susskind as suggesting that symmetries have nothing to do with fundamental equations, are just calculational tools for finding solutions. I think this is completely misguided, that a strong case can be made (and I do it here) that "symmetry" (in the sense of the mathematics of groups and their representations) lies at the very foundation of quantum mechanics, and thus any quantum mechanical theory, even string/M-theory, whatever it might be.

Wondering whether there will be an arXiv trackback to this, and whether Polchinski has something to say about it…

Update: The arXiv Monday evening has a large collection of excellent review articles entitled "Exact results on N=2 supersymmetric gauge theories", edited by J.Teschner (first is arXiv:1412.7118, last arXiv:1412.7145). Some of the results reviewed are based on deriving implications of the existence of the 6d (2,0) models discussed here and in the comment section.

Update: I've put this blog posting in the Multiverse Mania category, not because of the posting content, but because of comments in the comment section from Polchinski and Bousso.

Comments

1. **CIP**
   December 19, 2014

   Polchinski notes the analogy between S duality and the duality of descriptions in the Fourier transform. Such dualities of description have seemingly become ubiquitous in math, exposing deep connections between algebra, arithmetic, and geometry.

   Even the wave-particle duality that so confounded early quantum mechanics fits the pattern. Despite Susskind, these things are probably all quite deep.

2. **Giotis**
   December 19, 2014

   Well you don't have to resort to 6d SCFT to give a geometric origin of S-duality; as it is described in the paper the Montonen-Olive duality is explained by IIB self-duality.

   Moreover IIB self-duality on a circle is geometrically realized by compactifying M-theory on a 2-Torus (or similarly from F-theory) via modular invariance (i.e. the diffeomorphism invariance of the Torus).

   So overall the very existence of M-theory explains S-duality.

3. **Joe Polchinski**
December 19, 2014

Thank you for your review. Indeed, the landscape discussion was a bit of an aside and perhaps should have been omitted as a distraction. My remarks on symmetries are very much outside the orthodoxy and I was glad for the opportunity to present them.

About trackbacks, you seem to think that am responsible. I once stated my opinion, and someone, I don't know who, acted in response. I stand by my opinion, and believe that whoever acted did so correctly. It should be noted that your blog has no actual science content. There is science news, science opinion, science criticism, science sociology, occasional science invective, but no actual science. (Lubos, who also seems not to be tracked, does have science content but also has so much that is inappropriate that his signal/noise is miniscule). There is a primary literature of science, and a secondary literature of science criticism etc. It is great that the secondary literature exists and links the primary literature, but this is one-way, the primary literature should strive for a maximum signal/noise.

p.s. Regarding "they rest on multiple approximations and no exact theory," you might note that the preceding arXiv paper was directed at examining these approximations and making them more precise.

4. **Peter Woit**
December 19, 2014

Joe,
Thanks for the comments and thanks for writing the thought-provoking article. Your comments about symmetries struck me as quite similar to ones I've seen from Arkani-Hamed, especially about gauge symmetry, I think they're less outside current orthodoxy than you think. As for the symmetries "a calculational tool, not fundamental" point of view, Howard Georgi was warning students like me taking his Lie algebras class back in 1978 along much the same lines (it's not original with Susskind)

About your "no actual science" claim I'll have to respectfully disagree. There are lots of different things on this blog, but it's not unusual for it to contain more actual science than a typical arXiv paper on the landscape…

In any case, "actual science" by your definition doesn't seem to be the criterion that the arXiv is using to bar trackbacks to my blog, since they now allow trackbacks to a wide range of journalistic sources (checking at random those from yesterday, one is to the Atlantic magazine). Despite putting a lot of effort into this, I haven't been able to get an answer from the arXiv to the question of what criterion they are using to bar this blog. If you happen to find out, please let me know. At this point the only information I have about this is that you've called for such a bar and that has been very influential.

5. **Flavio**
December 20, 2014

Peter,

do not get worried about Joe's remarks about your blog. How can you two get along? Each of you two tells the other, politely, that he is not doing science. And you both believe this assessment of the other to be true, with every cell in your body.

There are only for possibilities: either of you can be right or wrong. But all four possibilities are of no help. But maybe I am wrong; maybe you see it differently.

Progress can only come by getting back doing science, by returning to the search for a solution to fundamental physics.

6. **M**
December 20, 2014

Recognising promising and failed lines of research is a key part of science. "Not Even Wrong" should have been on arXiv

7. **Peter Woit**
December 20, 2014

Flavio,
I don't at all think he's not doing science. The great majority of the article was about important and interesting scientific work. Better understanding these dualities is a great scientific problem, with both physical and mathematical aspects. As for the string landscape, for lots of it I'm willing to admit it's science, just really bad science…

8. **Mike Duff**
December 20, 2014

Giotis,

I agree with your remark "So overall the very existence of M-theory explains S-duality''. S-duality in D=4 follows from string-string duality in D=6 (hep-th/9501030) which in turn follows from M-theory in D=11 (hep-th/9506126). (Don't usually respond to blogs, but here I made an exception since M-theory is taking a bashing and this work somehow got overlooked in Joe's review.)

9. **Peter Woit**
December 20, 2014

Mike Duff/Giotis,
The problem with the "M-theory explains S-duality" argument is that, as Polchinski is careful to point out, you don't understand what M-theory is. The reason I mentioned the explanation in terms of the 6d superconformal QFT is that that seems to be something one has a chance of understanding independently of a full understanding of M-theory.
I seriously do think people need to keep clear what it is that they have a solid understanding of, and what is conjecture. Kudos to Polchinski for doing this somewhat better than usual.

10. **Giotis**
December 20, 2014

Yes of course professor Duff, what you mention is another classic derivation of S-duality from M-theory that was not included in the paper.

Peter not sure what you mean; we know enough to make that claim with confidence.

The reason why people often focus on the 6d SCFT (e.g. for the Langlands correspondence) and not on the Stringy/M-theoretic explanation of S-duality mentioned by professor Duff, is explained in page 5 of the seminal paper by Witten "Some Comments On String Dynamics" (http://arxiv.org/abs/hep-th/9507121).

Anyway the 6d SCFT is a prediction of IIB or M-theory.

11. **Peter Woit**
December 20, 2014

Giotis,
What I mean is that you can't claim to have explained something by showing that it is an implication of something else that is just as poorly understood. You're just relating one conjecture to another conjecture. If M-theory was much better understood than 4d qft that sort of relation might have explanatory power, but the opposite seems to be true.

12. **Mike Duff**
December 20, 2014

Giotis

Re S-duality from M-theory: Thanks for pointing out page 5 of the seminal paper by Witten, "Some Comments On String Dynamics" (hep-th/9507121). On this topic, see also page 33 in another seminal paper by Witten, "String Theory Dynamics in Various Dimensions" (hep-th/9503124).

13. **Peter Woit**
December 20, 2014

Giotis/Mike Duff,

I just took a look at the page recommended in hep-th/9507121, and I was amused to notice that Witten makes a version of the point I've been trying to make:
"Thus, if one asks, "How can the S-duality of N= 4 Yang-Mills theory be made
obvious?" one answer is that this can be done by embedding N=4 supersymmetric
Yang-Mills theory in the heterotic string and then mapping to a Type IIA theory by using string-string duality. The weakness of this answer is that it embeds the gauge theory in a problem with many other features – such as gravity – that may not be material. One would like to "flow to the infrared," eliminating as many degrees of freedom as possible, and obtaining the minimal theory in which the S-duality is still manifest. The self-dual string in six dimensions may be the answer to this question. The self-dual string in six dimensions does not look easier than the Type IIB model that we started with; certainly we understand it less. Nevertheless, it might be the right structure for understanding the four-dimensional field theory."

Witten talks here about the self-dual non-critical 6d string, these days it seems that attention is now on the simpler 6d superconformal QFT, presumably easier to understand. But the point is the same: embedding something you don't understand in something much more complicated you don't understand isn't a great explanation. Much better is to embed in the simplest thing that has the properties needed to explain what you want by this mechanism. What you want here follows from the 6d superconformal QFT, which is hard enough to understand. Embedding this in string theory or M-theory just puts you in a more complicated context, while it's the 6d properties that have some explanatory value.

14. **Mike Duff**
December 20, 2014

Peter Woit

Re your view that "The reason I mentioned the explanation in terms of the 6d superconformal QFT is that that seems to be something one has a chance of understanding independently of a full understanding of M-theory. I seriously do think people need to keep clear what it is that they have a solid understanding of, and what is conjecture."

Here is what Greg Moore says (http://www.physics.rutgers.edu/~gmoore/Strings2011FinalPDF.pdf).

"Important characteristics of the six- dimensional (2,0) theories S[g]: These theories have not been constructed – even by physical standards - but some characteristic properties of these hypothetical theories can be deduced from their relation to string theory and M-theory."

15. **David Ben-Zvi**
December 20, 2014

While it's certainly true that there is no mathematical definition or construction of the 6d SCFT (or even physical, as Mike Duff quotes from Greg Moore), the kind of object it is is clear mathematically, and one can formulate precise conjectures/axiomatics for its properties. Of course the main evidence for any of these constructions comes from string theory and M-theory, but on the other hand there are mathematical theories very close to it (eg its dimensional reductions or its Coulomb branch deformations) which can be defined and understood using current mathematical techniques.

For example in the workshop Peter links to Kevin Costello presented a mathematical definition of an approximation to theory X (the (2,0) theory) — roughly speaking it's the part of the theory seen by its local operators and surface defects, but ignorant of the 4-dimensional defects, and not enough to explain S-duality. This part makes sense as a perturbative quantum field theory and agrees well with many predictions in physics.

At least as far as mathematics goes, this is one of the great appeals of theory X – it's extremely useful to have a conjectural structure with this powerful predictive power (eg Langlands duality) that's close to things we understand or at least can formulate precisely; while we'd love to "go to 11" and see indescribably further through M-theory, this seems very far from the capabilities of contemporary math.

16. **Giotis**
December 21, 2014

Exactly professor Duff. Thanks for pointing out this excerpt.

@Peter some remarks:

As I have mentioned above 6d SCFT is a prediction/achievement of the second superstring revolution.

The best way we have to describe the theory so far is via AdS/CFT. Indeed the theory is dual to M-theory on AdS7xS4.

Although the theory sits in a conformal fixed point we should not forget that even in six dimensions it is the low energy limit of 6d LST (Little String Theory). Moreover the theory itself is known as the theory of tensionless strings in six dimensions (though of a solitonic nature).

Finally the discussion on whether we have to resort to the full machinery of String/M-theory is far from closed. Witten just made an argument at that point in time without expressing any certainties. Check for example his remark in chapter 4.2(page 15) of his paper "Geometric Langlands From Six Dimensions". This statement is similar (but stronger) to Moore's comment referenced by professor Duff above. Moreover Meng-Chwan Tan reproduced (http://arxiv.org/abs/0807.1107) the field theoretic results of the aforementioned paper regarding Langlands correspondence using the dualities and machinery of M-theory.

From another stringy point of view S-duality reduces to T-duality as it was demonstrated by Vafa in his classic paper "Geometric Origin of Montonen-Olive Duality" (http://arxiv.org/abs/hep-th/9707131).

Finally we should not forget that S-duality and T-duality are just parts of a bigger U-duality group which can only be understood within the general context of M-theory.

17. **Chris Austin**
December 21, 2014

On the issue of whether or not the 6d interacting superconformal field theories have Lagrangians: on pages 10 and 14-15 of 0712.0157, (cited by Giotis in the post on Weinberg and Seiberg), Witten seems to argue that an obstruction to these theories having Lagrangians in 6 dimensions is that when you compactify them on an S^1 of radius R to 5 dimensions, R occurs in the denominator of the resulting d = 5 Yang-Mills action, (so that the Yang-Mills coupling constant is proportional to \sqrt{R}), rather than in the numerator, as would normally be the case for a KK reduction. But it seems to me that a qualitative counter-example to this argument is provided by Witten's own work on obtaining type IIA superstring theory by compactifying d = 11 supergravity on an S^1 of radius R, on page 4 et seq of hep-th/9503124: the resulting superstring coupling constant is proportional to R^(3/2). The reason for this is that the type IIA superstrings result from solitonic d = 11 2-branes that wrap the S^1, (the 2-branes are the classical solutions of d = 11 supergravity found by Duff and Stelle). Could it not be possible that the 6d (2,0) theories have Lagrangians that admit classical 1-brane solutions, and on compactification on an S^1, the d = 5 Yang-Mills fields arise from 1-brane configurations that wrap the S^1?

18. **Urs Schreiber**
December 21, 2014

To amplify again what Giotis mentions above: there is an actual definition of the 6d (2,0)-CFT is via AdS7/CFT6 holography and it translates to a good mathematical definition in a suitable limit.

This deserve a reminder from time to time. In that same String2014 "vision talk" already mentioned above, "Physical Mathematics and the Future", Greg Moore in section 5.1 lists some ideas of how to capture the 6d (2,0)-SCFT, only to conclude (on p. 28) that:

> As stressed to me by Edward Witten, thanks to the AdS/CFT correspondence, we do have an understanding of the complete solution of the theory in the large rank limit for su(N) theories

In the limit in which the Chern-Simons terms in the dual 7d theory dominate, this even becomes essentially a mathematical precise definition, where the partition function of the 6d theory is obtained from the geometric quantization of the 7d Chern-Simons theory in direct higher analogy to how the 2d WZW model arises from 3d Chern-Simons theory (CS3/WZW2 correspondence). And this is the way that in the abelian case and for just the 2-form sector Witten has studied the 6d theory since

– E. Witten, "Five-Brane Effective Action In M-Theory", J. Geom. Phys.22:103-133,1997 (arXiv:hep-th/9610234)

– E. Witten, "AdS/CFT Correspondence And Topological Field Theory" JHEP 9812:012,1998 (arXiv:hep-th/9812012)

19. **Peter Woit**
December 21, 2014

Urs,
I'm a bit dubious about your argument that at large N, AdS7/CFT6 is nothing but the phenomenon we understand in terms of geometric quantization for AdS3/CFT2. Wouldn't the same hold true for the well-known AdS5/CFT4, and is that really all there is to that in large N? I've never heard anyone make that claim before.

In any case, the initial point remains that you're trying to explain one conjecture (electro-magnetic duality) in terms of others that are equally if not more mysterious (AdS/CFT + M-theory).

20. **Urs Schreiber**
December 21, 2014

In the limit where the CS terms dominate. That's the content of

— E. Witten, "AdS/CFT Correspondence And Topological Field Theory" JHEP 9812:012,1998 (arXiv:hep-th/9812012):

> This flux [in 4d SYM] is encoded in the AdS/CFT correspondence in terms of a five-dimensional topological field theory with Chern-Simons action. A similar topological field theory in seven dimensions governs the space of "conformal blocks" of the six-dimensional (0,2) conformal field theory.

For just the abelien self-dual 2-form theory in 6d, it's very construction in

— E. Witten, "Five-Brane Effective Action In M-Theory", J. Geom. Phys.22:103-133,1997 (arXiv:hep-th/9610234)

is via abelian 7d Chern-Simons theory in direct analogy to CS3/WZW2. This statement later became the main theorem (i.e. was made mathematically rigorous) in

— M. Hopkins, I. Singer, "Quadratic Functions in Geometry, Topology, and M-Theory" J. Differential Geom. Volume 70, Number 3 (2005), 329-452. (arXiv:math.AT/0211216)

21. **Peter Woit**
December 21, 2014

Urs,
You're just talking about a topological limit or sector of the theory. I don't see how that gives you electro-magnetic duality of the 4d theory, that seems to me to require behavior under conformal transformations that you can't see in the TQFT limit, or am I missing something?

22. **Urs Schreiber**
December 21, 2014

The 7d CS theory is topological, not the 6d theory that it encodes holographically. Just as for CS3/WZW2. The conformal structure in 6d arises as the polarization structure for the geometric quantization of the 7d theory.

23. **Peter Woit**
December 21, 2014

Urs,
OK, but based on what I do understand here (the subtleties of getting from 3d Chern-Simons to a 2d CFT), I'm suspicious that to do what I don't understand here (get from 7d Chern-Simons to a 6d CFT) you need to make some conjectural assumptions at least as strong as electro-magnetic duality.

In any case, what you seem to be claiming is that one just needs to understand 7d Chern-Simons, not the full M-theory, to get non-abelian duality.

24. **Peter Woit**
December 21, 2014

And I'm still wondering about AdS5/CFT4. 5d Chern-Simons is enough to give you 4d large N CFT??

25. **Urs Schreiber**
December 21, 2014

No. Check out the articles that I pointed to for the statement.

26. **Joe Polchinski**
December 22, 2014

Peter,
I don't speak for the arXiv, but clearly this is a judgement call, a question of signal/noise. Let me explain what I mean by `no science.' Your most recent post on the landscape:
"The latest news (arXiv:1410.7776) is that KKLT doesn't actually work, that you can't get stable string vacua that way. I don't think though that this will have any effect on multiverse mania and its use as an excuse for the failure of string theory unification…"

First, you seem to just assume that this paper is correct. An authority on the process of science might be expected to recognize that just because a paper appears on the arXiv, it cannot be assumed to be correct. Second, there is absolutely no discussion of the content of the paper, or what are the scientific issues involved. Rather, you just use it as an excuse to launch into your standard uncharitable assessment of a group of scientists, and to indulge in some of your favorite charged words ("mania", "failure"). Third, you get both the science and the sociology wrong, see arXiv:1412.5702.

I see zero signal here, and a lot of noise. And this is a very representative example. So no, I do not think that the arXiv should link to this.

p.s. Thanks to Mike Duff and others for the discussion of references.

27. **Maurice Carid**
December 22, 2014

Hi Peter,
with all due respect, but I think Dr. Polchinski has a valid point here.
For a string-theory/landscape unrelated example: in your entry
from Nov 3, 2014 "Last week's hype" you slandered an arXiv entry
as "university press-release-driven hype" and the press releases themselves as
"nonsense spread around the media". When Als and I – both after having read the paper – challenged you to explain what's wrong with the paper and the press releases, all you contributed was "Maurice/Als,
I've already wasted more time on this than is wise."
What useful information would a trackback to your blog entry have
conveyed to the readers of that paper?
cheers & no hard feelings!
maurice

28. **Peter Woit**
December 22, 2014

Maurice Carid,
A statement is not slander if it is accurate. I think my characterization of that paper is pretty much the same as the way most physicists would describe it.

29. **Peter Woit**
December 22, 2014

Joe,
You're avoiding the question of what the arXiv policy is under which I am banned. What is it? If you don't know what it is, don't you think you really should ask someone before publicly defending it? I'm having a lot of trouble taking seriously your claims that you don't have any responsibility for this or know who does. This disagrees with what I've been told, which is that people at the arXiv point to you to justify this decision.

You seem to indicate that the arXiv policy is somehow based on a "signal/noise" evaluation, one that you have performed and found this blog wanting, largely because it regularly refers to the research program you are heavily invested in as a failure. The obvious problem is that others see what is signal and what is noise quite differently than you do. I suspect that my characterization of the anthropic string landscape program as pseudo-science driven by refusal to acknowledge failure is one that a sizable fraction of the scientific community would agree with (see the Ellis/Silk piece in Nature, although you likely dismiss that too as "noise"). You are very obviously using the "signal/noise" business as an excuse to ban a legitimate scientific point of view that makes you uncomfortable.

As for the mention here of arXiv:1410.7776, the background there is that I was contacted by someone expert on that topic who felt that that paper and the research program it was part of posed a serious challenge to widespread assumptions among theorists about KKLT moduli stabilization, that this was not getting sufficient attention from other theorists, so they wanted me to make this issue more widely known. My initial reaction was not to get involved on the grounds that the string landscape business, as serious science, is what some would accurately characterize as noise, not signal. In the end I decided to briefly mention it as one of six short items. Rereading what I wrote, I still think it's precisely on target as regards the sociology and the evaluation of that line of research.

As for your claim that I assumed the paper was correct and that I'm too dimwitted to realize that papers on the arXiv are sometimes not correct, that's just ridiculous. It's interesting to note that my brief mention here did have the effect my correspondent wanted, causing extensive discussion at another blog, and perhaps this even had some influence on arXiv:1412.5702. If what I write here is noise, it's noise that a lot of people in the field take seriously, and that's the problem that seems to be bothering you.

30. **Raphael Bousso**
December 22, 2014

Peter,

You write that you are not too "dimwitted" to recognize that an arXiv paper might be incorrect. We should accept that.

There are two remaining possibilities. One is that you analyzed arXiv:1410.7776 carefully and convinced yourself that the technical issues it raises support your claim that "KKLT doesn't actually work." If so, I'm sure you will have an equally specific response to arXiv:1412.5702, which does not reach this conclusion.

I would normally recommend that you post your analysis on the arXiv. On the other hand, by posting it here you could silence those who say that your blog contains no science. Anyway, you should post it somewhere, since the technical questions at issue are of scientific interest quite independently of any applications to KKLT and the landscape (which you may feel would not by themselves merit the effort of writing up your analysis).

The only remaining possibility is that you knowingly choose to advertise as "news" any paper that you perceive as fitting your narrative, without having any idea whether it is correct. I suspect that this wouldn't bother your clientele, so you might as well let us know right away whether a detailed analysis will be forthcoming from you.

31. **Dom**
December 22, 2014

As an interested lay person, I enjoy reading Peter's blog, I have tried all of the blogs he links to and although some interest me, only this one I refer to on a daily basis. I'm not actually that concerned (for example) whether the string approach is correct or not, I prefer to read lots of views. I would say one thing though as an outsider, the more confident I am about my approach to the problems I have to solve professionally, the more I welcome sceptical/hostile enquiry. When people with presumably enormous intellects get so upset that people criticise their ideas I can only conclude that there is some underlying and considerable internal lack of confidence. Einstein's reported reply to the book "100 Authors against Einstein" – namely "If I were wrong, one would be enough." strikes me as how a confident person deals with it.

32. **Bill**
December 22, 2014

Took a look at recent trackbacks; certainly, this blog would not decrease signal/noise ratio. Was surprised to see how few trackback there are on an average day. Don't see why anyone would make such a big deal out of (or even have a strong opinion about) this.

@Raphael Bousso: You can insult Peter all you want, but why such animosity toward his "clientele"?

33. **Bernhard**
December 22, 2014

It's pretty clear the not linking of the arXiv to NEW has absolutely nothing to do with science given other completely non scientific material they link to. This censorship that reminds us of inquisition times. If the policy of the arXiv was to link only to highly technical and (as best as possible), unbiased material, that is one thing. But since there is no such thing (Motl, really?), the sober conclusion is that the ban is pivoted by string theory critic. By the way, professor Polchinski, if you only "stated your opinion" to someone that happened to have veto powers on the arXiv, that is the same as making the ban yourself, as you are aware of your own influence and power on the field (that you conquered with talent and hard work, but I'm afraid still not justifiable).

34. **Doug McDonald**
December 22, 2014

As to signal/noise, in the blog business, especially blogs like this,
its not a dichotomy, its a trichotomy:

signal/metasignal/noise

I see this blog as being intended as metasignal

35. **Physics postdoc**
December 22, 2014

As a physics postdoc who does GR but not string theory, I've learned a lot about dualities in string theory and their relation to the 6D theory from the discussion in this comment section and I've picked up some great references. This is typical of my experience with Peter's blog, and has kept me reading along for about 6+ years. So I disagree with Joe and Raphael. My experience is that this blog has a very high signal-to-noise, and I think this very comment section is an example. Peter deserves all the credit for this, I don't know anyone who does a better job or puts more energy into moderating great discussions on a physics blog.

36. **Peter Woit**
December 22, 2014

Raphael,
A few explanations of things you don't seem to understand:

About my "clientele". A sizable part of it is string theorists, with the one who contacted me repeatedly to suggest I mention the line of work in question just one of many. When you insult people who find the information on this blog worthwhile, you're insulting a large number of your colleagues.

You have it completely backwards if you think that "KKLT doesn't work" fits my narrative, quite the opposite. I'm a big fan of Bousso-Polchinski, KKLT, and Susskind's argument for anthropics and the string theory landscape. If you, Joe, or others can convince your colleagues that string theory is a theoretical framework with essentially zero predictive power, that fits my narrative perfectly and I'm happy to support you. I've been saying this ever since the landscape business started, for an example from the earliest days of this blog, see
http://www.math.columbia.edu/~woit/wordpress/?p=13&cpage=1#comment-111
I mentioned arXiv:1410.7776, despite it going against my favored "narrative" because I thought some people would find it interesting, and it seems they did (I'm still wondering whether it motivated Joe to write that paper…).

About the technical details in question, of course I'm not going to devote time to them and anyone reading the "KKLT doesn't actually work" clause of that sentence in context would recognize that I wasn't vouching for it. I've ad nauseam made the case that this kind of construction is not science, but pseudo-science: it's designed not to give a plausible way of reliably calculating something that can be compared to experiment, but instead to provide an elaborate excuse for not being able to do this.
I don't see any point to taking seriously the details of this elaborate excuse. My non-expert take on the details is that Joe likely has it right with his comment that these arguments "rest on multiple approximations and no exact theory." Maybe you can find an obscure deep corner of parameter space with stabilized moduli and hopelessly complicated solutions, maybe you can't, but in either case this has nothing to do with serious science (in Joe's lingo, it's just "noise").

37. **Anonymous**
December 22, 2014

Raphael

Since when is “you must not discuss a disputed preprint, unless you yourself have posted a preprint on the subject” how science is done? Your attitude seems to be that those outside of your club should keep their mouths shut about your field. Regardless of whether the preprint in question is correct, this is deeply deeply unscientific.

38. **Peter Woit**
December 22, 2014

Anonymous,

People really should take a look at the posting that so upset Bousso and Polchinski, it’s
http://www.math.columbia.edu/~woit/wordpress/?p=7266

The short sentence
“The latest news is that KKLT doesn’t actually work, that you can’t get stable string vacua that way.”
with “latest news” a link to arXiv:1410.777 is the full and complete discussion of the paper in the posting. I don’t see how it’s not obvious that that was nothing more than a pointer to something people might be interested in, just giving the gist of the paper’s claim.

So, Bousso isn’t objecting to my discussion of a paper, he’s objecting to my mentioning a paper. This is really, really odd.

39. **Maurice Carid**
December 23, 2014

Hi Peter,
Because you gave us no clue why you think that
http://arxiv.org/abs/1402.6144 is “university press-release-driven hype”
I cannot be sure. But in this case the suspicion of Dr. Bousso that you
“advertise as “news” any paper that you perceive as fitting your narrative, without having any idea whether it is correct” is correct, suggests itself strongly (I’d say “even in case you have no idea…”, though.).
The above paper is not about the landscape or string theory
but strictly only about the many worlds of quantum mechanics. You lauded the work of David Wallace on this idea on your post from Dec 1, 2014. The above paper is a much more mathematical and concrete elaboration on this subject than Wallace’s more philosophical musings.
It thus seems to be excluded that you dismiss the paper in principle because of
its subject matter.
There seem to be two remaining possibilities. Either Dr. Bousso’s quote above is correct for this case: u just took a glance at the title, thought it’s about the landscape or “string theory explaining QM” and slandered it.
Or you actually read it and found some technical flaw in the paper. If the latter is correct I challenge u to briefly reveal the flaw. (B.t.w. I have no connection to the authors of the above paper, I just read it carefully.)

40. **Joe Polchinski**
December 23, 2014

Just for the record (and my memory is not perfect here, it’s been a long time), I believe that my original comment about trackbacks, which had whatever influence it had, was made publicly on this blog around 2006, and that it was motivated by a discussion, initiated by Peter, about whether Steven Weinberg was senile. It’s true that Peter concluded that he was not, but you chose to publish the original speculation. Note that Weinberg has written at least three books and thirty research papers since that time. Now you’ve since toned down `senile’ to `mania’, `pseudoscience’, but it’s still not scientific discourse.

You know Peter, you repeat the same rants so often, if the arXiv did link to you they would have to include an arXiv warning “this post has significant text overlap with 20 previous posts by the same author.” 🙂

41. **AReader**
December 23, 2014

Hi Peter,

I do like reading your blog, because I think it is important we’re looking for alternative theories …

I was just confused about this bit from you: “I’m a big fan of Bousso-Polchinski, KKLT, and Susskind’s argument for anthropics and the string theory landscape”. I was always under the impression you felt that string theory and multiverse are “wrong” – or have I misunderstood you, and you think they are quite likely to be correct theories?

Thanks.

42. **Peter Woit**
December 23, 2014

Joe,

I’d been told by a physicist who talked to you a few years ago that you were slandering me, telling him and other people that you didn’t read my blog because I had accused Weinberg of being senile. This physicist told me that he had to explain to you that what you were saying was not true. Your behavior then and now was and is completely unprofessional and you should be ashamed of yourself.

Some facts, with documentation:

1. I have never thought that Weinberg is senile or said anything like this, privately or publicly. Instead I have said exactly the opposite. The blog entry in question is this one
http://www.math.columbia.edu/~woit/wordpress/?p=289
in which I discussed in detail Weinberg’s Living in the Multiverse article, hep-th/0511037.

The morning that I was writing this, a colleague came into my office and I showed him the Weinberg paper. He reacted with a comment that Weinberg must be senile if he believed this was science. I argued with him that no, unfortunately for physics that wasn’t it, that Weinberg was as sharp as ever, but somehow this was becoming a popular point of view among physicists.

In the comment section of the blog that afternoon, responding to a comment from Thomas Larsson that "the heroes of your youth have become pathetic old men" I wrote, in full
"Hi Thomas,

One of my colleagues this morning, after being shown the Weinberg article, commented that Weinberg must just be senile. Unfortunately I don't think that's what's going on. Weinberg wants to be part of whatever the hot topic in particle theory is, and the landscape is the hot topic these days. It's being driven mainly by younger people, not by seventy-year-olds, and you can't put their behavior down to senility."
Yes, one of the "younger people" I had specifically in mind was Polchinski.

I think my meaning in that comment was perfectly clear: I was disagreeing with Thomas and arguing against any attempt to attribute senility to Weinberg.

2. Polchinski's argument that trackbacks should not be allowed to my blog was made at this blog posting:
https://golem.ph.utexas.edu/~distler/blog/archives/000760.html
see this comment
https://golem.ph.utexas.edu/~distler/blog/archives/000760.html#c003357
Neither he nor anyone else at the time mentioned my supposed accusations about Weinberg. He was personally outraged about this blog entry of mine
http://www.math.columbia.edu/~woit/wordpress/?p=73
which discussed in unflattering terms an article by him and Bousso in Scientific American promoting the multiverse, anthropics, etc. This was one of the first such articles in a major publication by well-known physicists, perhaps the first that made clear the extent of the problem in the physics community. When I saw his comment, I didn't recognize the text he was complaining about as mine, realized this by googling it. My reaction was that perhaps that was over the top, so in a comment responding to him I apologized for it. Many people then contacted me to tell me they thought I was wrong to do so, that what I had written was perfectly justifiable. Given Polchinski's later behavior, they were right, and I was wrong.

One odd thing about this was that Polchinski's example of what was wrong with my blog was not a discussion of a scientific paper on the arXiv, but of a popular promotional piece in a magazine. It was unclear to me then and remains unclear to me now why he thought that was a good argument against allowing links to discussions of arXiv preprints on my blog.

43. **Peter Woit**
December 23, 2014

AReader,
No, I don't think string theory and the multiverse are "wrong", I think they are "not even wrong": they don't predict anything, so can't be "wrong". Interpreting the Bousso-Polchinski argument as "if string theory make sense and implies anything, it implies a landscape with just about every possibility", that's perfectly in agreement with my point of view. We just disagree about where that argument leads you. I (and I think most physicists) believe it leads you outside the bounds of science, into another sort of activity.

44. **Hamburger**
December 23, 2014

I have been reading Peter's blog for about a decade now without much active participation in the comments. I am now chiming in in support of him.

I find the scientific discussions in this blog very valuable with a high signal to noise ratio. Other blogs that I reed are Tommaso Dorigo, Scott Aaronson, Sean Carroll, and Tim Gowers. I feel that all these blogs have similar signal to noise ratio. (But I do not know if these arXiv trackbacks to these blogs.) In any case, exclusion of Peter looks like at best a childish behavior and at worst a corrupt way of behaving at people one disagrees with.

45. **Curious Mayhem**
December 23, 2014

If non-scientific sites like The Atlantic are tracked-back on arXiv, then Not Even Wrong should certainly be tracked-back on arXiv as well.

The trichotomy of signal/metasignal/noise is germane here. Not Even Wrong is metasignal. It isn't and doesn't pretend to be publishing original research. It does follow and comment on original research, in a scientifically informed way that is aware of multiple papers, ideas, lines of research, etc., at once. The idea that it's noise is nonsense.

46. **Joe Polchinski**
December 24, 2014

Peter, Yes, you repeated an anonymous suggestion that Weinberg is senile and disagreed with it, so you got to put the idea out there without anyone taking responsibility for it. And even the rest, your ridiculous attempts to psychoanalyze Steve Weinberg: the idea that he was just following a hot topic, when he had actually created that topic twenty years earlier, it was the young people who were following him. It's fine if you want to discuss this on your blog, but I still don't think it's arXiv material. The arXiv is for science.

47. **Yatima**
December 24, 2014

The arXiv is for Science.

No disrespect intended, but I can only read that in the voice of GlaDOS, continually pursuing Science.

This day is off to a good start.

48. **M**
December 24, 2014

While inventing the multiverse, Weinberg had enough free time for writing a few papers about the physics of our little universe. What a pity that string theory is so deep that younger generations no longer have enough free time.

49. **anon**
December 24, 2014

In case readers of this blog want to see the other side of this argument, let me give some support to Joe in this.

Though I don't have any first hand knowledge of trackback policy, I think it's pretty obvious to everyone that in Peter's case there was no policy. Someone just decided not to allow trackbacks to Peter's blog.

This might seem unfair, but to be honest there is no constitutional right to have your blog linked to the arXiv. Though the arXiv is not quite a peer-reviewed journal, it does by necessity exclude certain kinds of material which might be judged to be unsuitable.

Peter's blog is unsuitable for two reasons:

1) Peter has a controversial and highly negative view of a significant fraction of current theoretical research. Therefore many (though perhaps not all) scientists would be upset to have Peter's commentary linked to their arXiv preprints. Since the arXiv serves the scientists who upload their papers, I don't think administrators really had a choice but to exclude links to Peter's blog.

2) One might still argue that relevant scientific criticism of a paper should be easily accessible through the paper's arXiv preprint, whether the authors like it or not. This is where Joe's point is crucial: Peter's criticism is usually not relevant to the scientific issues under consideration. A relevant scientific critique must provide new knowledge, in particular one of the following: a) an argument that the analysis of a paper is erroneous or in contradiction with accepted facts, or b), a suggestion of a concrete alternative approach which is arguably more promising. But Peter's critiques are far more fundamental than this. He just doesn't think that the technical issues people are grappling with are worthwhile. This is Peter's scientific judgement and is ultimately his opinion, it is not a technical criticism relevant to any specific paper on the arXiv. The thing is, all scientists come to their own conclusions on the relative merit of various lines of scientific research, and find much of it wanting. No scientist really needs Peter's opinion on these matters, especially since his views are pretty simple and not extremely deep. I should emphasize that Peter has no scientific argument that string theory does not describe our universe. There are, however, scientific (albeit distressingly theoretical) reasons for believing that it does. However, I think Peter does make a convincing argument that we will probably never know for sure whether string theory is right. I hope this is not the case.

I like Peter's blog a lot. It's fun to read and disagree with. He runs a tight ship, and links a lot of interesting stuff. But I think it plays a role quite distinct from papers that appear on the arXiv, and see no need to connect them.

50. **Peter Woit**
December 24, 2014

Joe,
Anyone who follows the link I provided can read the 2006 discussion about arXiv trackbacks for themselves, and see that it was not, as you claimed here, about Weinberg. It was about your thin-skinned reaction to my accurate characterization of your Scientific American article as pseudo-science.

I note that you don't deny doing what I have been told you have been doing, lying to people in private for years about this issue, for the purpose of attacking my reputation. This is not just sleazy and unprofessional, but actually illegal.

51. **Peter Woit**
December 24, 2014

anon,
I disagree with many of your claims, e.g. that I have no scientific argument that string theory does not work, but the issue at hand is the arXiv policy. You don't seem to know what it is any more than anyone else. I think if you follow most trackbacks to the arXiv you'll find that very few of them are to the kind of technical discussion that I'm supposedly not providing.

I think you do though get at the reason the arXiv is doing what it is doing, and Polchinski's behavior also makes this clear. People don't like criticism, especially accurate criticism, and a decision has been made to ban trackbacks to my blog because of its critical point of view about a certain scientific research program.

52. **Sesh**
December 24, 2014

I am a working physicist, and I write a blog that refers to arXiv papers. Trackbacks from my blog do appear on the arXiv (not that it makes much of a difference to me whether they do or not, my blogging software sends the trackback links automatically). With that context out of the way, I have the following observations:

1. The arXiv includes trackbacks from a number of "journalistic" sites that contain no serious technical discussion, such as the Atlantic (clearly a departure from the trackback policy as stated in 2006).

2. The argument that to be included in trackback lists blogs should contain "actual science content" is not just obviously not current arXiv policy, it also appears unworkable. Are there *any* blogs that do this? If I have something that constitutes "actual science content" (i.e., an original research paper), I put it on the arXiv direct, not on my blog. Surely blogs invariably contain only the "meta signal" of science discussion, criticism, opinions, news etc. irrespective of their technical level or whether the author is an active researcher or not.

3. Bearing the above point in mind, when I follow trackback links from the arXiv – which I only rarely do, and only for papers outside my field of expertise – I do so precisely because I want to read a less technical (or even non-technical) discussion about the paper in question, including possible general criticisms. The primary literature is already there on the arXiv in the form of the actual papers, when I follow trackback links I am specifically looking for secondary literature. To me this seems to be the main point of trackbacks.

4. The signal/noise ratio of any blog is also a function of the quality of the comment threads. This blog seems to have a very high readership from among practising physicists, and therefore a far higher standard of discussion in the comments (whether or not they agree with the original posting) than almost any other science blog I know of.

December 24, 2014

Dear Dr. Woit,

AFAIK string theory was able to derive Black Hole area/entropy relations from first principles and, from a numerical perspective (at equivalent rigor level as taken by lattice QCD theorists) it nonperturbatively implies on a 3+1 world like ours (http://arxiv.org/abs/1108.1540). So in my humble perspective, it is not the theory that is "Not Even Wrong" … but the ability of modern physicists to analyse that from the numerical side that is still too naive.
Regards

Num.

54. **Peter Woit**
December 24, 2014

NumCracker,
While the general issue of "is string theory not even wrong?" is off-topic here, the specific model you mention is discussed by Polchinski in his "Dualities" paper. There he writes about the sort of Matrix theory you mention

"One challenge that remains here is that if one compactifies some of the dimensions (to get down to the four noncompact dimensions of our vacuum), Matrix theory becomes complicated, and if more than three dimensions are compactified its form is not known."

About the specific matrix model you discuss, he writes in a footnote:
"There is a covariant form of Matrix theory, based on ten Matrices X^u, which is supposed to describe IIB string theory [46]. However its full interpretation is not clear. One issue is that time, which is one of the ten matrices, must be Euclidean."

I don't believe that that it's accurate to say that the theory is as well defined as lattice QCD, or that the issue here is just not big enough computers.

55. **Raphael Bousso**
December 24, 2014

Thanks for the various responses to my earlier comment. Some readers took offense at my suggestion that folks don't read this blog because Peter's opinions are founded in deep technical expertise; yet the very same posters went on to explain that indeed, they come here for different reasons. I, too, visit regularly; the site is well curated and has useful links. (I even recall taking advantage of a funding opportunity that I might have overlooked had it not been condemned on these pages.) But let's not mistake the services and the discussion offered here with scientific research, as Peter does in asserting that his blog "contains science".

Doing science at any robust level does require a high degree of technical competence, along with other skills. This is what makes progress slow and hard-earned, much unlike the opinions voiced on blogs. The two papers referred to earlier illustrate this well. They engage in the presentation and analysis of a technical question that is of some interest beyond the string landscape, so no excuse for reflectively dismissing them. The question also bears on the validity of the KKLT construction.

Peter admits he has not made an effort to follow. Yet, as he notes, the validity of some construction of this type is central to his criticism of string theory on the grounds that it has many vacua. This is only the starting point of his many confident declarations about the subject; yet he concedes he has no real understanding of the case for or against its validity.

Rigorous criticism is what drives science; but simply jumping to a poorly founded conclusion and holding onto it independently of any developments is not rigorous criticism. After evidently taking our claim that string theory has many vacua on hear-say, Woit goes on another leap to conclude that therefore the theory is unpredictive and hence unscientific.

I know much less than Peter thinks he knows, so I have no pat conclusions to offer. One thing I know, from actually trying, is that it's a lot harder (but not impossible) to work out predictions in string theory than it was for the Standard Model, which also has a lot of solutions. (This is largely because we can test the Standard Model directly at the energy scales where it is simple—we don't have to infer the Higgs mass from an eV scale experiment. In quantum gravity, we expect the theory to be simple at the Planck scale, and if someone could access that scale there would be plenty of predictions to check.) But Peter isn't merely saying that progress is too slow, and the connection with experiment too difficult to establish, for quantum gravity research to be worth anyone's time—a legitimate if radically defeatist position. He simply knows that string theory is not science. Maybe he knows more than I do, but his response to my comment does not give me great confidence.

56. **Peter Woit**
December 24, 2014

Raphael,

A few quick comments before I'm off to holiday celebrations:

1. I'm glad you've found information here useful!

2. About KKLT, etc. No, I'm no expert on validity of the approximations used. I have though paid close attention (and often written about on this blog) to papers which try to get actual predictions out of such scenarios. As an example, attempts to decide whether this predicts high or weak-scale SUSY breaking. This effort convinced me that there was no plausible vision for this working out. Others may disagree, and they should keep working at this if they want, but I think it's a fair assessment that the past ten years have not been kind to such efforts. In recent years I see few serious attempts to make predictions, replaced by a lot of experts instead just assuming that, if these things work, they have very little predictive value and then, instead of abandoning the ideas, saying that, well, nothing we can do, that's how nature works. This seems to me a serious problem for the field.

2. I've never said "string theory is not science". String theory is a huge subject, with all sorts of science going on, and some mathematics. Even KKLT is science, but it's failed science. Once you come to the point where it becomes clear that your favored idea about nature has led you into something very complicated, with no positive evidence for it, and lots of evidence that the idea is unpredictive, the scientific method says you give up and do something else. Refusing to do this and instead asking for a change in the scientific method is the problem, and the point where the subject turns from science into pseudo-science.

3. Sure, maybe my evaluation is wrong, and people will find some way to turn this back into science. From everything I've seen, that's not happening though, with things headed in the other direction.

I think it should be clear to all where we disagree and are making different judgments, and future developments may make clear whose were better. So far, when I look back at what I was writing about this a decade or more ago, I think that writing holds up well.

Anyway, off to holiday dinner, best wishes to all, whatever their views on KKLT and the multiverse….

57. **NumCracker**
December 24, 2014

Dear Dr. Woit,

I am not telling that such matrix models are at the same foot as QCD, actually they have no fermionic sign problem on the lattice, what I am asserting is that the really interesting physics of them may most likely dwell on a nonperturbative sector. QCD bound states (e.g. are there tetra-quarks?) is a similar example in QFT that equally can not be understood by any advanced kind of math available nowadays, except by computer methods and hard numerical processing: does it make it a "Not Even Wrong" theory? NO! Maybe It just proves that most brilliant humans are just stupid mathematicians when faced to Nature's mysteries, but this also shows us that our specie is still very skilled in finding right answers by brute (numerical) force. BTW if IKKT is not a consesus around string theorists, BFSS model is, and you can see it is as (or more) suitable to numerical attack as QCD on deep infrared here: http://arxiv.org/abs/0707.4454
You have a beautiful blog here, which is read by imminent physicists, maybe more of them will find it encouraging to try to find realistic nonperturbative ST/Matrix vacua, by aforementioned battle-tested methods from QFT, maybe dualities would be even part of the predictive game (e.g. in the spirit of hep-lat/0208020). Maybe even Matrix models will be for ST what Wilsonian latticization was for QFT.

Merry Christmas

December 24, 2014

Anon argues again trackbacks from arXiv to this blog .

First, “Peter has a controversial and highly negative view of a significant fraction of current theoretical research.”

Well, no. It’s controversial to string theorists. It’s not terribly controversial to physicists outside that subfield. Many will agree or disagree at some level, but it’s neither a radical nor a marginal position.

Also, hello! string theory is not a “significant fraction of current theoretical research.” It’s a significant fraction of high energy theory. But that itself is only a small portion of theoretical physics. (If you look at NSF funding, it’s about 0.5% of all of physics, or maybe about 4-5% of all of theory; these numbers vary from year to year, of course.) It’s exactly this kind of egocentrism (theory = high energy theory) that Peter is arguing against.

Second, Anon says ” many (though perhaps not all) scientists would be upset” to be linked to Peter’s criticism. My God, are you a physicist or a kindergarten teacher? Have you never received a referee report? Never been on a tenure committee? In a faculty meeting? Didn’t you have to defend a Ph.D thesis? Peter’s criticism is calm and measured compared to the vicious nastiness we face every day as working physicists. The idea that this blog will hurt the poor wittle feelings of those poor wittle posters on arXiv is raving nonsense.

59. **Chris Oakley**
December 24, 2014

Peter,

Raphael Bousso appears to be a landscaper, and not the kind that can do something useful in your garden. Your blog enabled him to find another source of funding.

You are therefore failing in your basic mission to stamp this kind of thing out.

A careful re-evaluation may be called for.

60. **Lee Smolin**
December 25, 2014

Dear Joe and Peter,

I agree with Joe that global symmetries cannot be fundamental and have made this point in both recent books. The reason is that global symmetries are forbidden in a relational framework such as general relativity. The principle that all observables represent dynamically evolving relationships implies that any two physically distinct events must be distinguishable by their values of local observables. Hence no exact global symmetries.

This goes back to Leibniz’s principle of the identity of the indiscernible. Indeed, general relativity with spatially compact boundary conditions has no global symmetries, ie GR has no killing fields on its configuration space, as was proven by Kuchar in the 1970s.

Symmetries feature in theories that describe subsystems of the universe and represent transformations of an external frame of reference relative to the subsystem modeled. Thus GR with externally imposed boundary conditions can have global symmetries which represent translations of their asymptotic regions relative to an isolated system. This is btw why a framework with asymptotic regions such as AdS cannot be a fundamental description of a physical theory.

Penrose used to make a similar argument, and proposed long ago that all the global discrete symmetries, including time reversal symmetry symmetry and parity, should break down in a fundamental theory.

This does not apply to gauge invariances, which reflect the presence of relational observables. Nonetheless, for other reasons I also agree with Joe that many fingered time may be emergent. It is indeed dual to a three dimensional local conformal gauge invariance, as is shown by shape dynamics.

Best wishes for the holidays,

Lee

Winter Break

December 23, 2014
Categories: Uncategorized

Blogging here should be light to non-existent for a while, with family holiday celebrations tomorrow and departure for a trip to Europe the day after. Travel plans still in flux, but the general idea is to head south after arriving in Paris, spend a couple weeks on the road and mostly in Italy, end up back in Paris January 6, back to New York on the 11th.

I somehow seem to have caused in the last posting (see the comment section there) an eruption of an even odder version of the kinds of attacks from string theorists that were common in 2006, a period known to aficionados as the "String Wars". The new version is more like the "Multiverse Wars". From past experience I know that involvement in such things is not a good way to spend your vacation, so I think when I head to the airport I'll likely shut off comments. In the meantime, I hope the holiday spirit will reign…

Update: Off on vacation, comments will be off. Some last minute links that may be of interest:

- A paper on the hot topic of black holes and quantum gravity that at first glance looks quite interesting (also this). If this is new, surely by the time I get back experts will have been heard from.
- Mochizuki on efforts to understand his proof of abc.

Comments

   So have any experts weighed in on the Nomura papers?

Back

January 13, 2015
Categories: abc Conjecture, Uncategorized

Now back from vacation, and as far as I can tell, not much happened while I was away. Here are a few things I've seen that may be of interest:

- Mochizuki has posted a long progress report on "activities devoted to the verification of IUTeich." New Scientist has an article about this here, which quotes Minhyong Kim making comments I think most experts would agree with:

  > Some mathematicians say Mochizuki must do more to explain his work, like simplifying his notes or lecturing abroad. "I sympathise with his sense of frustration but I also sympathise with other people who don't understand why he's not doing things in a more standard way," says Kim. It isn't really sustainable for Mochizuki to teach people one-on-one, he adds, and any journal would probably require independent reviewers who have not studied under Mochizuki to verify the proof.

  Lieven Le Bruyn has a less charitable take (see here and here):

  > If you are a professional mathematician, you know all too well that the verification of a proof is a shared responsability of the author and the mathematical community. We all received a referee report once complaining that a certain proof was 'unclear' or even 'opaque'?
  >
  > The usual response to this is to rewrite the proof, make it crystal-clear, and resubmit it.
  >
  > Few people would suggest the referee to spend a couple of years reading up on all their previous papers, and at the same time, complain to the editor that the referee is unqualified to deliver a verdict before (s)he has done so.
  >
  > Mochizuki is one of these people.
  >
  > His latest Progress Report reads more like a sectarian newsletter.
  >
  > There's no shortage of extremely clever people working in arithmetic geometry. Mochizuki should reach out to them and provide explanations in a language they are used to.

  Mochizuki's progress report strikes me as quite an odd document, especially in its insistence that experts need:

  > to *deactivate the thought patterns* that they have installed in their brains and taken for granted for so many years and then to start afresh, that is to say, to *revert to a mindset* that relies only on *primitive logical reasoning*, in the style of a student or a novice to a subject.

  He at times seems to be arguing that his ideas are nearly disconnected from the rest of known mathematics, and the only way to understand why the abc conjecture is true. This is highly implausible, since the great beauty and strength of mathematics is the way in which deep ideas are interconnected, with many paths from one place to another. If he wants to convince people that he really has what he claims, the best way to do it would be to follow the conventional route: write himself a document giving an exposition of a proof of abc, in as clear and simple terms as possible.

  Unfortunately, that doesn't seem to be what he has planned, with his efforts devoted to getting others to start from the beginning and master his long series of papers. If this works, at some point there will be others able to write up a proof of abc using his ideas, and when that happens, experts may have something they can work with. This looks now like a story that is going to go on for a long time…

- The last couple weeks in Jerusalem there was a Winter School on General Relativity. It included a final session (video here) largely devoted to defending string theory as the one true path to quantum gravity. This included a panel discussion where Carlo Rovelli held his own in a battle of the LQG/string wars, with him ganged up on by Gross and Arkani-Hamed. Mostly I don't think there were any new arguments, just a rehash of the tediously familiar. Gross did give an enthusiastic call for all students to read the Dawid book discussed here.
  For yet another promotional effort about strings, one that seems like it could have been written exactly the same way twenty years ago, see here.
- One new argument from the Rovelli side was to point out that "Nature talks", and what it has said at the LHC so far is that SUSY is not there, blowing a big hole in the expectations of the superstring theory community. The Economist has a piece about how the upcoming LHC run at 13 TeV will be:

  > the last throw of the dice for the theory, at least in its conventional form.

  As often the case though, the article misrepresents the strength of arguments for SUSY:

  > But, though the Standard Model works, it depends on many arbitrary mathematical assumptions. The conundrum is why these assumptions have the values they do. But the need for a lot of those assumptions would disappear if the known particles had heavier partner particles: their supersymmetric twins.

  This is pretty much complete nonsense, since the problem with SUSY has always been that it doesn't actually explain why the SM model parameters take the values that they do, and this has always been the best reason to be skeptical about it.

  On the other hand, the Economist and Rovelli do get the basic story right: Nature talks, and if what it says in LHC Run 2 is that the theoretical physics community has been barking up the wrong tree for the last forty years, it will be interesting to see if theorists are still willing to listen.

   January 13, 2015

   Peter, happy new year.

   On a light-hearted note, an interesting poster has been seen around CERN after the winter break…
   http://i57.tinypic.com/2yvs8b6.jpg

2. **Bob**
   January 13, 2015

   While it may be implausible that there aren't connections between the rest of mathematics and IUTech, that doesn't mean that Mochizuki or anyone else knows what they are … it might take some time indeed to find them … and it seems there's still a question of whether it will ever be studied enough to be.

Mochizuki does seem enamoured with his work and he may well want to believe that it is truly isolated, as that would add substantially to the degree of his achievement. Given this, he might not be looking too hard.

Definitely a good candidate for automated proof checking as I saw someone mentioning on one of those linked blogs, perhaps a task for one of his acolytes. That would make people stand up and take notice. I know that tends to take years, but in this situation the alternative could take longer …

I do wonder if some of his acolytes are giving too much deference to Mochizuki in not pushing for more rework of the papers.

And there would also seem to be lots of reasons a person might not want to ever travel (unrelated to mathematics) and most they wouldn't necessarily want to talk about. I'm aware Mochizuki has been abroad before but things change …

3. **Douglas Natelson**
January 13, 2015

acTeVist – that's great. I love how 200 years from now one of the focus topics is how condensed matter physicists still don't "get it".

4. **Peter Woit**
January 13, 2015

acTeVist,

Thanks! Although I'm not sure how funny it is….

5. **Als**
January 14, 2015

"Mochizuki has posted a long progress report "

I found Mochizuki's remarks on the Langlands program quite interesting.

"it will be interesting to see if theorists are still willing to listen"

They have been willing to listen for at least a decade, the problem is that nobody can find an alternative.

6. **Bernd**
January 14, 2015

Nature has already spoken, the electron EDM measurement of the ACME collaboration essentially rules out SUSY partner masses up to 10 TeV, i.e., higher than what the LHC Run 2 will achieve.

7. **Andrew**
January 14, 2015

Efstathiou: Paper testing BICEP2 might already be submitted, but have to wait for arXiv submission in ~2 weeks to learn more. He also said "it is pretty easy to infer what the answer will be". It's Just Dust. The Story is Over((

8. **Shantanu**
January 14, 2015

Peter, a discussion between Freese, Tegmark and Gleiser on grand unified theories.
(although lot of the discussion was about origin of consciousness etc)

https://www.youtube.com/watch?v=hoTgId9inb8

9. **ptmalloy**
January 14, 2015

The brief comment by Mochizuki. His comment about reverting the mindset of a novice sounds a lot like a call to "beginners mind."(http://en.wikipedia.org/wiki/Shoshin
).

Mochizuki is a family name associated with the samurai class and the samurai were among the patrons of Zen.

Not that this necessarily means much, other than to suggest Mochizuki is using a familiar cultural idiom to describe how he expects people to approach his work.

10. **Andreas**
January 14, 2015

There is a 3-weeks seminar in March about IUTT at RIMS, talks by his students Yamashita and Hoshi and Minhyong Kim is there giving a talk aswell according to the program. In addition, Yamashita will publish a 200-300pages proof in the proceedings of the seminar, so i guess soon afterwards.

If the seminar and especially yamashita's writeup is good, the situation could clear up much faster than your pessimistic thought of "a story that is going to go on for a long time…" – don't you think so?

11. **Peter Woit**
January 14, 2015

Andreas,
Maybe Yamashita will produce the kind of document needed, that seems the most likely way for this to happen in the near future. We'll see.

I did note though that Mochizuki writes
"This led me to pose the following question to Hoshi: If one were to assign to the level of understanding of IUTeich that he achieved as a result of reading through the papers on IUTeich at least five times a score of "100", then how would he rate the level of understanding of IUTeich that he achieved as a result of attending Yamashita's seminar? The answer that he gave me was a score of roughly "10 to 15"".

and describes Yamashita as writing a “survey” of IUTeich (rather than a proof of abc). Yamashita on his website does label the document as “A proof of abc conjecture after Mochizuki” which is more promising.

12. **Cormac O'Raifeartaigh**
January 14, 2015

Hi Peter, the conference in Israel was a few days, not a couple of weeks! The poster suggests that it was mainly focused on the history and philosophy of general relativity to commemorate the centenary, looks very interesting
http://www.vanleer.org.il/sites/files/SpaceTimeConf_3.pdf

I had hoped to go, but couldn’t really justify the trip as there was no session on cosmology. This was a bit disappointing from my partisan viewpoint; our group contend that Einstein’s cosmic models of 1917, 1931 and 1932 (and his abandoned steady-state model) offer quite a lot of insights into his thoughts on space-time. Ah well, another time…

13. **Cormac O'Raifeartaigh**
January 14, 2015

Sorry Peter, I get it now. What you called a winter school on GR was actually the 29th Jerusalem winter school on theoretical physics – the conference I mentioned was a GR centenary conference in Jerusalem on Jan 5-8, that coincided with the winter school for a few days…which explains some of the talks you referred to!

14. **JG**
January 14, 2015

Wonder if I can get an accumulator (combo bet) on no primordial gravitational waves observed, no SUSY particles observed and no proof of the abc conjecture observed for 2015

15. **Shai Hulud**
January 15, 2015

Bob,
Given the vast length of Mochizuki’s proof and the complexity of even the normal and understood machinery of algebraic geometry that he is building on, I think it’s fair to say that this is *not* something proof assistants are likely to be able to handle any time soon. (Even if someone was willing to do the work of formalizing hundreds and hundreds of pages of proofs.)

The same could be said for Wiles’ proof of FLT, Deligne’s of the Weil conjectures or Falting’s of the Mordell conjecture (which is what Mochizuki is comparing his work to) and these three cases are (and were at the time) a lot less weird than Mochizuki’s work. In fact, it isn’t even clear if Mochizuki is claiming to have a proof of abc in ZF, the foundational paper on IUTeich being littered with references to grothendieck universes.

16. **Justin**
January 15, 2015

Glad you’re back Peter with everything okay. If I’m not mistaken, you were in or around Paris at the time of the terror. Glad you were not involved.

17. **Peter Woit**
January 15, 2015

Justin,
Thanks. Yes, I was in Paris during all of that. A very sad situation, but I was impressed by the way the French dealt with it.

18. **Arkadas**
January 15, 2015

Le Bruyn’s comment on his screenshot of Mochizuki’s note comes off as a bit of a cheap shot.

Had not noticed this page before.

19. **Kevin NYC**
January 15, 2015

I thought of comments Prof Woit has made here when I watched the season premier of PBS NOVA and they had a very good episode about the LHC and the Higgs,.and the restart.

But they had Jim Gates on to describe SUSY and he said that as a young man he found it to be very satisfying as a theory because it really could explain everything… then he looked wistful and said that after the restart they did find some evidence.. because he did not want to be sbown that he has wasted 20 years of his life on a completely flawed theory.. which actually explained nothing because nature did not work like that.

A sad but telling moment that string theorists will confront as they get older. Compare Higgs in his old age to.. Witten?

20. **electron EDM**
January 16, 2015

@Benard
Nature has already spoken, the electron EDM measurement of the ACME collaboration essentially rules out SUSY partner masses up to 10 TeV, i.e., higher than what the LHC Run 2 will achieve.
^

how solid is this result? what is a % confidence interval. Could a sufficiently sensitive EDM measurement of the ACME collaboration essentially rules out SUSY partner masses up to the planck scale, i.e lower bound for EDM measurement under 10^-38

21. **Bernd**
January 16, 2015

@electron EDM:

The current upper bound is 8.7 × 10^(–29) e·cm with 90% confidence. Going all the way down to the Planck scale will be difficult because the SM has a nonzero electron EDM around 10^(-38) e·cm, from where you'll be measuring against a nonzero background.

22. **Klaus**
January 16, 2015

Bernd, the Planck scale is just 10^-33 cm, so there is good chance to achieve it in EDM measurements, whatever the noise at 10^-38 cm may be …

23. **Bernd**
January 16, 2015

@Klaus:
Generically, new CP-violating terms couple to the electron EDM proportional to the inverse of the mass scale squared. Even the most drastic assumption of the dipole moment being proportional to the electroweak scale only gives you corrections from the Planck scale at a sensitivity of 10^(-53) e·cm, i.e., way below the SM value.

24. **neo**
January 16, 2015

Bernd

are there experiments underway to lower that bound?

25. **Noah Smith**
January 17, 2015

How about people stop picking on Mochizuki? If no one ever understands his theory, who gets hurt? He's not hurting anyone, no matter how sane or insane he turns out to be. Give the guy a break, jeez.

26. **Bernd**
January 17, 2015

@neo:
ACME is upgrading the experiment, expecting another order of magnitude improvement in sensitivity. The group of Ed Hinds at Imperial is working on laser cooling of YbF molecules that should give another order of magnitude, so we're talking of probing a scale of 100 TeV here.

27. **Aleksandar Mikovic**
January 17, 2015

The discussion on string theory vs alternative theories by Gross, Rovelli, Arkani-Hamed and Polchinski was very revealing. The string camp arguments are: (1) string theory is the only extension of GR and QM which generalizes the graviton scattering amplitudes and (2) string teory is the only game in town. According to (1) we do not need to worry about the experimental discrepancies, like the absence of supersymmetric particles in LHC, while (2) explains why so many young people are still attracted to string theory. Rovelli was quite right to say that we should "listen to Nature", because the statements like (1) are based on certain assumptions,
which we know that are true for a certain range of the length scale, but we have no idea what happens outside of this range. That is why we need a hint from an observation or from an experiment.

The second statement, emphasized by Gross, is referring to the fact that it is very difficult to extract the semi-classical results for LQG (the loop quantum cosmology results, strictly speaking, do not count, because loop QC is a truncation of the full theory). However, in the past four years have been made important advances as far as the semi-classical limit of the spin foam models is concerned. SF models can be considered as the lattice formulation of LQG, so that in the strict sense they are not the same as LQG, but it is expected that they will give LQG in the continuum limit. Anyway, by using the effective action approach from QFT, one can obtain the classical limit for a SF model and calculate the quantum corrections. The classical limit of the standard SF models is the area-Regge theory, which is almost, but not quite, the GR. If the Lorentz group of a SF model is replaced by a categorical generalization
(2-Poincare group) one obtains a spin-cube model, and those have the desired classical limit, which is the Regge formulation of GR.

@Noah Smith

He wouldn't get the flak if he hadn't claimed such a big result. source

Why not post something like "I have some original approaches to mathematics and I might be able to develop a proof of some long-standing conjectures in this new framework. They might not conform to the standard ZF axioms or such, but I think it's an interesting new approach"

29. **neo**
January 17, 2015

@bernd

based on the current ACME results, what is the % likelihood that SUSY will show up in LHC run 2? If SUSY does show up in LHC run 2, does this mean there is a problem with ACME?

30. **Bernd**
January 19, 2015

@neo:
If the interpretation of the ACME result in terms of sufficiently heavy superpartners is correct, then the likelihood is certainly less than 10% for a detection during LHC Run 2. Probably much less, depending how large the mass scale that the LHC can probe is ultimately going to be (which is much less than 13 TeV).
In case the LHC should see something, this most likely means that there is some fine-tuning going on to make the electron EDM sufficiently small. I'm sure it's possible to cook up a variant of SUSY that produces such a fine tuning, but in terms of probabilities you should use your own discretion how much credibility you want to attach to such a theory.

31. **Doong**
January 19, 2015

Hi,

From any of these two articles from PhysicsWorld,
1> “Measuring (almost) zero” by Chad Orzel, or
2>“Search for electron’s electric dipole moment narrows”

or simply from the Wikipedia entry on ‘Electron electric dipole moment’, and references therein like, ‘Order of Magnitude Smaller Limit on the Electric Dipole Moment of the Electron’- http://arxiv.org/abs/1310.7534

It maybe noted that –
1>Within the standard model of elementary particle physics, Electric Dipole Moment of the Electron is predicted to be non-zero but very small, at most 10–38 e•cm or about about 10–39 e•cm
2> Present experimental range for EDM covers less than or upto,- 8.7 × 10–29 e cm

As such the naïve question (for me at least going by the numbers) is-

Why couldn’t any super-symmetric particles or some modified version of Standard Model via SUSY be lurking in the gap, or in other words,

if EDM is found positive within the still unexplored range why can’t we consider it’s existence owing to Super-symmetric particles among other explanations?

Else can we say that if ACME results closes the gap with a negative result, and the nearer it is as such to the SM limit, the lesser is the probability of detecting a super-partner, till none, if the gap is fully closed with a null result?

Any pointers will be much appreciated.
Thank you.

32. **neo**
January 25, 2015

@Bernd

“The current upper bound is 8.7 × 10^(−29) e·cm with 90% confidence”

doesn’t this upper bound already eliminate SUSY?

Supersymmetric models predict that |de| > 10−26 e·cm (ref below)

SUSY predicted effect on Electron electric dipole moment |de| > 10−26 e·cm is >> > 8.7 × 10^(−29) e·cm by 3 to 4 orders of magnitude

improving the upper bound to 10e-30 or -31 e·cm would only increase the % confidence.

not only will LHC2 run not see SUSY but no upgrade at any scale will, either.

ref: Arnowitt, R.; Dutta, B.; Santoso, Y. (2001). “Supersymmetric phases, the electron electric dipole moment and the muon magnetic moment”. Physical Review D 64 (11): 113010. arXiv:hep-ph/0106089

Short Items

January 19, 2015
Categories: Uncategorized

- The latest issue of the New York Review of Books has an article about the new Turing film, explaining in detail how it gets pretty much everything completely wrong about Turing and his story (see my review here). In related news, this week it was announced that the film is one of the final Oscar nominees for Best Adapted Screenplay.
- The DESY research magazine femto has a sequence of articles about the LHC, SUSY and BSM physics.
- The Swedish Research Council has just announced a ten-year grant of $60 million SEK (about $7 million) to bring Frank Wilczek to Stockholm University.
- Mike Duff has some complaints about the Dean Rickles "A Brief History of String Theory" (for mine, see here.)
- Jim Stewart, a mathematician who became wealthy based on his popular Calculus book (which we use here at Columbia) passed away last month at the age of 73. For more about him, see here and here. I had the pleasure of meeting him a couple times, with one occasion including a tour of his remarkable home in Toronto, Integral House.
- For a new book about a certain mathematical point of view on QFT, see Factorization algebras in quantum field theory, by Kevin Costello and Owen Gwilliam.
- Quanta magazine has a nice article by Kevin Hartnett on Ciprian Manolescu's work on the triangulation conjecture.

Update: One more. The Yale Art Gallery now has an exhibition of prints based on equations chosen and drawn by well-known mathematicians and physicists. It's called The Art of the Equation, and impresario of the project Dan Rockmore will be discussing it there at 5:30 on Thursday January 22.

   Dr. Woit,

   We've been running a website that excerpts one old paper in the mathematical sciences per day. About a quarter of the posts are related to physics. Unfortunately, the physics posts don't seem to get much attention from the physics community. Understandably old physics is only of interest to a minority of the physics community, but if you know anyone who is interested in that sort of the thing please feel free to share the following:

   http://www.mathmarauder.com/archives/category/field/physics

2. **Cormac O'Raifeartaigh**
   January 19, 2015

   Wow! That maths marauder website is great.
   Amazing to see relativity discussed like this in 1904, and from this perspective. I think the difference is that AE started from the opposite end; ff you assume with a universal speed of light as a principle, what does that imply about space and time?
   Great website..

   January 20, 2015

   I'd love to look at the mathmarauder page, but it has been unreachable since yesterday (and I have been too lazy to use the web archive/wayback machine). I hope that page is going to continue – it sounds fun and informative.

9. **Anonymous**
January 20, 2015

Chris,

Perhaps the biggest difference is that the axiomatic treatments you're referring to are in Lorentzian signature, whereas Costello-Gwilliam are in Euclidean. As a consequence, the algebra of observables in these two situations satisfy different properties.

10. **Abdelmalek Abdesselam**
January 21, 2015

@Chris and Anonymous

I think the main difference is that the Costello-Gwilliam approach is in the setting of formal power series in "h bar". The axiomatic/algebraic approach a priori is non-perturbative although recently it has developed a sub-area addressing pertubative renormalization etc. ; see for instance the recent work of Katarzyna Rejzner and references therein. The difference between Lorentzian and Euclidean signatures is not that big a deal, especially because the precise connection is given by the Osterwalder-Schrader Theorem which is a result from axiomatic QFT.

11. **timothy212**
January 21, 2015

Dear all
Can anyone illustrate on the prospect of various constructive quantum field theory like
1.) Axiomatic approach
2.) Owen Costello approach
3) topological qft
4) Balaban approach
5) others ..
and how far each one is from constructing the ultimate 4 dimension interacting qft and also the mass gap problem
One interesting thing is it seems like the
Axiomatic approach is mainly pursued
By European universities and almost no
US researchers doing that .
Do you guys know why ?
Thanks

Tim

12. **Igor Khavkine**
January 21, 2015

@Abemalek,

Just a quick note. The difference between Lorentzian and Euclidean **is** a big deal if the background you are interested in is not Minkowski space (or, more generally does not have a nice timelike Killing vector). In the absence of such time translation symmetry there is no known analog of the Osterwalder-Schrader Theorem or even of the Euclidean formalism. And even just having a Killing vector is not enough (I believe the spacetime has to be static, and not just stationary), e.g., AFAIK QFT on Kerr does not have a Euclidean version.

13. **Abdelmalek Abdesselam**
January 21, 2015

@ Igr,

I didn't make it explicit but I was talking about flat space.

14. **Igor Khavkine**
January 21, 2015

@Abdemalek,

I'm well aware and my comment was aimed at the larger audience. And that's fine if all that you are interested in is Minkowski space. However, it's worth reminding people of the fragility of the link between the QFT formalisms in these different signatures, because the attitude of "Why bother with Lorentzian signature at all?" is troublingly common.

While I'm on the subject, another point that's often overlooked is the relevance of this issue for non-perturbative QFT. Quite a number of people are happy to accept that lattice gauge theory provides a non-perturbative construction of QFT (or at least a path eventually leading to one). However, that method is contingent on the Euclidean formalism and hence breaks in non-static backgrounds, for which then there's not even a suggestion of a method that could lead to a non-perturbative construction.

15. **Bernhard**
January 21, 2015

6M SEK per year for a grant including a Nobel Laureate is actually reasonable. Because of the large overhead costs at Swedish Universities, about 2 M SEK per year are needed just to cover his salary (given that you need about 1M just to cover a random postdoc). Given that he will need students and travel money for his team, 60M SEK end up not being extravagant.

16. **Dean Rickles**
January 24, 2015

Hi Peter,

I just read the Michael Duff review. Since his complaints make no sense at all and get things entirely the wrong way around, this is probably a good place to vent:

(1) He complains that I don't explain how M-theory came to be. Yet I very explicitly noted in the preface that I was dealing with the earliest phases of string theory, and offer only a glimpse of M-theory, with considerably less detail involved.
(2) He says I "echo the Wikipedia version of the History of String Theory, according to which research on branes began only in 1995". Nothing could be further from the truth. There is section after section, and footnote after footnote where I point out that most of the D-brane apparatus was discovered much earlier, going back to the late 1980s – including Duff's work. I'm particularly annoyed at this one, since it was one of the key myths I wanted to correct. (Ditto his claim that I buy into the talk of "superstring revolutions" – another myth I explicitly argued against in the book)
(3) He says I only mention "membranes" in a "derisory" way – I've no idea where he gets this from. There is nothing in the least derisory about anything I say about them!
(4) Worst of all, he complains that I "belittle the role of supergravity" by referring to a "decade of darkness" in the 70s and 80s. But this is an ironic title! The whole point is to show that the 'dark days of string theory' is also a myth, and supergravity is identified as the central player in this story. Yet apparently I "downgrade supergravity" with "zeal". That is a stunning statement given the pains I went to to tell exactly the opposite story.

Incidentally, my final paragraph contains the remark: "The lesson I think emerges from this is that, while the mythological presentations of 'revolutions' and 'dark years' and so on, make for a good story, a more accurate depiction reveals a somewhat less turbulent life story, though no less interesting for it."

So I'm truly flummoxed by this review of Duff's…

Best,
Dean

17. **Urs Schreiber**
January 24, 2015

@Abdelmalek Abdesselam,

even on Minkowski spacetime/Euclidean space, it is not a priori clear how to apply Osterwalder-Schrader or any other result in Haag-Kastler-style AQFT to those factorization algebras. Because, while the conceptual idea is similar in both cases — to encode a QFT by its system of assignments of collection of observables to regions of spacetime (Heisenberg picture!, dual to the Schrödinger picture of say the cobordism hypothesis) — the technical implementation is quite a bit different. In those factorization algebras the "collection" of observables assigned to a spacetime region is not only not C*, but is not even an algebra at all, it is just a chain complex (a quantum deformed BV-complex) without a product operation. The whole system of these chain complexes as the space region varies does inherit an operadic homotopy-algebra structure sort of globally by way of inclusion induced by spacetime regions into each other, but there is a priori no "net of algebras", not even in Fredenhagen's perturbative relaxation of the Haag-Kastler axioms.

There might be a good translation between these two formalizations of Heisenberg-picture stype QFT, and maybe once it's there it would allow to transport results such as Osterwalder-Schrader from Haag-Kastler-style axiomatics to factorization algebras. But for the moment this is wide open, as far as I am aware.

18. **Peter Woit**
January 24, 2015

Hi Dean,
Glad to provide a venue for you to respond!

19. **Tim Nguyen**
January 29, 2015

@timothy212

Each of the approaches you mention are addressed at different aspects of QFT (topological, perturbative, constructive). Each have their own goals and limitations and as such are not as comparable as your question might suggest. For the axiomatic QFT you are asking about, the main goal seems to be to overcome the limitations of formulations QFT formulated on flat space, since our universe is curved not flat. Moreover, there is a [Haag's theorem](#) which roughly says the usual interaction picture of QFT's doesn't exist, hence the emphasis of the axiomatic school on algebras of observables rather than their representations.

As for why it hasn't caught on broadly, my guess is that it's because 1) it's still perturbative 2) it's not relevant to the majority of interesting physics already taking place on flat space or on (compact) Euclidean manifolds.

But your question raises a good point: it's clearly a sign that there is much to learn and much work to do in QFT when there are many disparate schools of QFT that don't actively communicate. Any particular school will have its own problems internal to its own (e.g. if you are interested in TQFT, you can go off and study category theory and leave physics behind). On the other hand, I think real progress will be made once more emphasis is put on solving important framework-independent problems in QFT, e.g. mass gap, making sense of many of Witten's remarkable results (which did not come about by adhering to any particular formalism).

20. **Tim Nguyen**
January 29, 2015

@Igor

If I understand correctly, couldn't one just simulate QCD on a curved background by modifying Wilson's lattice action to be plaquette dependent to account for a spatially varying metric?

21. **Peter Woit**
January 29, 2015

Tim,
Yes, you could do QCD on a curved Euclidean signature background as you suggest. I think the problem Igor is concerned about is that you lose the usual argument connecting the theory to a physical Minkowski signature theory.

For something related, I was going to give a link to a video of a lecture by Graeme Segal about Wick rotation

https://www.youtube.com/watch?v=vTvXHL6ZJik

22. **JG**
January 29, 2015

Not sure if this is a good place to post this, but latest rumours are that the BICEP2/Planck analysis is out next week and there is no B-mode signal due to gravitational waves.

eg according to Peter Coles

> Hearing that the #Planck/#Bicep2 cross-correlation results will be out next week (and the only B mode in CMB is from lensing, not GWs)

23. **Peter Woit**
January 29, 2015

More specific rumor I've seen is that this will be in an arXiv paper out Monday night.

The NSA, NIST and the AMS, Part II

January 19, 2015
Categories: Favorite Old Posts, Uncategorized

Last summer I wrote here about an article in the AMS Notices which appeared to make misleading claims about the NSA's involvement in putting a backdoor in an NIST cryptography standard known as DUAL_EC_DRBG. The article by Richard George, a mathematician who worked at the NSA, addressed the issue of the NSA doing this kind of thing by discussing an example of past history when they were accused of doing this, but were really actually strengthening the standard. He then went on to claim that:

> I have never heard of any proven weakness in a cryptographic algorithm that's linked to NSA; just innuendo.

This appears to be a denial of an NSA backdoor in the standard, while not saying so explicitly. If there is a backdoor, as most experts believe and the Snowden documents indicate, this was a fairly outrageous use of the AMS to mislead the math community and the public. At the time I argued with some at the AMS that they should insist that George address explicitly the question of the existence of the backdoor, but didn't get anywhere with that. One of their arguments was that George was speaking for himself, not the NSA.

The question of fact here is a very simple and straightforward mathematical one: how was the choice used in the standard of points P and Q on an elliptic curve made? There is a known way to do this that provides a backdoor. Did the NSA use this method, or some other one for which no backdoor is known? The NSA refused to cooperate with the NIST investigation into this question. The only record of what happened when the NIST asked about how P and Q were chosen early on in the development of the standard is this, which indicates that people were told by the NSA that they were not allowed to publicly discuss the question.

Remarkably, the latest AMS Notices has a new article with an extensive discussion of the DUAL_EC_DRBG issue, written by mathematician Michael Wertheimer, the NSA Director of Research. At first glance, Wertheimer appears to claim that the NSA was unaware of the possibility of a backdoor:

> With hindsight, NSA should have ceased supporting the dual EC_DRBG algorithm immediately after security researchers discovered the potential for a trapdoor. In truth, I can think of no better way to describe our failure to drop support for the Dual_EC_DRBG algorithm as anything other than regrettable.

On close reading though, one realizes that Wertheimer does not address at all the basic question: how were P and Q chosen? His language does not contain any actual denial that P and Q have a backdoor.

For a careful examination of the Wertheimer piece by an expert, see this from Matthew Green. Green concludes that

> … it troubles me to see such confusing statements in a publication of the AMS. As a record of history, Dr. Wertheimer's letter leaves much to be desired, and could easily lead people to the wrong understanding.

In a recent podcast on the subject Green states

> I think it's still going on… I think that the NSA has really adopted a policy of tampering with cryptographic products and they're not going to give that up. I don't think that this is a time that they want to go out admitting what they did in this particular case as a result of that.

Given that this is now the only official NSA statement about the DUAL_EC_DRBG issue, the Notices article has drawn a lot of attention, see for instance here. The Register summarizes the story with the headline NSA: So sorry we backed that borked crypto even after you spotted the backdoor.

The publication of the George and Wertheimer pieces by the AMS has created a situation where there are just two possibilities:

- Despite what experts believe and Snowden documents indicate, the NSA chose P and Q by a method that did not introduce a backdoor. For some reason though they are unwilling to state publicly that this is the case.
- P and Q were chosen with a backdoor, and the AMS has now repeatedly been used to try and mislead the mathematics community about this issue.

I've contacted someone at the AMS to try and find out whether the question of a backdoor in P and Q was addressed in the refereeing process of the article, but been told that they won't discuss this. I think this is an issue that now needs to be addressed by the AMS leadership, specifically by demanding assurances from Wertheimer that the NSA did not choose a backdoored P and Q. If this is the case I can see no reason why such assurances cannot be provided. If the NSA and Wertheimer won't provide this, I think the AMS needs to immediately cut off its cooperative programs with the agency. There may be different opinions about the advisability of such programs, but I don't think there can be any argument about the significance of the AMS being used by the NSA to mislead the mathematics community.

Update: There's an Ars Technica story here, with a peculiar update of its own:

> An NSA spokesperson emailed Ars on Friday to say Wertheimer retired in the fall of 2014 and submitted the article after he left his position. The *Notices* article made no mention of his retirement.

Another odd thing about the Wertheimer piece is that in a different part of it he seems to reveal what I would have thought the NSA considered a closely held piece of information about Taliban communication methods (see here). If he can discuss that publicly, why can't he say whether P and Q were backdoored?

Update: This is getting international attention, with le Monde reporting the AMS Notices piece as an admission by the NSA that they backdoored DUAL_EC_DRBG.

Update: The NIST has put out a revised draft on its cryptographics standards process and asked for comments. On the NSA problem, it says that no changes have been made to the NSA-NIST Memorandum of Understanding, and that

> cooperation with NIST is governed by an MOU between the two agencies and technical staff meet monthly to discuss ongoing collaborative work and future priorities.

It seems (see the NIST VCAT report) that, despite its obligations under the MOU, the NSA has refused to explain what it did with regards to compromising the DUAL_EC_DRBG standard, and experts believe (see above) that the NSA is committed to continuing to tamper with cryptographic products. Under these circumstances I don't see how the NIST can expect anyone to not be suspicious of their standards.

A promise is made to identify NSA contributions to standards, but a footnote says that names of some NSA staff cannot be revealed and that documents involving NIST-NSA collaboration provided in response to FOIA requests may be redacted. I don't see anything here that would keep the NSA from misleading or corrupting NIST staff to produce a backdoored standard, while keeping their input out of any record available to the public.

Comments

1. **Roger**
   January 19, 2015

   You admit that the AMS articles do not deny that the NSA could have a backdoor to DUAL_EC_DRBG. So maybe the NSA does have a backdoor, but the info is classified. The backdoor would not be a proven weakness unless the NSA leaked the data, or someone got it by solving a discrete log problem.

   Why are you blaming the AMS? It is just reporting the different views on this subject. If you do not believe that we should have a military intelligence agency doing work like this, then complain to President Obama, not the AMS.

2. **Peter Woit**
   January 19, 2015

   Roger,
   I think all the evidence is that there is an NSA backdoor to this standard, and that Matthew Green is right: they're not admitting this because they intend to keep compromising standards. If so, the two Notices pieces are intentionally misleading and the AMS is being used by the NSA to mislead the math community. This is not about "views on the subject", it's about what the facts of the matter are, and these are not letters to the editor, but refereed articles.

   Even those who have no trouble with the NSA backdooring NIST standards should not be happy with the AMS being used this way.

3. **guest**
   January 20, 2015

   "I think this is an issue that now needs to be addressed by the AMS leadership, specifically by demanding assurances from Wertheimer that the NSA did not choose a backdoored P and Q".

   Well, I think that if and whenever such assurances will be given, you should not trust them very much.

4. **Anonymous**
   January 20, 2015

   I don't understand what you consider misleading about Wertheimer's statement. Is it that you feel the use of "discovered" in the clause "after security researchers discovered the potential for a trapdoor" suggests that this was the first discovery of that potential? To me it doesn't suggest that. (For comparison, in his Notices article on this subject Hales refers to "the back door algorithm discovered by Ferguson and Shumow," and he certainly doesn't intend to suggest that NSA had previously been unaware of it. It would be overly fastidious to reply "No, NSA discovered it, while Ferguson and Shumow merely re-discovered it.")

   As I read it, Wertheimer's statement seems clear and unambiguous. He says it was a mistake for NSA to continue supporting the algorithm once the public knew it had the potential for a back door. That may be a cynical or distasteful statement, but I'm not convinced it was intended to mislead anyone.

5. **Peter Woit**
   January 20, 2015

   guest,
   Maybe I'm not cynical enough, but I suspect that (assuming the backdoor) the reason Wertheimer does not address the P,Q issue is that an out and out bald-faced lie to the math community is beyond what he is willing to stomach (and that he has plenty of mathematician colleagues who also would not stomach this if it was done by someone speaking for them). Besides that, the Snowden (or other) documents may very well contain the details of what happened and this may someday come out, providing some incentive not to put your name to a public lie.

   Anonymous,

   Taken as a whole, the article basically claims to address in detail the controversial issue of the accusation that they backdoored a standard, while cynically evading ever actually addressing the issue. I don't see any way to characterize this as other than misleading, and think it was a huge mistake by the AMS to allow this to appear in the Notices without requiring that the issue be addressed (even if by explicitly saying that the NSA refuses to answer the question).

   Beyond the evasion of the central issue, there's also a string of other misleading statements about the history of this issue, for the details of those, see Matthew Green's account (his conclusion "could easily lead people to the wrong understanding" is a synonym for "misleading").

   Did you read the le Monde article? If the Wertheimer statement was not misleading, why are they reporting that the Wertheimer article admits the NSA backdoored the algorithm (when it carefully does no such thing?)

   I still think that the way Wertheimer's statement is written, he encourages the "we should have stopped this once we found out there was a problem" reading rather than the cynical "we should have stopped this once we were caught" reading (the French are cynics..) . The ambiguity is intentional, misleading and the AMS should not have allowed this to happen.

6. **Michael**
   January 20, 2015

   Why should anyone be surprised? If they are willing to backdoor to begin with, why would they not continue to try to mislead the public? The whole point of backdooring is to be able to monitor communications without people knowing it. Surely their opinions on this haven't changed retroactively just because they got caught. So big surprise, he's being shifty and evasive. But unintentionally he is just making things clearer than before. If he had nothing to hide, he'd lay the truth out.

7. **Anonymous**
   January 20, 2015

   The CIA has a long and well known history of infiltrating, directing, and manipulating media sources for their own ends. One might expect the editors of AMS Notices would be aware of this history and be cautious about allowing themselves to be used as a conduit for such disinformation.

   http://en.wikipedia.org/wiki/Operation_Mockingbird
   After 1953, the network was overseen by CIA Director Allen Dulles, by which time Operation Mockingbird had major influence over 25 newspapers and wire agencies. The usual methodology was placing reports developed from intelligence provided by the CIA to witting or unwitting reporters. Those reports would then be repeated or cited by the preceding reporters which in turn would then be cited throughout the media wire services. These networks were run by people with well-known liberal but pro-American big business and anti-Soviet views such as William S. Paley (CBS), Henry Luce (Time and Life Magazine), Arthur Hays Sulzberger (New York Times), Alfred Friendly (managing editor of the Washington Post), Jerry O'Leary (Washington Star), Hal Hendrix (Miami News), Barry Bingham, Sr. (Louisville Courier-Journal), James Copley (Copley News Services) and Joseph Harrison (Christian Science Monitor).[6]

http://en.wikipedia.org/wiki/CIA_influence_on_public_opinion
In 2012, Tricia Jenkins released a book, The CIA in Hollywood: How the Agency Shapes Film and Television, which further documents the CIA's efforts at manipulating its public image through entertainment media from the 1990s to the present. The book explains that the CIA has used motion pictures to boost recruitment, mitigate public affairs disasters (like Aldrich Ames), bolster its own image, and even intimidate terrorists through disinformation campaigns. That same year CIA was portrayed by Aidan Gillen in the third installment of the Christopher Nolan's Batman film series.
USA 2014
The CIA worked with prominent national security reporter Ken Dilanian while he published articles for the L.A. Times to secure positively written stories informed by CIA narrative. [36] Specifically, Dilanian sent full stories to the CIA before they were published on at least one occasion and on at least one other radically rewrote a story on the CIA's urging. The CIA also encouraged a publication indicating few collateral deaths were associated with a strike from its controversial drone strike program in contradiction to eye witness testimony recorded by an Amnesty International investigation [37] and which also contradicts a documents obtained by a FOIA request indicating that acceptable numbers of collateral damage are pre-calculated for drone strike targets and while typically valued at around 10 innocent deaths can sometimes be significantly more. [38]

http://monthlyreview.org/1999/11/01/the-cia-and-the-cultural-cold-war-revisited/
U.S. and European anticommunist publications receiving direct or indirect funding included Partisan Review, Kenyon Review, New Leader, Encounter and many others. Among the intellectuals who were funded and promoted by the CIA were Irving Kristol, Melvin Lasky, Isaiah Berlin, Stephen Spender, Sidney Hook, Daniel Bell, Dwight MacDonald, Robert Lowell, Hannah Arendt, Mary McCarthy, and numerous others in the United States and Europe. In Europe, the CIA was particularly interested in and promoted the Democratic Left and ex-leftists, including Ignacio Silone, Stephen Spender, Arthur Koestler, Raymond Aron, Anthony Crosland, Michael Josselson, and George Orwell.

8. **Shannon**
January 20, 2015

Just to be clear, you say you "think the AMS needs to immediately cut off its cooperative programs with the agency," by this you mean that the funding program of the NSA/AMS
(for personal grants and optionally supporting a recipient's graduate student) should be discontinued, right? It is probably unusual for the AMS to say that they want to stop a funding opportunity offered by a government office, turning down money on moral grounds.

9. **Peter Woit**
January 20, 2015

Anonymous,
I don't think any of this is relevant here (and I really don't want to get involved in general discussion of the history of the activities of the CIA and NSA). In this case what is coming from the NSA is being published with their name on it, and to the extent it's misleading, it is so not surreptitiously, but out in the open.

The relevant historical analogy though may be that in the DUAL_EC_DRBG case the NSA took advantage of the NIST and its cryptographers to put out bad crypto, here they're taking advantage of the AMS and its editors to put out misleading information about the earlier NIST story. In the NIST case the problem was that NIST cryptographers didn't push back when being used by the NSA, here it seems the editors didn't push back.

10. **Peter Woit**
January 20, 2015

Shannon,
If the NSA really is using the AMS to mislead the math community, all I'm saying is that an appropriate response would be for the AMS to withdraw from cooperation with them. This doesn't mean shutting off the NSA grant system, it means the AMS should tell the NSA it doesn't want to lend its name to this or to any longer play a role in their administration. As far as I can tell, currently the main AMS involvement in the grants is in choosing review panels, so de facto the main change would be that the AMS would tell the NSA they had to do this themselves (like the NSF and every other agency that provides research grants to mathematicians).

11. **Fred P**
January 21, 2015

Presentation on the issue from 2007: "WHAT WE ARE SAYING: The prediction resistance of this PRNG (as presented in NIST SP800-90) is dependent on solving one instance of the elliptic curve discrete log problem. (And we do not know if the algorithm designer knew this before hand.)"

Blog post from a security blogger at the time: Even if no one knows the secret numbers, the fact that the backdoor is present makes Dual_EC_DRBG very fragile. If someone were to solve just one instance of the algorithm's elliptic-curve problem, he would effectively have the keys to the kingdom. He could then use it for whatever nefarious purpose he wanted. Or he could publish his result, and render every implementation of the random-number generator completely insecure.

12. **David Roberts**
January 23, 2015

The *Notices* article now says at the top of the first page:

> POST-PUBLICATION EDITOR'S NOTE: This article is a part of the ongoing series "Mathematicians Discuss the Snowden Revelations". At the time of the writing of this piece Michael Wertheimer was the Director of Research at the NSA; he recently retired from that position. He can be reached at nsapao@nsa.gov.

13. **Punished Gamer**
January 23, 2015

> P and Q were chosen with a backdoor, and the AMS has now repeatedly been used to try and mislead the mathematics community about this issue.

It's psyops from the start. Deny, evade, use the spiral of silence and make sure all affiliated publications stay on message. The goal is to outlast first outrage, then interest, and finally memory. When you see articles proclaiming things like "This NSA backdoor conspiracy again", you'll know they've moved onto the final stage: Mockery, painting anyone still concerned as a tinfoil hatter to discourage inquiry.

Psyops is not about argument. It's about "feels over reals". In the absence of clear evidence, and open debate, its easy to turn people away or off with distraction, confusion, and ridicule. Over time, and in the absence of any kind of investigative media, it will eventually work.

Elliptic Curve cyptography is done. No-one can trust the NIST standards, possibly their research, and more importantly no-one can trust **everyone** to not be using those standards. This isn't about trusting the mathematics, it's about trusting the implementations. Thos have been compromised and short of a total worldwide agreement to adopt new, compromise-exclusionary ones, ECC is not going to be able to be trusted by anyone.

And we can't have the agreement while the psy-ops campaign to shut down debate is in effect. RiP ECC.

14. **Carey**
January 23, 2015

I don't understand; or, rather, I think I do. This is a clash of cultures where there is an expectation that a mathematician is a mathematician is a mathematician, upholding certain ideals, wherever they happen to be sitting. This is an unreasonable expectation. The NSAs sole mandate is to intercept communications and decrypt them into plain text if needed. By definition it is their responsibility to facilitate, create, and guard backdoors an trapdoors in crypto when the opportunity arises. They are under no obligation to discuss it. People involved will be given National Security Letters (NSLs) and they will not be permitted to speak out it. However, it was total naivete to involve them from the get-go. Haranguing them for a mea culpa is a wast of time and is about as naive as the farmer wondering why that nice boy didn't just east as much corn as he wanted.

15. **tt**
January 23, 2015

Actually that is not their "sole mandate". They are supposed to also be protecting
US government communications. By introducing a backdoor (and assuming noone else would figure it out) they have weakened their own communications.

16. **Peter Woit**
January 23, 2015

Carey,
Like Wertheimer, you're ignoring the main point here. It's one thing for the NSA to act secretly and refuse to discuss it, that's what they do. It's quite another to instead go public, and do this by putting out misleading information via the the AMS.

I do think the AMS was naive here, with their conception that they are just hosting an exchange of people's viewpoints, and thus trying to get the view of someone on the NSA side was important. The problem is that the Wertheimer article is instead essentially an official response from the US government about a matter of fact, the only time it has been willing to address this matter of fact. Presented with such a document, the AMS should have realized it was in danger of being used, and insisted that the Wertheimer article address clearly the question of the backdoor instead of misleading about it.

17. **Carey**
January 23, 2015

@tt: good point, they do have precisely that dual mandate. I misspoke.

@ Peter: I don't think I am ignoring it. This was my point about the clash of cultures. Retired or not from NSA at the time of writing the piece, Wertheimer is a mathematician and, if you read some of his bio, pretty far from the stereotypical apparatchik. Maybe he just feels like discussing the issue with his peers. But, even if it was an intentional attempt to mislead the public, per your suggestion, so what? It seems to me that the issue was involving the NSA to begin with. I suppose I am not debating a fact but a matter of opinion. It doesn't bother me that they aren't coming clean or that they may be deliberately misleading the public. I expect that given their jobs, right or wrong. I do agree with you that the AMS has put itself in a funny spot by being a medium for the discussion.

18. **Peter Woit**
January 23, 2015

Carey,
I think it wasn't a mistake, but perfectly reasonable for the AMS to try and get a response from the NSA to the accusations about the backdoor. It's surprising they did get a response (and no, given NSA security, I don't think this came about because some guy just felt like talking about it, this was a policy decision, probably made at a very high level).

I seem to be less cynical than most people in that I'm surprised that someone at the NSA, given the chance to just say "no comment", would instead decide to write an intentionally misleading public statement. My suspicion is that that's not the way Wertheimer sees it, but that he's so used to the point of view that outsiders have no right to know anything that he doesn't realize what he is doing. It really was the job of the AMS to point it out to him and ask for either a real answer to the question or a clear statement that he wasn't allowed to provide one.

19. **Roger**
January 23, 2015

Peter, even if Green is right that the NSA plans to continue nefarious spy schemes, I don't see anyone being misled. As Fred points out, it has been known since 2007 that anyone with a solution to the EC discrete log problem can create a backdoor to the pseudorandom number generator, and that you can eliminate the problem by generating your own P and Q. The NSA is not saying whether it has that discrete log value or used it to spy on anyone.

I am not sure why it matters that the NSA spell this out for you. If you are concerned that the NSA is spying on your random numbers, then I suggest using your own P and Q or another generator, regardless of what the NSA says. You seem to think that the AMS needs to get some assurances from the NSA for you, but I do not see how any such assurances would do you any good.

20. **Peter Woit**
January 24, 2015

Roger,
The record shows that the people at NIST were misled about this (see the report of their investigation). The assurances I think the AMS now needs from the NSA are about whether they've been used to mislead the math community. To all appearances, this is what has happened, so the NSA owes both the AMS and the math community an explanation.

Snowpocalypse 2015

January 27, 2015
Categories: Uncategorized

For the last few days the media in New York have been filled with continuous frantic warnings of the deadly storm of the century bearing down on the city. Grocery stores have been emptied, with long lines of desperate people trying to stock up on supplies.

Midday yesterday Columbia announced that classes were canceled starting at 3pm, Barnard went one hour better, canceling classes starting at 2pm. The city announced that it would be illegal to be in the parks after 6pm (a snow-covered branch might fall on you), the transit system would start shutting down at 7pm and by 11pm there would be no public transit, and all roadways in the entire tri-state area would be closed to non-emergency traffic. The mayor's office warned people not to try and order takeout delivery since it would be illegal for the delivery people to travel on the streets to deliver it.

By late afternoon the university was deserted, and stores on Broadway had signs announcing early closing due to the impending disaster. Weather reports the day before had said the storm would start at 1pm Monday, but by early evening there hadn't been much more than snow flurries, with maybe an inch or two total accumulation. When I went to sleep around midnight, the city was completely locked down, with the TV news channels filled with blaring warnings of the two to three feet of snow about to arrive, interspersed with press conferences from public officials telling people to barricade themselves in their homes and not go outside.

The strange thing about this was that if you actually looked at the weather report, they were now forecasting 3-5 inches of snow overnight. Waking up in the morning and looking out the window, all that was visible were more flurries, and a total accumulation of 2-3 inches, with the streets clear. Turning on the TV news, the huge "Blizzard of 2015" logos were still up, and camera crews seem to have been sent out to search the region (mostly unsuccessfully) for a snow drift to put a reporter in front of. The contrast between looking out the window and watching TV was pretty dramatic.

Anyway, my class today is canceled, so students will have to wait until Thursday to hear more about the mathematics of quantization of the harmonic oscillator (complex structures, squeezed states, coherent states). Lecture notes still being worked on, but this is chapter 21 of the current notes.

Columbia never used to shut down at all, New York City never used to shut down the transit system, and the states never used to shut down all roadways. Until the past decade or so people tried to go about their business here in the winter, taking action to shut things down only once snow had arrived and was causing a problem. The US has now become a nation of hysterics, with media-driven hype frightening everyone about everything, and public officials desperately taking action to protect the citizenry from imaginary threats.

Luckily for us all, people cowering in their homes do have the internet and can still learn quantum mechanics. MIT has just announced that edX will have an online version of their quantum course, Mastering Quantum Mechanics, which looks quite good and will start February 10. The instructor will be Barton Zwiebach, and I'm glad to see that one of the topics covered will be squeezed and coherent states of the harmonic oscillator.

Comments

1. **ghassan**
   January 27, 2015

   Peter,
   The hysteric reaction to announced hypothetic threats is not a US-Only thing, You know France very well, and it is the same thing over here. The working principles of weather forecasters, politicians, … is that they will not be blamed for taking measures to protect against something that never happens, but they will be sued for not doing anything if the threat materialises. The much fabled "precautionary principle" (now part of the French constitution).

   rgds

2. **Joel Rice**
   January 27, 2015

   wow did you get that right. North of the city we got a few inches of snow, and no traffic outside. Nothing like some storms in the sixties with drifts blocking doors so we could not get out of the house ! There was some 'political' change at the weather channel, and they decided to go for this over-the-top style of 'reporting'.

3. **Shecky R**
   January 27, 2015

   Well, let's be blunt: generations today are "softer" than they used to be when it comes to putting up with temporary hardship! But, in fairness to government and politicians, I don't blame them for erring on the side of caution, given the absolute thrashing they will suffer whenever a true emergency or disaster arises, and lives are lost and well-being threatened. Our entire medical system is built on the same ongoing scheme, of outrageous costs, in order to curtail death and suffering whenever technically possible, instead of accepting it as part of life.

4. **Bee**
   January 27, 2015

   Meanwhile in Germany the hot topic this morning was the facebook outage…

5. **Jeff M**
   January 27, 2015

   Well, up here in CT we got dumped, almost 2 feet and still coming down. Right you are about hysteria though, up here everyone goes nuts in the grocery store. I'm like "it's New England, it snows 2 feet at least every couple of years." We got 3 feet two years ago. It really didn't used to be like this, even in the city. I remember the Lindsay blizzard, the blizzards in '78, the one in '96 when there were people skiing down Lorimer Street and my terrier mix kept disappearing in the snow in Lindsay Park. Subways didn't shut. Key Food was open. My wife works for a NYC company, which is of course shut. Her main office person in the city actually spent the night at the office, woke up to 6″ and was like WTF? My wife is of course working on the computer, I will light a fire later…

6. **Chris W.**
   January 27, 2015

   Peter, that URL bounces to MIT's main online course page. This link goes directly to *Mastering Quantum Mechanics*.

7. **Peter Woit**
   January 27, 2015

   Chris W.,
   Thanks, was missing an x, fixed.

   Jeff M.,
   I've heard the reports of 6″ here in the city. Always hard to tell with blowing snow, but up near Columbia I'd say it's more like 2″, and that seems typical for reports from areas north and west of here. The governor's decision to shut down the subway system (first time in history this was ever done because of snow) seems especially odd in Manhattan, where virtually all of it is underground. The subway has problems not when the snow falls, but when it melts.

   Bee,
   Mercifully the US seems to have escaped that disaster (not that I would notice…).

8. **Thomas Larsson**
   January 27, 2015

   Weren't some Italian scientists convicted of manslaughter because they didn't warn the public about some earthquake in advance? Better safe than sorry.

   "NYC Mayor: 'Reconcile Yourselves With Your God, For All Will Perish In The Tempest'"

   http://www.theonion.com/articles/nyc-mayor-reconcile-yourselves-with-your-god-for-a,37850/

10. **Jeff M**
    January 27, 2015

    Yeah, that Onion bit was great 🙂 Peter, I would believe N and W was less, I think some of the Central Island got a bunch of snow, my wife's company is in Greenpoint so more than 5 miles from Columbia. It is completely nuts they closed the subway in Manhattan, really any of the underground lines. They NEVER used to close the whole subway, though of course at times with say tons of snow the above ground lines would stop running for a while, or with flooding some of the underground lines would stop.

11. **CIP**
    January 27, 2015

    And when I was a kid we had to walk six miles to school through six feet of snow….

12. **Carey**
    January 27, 2015

    Onion is great re the blizzard…

    Blizzard Survival Tips

13. **Yaakov Baruch**
    January 27, 2015

    Awesome post! Similarly, I grew up playing with caustic soda, sulfuric and nitric acid, and lots of other lively chemicals, which I could buy at my local pharmacy. Sadly nowadays kids can only read (or watch videos) about this stuff. How sad (and not one iota safer).

14. **Harlequin**
    January 27, 2015

    I can see some benefit to shutting down before a storm, because there are situations that are less dangerous if people have already gotten themselves to shelter before the snow begins. (I'm thinking of the big blizzard in Chicago a few years ago where order a thousand cars ended up snowed in on Lake Shore Drive–the storm hit at the end of the workday, and the city chose to keep Lake Shore open instead of letting those ~1000 cars get snowed in on the surface streets where they'd block emergency vehicles. If there'd been an earlier snow emergency called, maybe more of those people would've gotten home; as it was, many stayed with their cars all night.) That doesn't explain why the emergency management team hadn't figured out by midnight that they didn't need to stay closed for the morning, though. Nor does it answer why the underground trains shut down, unless it was more incentive for people to stay inside…

15. **Peter Woit**
    January 27, 2015

    Harlequin,
    Yes, it would be less dangerous if everything shut down, everyone got off the streets and stayed home whenever a snow storm was coming. Since there are snow storms pretty regularly in this area from December through March, best way to avoid any danger would be to implement this December 1, let people come back out of their homes only on April 1….

16. **Neil**
    January 27, 2015

    "let people come back out of their homes only on April 1…."

    Just in time for April Fool's day. We don't need the LHC to find WIMPS.

17. **sandy**
    January 27, 2015

    It's easy to criticize and claim 'hype' but the memories of Superstorm Sandy are probably still fresh in the minds of the city leaders (that includes the police and other emergency workers). They're not taking any chances. They are wise not to.

18. **Peter Woit**

January 27, 2015

sandy,
“Don’t take any chances” does seem to be the new motto at work here (by the way, it’s also the motto at work in the NSA’s plan to collect all information about everyone, all the time).

It might have been a good idea though for someone to explain to the Governor the difference (re flooding) between a snowstorm and a hurricane before letting him shut down the subway system.

19. **sandy**
January 27, 2015

According to CNN Headline News, coastal flooding is now a problem (admittedly in Massachusetts, not NYC). I believe not all of the coastal structures in NY+NJ which suffered flooding damage due to Sandy have been repaired. I recall Chris Christie (last year?) complaining about the attitudes of some of the residents in those regions. Depending on circumstances, the flooding situation in NY/NJ could have been very different.

20. **Peter Woit**
January 27, 2015

sandy,

Among all the hysterical weather warnings for Manhattan the past couple days, I seem to have missed the ones about how the island was going to flood.

21. **sandy**
January 27, 2015

I have to deal with 2 feet of snow in my driveway. At least I didn’t lose heat and power, unlike back in 2012. Back in the good old days that everyone hankers for, there was no social media and blogs, indeed not even the internet. Today, the smallest incident (or mishap) can or will be posted online and possibly go viral. The city leaders, and those in other regions also, have to operate under that scenario.

22. **Harlequin**
January 27, 2015

We can (and apparently do) disagree on what level of danger is necessary before steps are taken. But there’s a time lag in getting large groups of people to do stuff, like evacuate or get home, and so you can’t always wait until the storm hits before you start asking people to get off the roads. It’s mostly that point that I was responding to.

It’s about a balance of risks; I think a foot-plus of snow dumped on the city in a short time would have been dangerous, and taking precautions in that very rare case (even though it didn’t end up happening) isn’t unreasonable. Again, the subway, possibly unreasonable–as I also agreed in my first comment. And I wasn’t putting danger before everything else, what with my “they should have turned everything back on once they realized the storm wasn’t so bad” bit at the end. Obviously, it’s your blog and you can say what you like, but it seems a bit weird to take my point to an extreme illogical end that’s been refuted by the stuff I already wrote.

(And my perspective may also be informed by having grown in up the Midwest, where many of the highway ramps have gates that can be closed in case of snow emergency, and schools build in an extra week or two to the calendar because the expectation of snow days is so high–your statement that “the states never used to shut down all roadways” is totally foreign to me. It wasn’t common, but it did happen. That said, the university in my hometown has closed a few times in the last few years. It never used to, even when everything else shut down.)

23. **Peter Woit**
January 27, 2015

Harlequin,
Apologies for uncharitable comments. Looking out my window at the beautiful day, snowless streets, and locked up University may be making me kind of crazy…

My understanding is that announcing a closing of all roads over the tri-state area, many hours in advance, at a time when there was no snow, was completely unprecedented for this area. This wasn’t a case of prudent closing of highways when a blizzard starts.

Manhattan really is a different kind of environment than the rest of the US. People don’t have cars, and even when a foot of snow falls (not uncommon), sidewalks quickly get shoveled so it’s not hard to get around by foot and public transit. There are only a few arteries buses travel on, and those get plowed quickly. Shutting down the subway and bus system immediately brings the place to its knees: most people can no longer get to work or conduct their business, and everything has to shut down. This has never been done before in the history of the city because of a snow storm, I think what happened is just completely outrageous. The media and politicians however are busy telling themselves what a great job they did, how this had to be done in order to “not take chances”, and I fear the obvious lesson is not going to be learned.

24. **Peter Shor**
January 27, 2015

On the other hand, here in Massachusetts, I easily have two feet of snow in my yard. The city of Framingham, not very far away, had 2.5 feet early this afternoon, and I think nearly six inches have fallen since then. So the total snowfall amounts here are comparable to the Blizzard of ’78, but the aftermath is going to be much less costly because everything was shut down.

25. **CIP**
January 27, 2015

The only thing that will inspire more whining in New Yorkers than a real disaster is narrowly missing a predicted one. This was a really big snowstorm, and NY was lucky enough to only catch the edge of it. And Gloria would have been a really disastrous hurricane for NY if it had deviated a degree or two from the trajectory it actually took.

26. **sandy**
January 27, 2015

Long Island is not so far from NYC (Queens, anyone?), and some parts received substantial snowfall. A small difference in the track of the storm could have made a substantial difference to NYC. You may need a subscription to read this, but anyway there was quite a bit of snow at MacArthur airport on LI.

http://www.newsday.com/news/weather/travel-ban-continues-for-east-end-towns-as-snow-continues-to-pile-up-1.9853573

The National Weather Service reported that as of 1 p.m. 24.8 inches of snow fell at Long Island MacArthur Airport. That is second only to the 27.8 inches that fell there Feb. 8 and 9, 2013, according to records the weather service has kept since 1984.

27. **srp**
January 27, 2015

I am glad that our host has recognized the excessive risk aversion that has infiltrated almost every aspect of public policy over the last thirty years. You could fill a large volume with scientists expressing laments along the lines of Yaakov above. You could easily do the same with even late baby boomers and early Gen Xers marveling over the new terror for children going about and playing without adult supervision, along with amazing horror stories of parents being pulled in by police because their ten-year-old was playing alone in a park or even outside their house.

That's without even getting into scientific-regulatory issues about radiation exposure, GMOs, drug approvals, etc. (I remember reading Crease and Mann's The Second Creation about the history of particle physics where a then-contemporary physicist had a good laugh at their expense when they proposed recreating Rutherford's experiment that discovered the nucleus–it would have been regulatorily impossible to do that experiment in New York City in the 1980s.)

Anyway, not trying to start a big woolly political debate of the kind Peter hates, just expressing some sympathy for his frustration with the snow-phobia.

28. **Nobody**
January 27, 2015

It's a step in the asinine infantilization of adults, which we seem to like, because we keep electing would be mommies and daddies. I can only shake my head at those here who are actually justifying it.

29. **Peter Woit**
January 27, 2015

srp/Nobody,
I do detest ideological discussions, and in this case I just don't see this as a right/left issue. Closing down the area was a joint Christie/Cuomo effort and, as a general rule, conservatives are every bit as willing to become hysterically fearful about things as liberals. This unfortunately seems to be a bipartisan trend. Not sure who to blame, one can always blame the media…

Peter Shor/sandy/CIP,
I've been in New York several times when it got two feet of snow, and honestly it just wasn't a big deal, no "disaster" at all. There were some subway delays, streets in the outer boroughs took a while to clear. Nowhere near the impact this two inches has had.

And, as I pointed out in the posting, at the point the hysterics shut everything down in the city last night, weather.com was predicting 3-5 inches of snow….

30. **Michael**
January 27, 2015

If the storm's track were 50 miles to the west of it's actual track, the snowpocalypse would have happened. They simply don't have the ability to predict storm paths with extreme accuracy with current technology. All they knew is that there was a chance of a major snowstorm. Given the problems that would arise if the storm did hit New York City, it was prudent to prepare for the storm as people did.

31. **Anonyrat**
January 28, 2015

The Weather Channel was quite clear about the differing predictions of three major weather models.

And this is what happened in February 2014:
http://www.cnn.com/2014/02/13/us/nyc-deblasio-schools/

> New York Mayor Bill de Blasio, who took office 44 days ago promising to bring together residents of a divided city, **was widely vilified Thursday for keeping the nation's largest school system open during a brutal storm expected to leave up to 14 inches of snow in some areas.**
>
> While millions of children in the region were given the day off, New York City public schools — with 1.1 million students — remained open, triggering an avalanche of anger from many students, parents and even one well-known weather anchor.
>
> "It's always a tough decision based on imperfect information," de Blasio told reporters late Thursday morning.
>
> The mayor said the National Weather Service reported as little as 3 inches of snow on the ground at the start of the school day, with warmer conditions than in previous storms. Since 1978, he said, New York City schools have closed due to snow just 11 times.
>
> "At the time," he said, "we thought our children would be able to get to school safely."

32. **Anonyrat**
January 28, 2015

See above. So my response to "The US has now become a nation of hysterics, with media-driven hype frightening everyone about everything, and public officials desperately taking action to protect the citizenry from imaginary threats" is that it is the people who have become hysterics, the media is merely a reflection of the people, and public officials are responding to brutal criticism in the past.

33. **Rehbock**
January 28, 2015

I have sympathy for public officials. Damned if they do and don't. But you have it right that the nation has become hysterical over imaginary threats.

34. **PaulS**
January 28, 2015

I'll go the December 1 – to – April 1 thing one better.

If the snowstorm *had* materialized, it's at least conceivable that somewhere, somehow, at least one person might have managed to kill him- or herself. It would have been an accomplishment, since the city is chock full of buildings and suchlike, making it hard, for example, to get well and truly lost in any weather conditions whatsoever – unlike the Midwest where I now live, which has very large open or wooded areas.

But never mind. After all, we're freaking out over vague hypotheticals here, solely for the sake of Nielsen ratings, and the careers of braying, self-aggrandizing hucksters and drama queens like Andrew Cuomo (who takes after his father in that respect.) Remember too that back when the City *didn't* close down completely, going out was nonetheless *voluntary*. Basic liberty has been another casualty of mindless hysteria, and not just with snowstorms.

Anyway, so we're worried out of our minds over just one purely hypothetical (and foolish) person. So let's not forget – an *actual, non-hypothetical* person is murdered in the City, and another dies in traffic, nearly every single day. It follows inexorably that only valid "precautionary" solution consistent with the actions of the politicians on Monday and Tuesday is simply to lock the City down from December 1 to December 1 rather than April 1, i.e. permanently. Only that way can the mindless hysterics be truly "safe".

Come to think of it, permanent lockdown doesn't seem too far from what those bossy "precautionary" hysterics are really after.

    January 28, 2015

    I blame the media! And, in a way, nature itself. Only a small group is in favour of blizzards and hurricanes and tornados. Most people don't want the bother or the risk, and so if you attack these acts of nature, they have no constituency to protect them. This is great for a politician, because usually whatever he does he will.have active resistance.

    Now we have a backlash because nothing bad happened. This is preferred to the other kind of backlash, when a politician is blamed for something bad.

    Oh well.. the funny part is that Coumo closed the Subways without even talking to DeBlasio. 15 minute heads up… haha..

36. **Visitor**
    January 29, 2015

    Living in Manhattan, I find the fact that the subways were closed to be a source of personal embarrassment.

37. **Bozo**
    January 30, 2015

    Growing up in Urbana, Illinois, every year we'd put chains on the car for at least a week, usually two. Nowadays I am pretty sure most people in Urbana don't even own a set of chains. And don't have snow tires either. Yet everyone survives, except for those in SUVs who have watched too many commercials and think they can fly through the air, and can round corners at high speed without rolling, just because they have 4-wheel drive.

    Is it because the winters are so much milder (which is in general certainly true- a snowman built this year lasted only a week, and when I was a kid we'd have snow piles until April sometimes), because of front-wheel drive, or better tires, or because
    the road maintenance is more effective?

    Right you are, Peter, about the over-protection in all things. The same goes for
    speech, where you can't risk offending anyone. And yet there is something schizophrenic in American culture: at the same time, Bush et al revelled in making it ok to say "kill", and delighted in starting unnecessary wars and in implementing actual gulags complete with torture spas for the visiting tourists. At least presumably they weren't being called names while undergoing waterboarding.

    To resolve this dichotomy in the future, I suggest that next time mayor pay Chris Kyle to station himself on top of the Dakota and take headshots at anyone caught cross-country skiing in Central Park. A very non-wimpy way of protecting the citizenry from nature!

38. **Alan K**
    January 31, 2015

    I lived practically all my life in Wisconsin (I am 44). The last few years I have lived in North Jersey. It was comical the other day when I went to the grocery store to pick up a single item, I could not believe the hysteria of people clearing off the shelves. I just shook my head. Mob mentality.

    When I attended high school in the eighties in Wisconsin, in the winter it was just a given to wake up a bit early and go out and shovel the snow (often well over a foot of snow). Then, yes, I actually walked to school in the snow. And weeks on end it would be below zero. It was the norm. It was life. School was rarely canceled for snow and never canceled for cold. They have these things in New Jersey out here called "delayed openings" for school. HAHA. Things have really changed over the decades.

    Alan

Mathematics Without Apologies

January 27, 2015
Categories: Book Reviews

If you'd asked me ten years ago to describe a book I'd love to read that could be characterized as part of an "incredibly unlikely trend in books about math for the general public", I might have chosen "brilliant meditations on the practice of mathematics and on mathematics at the deepest level, from first-rate mathematicians, focusing on the Langlands program, with expert-level discussion of the subject." And yet, here we are, not much more than a year after Edward Frenkel's Love and Math, with the publication last week of another very different but equally fascinating example of exactly this trend: Michael Harris's Mathematics Without Apologies. If you are interested at all in what mathematics really is and what the best mathematicians really do (and you're up for an intellectual challenge) I highly recommend that you get a copy and set some time aside for delving into this unusual book.

While Harris shares many of Frenkel's themes and concerns, his style is very different, favoring density, indirectness, the post or post-post-modern, and deep engagement with history, philosophy and sociology. Only one of these two authors assumes a familiarity with Max Weber. Where Frenkel is ever guileless and straight-forward, Harris has a whole chapter on the "trickster", taking some pride in being known for "Harris's tensor product trick." While reading, more than once one wonders whether one is really supposed to take something seriously (for instance, there's quite a long bit about Thomas Pynchon's novels and conic sections…).

Normally when I'm reading a book I want to later write about, my practice is to fold down the corners of pages that contain something new, unexpected, especially insightful, or something I'd really like to argue with. Then I can start writing by reviewing those pages. My problem with this book is that I ended up folding down the corners of a large fraction of the pages, so when I sat down to write, my usual method would force me to reread pretty much the entire book. Not a bad idea, since I'm convinced I missed a lot the first time through, but other tasks beckon and it's not a quick read.

I'm not sure I can do much better here than randomly list a few of the themes of the book: the pleasures of doing mathematics, the role of pure mathematicians in society (Wall Street!) and many forms of art and culture, how best to explain number theory to an insightful actress, the philosophy of mathematics and philosophy of Mathematics (two different things), Indian Metaphysics, n-categories, the yoga of motives, Voevodsky's univalent foundations, the life and thought of Alexander Grothendieck and Robert Langlands, etc., etc. There's also serious doses of sex (including an extensive discussion of Frenkel's film), drugs (from Erdos to Andreas Floer to late nights at Oberwolfach) and rock and roll (from the "Math Rock" genre which I'd never heard of before to the IAS house band "Do Not Erase").

Harris manages to move back and forth between the deepest ideas about mathematics at the frontiers of the subject, insightful takes on the sociology of mathematical research, and a variety of topics pursued in a sometimes gonzo version of post-modern academic style. You will surely sometimes be baffled, but definitely will come away knowing about many things you'd never heard of before, and with a lot of new ideas to think about.

For some more about the book, including some early versions of some chapters, see Harris's website here.

Update: Princeton University Press now has a Q and A with Harris about the book up here.

Update: The book now has a blog.

Comments

1. **Shecky R**
   January 27, 2015

   Good to hear… I just saw this volume in a bookstore last weekend (having seen no pre-publicity for it?) and, leafing through it, thought it looked darn good… and different. Hope to start reading it next week, and now even more anxious to do so!

2. **Ninguem**
   January 28, 2015

   I was never sure what was going on with this book. It is serious or a parody (like in the Pynchon chapter you mention) and we're being made fun of? Does he dislike people who make tons of money or is Jim Simons OK? What about the quants, are they cogs in the machine or morally responsible? And what about Frenkel? I don't think he likes Frenkel.

3. **Peter Woit**
   January 28, 2015

   Ninguem,
   I don't think it's ever a parody, mostly it's completely serious, but not always. Harris is not a black and white thinker, and has a well-developed sense of humor. I can't speak for him, but I can assure you it's possible to have a more complicated view of Jim Simons and the money coming into math research from the finance industry than just "it's bad" or "it's good". I don't see any evidence at all that he dislikes Frenkel. In terms of his mathematical research I know he's quite interested in geometric Langlands and the things Frenkel has worked on.

4. **Peter Woit**
   January 29, 2015

   Michael Harris has told me that a series of questions and answers about the book will soon appear at the Princeton University Press blog site. One of them addresses Ninguem's question:

   3. The text refers to any number of controversies and polemics, historical or contemporary. But the author doesn't come down clearly in favor of a solid position on anything. Is this a "postmodern" book? Or does the author just not care?

   I am certainly opinionated about a great many things, and it is my considered opinion that most of the sharpest controversies — like platonism vs. nominalism, or positions on what Wigner called "the unreasonable effectiveness of mathematics" — miss the features that make it really interesting to be a mathematician. To avoid distracting the reader with pointless polemics, I consciously chose to present those features with a minimum of ideological adornment, and to allude to controversies only obliquely. I'm told there's a risk that some will find it disorienting to read a book about mathematics that doesn't tell them what to think; but it's a risk I'm willing to take. [Regarding the controversy over the role of mathematics in finance: the allusions in the book are admittedly hardly oblique, but I tried to limit myself to reporting positions that have already been expressed in the press. I have my own opinions, of course, but why should anyone care what I think?]

5. **Art Brown**

January 31, 2015

It appears Harris' title is referencing (refuting?) Hardy's famous essay. Is there more to the relationship than the cover?

6. **Peter Woit**
   January 31, 2015

   Art,
   Yes, it's definitely a reference to the Hardy book, and there's quite a lot of discussion of the Hardy book in Harris's. In some sense, the Hardy book (while very different) is the closest historical analog of this one, in the sense of having many of the same themes: why mathematicians do mathematics, the role of mathematics in the wider culture, etc.

7. **Art Brown**
   February 1, 2015

   Thanks very much. It's even nicer to have two treats in store. (I never got around to reading Hardy; I see it's now free.) Although with your notes and the MIT QM course life will be busy…

8. **Pete**
   February 4, 2015

   Thanks again for reviewing another popular math book.

   Love and Math is one of the best books on the subject I've read in several years, especially since Frenkel touches on ideas of mathematical realism and maths amazing ability to uncover the deepest structures of our universe. Now that you say this one is on par with it, I'll definitely have to make a stop at the local bookstore.

It Really Is Just Dust

January 29, 2015
Categories: Uncategorized

The Planck collaboration has an inimitable way of releasing important new results, they like to do it in French (see here for instance). Tonight a French Planck website contains the long-awaited news of the results from the BICEP2/Keck/Planck collaboration to reanalyze the BICEP2 data on polarized B-modes, in a way that allows proper estimation of the contribution of dust. The bottom line is that the BICEP2 claims of seeing a primordial r=.16-.20 that got a huge amount of media attention last year have been shot down. The new analysis says that r is less than .13. I don't see a paper yet, rumor is that the paper will be on the arXiv Monday night.

My understanding is that full polarization results from Planck's own data are still not quite ready, as has been the case for quite a while now.

Hat tip for this news to Steve (retired LLNL physicist). Thanks Steve!

Update: The Planck collaboration now has information available about this (in English!). An NSF version is here, NBC News here. It still looks like we'll have to wait until next week for the paper, which has been submitted to PRL.

Update: The paper is now available here.

   January 29, 2015

   We are not so far from the 200th anniversary of the Waterloo's battle. This is a mark of resistance against the linguistic domination of the Perfide Albion !

2. **JG**
   January 29, 2015

   Google Chrome browser it offers automatic translation

   > It turns out that the part of the dust had been significantly underestimated.
   >
   > Once the part of the galactic emission subtracted correctly, there is always an excess but it is too small for this to be considered a detection and could be the result of simple changes associated with experimental sounds.

   Not a perfect translation, but you get the gist

3. **Sakura-chan**
   January 29, 2015

   Off-topic, but pretty big piece on Zhang in the New Yorker.

   http://www.newyorker.com/magazine/2015/02/02/pursuit-beauty

4. **BMc**
   January 29, 2015

   " D'après les modèles à leur disposition, la collaboration BICEP estimait que cette part était négligeable, tout au plus très faible. Avec une seule fréquence d'observation, ils n'avaient pas d'autre possibilité pour évaluer le signal d'origine galactique…"

   A tiny bit of sarcasme there?

   I'm trying hard to laugh about this whole situation. But I can't.

5. **Peter Woit**
   January 29, 2015

   My own translation of the last part:

   > The spatial distribution of the Planck 353 GHz signal shows up in the 150 Ghz map of BICEP2 and of KECK: these last two thus contain a non-negligeable contribution from galactic dust. Once the galactic dust emission is correctly subtracted there is still an excess, but at the present time too small to count as a detection and could be the result of simple fluctuations due to experimental noise.
   >
   > The parameter r measures the size of the signal produced by primordial gravitational waves. Today's limit is a bit less strong because there is a small excess: too small to be a measurement of anything, but sufficient to weaken the limit [from r=.11 without the BICEP2/KECK data to the new r=.13]

6. **West**
   January 29, 2015

   Looking at the likelihood(?) plots at the bottom of the page, the K+P and B+P curves have some pretty dramatic separation. As the Keck array was supposed to be noticeably more sensitive than BICEP2, I would go put money on a small value of r as suggested by the red curve.

7. **Peter Woit**
   January 29, 2015

   Just noticed that I hadn't clicked on the "Expert" level to see the plots that West is referring to. One needs to be sure to do that.

8. **JG**
   January 29, 2015

The “expert” page makes it clear that we haven’t really got that much more certainty on this than what was known since last year.

> What is certain today is that the primordial origin signal is not at the level previously estimated – at most about half. Given the instrumental uncertainties (remember that the signal is incredibly weak!), We can not say more today. It will take further measures of extreme sensitivity at other frequencies to better understand the question …

So 700 million euros wasn’t enough for the Planck mission to decide this one – maybe that’s why they prefer to release updates on obscure french wep pages rather than youtube and a harvard-like press conferences

Results from POLARBEAR, Spider, BICEP3 etc will decide this I guess

9. **Physicsphile**
January 29, 2015

JG,

Planck may not have been able to significantly constrain primordial gravitational waves but they have had some other very useful results. For example they have shown that the non-gaussianity parameter is very small which rules out many proposed inflation models.

10. **AW**
January 30, 2015

Dear Peter,

I think the heading of your blog post is a bit strong:

“It really is just dust”

You yourself just quoted from the Planck website in your own translation:

“Once the galactic dust emission is correctly subtracted there is still an excess, but at the present time too small to count as a detection and could be the result of simple fluctuations due to experimental noise.

The parameter r measures the size of the signal produced by primordial gravitational waves. Today’s limit is a bit less strong because there is a small excess: too small to be a measurement of anything, but sufficient to weaken the limit [from r=.11 without the BICEP2/KECK data to the new r=.13]”

This statement is inconsistent with saying “it really is just dust”. For that I would require the analysis to show the absence of any residual excess at a level of $r < 0.01$ with a least 3 sigma significance.

This not the case. On the contrary, the statement on the Planck website might very well be construed to imply a residual excess (with definitely $r > 0.01$ given their current sensitivity) at 1-2 sigma level (this would fit with their notion, that the excess, while there, might still very well be a fluke). So I think your title is misstating their results and hence too strong.

11. **Anthony Reynolds**
January 30, 2015

I went to a colloquium on Wednesday given by Paolo de Bernardis at LMU-Munich, and Slava Mukhanov worked hard to get him to say that BICEP2 was wrong. He finally did. But he also said that Planck would publish something in February (he didn’t say when in February), and he wouldn’t say what those conclusions would be. I guess that might be the arXiv paper “due out” on Monday.

http://www.physik.uni-muenchen.de/aus_der_fakultaet/kolloquien/asc_kolloquium/archiv_wise14/bernardis/index.html

12. **chris**
January 30, 2015

The link points to an empty page. Have they taken the results down again?

13. **peppe**
January 30, 2015

The cached page https://webcache.googleusercontent.com/search?q=cache:http://public.planck.fr/resultats/253-la-reponse-de-bicep2-keck-planck

14. **Sesh Nadathur**
January 30, 2015

Planck people I spoke to this morning were surprised to hear that the results had been announced already. I suspect it was unauthorised jumping of the gun, which is why they have been taken down. The paper has already been submitted to a journal a couple of weeks ago, and will be on the arXiv early next week, followed a few days after by the Planck 2014/2015 release papers (or so I’m told).

15. **stringph**
January 30, 2015

So if ‘It’ = ‘what caused the BICEP collaboration to claim a detection’, then the new results show ‘it’ was exactly dust. If the dust had not been there (or had been accurately subtracted) the measurements would be a lot smaller and they could not possibly have claimed detection.

16. **martibal**
January 30, 2015

According to a cosmologist friend, it seems that someone has given to people outside the collaboration the “secret” URL of the non-yet public and still in preparation Planck page on the Planck/BICEP analysis, in violation of all ethical rules. Unless the page has been cracked. In any case it seems that the page was not “searchable” and the URL complicated enough not to be randomly found. This friend ask people not to sprea
d the google cache page.

17. **Peter Woit**

January 30, 2015

AW,
I don't think it's misleading. It's a null result, definitively showing that the original BICEP2 claims were wrong, and that's the obvious meaning of the title.

Your .01 criterion is randomly chosen. Of course all one can do here is put bounds (unless you have a real observation). You can't claim evidence for something based on 1-2 sigma, especially something extraordinary ("extraordinary claims require extraordinary evidence"). Claims from BICEP2 that "maybe we really did see something and weren't wrong" are what would be misleading.

18. **Peter Woit**
January 30, 2015

martibal,
One of many odd things here is that if this was a page not intended for the public you would normally make that clear by putting something at the top indicating that. It looked exactly like an intended official announcement, and that site is exactly the one used last year by Planck as the only place for official news from the collaboration.

If it had been clear that was not meant to be public, I would have not linked to it (although I might have mentioned "rumors about r <.13"…..)

19. **AS**
January 30, 2015

I have a paper comparing my predictions for r and ns to the global fit of Planck, Bicep and Keck. Should I cite a web page disappeared even from webcache or wait?

20. **Peter Woit**
January 30, 2015

AS,
You could cite various tweets on Twitter, a BBC news story, or maybe this blog…

21. **Sasha**
January 30, 2015

Peter

What other projects associated with the primordial gravitational waves will produce results this year?

22. **JG**
January 30, 2015

AW

[ESA seems to support the wording in Peter's headline]()

23. **Peter Woit**
January 30, 2015

Sasha,
I know little about the current state of other CMB experiments, perhaps someone better informed can comment about what to expect.

24. **JG**
January 30, 2015

[Paper released]()

(and to clarfiy my above comment, I meant that the ESA public announcement implies that the entire signal can be attributed to dust – which is what I interpreted Peter's headline to mean – since obviously he isn't making a prediction about the entire future of observations in this field)

25. **West**
January 30, 2015

@Sasha: SPIDER just finished its flight down on Antarctica. The collaboration has a nice set of blog entries about the balloon flight. https://spiderontheice.wordpress.com/

26. **Mark**
January 30, 2015

Has there been any commentary from the BICEP2 team about their flawed initial analysis? In other words, is anyone eating crow and acknowledging the mistake in their – shall we say "over exuberant" – analysis?

27. **West**
January 30, 2015

@Mark: At least from the quotation from Kovac given to Nature News, not really. http://www.nature.com/news/gravitational-waves-discovery-now-officially-dead-1.16830

I find the quotation "These [original dust maps] seemed to indicate that the region of the sky chosen for our observations had dust polarisation much lower than the detected signal" rather problematic. After the March announcement there were a number of papers showing that a careful analysis using the preliminary dust maps (Planck's?) meant there was a sizable microwave foreground from dust. Did anyone go back and dig through the other noise models and quantify their actual uncertainty?

28. **B**
January 30, 2015

The New York Times now has an article "A Speck of Interstellar Dust Rebuts a Big Bang Theory" quoting Dr. Clem Pryke of BICEP "We can't say with any certainty whether any gravity wave signals remain… Obviously, we're not exactly thrilled, but we are scientists and our job is to try and uncover the truth. In the scientific process, the truth will emerge."

[http://www.nytimes.com/2015/01/31/us/a-speck-of-interstellar-dust-rebuts-a-big-bang-theory.html?hp&action=click&pgtype=Homepage&module=first-column-region&region=top-news&WT.nav=top-news]

29. **Sasha**
January 31, 2015

West,
I know about SPIDER. But I wonder when the results will be available? Anyone heard the news or rumors about Bicep3? Will there be more results from Keck and Polarbear?And whether or not to hope for a positive result?

30. **Jim Akerlund**
February 3, 2015

Here is the arXiv version 1502.00612.

Short Items

January 29, 2015
Categories: Uncategorized

- Science magazine this week has an article and a podcast about the NSA and the AMS. AMS president David Vogan is portrayed as outraged at the NSA's misuse of mathematics, but without much support for doing anything about it:

  > But after all was said and done, no action was taken. Vogan describes a meeting about the matter last year with an AMS governing committee as "terrible," revealing little interest among the rest of the society's leadership in making a public statement about NSA's ethics, let alone cutting ties. Ordinary AMS members, by and large, feel the same way, adds Vogan, who this week is handing over the presidency to Robert Bryant, a mathematician at Duke University in Durham, North Carolina. For now, U.S. mathematicians aren't willing to disown their shadowy but steadfast benefactor.

  Two odd things from the piece and the podcast:

  1. The NSA budget is highly classified. Essentially nothing is known about it, with estimates of its total ranging from \$8 billion to \$25 billion/year (by the way, can anyone tell me why that number is a secret?). Precisely one line item in their budget is publicly reported: the \$4 million to the AMS-administered grant program. The AMS seems to be the only organization in the world that the NSA has a publicly disclosed relationship with.
  2. The reporter said he tried but was unable to get in contact with Richard George, the ex-NSA person who published a piece in the Notices claiming the NSA backdoor was "just innuendo".
- On a much more positive note, this week the New Yorker has a really wonderful piece about Yitang Zhang.
- There's an interview at the Huffington Post with Lenny Susskind about The Future of Physics. It looks like his point of view is that there is no known alternative, no matter what happens at the LHC, that fine-tuning is evidence for the multiverse is evidence for string theory. The only alternative now: hope for an unforseen surprise.

Update: Paul Frampton tells me that he has published a book telling the story of what happened to him. It's now available on Amazon.

Comments

1. **Als**
   January 29, 2015

   It seems that Susskind's interview is from 2006.

2. **Peter Woit**
   January 29, 2015

   Als,
   Thanks Als, I should have seen that. Interesting (or sad…) that nine years later it seems as current as then. In 2006 I guess there was more reason to "expect the unexpected" at the LHC.

3. **Richard**
   January 29, 2015

   David Vogan was a truly decent and admirable person (as well as being a tremendously talented and generous mathematician) when I knew him at MIT in the 1980s and it seems that some things do not change.

4. **Yatima**
   January 29, 2015

   by the way, can anyone tell me why that number is a secret?

   Because knowing the actual budget of a bureaucratic outfit is like knowing someone's True Name: It gives you power of it. That cannot be allowed to happen. So it's somewhere in this 52 billion lump sum (extra expenses are, I suppose, excluded because this sounds suspiciously low to me).

   Related reading: A psychological history of the NSA

5. **Anon**
   January 30, 2015

   Here's almost everything you wanted to know about the intelligence community budget. The justification for keeping it such a safeguarded secret is so that weaknesses aren't found and exploited in various programs.

   http://cryptome.org/2013/08/spy-budget-fy13.pdf

6. **Anon**
   January 30, 2015

   The relevant slides appear to be p. 84 for a budget of around 12 billion and page 159 with a listing for cryptologic math and IDA research

7. **Oldster**
   January 30, 2015

   The following exchange is part of that Huffington Post interview with Susskind in 2006:

   Odenwald: If string theory loses its experimental support at the LHC, wouldn't it be far worse than merely going back to cosmology circa 1975 or even 1965? We would have to question the very mathematical tools we have been using for the last 50 years!

   Susskind: I agree with your analysis, except that I would add: Expect the unexpected. Unforseen surprises are the rule in science, not the exception. Remember: Stuff happens.

   That "50 years" comment jumped out at me, and I notice Susskind seemed to agree with it. I wonder if they were both thinking that quantum field theory itself could face new doubts in that case. I'm old enough to remember when Dirac stated doubts about QFT …

8. **tt**
January 30, 2015

Frampton missed an opportunity. He should have called it
"Frampton comes online"

9. **Michael Hutchings**
January 30, 2015

I question the statement "Ordinary AMS members, by and large, feel the same way" (about not making statements about the ethics of the NSA, let alone cutting ties). How about a survey or a poll? I imagine that those who receive financially support from the NSA would like to continue to do so, but this is probably a small fraction of academic mathematicians, and I would expect many of the rest to have serious ethical concerns (if they are paying attention at all).

10. **Grad Student**
January 30, 2015

Yes, the fact that Susskind's remarks are basically the same today show how physics/string theory has stalled.

Susskind, Frampton, et al. definitely had a lot more hope of "Seeing something unexpected" a few decades back:

https://www.youtube.com/watch?v=y7rFYbMhcG8

🙂

11. **Peter Woit**
January 30, 2015

Michael,
I have no data at all to support this, but my guess from talking to people is that if you remove the "I don't care" majority, sentiment among mathematicians who do care is much more heavily on the anti-NSA side. Even among those with NSA grants you might find some who don't see why the AMS is involved in this (as far as I know there's no good reason for that program to not just be run by the NSA, leaving the AMS out of it).

12. **jsm**
January 30, 2015

Of course, NSA funnels the money through the AMS for the prestige and influence it buys them — if it simply wanted to help math in the US, it could give the money to NSF. The shocking thing is how little the AMS has been willing to sell itself out for.

Vogan surely knows more about the mood among the AMS membership than the rest of us — after all, he's served on many committees. Judging by the Elsevier boycott, I'd guess that a petition to sever the AMS's ties with NSA would get about 2000 signatures (the same 2000).

13. **Martin S.**
January 31, 2015

Regarding a poll,
it seems that those who hope for a safe employment and/or do not know a freer world, like them.

14. **Peter Woit**
January 31, 2015

Martin S.,
I doubt those numbers are very meaningful, with most respondents probably not having any idea what the NSA is or does (not everyone in the US carefully follows the Snowden revelations…). The pattern of NSA favorability falling sharply with age may just reflect that as people get older they are more likely to have figured out what the NSA is.

15. **Visitor**
February 1, 2015

"The pattern of NSA favorability falling sharply with age may just reflect that as people get older they are more likely to have figured out what the NSA is."

Or maybe the older people are the less likely they are to have grown up in the "let's put our whole lives online via Facebook, Twitter, and the rest of that" world.

Of course, that doesn't include the ideological baggage that your "figured out what the NSA is" carries, but it might be more accurate for lacking it.

16. **NoGo**
February 3, 2015

Hello Mr Woit!
Like your blog very much.
I thought you may find this article interesting, and am very curious what you think of it:

For some reason it makes a bit of a splash in Russian mainstream media…
Thanks!

17. **Peter Woit**
February 3, 2015

NoGo,
Sorry, but understanding exactly what those authors have shown that is new is beyond my expertise. Personally I'm happy to characterize the wavefunction as "real", to the extent that anything is "real", but that's just words, capturing likely not at all whatever the actual issue addressed by the paper might be.

18. **Shantanu**

February 4, 2015

Peter, something OT.
Another brilliant paper by Avi about hiring

19. **abbyyorker**
February 7, 2015

I read Frampton's e-book and I wish him all the best. That bikini model was hot. But it's hard to believe he was THAT naive, especially reading the nyt transcript of his joke messaging from the airport. Anyway, he did his time and good luck to him.

20. **Jean D**
February 28, 2015

«by the way, can anyone tell me why that number is a secret?»

In the 6th Century, Sun Tzu put it this way: «Appear strong where you are weak and weak where you are strong.» This way the other guy can't tell how many «chariots» you can really field.

Even though everyone knows what they personally would do with an X37-B, no one knows for sure yet what it's all about. A lower figure would indeed point to the Air force only testing a concept, the higher figure may put a sat killer laser like on the Argleigh Burke class of ships on its next flight. All good engineers can tell you everything is feasable, and will also tell you exactly how much it will cost.

Surely you must know we can infer many things with the proper and true data. You PhDs do the same with the Universe.

A Letter to the AMS

February 3, 2015
Categories: Uncategorized

Leonid Reyzin at Boston University has drafted a letter in response to the recent article published in the Notices by Michael Wertheimer of the NSA (discussed here). He's collecting signatures, and if you're a member of the AMS I urge you to consider contacting him and adding yours. If you know others who might be interested in signing, please forward the link to them.

Comments

1. **Steve Huntsman**
   February 3, 2015

   NSA strengthened DES against the then-classified technique of differential cryptanalysis by improving the S-boxes. It is not fair to say that NSA weakened DES by reducing its key length without looking at this.

2. **Peter Woit**
   February 3, 2015

   Steve Huntsman,
   Yes, suspicions about the DES S-boxes turned out to be unfounded (and the NSA via Richard George has used the AMS Notices to suggest that the same is true for DUAL_EC_DRBG). But that this suspicion was unfounded has nothing to do with the DES key length issue mentioned in the letter, where there seems to be no question that the NSA pushed for a shorter key length so that they could break such encryption. Even they haven't tried to claim that shortening key length was a way to strengthen DES.

3. **Roger**
   February 3, 2015

   It says "blacklisting an inventor of DES from other cryptography jobs". Who was that?

   Wikipedia:
   The team at IBM involved in cipher design and analysis included Feistel, Walter Tuchman, Don Coppersmith, Alan Konheim, Carl Meyer, Mike Matyas, Roy Adler, Edna Grossman, Bill Notz, Lynn Smith, and Bryant Tuckerman.
   http://en.wikipedia.org/wiki/Data_Encryption_Standard

   You say: "there seems to be no question that the NSA pushed for a shorter key length so that they could break such encryption."

   There is some question about that. For details, see this AMS Notices article that only says:
   "There have been persistent rumors that NSA had pressed for the shorter key length."
   http://www.ams.org/notices/200003/fea-landau.pdf

   Yes, there were rumors, but I do not see those rumors confirmed anywhere.

4. **tt**
   February 3, 2015

   details and a citation on the blacklist here (Horst Feistel is the guy)
   http://ethanheilman.tumblr.com/post/108115952435/a-response-to-wertheimers-encryption-and-the-nsa

5. **Peter Woit**
   February 3, 2015

   Roger,
   "NSA tried to convince IBM to reduce the length of the key from 64 to 48 bits." is not a "rumor", it's based on the declassified, sanitized version of the NSA's own history. See the reference at the Wikipedia page.

6. **Michael Hutchings**
   February 3, 2015

   I would like to sign something, but I don't feel qualified to sign this particular letter, because it refers to a lot of history which I don't really know anything about. I think one could get more signatures with a letter referring to broader principles, something along the lines of "The AMS should convene a task force to consider reducing or eliminating ties with the NSA, due to serious ethical concerns about this relationship [references]."

7. **Ninguem**
   February 4, 2015

   Is it only for members of the AMS?

8. **Ethan Heilman**
   February 4, 2015

   In regards to the history of the DES key length it is from the NSA's internal history, "Book III: Retrenchment and Reform" which can be found here at cryptome.

   > "NSA worked closely with IBM to strengthen the algorithm against all except brute force attacks and to strengthen substitution tables, called S-boxes. Conversely, NSA tried to convince IBM to reduce the length of the key from 64 to 48 bits. Ultimately, [*] they compromised on a 56-bit key."

   Also see NSA attempting to clamp down on feedback register techniques:

> “In 1977, a patent controversy stirred the already-choppy waters. George Davida, a University of Wisconsin professor, applied for a patent on a cryptographic device using advanced mathematics techniques and [— — — — —-] shift registers. The COMSEC organization was unruffled, but DDO, fearing the spread of shift register techniques that would give the SIGINT side problems, recommended a secrecy order, which was duly put in place by the Patent Office. The inevitable public debate turned on the issue of academic freedom. NSA answered that if Davida had published the technique in an academic journal he would have been protected, but since he had instead applied for a patent, it appeared that he was in it for the money and thus lacked First Amendment protection. This was incontrovertible logic but bad politics, and once again NSA was forced to back down. The Davida patent was reinstated.”

And ITAR restrictions which was used to threaten IEEE authors with censorship.

> “NSA hunted diligently for a way to stop cryptography from going public. One proposal was to use the International Traffic in Arms Regulation (lTAR) to put a stop to the publication of cryptographic material. [..] The Institute of Electrical and Electronics Engineers would be holding a symposium on cryptography in Ithaca, New York. Concerned about the potential hemorrhage of cryptographic information Meyer sent a letter to E. K. Gannet, staff secretary of the IEEE publications board, pointing out that cryptographic systems were covered by ITAR and contending that prior government approval would be necessary for the publication of many of the papers.”

When threats didn’t work they attempted to slow down academics via other means.

> “It was essential, then, to slow the rate of academic understanding of these techniques in order for NSA to stay ahead of the game. (There was general recognition that academia could not be stopped, only slowed.) ”

9. **Peter Woit**
February 4, 2015

Ninguem,
I don’t think signers necessarily need to be members of the AMS, you should contact Leonid Reyzin if you’d like to add your name.

Michael Hutchings,
The letter is specifically intended as a response to the Wertheimer article, but I completely agree that a letter of the sort you indicate would be a great idea (do you want to organize it?).

My impression is that when all this started post-Snowden, there was little enthusiasm at the AMS for taking any action to cut ties with the NSA. The decision was instead to encourage discussion, and that’s the goal of the Notices articles and letters. Interestingly, I haven’t seen much in the way of practical discussion of exactly what the AMS ties to the NSA are, and exactly what steps might be possible to change them. However, the two articles from NSA people it seems to me have helped make clear what the fundamental problem with that organization is: it operates outside the usual constraints of the bill of rights and democracy. As a result, people working there like George and Wertheimer find it natural to respond to the basic question (did the NSA backdoor DUAL_EC_DRBG?) by writing an evasive and misleading piece in the Notices. Their attitude appears to be that the public and the math community have no right to ask this kind of question, and deserve to be misled if they try.
This may be having an effect at the AMS, making people more open to a discussion about cutting ties with the NSA. I don’t know if a letter or other action is the best way to move this forward. As of this weekend the AMS has a new president (Robert Bryant), who may bring a different perspective to the question.

10. **Michael Hutchings**
February 4, 2015

I was hoping for a letter that lots of people could sign to express their concern without having to know the detailed history. However the person who organizes this letter should probably still know what they are talking about, so I wouldn’t be the best person for the job. I could still do it though if no one else will. Maybe we should first see if Robert Bryant will do something.

Planck Data Out

February 5, 2015
Categories: Uncategorized

Long awaited data from the Planck satellite was released today, papers available here. The accompanying press release leads with results about the timing of the first stars, 500 million years or so after the big bang, with little mention of the very early universe. This is also the main topic of BBC News coverage.

This paper reports a bound on r of .08-.09, exactly what Shaun Hotchkiss was predicting earlier this week here. This appears to be pretty much the end of the line for hopes that Planck would see primordial gravitational waves, with the paper seemingly pointing to other experiments being necessary to get below r=.05 (see page 35).

The BBC News story also characterizes these bounds as ruling out the simplest inflationary models, requiring they be supplemented by "exotic physics".

> What is clear from the Planck investigation is that the simplest models for how that super-rapid expansion worked are probably no longer tenable, suggesting some exotic physics will eventually be needed to explain it.
>
> "We're now being pushed into a parameter space we didn't expect to be in," said collaboration scientist Dr Andrew Jaffe from Imperial College, UK. "That's OK. We like interesting physics; that's why we're physicists, so there's no problem with that. It's just we had this naïve expectation that the simplest answer would be right, and sometimes it just isn't."

For about as long as I can remember, string theorists and multiverse fans have been pointing to Planck data as the test of their ideas. For cosmic strings, the last Planck data release had a paper ruling them out. I don't see a paper on this topic out or projected for the new data, it seems that this is now something not even worth looking for.

We've also been hearing for years that Planck will test supposed evidence of bubble collisions indicating other universes, see for instance this article about this paper, where the article states that

> Data from the Planck telescope should resolve the question once and for all.

I don't see anything in the new data even looking for this. Has it already been ruled out, without any publicity, or did the Planck people think it was something not worth even looking for?

Comments

1. **Ben Gold**
   February 5, 2015

   The bubble-collision paper you reference is looking for the signature in temperature only. I think I've seen some calculation of polarization signatures for specific multiverse models, but I'm unaware of a general "bubble collision"-type search that uses polarization. So I think the answer to your question is "mostly ruled out without publicity", but also that even defining a generic polarization signature for such models is hard, so there could be room for something clever.

2. **Peter Woit**
   February 5, 2015

   Thanks Ben,
   What about this one
   http://arxiv.org/abs/1109.3473
   which claims a polarization signal?
   For the Planck data, is this in the category of already ruled out, Planck thinks not worth looking for, or results buried somewhere I didn't see?

3. **Ben Gold**
   February 5, 2015

   OK, the punch line of that paper (which is looking basically at the E-mode generated by the temperature gradient) seems to be that small spots would be detected first in temperature, and "very large spots [angular radius > 25°] could be detected almost as easily in polarization as temperature".

   There are some particulars of the signature that might make it stand out a bit more, but basically the upshot is that you'd be looking for large-scale E modes (and TE correlations), where there's plenty of ordinary signal (unlike B modes) and where Planck has been having trouble this whole time.

   Side note – while it looks like Planck has released a lot of data, it notably does not include polarization power spectra, or in fact any polarized maps except for the LFI frequencies (where foregrounds are larger) and, for some reason, at 353 GHz. Not the 100/143 that I'd think to use for CMB analysis.

4. **Peter Woit**
   February 5, 2015

   Thanks Ben,
   OK, so for that one I guess it's still wait and see…

5. **Jeff**
   February 5, 2015

   I just watched this on BBC and it was bizarre. After three minutes of talking about the earliest stars they cut to an expert who completely changed the subject (or they cut the segue) and babbled "Multiverse, multiverse, multiverse."

6. **Bernhard**
   February 5, 2015

   This whole story resembles SUSY so much…

7. **David**
   February 6, 2015

How does this reconcile with the earlier BICEP/Planck joint paper?

8. **Peter Woit**
February 6, 2015

David,
They get a somewhat stronger bound on r from their data. As Ben Gold explains, they still haven't finished the full analysis of their polarization data, presumably will do even better when that is done.

9. **Urs Schreiber**
February 6, 2015

It deserves to be highlighted more explicitly: the model of inflation strongly preferred by the Planck2015 data is — as was already the case after the Planck2013 analysis — the Starobinsky model.

10. **Anonymous**
February 6, 2015

Urs, there is no such preference. The data is not sufficient make such strong distinctions in any case, but with the new r distribution it is not true that the Starobinski model is preferred. More will be known in the coming years, no need to jump the gun.

11. **Peter Woit**
February 6, 2015

Urs/Anonymous,
You really can't claim strong support from experiment for your model when your model's prediction is that experiment won't see anything. All sorts of early universe models don't have observable primordial gravitational waves.

I just looked out the window, saw no large monster green turtles. This provides strong support for my theory that the universe is controlled by a large monster green turtle, one that lives on the other side of the planet….

12. **Urs Schreiber**
February 6, 2015

The Starobinsky model sits right in the center of the parameter range preferred by the Planck data, the famous figure 1 in arXiv:1303.5082, which is now confimed as figure 22 of arXiv:1502.01589.

Quoting Jörg Paul Rachen, member of the Planck collaboration, from his IMAPP talk just yesterday:

> The Starobinsky model is the model with the highest Bayesian evidence as it is right in the center of the likelihood peak and at the same time has the lowest number of free parameters.

13. **Anonymous**
February 6, 2015

The central value of r is nonzero (.03-05), but with (in)famously low significance. There is no statistically significant distinction among the many models in the allowed range, including Starobinski, but the latter is not at the central value. There's more data on the way, so anyway there's no need to guess right now.

14. **Urs Schreiber**
February 6, 2015

I am not guessing, I am quoting public statements made by experts with an identifiable name attached to them.

15. **Eduardo Lira**
February 6, 2015

Be it that SUSY doesn't show up at the LHC or that Planck sees only dust, it all leads over and over again to the ultimate objection critics make to ST: that it can't be falsified.
However, doesn't the history of physics record other circumstances where falsifiability was also absent and sometimes so for many years, but only to turn out different in the longer term? Consider for example the question about the chemical composition of stars that scientists asked themselves in the first half of the 19th century. You couldn't then (nor can today!) bridge the immense distances to the stars, so it seemed impossible to perform analysis of any kind to find out what they are made of. Among others, French philosopher Auguste Comte properly (or so it seemed then) presented the case as an example of a class of facts that were to stay forever hidden from human knowledge.
Any theory aimed at describing what stars are composed of that had been proposed those days wouldn't have been falsifiable, and should then have been classified as "not scientific". But of course later discovery of the absorption spectra phenomenon ultimately led astronomers and physicists to determine the precise composition of stars, never mind if you can't go measure it in situ.
Back to ST, can we discard the possibility of coming someday across the likes of spectra absorption lines that allow us to reveal the precise shape of Planck-scale space-time, and the inner structure (if there is any) of elementary particles? If you ask people like George Ellis and Joe Silk -to mention a recent reference in this blog- the answer would be that we'll never find out. In their own words, "the higher dimensions are wound so tightly that they are too small to observe at energies accessible through collisions in any practicable future particle detector" (Nature, Dec. 16, 2014).
But what if you replace the idea of "too small tightly wound higher dimensions, too small to observe" with "too large distances to the stars, too far to analyze", and also the one of "any practicable future particle detector" with "any practicable future means to reach a star"?
Could a future discovery nobody anticipates now take ST out of the not-even-wrong limbo, as it would have been the case for any "not scientific" (i.e. unfalsifiable) theory which happened to be proposed 150 years ago to try to predict the composition of stars, and which became falsifiable against all odds when spectra absorption was discovered and explained? As improbable as it may look today (and as it seemed in 1840 that we would stumble upon a means of finding out what stars are made of), if such a breakthrough comes to occur (whether this happens in the near future or 200 years from now is fundamentally irrelevant), confrontation of ST with the newly acquired way to probe reality will allow physicists to determine whether it is plainly wrong or just right, the latter if only in the broad sense of pointing in the right general direction for further construction and refinement.
A much less important consequence of this last hypothetical outcome is of course that the category where Auguste Comte belongs in history (whatever it may be) would be joined by numerous new members.

16. **Peter Woit**
February 6, 2015

Eduardo Lira,
Please, this is off-topic, has nothing to do with yesterday's Planck results. I will leave it though, just so I can point to a relevant FAQ entry (the problem with string theory is not that its predictions are unobservable, but that there aren't any)

http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=doesnt-string-theory-make-predictions-at-very-high-energy

I will however delete further off-topic comments that have nothing new and interesting to add.

17. **West**
February 6, 2015

@Urs: Did you happen to catch how much better the marginal likelihood (hate using "evidence" for this) is for the Starobinsky model than its competitors?

18. **West**
February 7, 2015

Am actually able to answer my own question now that the Planck collaboration's paper about constraints on inflationary models is out.

Table 6 (p.18) is a nice summary of the model comparisons using only Planck data and as Urs suggested yesterday, the Starobinsky model comes out on top. Mind you not by much, and if one includes the BKP cross-correlation results, some other models do just as well at fitting the data. The results lend credence to models with small r values but no single one has truly distinguished itself from the pack.

So in the end, we have a 95% upper limit on r at 0.08, no evidence for spectral running and an uncertainty interval (68%) for n_s at the sub-1% of the peak posterior value. Impressive work all around.

IPMU Conversation with Edward Witten

February 6, 2015
Categories: Langlands

I recently heard from Hirosi Ooguri that a transcript of a long conversation with Witten held at the time of his Kyoto Prize award has just appeared in the Kavli IPMU Newsletter. It's a truly fascinating document, giving some great insights into Witten's work at the boundary of math and physics and how he sees the state of ideas in this area. It's wonderful that he was induced to give such a thoughtful and extensive explanation of both the history and significance of these various topics.

Just to pick out a couple examples, the discussion of geometric Langlands describes a lot of detailed history that I was unaware of. I had noticed that in their first massive (still unpublished) paper that started the subject, Beilinson and Drinfeld credit Witten with "the main idea" (I wrote about this in detail here). But there was nothing in what Witten has written that corresponds to what they did, and experts I talked to didn't see how this came from Witten. Witten tells the true story this way:

> Actually, the very little bit of what Beilinson and Drinfeld were saying that I could understand made me wonder if the work of Nigel Hitchin would be relevant to them, so I pointed out to them Hitchin's paper in which he had constructed commuting differential operators on the moduli space of bundles on a curve. Differently put, Hitchin had in a certain sense quantized the classical integrable system that he had constructed a few years before. Although I understood scarcely anything of what Beilinson and Drinfeld were saying, I did put them in touch with Hitchin's work, and actually, in their very long, unpublished foundational paper on geometric Langlands that you can find on the web, Beilinson and Drinfeld acknowledged me very generously, far overestimating how much I had understood. All that had really happened was that based on a guess, I told them about Hitchin's work, and then I think that made all kinds of things obvious to them. Maybe they felt I knew some of those things, but I didn't. But anyway, there were ample reasons in those years to think that geometric Langlands had something to do with physics, but as you can see I still couldn t make any sense out of it.

He also describes how he came to the idea of interpreting geometric Langlands as a form of mirror symmetry, inspired by things he learned from David Ben-Zvi at lectures about the Langlands program bringing together mathematicians and physicists at the IAS.

He contrasts his work in recent years relating Khovanov homology and gauge theory with the geometric Langlands work, saying that he thinks the Khovanov homology ideas are in a form such that mathematicians are more likely to be able to appreciate their roots in gauge theory:

> I think it s actually very difficult to see what advance in the near term could make the gauge theory interpretation of geometric Langlands accessible for mathematicians. That's actually one reason why I m excited about Khovanov homology. My approaches to Khovanov homology and to geometric Langlands use many of the same ingredients, but in the case of Khovanov homology, I think it is quite feasible that mathematicians could understand this approach in the near future if they get excited about it. I believe it will be more accessible. If I had to bet, I think I have a decent chance to live to see gauge theory and Khovanov homology recognized and appreciated by mathematicians, and I think I'd have to be lucky to see that in the case of gauge theory and the geometric Langlands correspondence – just a personal guess

About the geometric Langlands story, he thinks there is still much to be understood, including its connection to conformal field theory:

> In fact, part of the original work of Beilinson and Drinfeld on geometric Langlands has still not been understood to my satisfaction. Here I have in mind the use of conformal field theory at what they call the critical level (level -h, where h is the dual Coxeter number) to construct the A-model dual of certain B-branes (the ones that are associated to opers, in the language of Beilinson and Drinfeld). Davide Gaiotto and I obtained a few years ago a reasonable understanding of what electric-magnetic duality does to the variety of opers, but I still do not really feel I understand its relation to conformal field theory. However, in the last few years physicists working on supersymmetric gauge theories in four dimensions and their cousins in six dimensions have made several discoveries involving the role of conformal field theory at the critical level, so the time may well be right to resolve this point.

Among the many other highly interesting comments, one was Witten's take on the possible connection of quantum field theory to number theory. He has a long history with this, going back to conversations with Atiyah in 1977 in which Atiyah suggested some connection between Langlands and Montonen-Olive. Witten writes

> I was skeptical about Montonen-Olive duality, I didn't seriously try to relate it to Langlands duality and I didn't try to learn what Langlands duality was. I did not learn anything more about these matters until the late 1980s. Then I learned just superficially about the Langlands correspondence. If one knows even a little bit about the Langlands correspondence and a little bit about conformal field theory on a Riemann surface, one can see an analogy between them. I wrote a paper that was motivated by that but then I realized that my understanding was too superficial to lead to anything deep, so I abandoned the matter for a number of years.

Later of course, he followed work on geometric Langlands and ultimately found the connection to gauge theory he worked out with Kapustin. As far as current prospects for connections to number theory, he has quite a few comments, but thinks the subject is still a dream that is not ripe:

> For me personally–it's a dream that eventually number theory would make contact with physics some time, but I doubt it will be soon. There are all kinds of areas where specific number theory formulas appear in physics, and these may be clues that the dream will come true one day. But to really get me excited, somehow the number theory would have to enter the physics in a more structural way. I m not that interested in a specific formula that comes out of a physics calculation in a more or less ad hoc fashion. Number theory would have to be more integrated with the physics to get me excited, and I don t see that happening soon. In my work, I concentrated on the geometric form of the Langlands correspondence because I could see that there was hope to really understand it in the context of the physics-based tools that were at hand. There might be something like that one day for the Langlands correspondence of number theory, but probably a lot is missing and we do not know what has to happen first.

This just gives a taste of the conversation, there is lots, lots more there, on a wide range of topics. Highly recommended reading for anyone with an interest in this area, I've never seen anything like it.

Comments

1. **Als**
   February 6, 2015

   Thanks for the link.

   Are there also interviews of the previous winners? I tried to find them but without success…

2. **Paul Frampton**
   February 7, 2015

   Peter, Your links are always useful but none more so than today's link to the December 2014 issue of the IPMU News with its interview about physics and mathematics at IPMU of Edward Witten by Hirosi Ooguri. I would not have read this otherwise and could not put it down before reading all seventeen pages. Edward always speaks perspicuously and Hirosi cleverly steers the interview. The distinguished theoretician Hitoshi Murayama put mathematicians and physicists in adjacent offices at IPMU.

3. **Giotis**
February 8, 2015

What can you say about this interview? Just amazing; it has it all and it's of historical importance.

Maybe the only thing that is missing is a reference to the quest for the identification of the underlying symmetry of String theory responsible for its rigid structure that would further restrict the theory. Finding this symmetry is of immense importance since it will shed light to its underlying structure (potentially with phenomenological implications).

A glimpse of this symmetry can be seen in the Higher Spin algebra of Vasiliev's theory in AdS which is expected to be a sector of String theory in its tensionless limit (where this symmetry would be unbroken).

Witten himself was one of the first people that motivated this in the context of Higher_Spin/ Free_CFT correspondence in his 2001 talk at the John Schwarz 60th birthday symposium.

http://theory.caltech.edu/jhs60/witten/1.html

4. **Tim Nguyen**
February 8, 2015

Thanks for the link Peter and your positive reaction to the interview parallels mine. I'm sure you must have been asked this before, but I'm curious how you reconcile your appreciation of the fruitful ideas coming out of string theory with the otherwise polemical views you have of string theory as a science.

5. **Peter Woit**
February 8, 2015

Tim Nguyen,
I really don't want this to turn into yet another of the same tedious discussions about math and string theory that have often taken place here. One interesting thing about Witten's commentary is that he makes very clear that no one really understands the origin of a lot of the fascinating structures he's talking about or what the right way to think about them is. As he points out, these things make clear that there is much we don't understand about QFT, much less string theory (which is becoming a very ill-defined term). To a large extent, the mindset of theorists for twenty years has been dominated by the conjecture that the big explanation is some mysterious 11d theory, and that if understood it would give a unified theory. I don't see any progress on this, or actually any good reason to think that 11d is the way to a unified theory (quite the opposite…). Thinking about these mysteries with more of an open mind about what the new structures are that we're looking for seems like a good idea, and I think Witten at his best (as is on display here) is often doing that.

6. **Tim Nguyen**
February 8, 2015

Peter,

Apologies if these are repetitive comments (perhaps you could link me to relevant past discussions if you so wish), but it seems to me that string theory being on the one hand unsatisfactory as a science and on the other, being a rich source for mathematics, can be seen as independent issues. The same tree can produce both good fruit and bad fruit and we reap the benefits so long as we know which is which. Perhaps this was implicit in your remarks.

7. **Ian Welland**
February 9, 2015

What applications have arisen from the mathematics invented by string theorists? If there aren't any, how can it justifiably be called good mathematics?

8. **Peter Woit**
February 9, 2015

Ian Welland,
Most mathematicians don't think "good mathematics = applied mathematics", and if you fired mathematics faculty whose research in recent years has not had significant applications, many of the best research universities in the world wouldn't have much of a math department anymore. Even if you believe "good=applied", pure math research often only finds applications very much later, even centuries later.

I'll delete any more comments of this kind though. If you're not interested in what Witten is talking about that's fine, just ignore it.

9. **Giotis**
February 9, 2015

Another thing that I would definitely expect to hear in a discussion like this and it was skipped for some reason is a reference to the Monstrous moonshine. This can also be linked to Witten's pioneered work on AdS_3_QG/Monstrous_CFT_2 correspondence.

Three-Dimensional Gravity Revisited (http://arxiv.org/abs/0706.3359)

10. **Justin**
February 10, 2015

Woit, Excellent interview with Witten.

But, didn't you find his outlook, while honest, a bit discouraging? e.g. gauge theory and Langlands won't be appreciated by mathematicians anytime soon, number theory and physics won't have any unification in any foreseeable future.

11. **Peter Woit**
February 10, 2015

Justin,
Not at all, I found his comments realistic and actually encouraging. The relationship of mathematicians to gauge theory is a complicated and long story. It never has been the case that mathematicians are able to adopt physicist's techniques for dealing with quantum Yang-Mills above 2d, for geometric Langlands or anything else. What mathematicians have gotten out of this is new ideas and inspiration about how to pursue their own methods (an old example was Seiberg-Witten, a nice new example is in

Witten's comments about Kevin Costello's work). Ultimately I think new ideas will come here from each side doing what it does best, not one side adopting the other's machinery.

About number theory and physics, I see lots of fascinating possibilities and connections, but agree with Witten that there is still no compelling picture of exactly what is going on here. I'd have been quite surprised if he claimed that major progress was imminent (few people work on this). What would have been discouraging would have been if he said he felt there was nothing there, that this couldn't lead anywhere, but that's quite different than what he was saying.

12. **Don Murphy**
February 10, 2015

I believe that Beilinson and Drinfeld gave Witten so much credit for helping them because they recognize that true genius is often the ability to see connections where most people do not. Witten has demonstrated this genius on many occassions.

13. **Jeff M**
February 10, 2015

Pardon my ignorance, but I'm kind of curious at the hero worship of Witten in the physics community. Clearly a great mathematician, they don't give you a Fields for nothing. My orals in grad school were presenting a JDG paper of his, brilliant bit of work. Took reading a whole book by John Roe to actually understand what he was doing. But physics? I understand that a big chunk of what people in physics work on, and have been working on for several decades, comes from Witten's work, but what of it has actually been shown to be true? What has he worked on that has been experimentally verified? I've been to some neat talks on topological quantum field theory, fun stuff, but any known relation to the real world? Just curious…

14. **Peter Woit**
February 10, 2015

Jeff M,
There really have been no major advances in theoretical particle physics that have been experimentally verified in now over 40 years. If you look at Nobel prizes, there have been no Nobel prizes for theoretical particle physics work done post-1973. So, yes Witten has not done anything at that level, but to be fair, neither has anyone else (he started grad school around 1973).

But he really has revolutionized how we think about quantum field theory. TQFT is mostly his doing. Anyone who looks at the history of this I think has to be in awe of how much he has done, with much of it way beyond what anyone else in the field was doing or capable of doing. The outcome of this so far has worked out much better for mathematics (his Fields medal is well-deserved, and that was awarded before Seiberg-Witten and much else) than for physics. But it's entirely possible that when progress finally comes in the future, his ideas will be part of it. There really is a history of overlap between good physics and good mathematics, so the mathematical qft successes could very well be matched by success on the physics front.

He's been I think overly enthusiastic about string theory unification, and slow to acknowledge that that idea hasn't worked out, but at least you don't hear him going on about the multiverse…

15. **MathPhys**
February 11, 2015

Peter,

"There really have been no major advances in theoretical particle physics that have been experimentally verified in now over 40 years."

Exact solutions in 2D statistical mechanics [e.g. Baxter's hard hexagon model] and their critical limits, the 2D conformal field theories [e.g. the c=1/2 theory that describes the critical limit of the Ising model] are, in my opinion, major advances in theoretical physics, that are less than 40 years old and examples of these theories were verified experimentally in the early 1980's in experimental studies of surface critical phenomena [my recollection is that these experiments were post Baxter's work, but before Belavin et al.].

This is the only corner of string theory [in the broad sense of the word] that I'm aware of that has been experimentally verified. Non-canonical critical exponents were measured in the lab, and the theory was right on the money.

16. **Peter Woit**
February 11, 2015

MathPhys,
My comment was intended to just be about theoretical HEP physics. Advances in QFT of course have many other applications. I don't think Witten though has ever shown a lot of interest in condensed matter/stat mech physics, although some of his work has applications there and I'm sure he knows quite a bit about the subject. He doesn't seem to be joining the current wholesale move of a lot of the string theory community into condensed matter.

17. **Justin**
February 11, 2015

Woit wrote,

"TQFT is mostly his doing."

Witten did lots for the subject, and deeply deserved his fields medal. But, let's not forget the importance of Atiyah who really suggested to Witten that knots might have a physical interpretation. Also, Floer's results were critical as well. And Seiberg-Witten does have two names in the title.

18. **Peter Woit**
February 11, 2015

Justin,
I wrote in detail about that history in my book, it's chapter 10 there. I stand by the claim that "TQFT is mostly his doing", although of course certainly other people were crucially involved.

19. **A.J.**
February 11, 2015

TQFT gets a lot of attention from mathematicians, but it's not what won Witten the respect of his fellow physicists. If I understand the history correctly, he was already famous by the time he started thinking about that stuff, for his work on 1/N expansions, on current algebra, on anomalies, on instantons, on chiral matter in supergravity, on positive energy in GR, and on SUSY breaking.

What has he worked on that has been experimentally verified?

He actually has worked on a few things which have been checked experimentally, but it's not what made him famous. People listen to him because he's done a lot to clarify the way people think about quantum field theories. It's too bad that he hasn't managed to predict any new resonances, but it's a bit blinkered to think that's the only worthwhile thing theoretical particle physicists can do. I'd say, for example, that Dirac's synthesis of Heisenberg & Schrodinger's work on quantum mechanics was far more important than his prediction of the positron. The former is critical for understanding quantum physics, whereas the latter was so dodgy that explaining it usually only confuses people who're trying to learn the subject.

20. **MathPhys**
    February 12, 2015

    He doesn't seem to be joining the current wholesale move of a lot of the string theory community into condensed matter.

    He's a wise man. But my point is that conformal field theories, which are the building blocks of string theory, have verified experimentally, on a theory by theory basis. These theories with predictions based on Virasoro algebra, affine Lie algebras, expectation values of vertex operators, etc, make physical sense.

21. **kashyap vasavada**
    February 12, 2015

    @MathPhys:
    Can you elaborate or give references for your statement about experimental verification?

22. **Thomas Larsson**
    February 12, 2015

    There are many experimentally realized system which behave like the Ising model or its cousins when they undergo second-order phase transitions. A monolayer of an inert gas on a graphite substrate is often quoted as a particularly clean system. Such systems were studied for many years before CFT – Ernst Ising got his PhD in 1925. It turned out, both empirically and by theoretical considerations, that similar statistical systems have identical and not just similar critical exponents, or completely different ones. This is called universality, and CFT yields an exhaustive classification of universality classes in 2D systems, and the RSOS models of Andrews-Baxter-Forrester gave concreate realizations of all classes as lattice models.

    This is absolutely wonderful work – basically the only experimentally verified theoretical discovery during my entire non-career – and I have argued for 25 years that BPZ deserve the next Nobel prize for this. However, from the statphys point of view it is also clear that this is not a ToE, not even in statphys. CFT explains universality in 2D (the string world sheet is two-dimensional), but it has nothing to say about the experimentally more interesting 3D case. And we know that universality is also present in 3D, empirically and theoretically (epsilon expansion), so one could ponder if the explanation could be similar to 2D.

23. **MathPhys**
    February 14, 2015

    The experiments that I know of were performed at the U of Washington, Seattle, in the early 80's. Theorists who were involved in the analysis of the results usually included M Schick. The critical exponents that were measured were non canonical, hence non trivial, and always agreed precisely with predictions based on 2D conformal field theories, which indeed came right after.

    I only wish to say that the mathematics of string theory, that is the Virasoro algebra with a central extension, vertex operator algebras, etc, is more than recreational mathematics, and more than an abstraction in a platonic plane. It makes non trivial predictions that can be measured experimentally.

    The fact that this mathematics is not sufficient to lead to a theory of everything is a different matter.

Short Items, and a Quick Book Review

February 13, 2015
Categories: Book Reviews, Multiverse Mania

- Peter Orland has a new blog, Ensnared in Vacuum, where he's writing about some non-perturbative QFT questions.
- Physics Today this month has book reviews of two books about theology and the multiverse (one of which I wrote about here). There was a time when I would have thought that discussions of theology wouldn't be what Physics Today covers, but evidently that's no longer the case.
- On a related topic, Kate Becker at The Nature of Reality has an article entitled Does Science Need Falsifiability? It's about the campaign by physicists like Sean Carroll and Lenny Susskind against the Popperazi who keep pointing out that giving up on falsifiability puts physics in danger of becoming, well, theology. Frank Wilczek has a very sensible take on the subject:

  > "I think falsifiability is not a perfect criterion, but it's much less pernicious than what's being served up by the 'post-empirical' faction," says Frank Wilczek, a physicist at MIT. "Falsifiability is too impatient, in some sense," putting immediate demands on theories that are not yet mature enough to meet them. "It's an important discipline, but if it is applied too rigorously and too early, it can be stifling."

  On Twitter, the usually mild-mannered Wilczek makes clear his feeling about this

  > Not often I refer to a "pernicious" "faction", but appropriate here.

  Mysteriously, he has a new website, for a company "Wolfcub Vision, Inc".

- Frank Close has a new book out, Half-Life, which is essentially a biography of the physicist Bruno Pontecorvo. It's also a gripping spy story, investigating the question of exactly why Pontecorvo fled with his family to the Soviet Union in 1950. There's no smoking gun found, but all the evidence Close lays out makes the case that it is quite likely that Pontecorvo had been spying for the Soviets, fleeing when warned that he was in danger of being exposed.

  Freeman Dyson has a much better review of the book in the New York Review of Books than I could ever write. He argues that Pontecorvo made a mistake by fleeing to enforced isolation in Russia, that in the worst case if caught he would have spent a few years in jail, then could have resumed his career. That things would go this way would not however have been clear to Pontecorvo: the Rosenbergs were arrested just before he fled, and things didn't work out so well for them.

  Besides the fascinating spy story, there's also a lot of history of nuclear physics during the 30s, 40s and 50s, much of which I wasn't aware of, as well as quite a bit about Pontecorvo's later work on neutrinos. If you're interested in the history of 20th century physics, this is something you'll find well worth reading.

Update: For another new book, Steven Weinberg's To Explain the World, I fear that I don't have the time to read it and write a review. However, here are two interesting reviews, pro and con.

Update: For two hints about "Wolfcub Vision", a commenter points out that Wolf cub=Wilczek in Polish, and a correspondent points me here.

Update: David Mumford has a posting Is it Art? at his blog, motivated by my friend Dan Rockmore's equations project. An article about the recent panel discussion of this at Yale is here.

Comments

1. **Peter Orland**
   February 13, 2015

   Hi Peter,

   Thanks for letting people know.

2. **Brandon B**
   February 13, 2015

   I'm confused, maybe ignorant, but what is Wilczek implying?

3. **Peter Woit**
   February 13, 2015

   My guess is that Wilczek is just expressing the same opinion as most scientists hold towards those who, like Carroll and Dawid for instance, are trying to claim that their favored theories are still science even if unfalsifiable: they're a minority (a "faction") and they're doing something blameworthy ("pernicious").

4. **martibal**
   February 14, 2015

   A bit off-topic but since the post is also about history of physics: I do not know if you have heard of that, but in Italy there is some "official announcement" (from a prosecutor – "procuratore" in Italian) that Majorana was alive after he disappeared, and was in Venezuela between 1955 and 1959. The elements do not seem so convincing at first sight (a postcard, a "physionometric" analysis of a picture) but enough for a prosecutor to make this claim.

5. **Krzysztof**
   February 14, 2015

   Wilczek means in Polish a wolf cub…

6. **Mesa**
   February 14, 2015

   So, the falsifiability argument is really about theories with different confidence intervals. Tight confidence intervals tend to come from the ability to do repeated, controlled experiments. There are plenty of interesting questions out there where you might want to develop theories but have very limited data and no ability to do repeated, controlled experiments. Climate studies, macro-economics, Planck-scale physics and cosmology are among them. It's fine to develop theories (or really hypotheses) in these disciplines that explain whatever data you do have, but the extreme limitations of such an enterprise need to be understood from the beginning. Lumping activities with wildly varying experimental confidence intervals and ability to do controlled experiments together all as "doing science" is where the trouble begins. They are really different categories of activities. The famous puzzle of the man hanging from a noose in his house with a puddle of water under him is a good example. N=1; can't do the experiment again. Plenty of interesting hypotheses. The smartest guy in the room comes up with the ice block hypothesis. It's elegant and explains the limited facts. Is it "true"? We will never know. Is it worth working on more elegant explanations for these kinds of puzzles? That is a matter of personal taste and available resources. Perhaps the work itself will help techniques that lead to solutions to other puzzles with more verifiable solutions.

7. **Peter Woit**
   February 14, 2015

   Mesa,
   I don't think that's the problem here, what you refer to is a conventional well-understood issue that never led to people arguing that falsifiability should be abandoned. The motivation of people like Carroll, Susskind, Dawid who are now arguing against falsifiability is very clear: they have specific untestable theories that they want to promote, of exactly the sort of thing that conventionally are not considered to be science, and that Popper's criterion was specifically designed to rule out as pseudo-science (multiverse explanations of the arrow of time for Carroll, multiverse explanation of why string theory says nothing about particle physics for Susskind, lack of any predictions by string theory for Dawid).

   Most physicists immediately see where this kind of argument leads and want nothing to do with it. What's amazing is how much traction those pushing this have gotten despite this.

8. **Ian Welland**
   February 14, 2015

   Well Wilzcek has an office at Arizona State University's biophysics floor right down the hall from mine, so that should give a hint as to what he's been up to. Maybe if I work up the courage I'll ask him, I see him wandering about from time to time.

9. **paddy**
   February 14, 2015

   I must object to Mesa's implied inclusion of climatologists (and even economists) in Carroll's looking glass world. I suggest he review what empiricism means.

10. **Mesa**
    February 14, 2015

    PW

    I think we a largely in agreement here. I am just pointing out that there are large swaths of this activity going on in other spheres as well, and these activities should be regarded as different in type from normal science. Whether they are worth doing or not can be debated, but it should be clear they shouldn't be the main line of inquiry. To me, lack of falsifiability is the same thing as small number of observations . Non repeatable small number of observation problems can't really be solved with any confidence, just discussed. However, that may not mean that they are not worth discussing.

    paddy

    I lumped together a group of activities where the data was limited (one way for data to be limited is to have only one history, ie small number of observations) and controlled experiments were not possible. Both climate science and macro-economics fit that description exactly, as well being highly complex systems too boot. I did not claim there was no data. One way to easily identify these types of fields is that there is a lot of emotional debate about fundamental issues, even among skilled practitioners. Again, macro-economics and climatology fit that description exactly. The debates then turn to arguments over extremely simplistic models and politics.

11. **Visitor**
    February 15, 2015

    " He argues that […] in the worst case if caught he would have spent a few years in jail, then could have resumed his career. That things would go this way would not however have been clear to Pontecorvo: the Rosenbergs were arrested just before he fled, and things didn't work out so well for them."

    As the Rosenbergs were executed after Pontecorvo fled to Russia, it is difficult to understand how their execution could have effected his decision to flee.

12. **Peter Woit**
    February 15, 2015

    Visitor,
    My point was that Pontecorvo had no reason to believe that the worst-case scenario if he stayed was a few years in prison for him. The later execution of Rosenberg and his wife shows that he quite rationally could have been worried about this. I don't know if it was known soon after Rosenberg's arrest that he would be charged with crimes carrying a death penalty, but it's possible that was the case.

13. **sm**
    February 15, 2015

    The 'con' review of Weinberg's new book erroneously states (unfortunately, before the pay wall where it can be seen):

    "As his active involvement in research declined, he has become a prolific contributor to what's called the "public understanding of science" "

    The reviewer clearly has little or no idea of Weinberg's recent research. Off the cuff, in the last 10 years Weinberg has made important research contributions to cosmology (and in the process written what could be the standard monograph in the subject), the interpretation of quantum mechanics, and particle physics (conformal symmetry). Indeed, in the last year or so he even pointed out that contrary to reasoning of one of his illustrious former colleagues, accepted by almost everyone, tetraquark states may indeed be 'visible at leading order in 1/N. I would guess > 99% of theorists would be happy to have Weinberg's research in the last ten years as their career achievement!

    Not that Weinberg really needs any defending here. We know he is in the same league as Bethe when it comes to research longevity. What boggles the mind is that a journalist could have the nerve to make such a judgement. In Weinberg's case it may have more than a little to do with the fact he seems, according to the journalist, to critically assess the received wisdom of Enlightenment 101!

    Dirac sometimes suffers similarly, with the ill-informed jibe 'he did little after the 1930s' or something to that effect.

14. **Too Distinguished**
    February 17, 2015

"Our current best understanding of science shows no evidence for a multiverse, so anyone who wants to posit one needs to come up with some significant evidence for one, experimental or theoretical, and I haven't seen that happening. … the question of multiple universes is well worth ignoring…"

It seems to me that significant theoretical arguments for the multiverse do exist, which is why you aren't ignoring them.

15. **Peter Woit**
    February 17, 2015

    Too distinguished,
    I'll just point out that you changed my "significant evidence" to "significant theoretical arguments" which is a different thing…

16. **Anonymous**
    February 17, 2015

    Frequently repeated is not the same thing as significant. Outside of a fairly small enclave (largely consisting of those with a vested interest), these arguments are seen as a total joke.

The Singular Universe and the Reality of Time

February 14, 2015
Categories: Book Reviews

Lee Smolin has a new book out last month, co-written with philosopher Roberto Unger, entitled The Singular Universe and the Reality of Time. To get some idea of what he's up to, there's a review by Bryan Appleyard at The Sunday Times (non paywalled version here), another Bryan Appleyard piece here, and interviews with John Horgan and at Scientia Salon. In other news about Smolin, he's one of the winners of this year's first Buchalter Prize in cosmology.

The book is written in a rather unusual style, with the first two thirds or so by Unger, the rest a shorter contribution from Smolin, together with a section discussing where they disagree. It's neither a popular science book, nor a technical work of philosophy, but something somewhere in between, best perhaps compared to something one rarely now sees, a work of "Natural Philosophy". I found the long section by Unger rather hard going and not very rewarding, and realized that I have a fundamental problem with this sort of writing. Arguments about physics and mathematics made in natural language leave me often unable to figure out exactly what is being claimed. Sometimes this is because I'm not familiar enough with a philosphical tradition being invoked and its associated use of terms, sometimes I suspect it's because natural language is just too imprecise and ambiguous.

The Smolin section is shorter and written with more precision, making it easier to get an idea of what he's trying to claim. To seriously address all his arguments would be a large project I'm not able to undertake, but here is a list of "hypotheses" or "principles" that he arrives at:

- The uniqueness of the universe.
- The reality of time.
- Mathematics as the study of evoked relationships, inspired by observations of nature.

For the first of these I don't really disagree. Smolin takes this as an hypothesis of no "multiverse", an hypothesis that science may be able to confirm or disconfirm. Our current best understanding of science shows no evidence for a multiverse, so anyone who wants to posit one needs to come up with some significant evidence for one, experimental or theoretical, and I haven't seen that happening. It's entirely possible that a compelling theory may emerge that naturally implies a multiverse, but that's not currently the case. Unlike Smolin, I wouldn't take this as an hypothesis, more just would say that the question of multiple universes is well worth ignoring until someone comes up with a good reason to pay attention.

For the second, one problem is that I'm not exactly sure what it means. I guess that when I hear the word "real" I'm always rather suspicious that a meaningless distinction is being invoked (i.e. is the wave-function "real"?), and start trying to remember what it was I once understood about ontological commitments from reading Quine long ago. Part of what Smolin is referring to I think I'm sympathetic with: the nature of time remains mysterious in a way that space isn't. While relativity treats them on an equal footing, in quantum theory this is not so clear. My suspicions about this mystery though tend to focus on the analytic continuation between Minkowski and Euclidean signature, which I'd guess is quite different than Smolin's concerns (see hypothesis three…)

What Smolin seems to have in mind here is the hypothesis that physical laws are not "timeless", but can evolve in time, with an example the ideas about "Cosmological Natural Selection" he has worked on. One problem with this is that the question then becomes "what law describes the evolution of physical laws?", with an answer re-introducing "timeless" laws. Smolin refer to this as the "meta-law dilemma" and devotes a chapter to it, but I don't think he has a convincing solution.

On the third hypothesis, about the nature of mathematics and its relationship to physics, I just fundamentally and radically disagree. For a shorter version of Smolin's argument, see this essay, which he has recently submitted to the FQXI essay contest. I've been writing something about how I see the topic, will blog about it here very soon. What I'm writing isn't a response to Smolin's arguments, but a positive argument for the unity of math and physics at the deepest level.

My problems with Smolin's point of view aren't especially about his arguments concerning Platonism and whether mathematical objects are "real" (see earlier comments about what's "real"), they're about arguments like this one, where he argues that the explanation for the "unreasonable effectiveness of mathematics" in physics is not some deep unity, but just

> mathematics is a powerful tool for modelling data and discovering approximate and ultimately temporary regularities which emerge from large amalgamations of elementary unique events.

The argument essentially is that mathematics is nothing more than a calculational tool that just happens to be useful sometimes in physics. This is a common opinion among physicists, and a big problem for me is that here Smolin is not taking a provocative minority point of view, but just reinforcing the strong recent intellectual trend amongst the majority of physicists that the "trouble with physics" is too much mathematics. As I've often pointed out, the failures of recent theoretical physics are failures of a wrong physical idea, rather than due to too much mathematics, with the multiverse just an endpoint of where you end up if you throw away all non-trivial mathematical structure in pursuit of a bad idea.

In his essay, Smolin gives a discussion of mathematics itself which I think few mathematicians would recognize, defining it as "the study of systems of evoked relationships inspired by observations of nature", and consisting in bulk just of elaborations of the concepts of number, geometry, algebra and logic. I started my career in physics departments, and I'm well aware of how mathematics looks from that perspective (even if you have a lot of interest in math, like I did). My experience of moving to work in math departments made clear to me that the typical ideas of physicists about what mathematics is and what mathematicians do are highly naive, with Smolin's a good example.

I'll end with just one example of what I see is wrong about the conventional physics view that Smolin represents. A big application of mathematics to physics is the use of the rotation group SO(3). In that case it's true that many of the applications can be thought of as concerning approximate aspects of complicated physical systems, and derived from working out precisely the implications of our experience dealing with the 3d physical world. But, besides the chapter on angular momentum operators (and thus SO(3) representation theory) in every quantum mechanics textbook, there's an earlier chapter where the Heisenberg commutation relations are given as fundamental postulates of the theory. A concise way of stating this postulate is that quantization is based on a specific unitary representation of a Lie algebra (the Heisenberg Lie algebra). This is not approximate, but the fundamental definition of what we mean by quantum theory. The structure here is very deep mathematics (appearing for instance in number theory, the theory of theta functions and of Abelian varieties), and is far removed from the kinds of mathematics that one runs into as typical approximate calculational tools when studying physical problems. This is just an example, but there are many others. I don't think that if you look at them you can sustain the argument that deep mathematics and deep physics are not close cousins with a unity we only partially understand.

Anyway, more detail to come about this…

Comments

1. **al**
   February 15, 2015

   " is the wave-function "real"? " of course it is but probabilities are not.
   A (verbal) description might look as if it is complete without being so, e.g. Russell's barber; in the real world you go there and check if the barber shaves himself.

Einstein's positivistic ghost is still much too "real".

2. **Peter Morgan**
February 15, 2015

Given that any set of formal rules could be chosen, and the consequences within that set of formal rules worked through, and called mathematics, then the question would seem to be how we decide which sets of formal rules are "interesting". Additionally, physicists seem often happy to work with a mixture of formal rules and slightly less formal rules, what perhaps might be called "engineering" rules and related to what Lakatos calls Bridge Principles.
Perhaps mathematics should be thought of as something other than or more than just formal rules, but if any set of formal rules is a putative mathematics (which I take to be a large set, and that people over millenia have tried many possibilities), from which we choose whichever sets of formal rules prove to be interesting, or, if we are physicists, "useful" with a judicious addition of engineering rules, then it would seem that evolution would ensure that mathematics will be effective.
I have repeatedly thought that I might put this into an FQXi contest entry, but I have no wish to read the literature I would have to read to put this in academic context, and anyway I don't much care whether this is what mathematics is or not. Tautology is wonderful: insofar as it continues to be useful, we will continue using it.

3. **Cormac O'Raifeartaigh**
February 16, 2015

Hi Peter, the first Appleyard piece you cited is protected by a paywall. The second will probably sound very impressive to ST readers but is actually quite poor – the argument is terribly muddled by the fact that the author repeatedly conflates theories that are backed by strong empirical evidence with ones that are not. Indeed, the author seems something of cosmology skeptic, which is a different sort of argument

4. **Peter Woit**
February 16, 2015

Cormac,
The Sunday Times link is paywalled, but the next link is to the same text, available for free at Appleyard's site.

5. **raisonator**
February 17, 2015

"Part of what Smolin is referring to I think I'm sympathetic with: the nature of time remains mysterious in a way that space isn't."
I see this exactly the opposite way. Time comes from Von Neumann algebras, something that Alain Connes has been preaching for quite a while, but which has been little recognized, I guess.
But where does space come from? Everyone who pretends to know and claims that space is not so mysterious has to answer the question why it comes with three dimensions.

6. **Cormac O'Raifeartaigh**
February 17, 2015

Apologies Peter, I misread the sentence. However, I remain unconvinced by Appleyard's arguments, I think he's making a very different point to (say) Ellis and Silk, mainly because he hasn't really understood the material, what do you think?

7. **Peter Woit**
February 17, 2015

Cormac,
I haven't paid much attention to Appleyard's views, but I seem to generally disagree with his point of view. For instance, in the review he writes

"In the late 1980s, when physicists were insisting they were on the verge of a "theory of everything", I found myself using some of the arguments that now appear in this book — I was, primarily, suspicious of the claim that the universe was made of maths."

as you can see from my essay, my point of view is diametrically opposite.

8. **Nathalie**
February 17, 2015

"Difficult though it is, you should buy it and, whether you read it or not, look after it. This might be one of the most important books of our time. Or not. Right or wrong, like Thomas Piketty's Capital in the Twenty-First Century, it is an event." So says Appleyard.

I don't see why I should spend my time on reading wild speculations which don't lead anywhere. Wouldn't it be much better to follow instead the advice "shut up and calculate" and thereby perhaps have a chance to contribute to the advancement of real knowledge?

9. **fermi**
February 17, 2015

I disagree with Appleyard and Woit both, especially Appleyard. The discussion of whether Mathematics has (or should have) an unfair and undue influence on physical theories is irrelevant: We don't choose what's to be relevant, the Nature does! If we can learn more about Nature by learning more about Math, I say the more power to Math then.

If there was another (equally predictive) alternative to Math for forming theories of Nature, I'd welcome it. But I don't know what it is, if indeed such an alternative exists. The philosophy certainly does not cut it. Of course religion explains everything, but it predicts absolutely nothing, and it is useless for a Scientific theory. What else is left but Math that Physics can rely on?

10. **JSi**
February 18, 2015

Mathematics being "a […] tool for modelling data and discovering approximate and ultimately temporary regularities" automatically follows if one denies the platonic status of any laws of nature. That mathematics is a "powerful tool" is an acknowledgment.

The quote just says (1) what we see is temporary, including the laws, and that (2) we have only an approximate description of what we see, and that (3) mathematics is powerful for describing what we see. All these sound quite fair to me, and also ultimately empirical.

If nature is somehow simple, as it may be because a simple structure is more probable (on some bayesian or complexity theory sense), then a branch of research studying formal structures and aiming for generality easily has structures similar to nature. That the coincidences are sometimes surprising may be because our intuition does not quite grasp the entire thing we have built (mathematics), or its relationship with structures of nature. That the structures are beautiful has more to do with the aspirations of the mathematician than with anything outside.

SO(3) in quantum mechanics puts mathematics in a position more like a language. But of course the whole theory and all the concepts, including three dimensions, invariances implied by the Lie group, etc., may all be approximations. That we have an expressive and elegant language to define a theory still does not give the theory any metaphysical privileges.

(I haven't read Smolin's book, which is one reason I might be wrong. Also I'm not a mathematician or a physicist.)

11. **Anonyrat**
February 18, 2015

If I ask "why are coordinate systems unreasonably effective in enabling computations about the physical world?" virtually everybody would reply that coordinate systems are not real, they are constructs we impose to enable measurement and calculation.

The relationship between mathematics and physics may be like that of coordinates to measurement and calculation.

12. **Bob Finney**
February 21, 2015

Roberto Unger also submitted an essay in the FQXI contest. Some of his observations are pertinent to this discussion.

"According to the first family of ideas, mathematics is discovery. It is the progressive (or recollected) discovery of truths that exist in a domain of mathematical facts uncomplicated by the vicissitudes and variations of the manifest world.

According to the second family of ideas, mathematics is invention: the free development of a series of conventions of quantitative and spatial reasoning. This conventional practice of analysis maybe rule-guided or even rule bound, but the rules themselves are inventions. There is no closed list of motives for this inventive practice. Some have little or nothing to do with the deployment of mathematical analysis in natural science. Others take this deployment as their goal." – Unger

Unger's central point:
"Mathematics is an understanding of nature emptying it out of particularity and temporality: a view of nature without either individual phenomena or time. It empties nature out of them to better focus on one aspect of reality: the recurrence of certain ways in which pieces of the world connect with other pieces. Its subject matter are the structured wholes and bundles of relations that outside mathematics we see embodied only in the time-bound particulars of the manifest world"

As a committed Platonist his essay has given me much to think about.

13. **Gva**
February 27, 2015

Smolin's writing on the subject of the "reality" of time rubs me the wrong way. There's an unnervingly moralizing tone to a lot of it that recalls creationists railing about the theory evolution damaging public virtue (other even less savory parallels come to mind). That this tone starts creeping into his work around the time he joins FQXi hardly calms my nerves.

Nebulous concerns about the effect that concepts in fundamental physics might have on society at large should be regarded as out of bounds in an intellectually honest debate, as it's ludicrously parochial to expect nature to shape itself to conform to human preferences.

Towards a Grand Unified Theory of Mathematics and Physics

February 14, 2015
Categories: Uncategorized

A draft of an essay I've written, with plans to submit it to the FQXI essay contest, is available here. Constructive comments welcome…

People who have a take on the subject that has nothing to do with what I'm writing about are encouraged to submit their own essays to FQXI, but not to post them here.

Update: Thanks to all commenters for often helpful comments. I've revised the essay a bit, mostly by adding some material at the end, material that to some extent addresses important issues raised by some commenters.

Update: The essay has been submitted and is posted here.

Comments

1. **Joel Rice**
   February 14, 2015

   Nice essay. But I don't see what is so geometrical about the CKM mixing, and suspect that it is Perfectly Reasonable Effectiveness of Mathematics.

2. **Anderson**
   February 14, 2015

   I don't know, but I always felt that saying "it seems unreasonable that mathematics, which is a creation of the human mind, should be effective in understanding the world" is kind of the same as a bird saying "it seems unreasonable that my wings, which were created by my body, should be effective in helping me navigate through space"

3. **Jeff M**
   February 14, 2015

   I've never understood why anyone thinks mathematics being effective is surprising. I mean, basic math is the real world. Animals count. When my dog is chasing a rabbit, it's doing all sorts of fancy computations, but it's just nature. Same as when I'm catching a baseball. No one says "wow, how surprising, English (or fill in your favorite other language) is so surprisingly effective at describing the real world." Math is a language. It's got more uncompromising rules, but still.

4. **CIP**
   February 14, 2015

   Peter,

   I like the way you showed how the development of mathematics and physics since Wigner has continued develop new and more powerful links between them – but I doubt that Wigner would have been surprised. I'm not sure though, that the aspired to unification is any closer than it was in Newton's day.

   Mathematics continues to proliferate worlds in in endless profusion, but physics (I hope) still seems to be pretty singular, despite the MW movement.

   PS – Since you referenced it, I looked at your QT, Groups, and Representations book. The part I read looks very promising, and a nicely chosen level. Publication date?

5. **Garrett**
   February 14, 2015

   That's an excellent piece. It could, though, use a minor copyedit–mostly some minor wording adjustments and a sprinkling of commas. You might also add to the abstract the point you are making that not only has mathematics been "surprisingly" useful in describing nature, but that advances in our description of nature have been "surprisingly" leading to new and deep mathematics. If I were to add something else, it would be that the success of mathematics, and specifically the ubiquity of Lie groups, representation theory, and differential geometry, in our description of nature strongly suggests that our world is, fundamentally, some rich and beautiful mathematical structure, come to life.

6. **Peter Woit**
   February 14, 2015

   Thanks Garrett!

   CIP,
   Thanks! I'm working on the last half of the book this semester while teaching a course based on this, hope is to have something fairly complete by the end of the semester in May. For a completely finished product, sometime next year…

7. **Metatron**
   February 15, 2015

   @Anderson and Jeff M

   The mathematics at hand is far from basic mathematics. For example, Einstein's theory of General Relativity makes use of Riemann's mathematical creation, differential geometry. I'm pretty certain in 1853, when Gauss asked Riemann to prepare a Habilitationsschrift thesis on non-Euclidean geometry, nobody could foresee higher dimensional differential geometry being applied in 1907 by Einstein to describe gravity as curvature in a four-dimensional spacetime. Moreover, the theory of Riemann surfaces is central to the study of worldsheet dynamics in string theory, a theory of quantum gravity. And let's not get started on Riemann's celebrated zeta function, as its generalization, L-functions play a pivotal role in the theory of Motives, which arises in the Langland's program.

8. **Marc Nardmann**
   February 15, 2015

   I would argue that the "intriguing pattern of U(1) hypercharges" (§4.2) is to a large extent understood: Instead of formulating the Standard Model with the group U(1) x

SU(2) x SU(3), one should — essentially equivalently — use S(U(2) x U(3)), which has U(1) x SU(2) x SU(3) as a sixfold covering. This reveals that the Standard Model fermion representation has a rather simple form: It is the direct sum of two parts, each of which is the restriction of a representation of the identity component of Spin(3,1) x U(2) x U(3). The first part is the tensor product of [A] the right-handed Dirac representation of the identity component of Spin(3,1); [B] the representation Lambda^even of U(2) on the exterior product Lambda^even(W), where W = C^2 is a 2-dimensional unitary complex vector space corresponding to weak interactions; [C] the representation Lambda^odd of U(3) on the exterior product Lambda^odd(S), where S = C^3 is a 3-dimensional unitary complex vector space corresponding to strong interactions; and [D] the trivial representation on a 3-dimensional unitary complex vector space C^3 corresponding to particle generations. The second part is the same up to replacing the right-handed with the left-handed Dirac representation and replacing the representation Lambda^even of U(2) with Lambda^odd.

This description encodes in particular the U(1) hypercharges. It is not mysterious that Lambda^odd(S) occurs here instead of Lambda^even(S): switching between these two exchanges particles with antiparticles. But the fact that the representation Lambda^* of U(2) — which has no obvious geometric origin — is coupled with the — clearly geometric — Dirac representation hints at a geometric origin at least of the weak interaction. In this sense I agree that we are indeed "missing some piece of geometrical structure", as you (PW) write. But while we do not yet have a good explanation of the Standard Model fermion representation, we should not make things even more mysterious than they are by expressing them in terms of U(1) x SU(2) x SU(3) instead of S(U(2) x U(3)).

By the way: "Wigners" -> "Wigner's", "solutons" -> "solutions", "or details" -> "for details".

9. **rfp**
February 15, 2015

great essay! Minor typo: in second bullet of Sec 8, it should be "for details" (not "or details").

10. **TonyK**
February 15, 2015

Also "underly" and "solutons".

11. **al**
February 15, 2015

Ivor Grattan-Guinness (who passed away last december) wrote in 2008 a paper that I would like to see quoted just as often as Wigner's essay:

Grattan-Guinness, I., "Solving Wigner's mystery: the reasonable (though perhaps limited) effectiveness of mathematics in the natural sciences." The mathematical intelligencer 30.3 (2008): 7-17.

12. **andrew**
February 15, 2015

how similar is wigner's thought concerning the "unreasonable effectiveness of mathematics" to putnam's no-miracles argument for scientifc realism? putnam thought that if theories weren't "real," confirmation of their novel predictions was miraclulous.

13. **Paul Levy**
February 15, 2015

While this article is far more coherent and persuasive than Lee Smolin's, it has one glaring weakness in common with Smolin's – it doesn't anywhere say what mathematics is. I don't think it's tenable to argue for a "grand unified theory of mathematics and physics" unless you answer this question.
For background, I'm a mathematician with a recreational interest in the philosophy of the subject. I read Wigner's article some time ago and wasn't particularly convinced by it, not least because the same wonder he feels about applications of mathematics to physics is often felt by mathematicians about applications of one field of mathematics to another – but this sense of wonder doesn't stop Platonism from being an obsolete philosophical framework.
As a specific comment, I think the quote you give from Frenkel about the Langlands programme is hyperbole. (However, I see the book can be downloaded online, so perhaps I'll be convinced by it…)

14. **Martin**
February 15, 2015

Einstein's starting point for the general theory was the equivalence principle:

http://en.wikipedia.org/wiki/Equivalence_principle

heavy mass is inertial mass.

Einstein thus tried to formulate a theory in which this distinction is not made anymore. Only after that did the mathematics come into view.

Another thing is that physical models are only effective, and thus not everyting derived mathematically from a useful model is necessarily true. See vacuum fluctuations. The idea that the vector potential A can be thought of as being a connection field only came after the Maxwell equations had been formulated, and these derived from the older descriptions of electricity and magnetism. Maxwell's idea to include the displacement current D was a physical insight.

The idea that mathematics can lift the veil of Nature in a post-empiricist manner is a form of Idealism.

15. **PFD**
February 15, 2015

One last typo (because the devil is in the details): " (…) it's difficult to impossible to predict (…)". Difficult or impossible? 😉
Also "it's" -> "it is"

Thanks for sharing. Good luck.

16. **JG**
February 15, 2015

I liked your essay, it is a bold suggestion that String Theory could be replaced one day by mathematical structures coming from ideas in the Langlands program.

I wonder how you decide what type of mathematics is going to be useful for describing nature – for example, is a rigorous measure theoretic Hilbert Space formulation of QM required? If not, why is measure theory not as applicable as, for example, number theory?

17. **Peter Woit**
February 15, 2015

Thanks to all who pointed out typos, those at least are fixed.

JG (and others),
I'm not making an argument that one can just look to mathematics to decide how to describe nature. One needs to first look at our empirically most successful theories (e.g. the SM and general relativity), and then try and understand, amongst the many ways of mathematically formalizing them, which of these ways relates them to the deepest known mathematical structures. If there really is a unity there, the known connections between successful physical ideas and successful mathematical ideas will suggest other such connections worth looking into. This may lead to progress, on either the mathematical or physics end.

18. **Peter Woit**
February 15, 2015

Paul Levy,

Yes, the unreasonable and unexpected effectiveness of one field of mathematics in another is common and I'd argue sometimes evidence for unity in mathematics that we don't yet understand. The argument for unity with fundamental physics is an argument that there is something going on here at the deepest levels that we don't understand, and from that point of view we likely don't yet know the correct best definition of "mathematics". There are lots of definitions one can now come up with for "mathematics", from looking at what mathematicians do and coming up with some generality that covers it all, but I don't think that leads to anything particularly interesting or truly gets to the heart of what the deepest mathematical ideas are telling us about.

19. **hopffiber**
February 15, 2015

A bit funny, but totally unsurprising I guess, how you write about all these nice subjects and ideas and totally avoid mentioning the words string theory even once, despite it being so intimately connected both to the geometric Langlands and the (2,0) theory. It's ok I guess, but somehow feels a bit bordering on intellectual dishonesty: string theory is really quite an important part of how people came to these ideas, so my advice would be to add a bit about how the Langlands duality is really a S-duality of string theory, how (2,0) is the world-volume theory of M5 branes and so on. Of course that would go totally against the narrative this blog is trying to sell, so as I said, it's really not surprising.

20. **Peter Woit**
February 15, 2015

hopffiber,
I don't see how adding discussion of the complicated story of often heavily over-hyped claims about string theory and the Langlands program would add anything worthwhile to the essay. If you want to discuss the ideas that are in the essay, that's fine, but if you or others just want to argue about "string theory", you'll have to find another posting where it's relevant.

21. **tomate**
February 15, 2015

I think the essay has lots of problems and it has no chance to win the contest:
– It's obviously written in a great hurry
– Very low-profile, but if that's your style that's OK
– There is no effort in being pedagogical, soon you go into rings and Lie groups, bundles and whatever. A basic understanding of what kind of physics is going on is completely missing.

My suggestion is, if you are serious about this, you should try to tell a story that people smart enough and with a background in physics, but not your own field, should be able to follow. Nevertheless, I do agree on the general ideas. For some quite different thoughts on the connection between mathematics and physics, you might want to take a look at the words of V.I. Arnold,

http://pauli.uni-muenster.de/~munsteg/arnold.html

Typos: "underly"!!!, "Milss"

22. **Peter Woit**
February 15, 2015

tomate,
Thanks. Actually I did put quite a bit of time into thinking about the essay, wrote a couple initial versions that I discarded as being unworkable. It is true that I put very little time into proof-reading, thanks to you and others for helping me there.

The main problem with the initial versions is that I started out trying to explain in detail more of the mathematics and physics, but then realized that I was starting to write something that would be at least 90 pages, not 9. To really explain Weil's use of the Heisenberg algebra and the adelic point of view on theta functions, what an automorphic representation is, topological quantum field theory, etc., etc. is a major project. The rules of the contest say you can add a page or two of technical material, but that wouldn't help significantly. So, I finally decided the best I could do was just lay out in the space given an outline of the ideas I'm referring to. Some experts will recognize what I'm talking about, others I hope will find something intriguing that encourages them to go out and learn more (I should try and find some more, better expository references). Trying to write about these topics without referring to rings or Lie groups, or that level of basic tools in mathematical physics I don't think is really possible without producing something content-free.

In any case, trying to win a contest is not why I decided to do this. This was just a good opportunity to put together these thoughts and get something written that perhaps others will find of interest.

23. **Mayer A. Landau**
February 15, 2015

In the bibliography, the publication date for Clifford Algebras and Lie Theory by Meinrenken is 2013 not 2003.

24. **Qwertz**
February 16, 2015

Refs. 1,2: bold type goes too far.
Refs. 2,4,8: "Birkhauser" -> "Birkhäuser".

Ref. 5: “A., and” -> “A. and”, comma after “Program” missing.
Ref. 14: “Grassmanians” -> “Grassmannians”, “curves.” -> “curves,”, “113(1982)” -> “113 (1988)”.
Ref. 15: “3(1988)” -> “117 (1988)”.
Ref. 16: Comma after “E.” missing.

25. **Art**
February 16, 2015

Maybe add a ref for Atiyah and Singer? and some discrimination of your conclusion from the MUH? You cover a lot of ground…

26. **lun**
February 16, 2015

One comment:

I think the relationship between mathematics and physics is more of an N to 1 correspondence than “unity”. It is true that the laws of physics are elegantly encoded in formal structures provided by mathematics (a school of mathematics known as constructivism posits this is in a sense a tautology because
we construct such formal structures in terms of what we know).
However, at least as far as we know, most formal structures thought up by mathematicians, or even theoretical physicists, have nothing whatsoever to do with the real world, and assuming they do because they are formal could mean a false lead.
For instance, in the speculation section of your paper you mention six-dimensional superconforman N=(2,0), which is indeed being studied for its formal properties. But I never saw any hint that such a theory has anything to do with the real world.
Likewise, the objects being touted as being relevant to the number theory connections you mention in section 6 are nothing like realistic quantum field theories, for pretty fundamental reasons.

Perhaps this way of thinking is too superficial and reductive, but on the other hand perhaps there are good reasons why such theories are unrealistic, and focusing on their “elegant properties” connected to mathematics will make us miss them: In the 19th century the leading minds of mathematics studied potential inviscid flow without asking themselves why this tended to be such a poor model for “real” fluids, especially low viscosity ones where such methods should apply best, because potential flow was so elegant and so connected to vector calculus. It turns out that real fluids are much more elegant and complicated and fascinating, for reasons that you would never understand focusing on potential flow.

27. **Peter Woit**
February 16, 2015

Mayer A. Landau, Qwertz, Art,

Thanks, typos fixed, some references added. Not sure whether it’s worth trying to refer to other points of view and draw distinctions, that’s a long story. For the MUH, I’d say the difference is that it also posits an identity of math=physics, but that all mathematical structures are equally good. My interest is in the question of why certain very specific mathematical structures appear in this context.

lun,
Yes, there are lots of mathematical structures and one real world. But the evidence is that there are certain more fundamental structures, and the puzzle is that these show significant relations to fundamental physics. The example of the N=(0,2) 6d theory was given mainly to illustrate the fact that it is becoming widely accepted that we need new ways to define qfts (beyond picking fields and a Lagrangian). Finding new such techniques might give added insight into the fundamental physical theory.

28. **Radioactive**
February 16, 2015

I mostly agree with tomate, and your excuses will really not fly. A good essay makes advanced subjects feel accessible, this one doesn’t. And further the thesis seems to be: The mysteries in physics are linked to some even more mysterious mysteries in mathemathics. The smart mathematicians, without any physical insight; knowing any facts about nature, or doing experiments, thought or otherwise, will be able to solve it all for us. You attack string theory for much less.

29. **Peter Woit**
February 16, 2015

Radioactive,

I wish I could do better at explaining some of these concepts in a few pages, but am not so sure it’s possible. There is no royal road….

Most of what I’ve actually written here is a long list of examples of things we DO understand, linking deep ideas about fundamental mathematics and deep ideas about physics. Yes, I expect more of this to come, illuminating mysteries both of mathematics and physics. You’re very defensive and skeptical at the idea that help from mathematics will solve problems in physics, but I can assure you that the reaction of many of my mathematician colleagues about my views is to be equally defensive and skeptical about the idea that anything coming from this kind of physics will help solve problems in mathematics. Personally I believe information flow in either direction is about equally likely.

As for the idea that all physicists need is “physical insight”, I don’t think this has historically worked very well in the absence of any experimental results to provide data for physical insight to operate on. If nothing new turns up at the LHC, the problem of no data is going to be a very significant one going forward, and I don’t think physicists should refuse to consider that what mathematicians know might be of help. And, hey, even if that doesn’t work out, they might find themselves solving the Riemann hypothesis problem and getting a million dollars…

30. **Ben**
February 16, 2015

Peter,

Regarding the remarks of tomate and radioactive, anyone who seriously follows fundamental physics generally, rather than just a particular approach, will understand the main import of most of your essay, and can easily look up the details. Nor is it inappropriate for the context; an essay about exotic smoothness structures by Torsten Asselmeyer-Maluga in the 2012 contest was probably much steeper from the perspective of the typical non-expert, but was nevertheless one of the winners, and now appears as one of the chapters of the resulting Springer book.

A quibble I have is the generality implied by "mathematics." No one will argue against the centrality of number theory, geometry, and representation theory, but mathematics is vastly broader than that, and I don't think this approach has any unique claim to represent the essence of mathematics, or to pair it with physics in a way that is necessarily superior to other approaches. However, some degree of hyperbole in advertising shouldn't offend anyone.

Typos: group of \mathbf{F}_p, move commas and periods inside quotes (illogical, I know!)

31. **Paul Florijn**
February 17, 2015

Peter,

IMHO section 8 should have an additional point of the following kind:

\item (or \bullet) If an unusual space-time structure, such as quantum foam, occurs around the Planck length or some other very small length scale, completely new mathematical structures could appear in QFT.

32. **Als**
February 17, 2015

I think that you're overcomplicating things.

The reason there are so many links between current math/physics research is the probable existence of a "universal geometry" which is the true geometry of space-time and the source of all the geometries encountered by mathematicians. I expect Grothendieck's favorite toys (topos, motives) to play a significant role in its eventual discovery.

33. **Faustino**
February 17, 2015

You say: 'I wish I could do better at explaining some of these concepts in a few pages, but am not so sure it's possible. There is no royal road….'
So is it not possible for a not specialist to undertendimg anything about the question why it seems unreasonable that mathematics, which is a creation of the human mind, should be effective in understanding the world?

34. **Dom**
February 17, 2015

Faustino:
As a non-specialist in these areas I would say that analogies can only take you so far, sometimes off in the wrong direction – e.g. the Higgs Field/British Prime Minister moving through a room one.

35. **Maurice Carid**
February 17, 2015

Hi Peter,

From the contest guidelines:
"Foremost, the intellectual content of the essay must push forward understanding of the topic in a fresh way or with new perspective. While the essay may or may not constitute original research, if the core ideas are largely contained in published works, those works should be the author's. At the same time, the entry should differ substantially from any previously published piece by the author. "

What is new in your essay?
Isn't it meant to be a review?

36. **verruckte**
February 17, 2015

I've never been surprised at the effectiveness of mathematics in describing and predicting the 'real world', either. I take it that they both are a description, or reflection, or condensation, of the same thing. I imagine there is some kind of of 'Ur'-reality that is not accessible to us. That's not very useful I suppose from a technical aspect, but as a layman that's how I think of it.

37. **Peter Woit**
February 17, 2015

Ben,
I agree that what I'm writing about is just one particular aspect of mathematics, just as I'm also writing about just one particular aspect of physics (which I awkwardly call "fundamental", with no corresponding word for mathematics). In the case of both physics and mathematics, the great majority of the subject and the questions people are addressing aren't about "fundamentals", and that's a good thing. It's only because people think about specific "non-fundamental" problems and discover new phenomena in math and physics that we find out about unexpected ideas about fundamentals. Just sitting around thinking about fundamentals themselves is typically an activity that goes nowhere.

38. **Peter Woit**
February 17, 2015

Faustino,
I think non-specialists can certainly can understand the general picture I'm trying to advocate. Understanding the specifics of the aspects of quantum field theory and

number theory I'm writing about does just require a major investment in time, you're not going to understand these things by reading an 8 page popular essay.

39. **Peter Woit**
February 17, 2015

Maurice Carid,

One comment would be that no ideas are ever completely new, with just about every sensible thing anyone comes up with having appeared in some form earlier.

I think some of the ideas about the relationship of QFT and number theory are new (they're new to me, I didn't understand them a few years ago, and don't know anywhere else they're written down). There are very few details in what I wrote, I hope to write something with specifics later this year.

I suppose the "grand unified theory of math and physics" claim isn't new, since I get claims of that sort in my e-mail or mailbox every few days. But maybe a non-crackpot such claim would be new…

40. **Radioactive**
February 17, 2015

There may be no royal road to geometry, but someone who has been down it can usually give a brief travel guide. You have undoubtedly read John Baez's and Terrence Tao's writings on very advanced topics that are neither trivial nor alienating.

A flow of ideas from mathemathics to physics and vice versa is welcome and, dare I say, necessary. But historically significant breakthroughs have come from experimental results, or in the case of GR thought experimental, from thinkers with incredible insight into the physics and the mathemathics involved. The historical precedent makes me very skeptical that progress in physics will come from what is basically pure math, but of course doesn't preclude it. However there is no argument that there is a 'lack of experimental results' when there are exciting developments from Plank and others coming quite regularly. The pessimism generated by the LHC's failure to drown us in new particles is also quite misguided. Null results have had an important place in physics. It is the lack of new ideas in light of it that is most disappointing.

As for the unreasonable effectivness of mathemathics: in math, where ideas are generalised as much as possible and no more, it is not surprising to me that connections can be found between different broad categories. Nor that complicated objects (like gauge theories) may have different aspects illuminated more or less by looking at them in different lights, using different, possibly very complicated, mathematical tools.

41. **Peter Woit**
February 17, 2015

Radioactive,
Tao and Baez are great expositors, but I think you'll find that their expositions are great because they write at the necessary length. I had a 9 page limit, not 90, so was not doing exposition. If you want exposition, try the book I'm writing, which seriously tries to do that (although surely not as well as Tao or Baez). It's at 450 pages and more to come…

Sorry, but claims that all is fine with fundamental theoretical physics research because of "exciting developments from Plank and others coming quite regularly." is just hype. There's a reason for little to no progress beyond the standard model over the last 40 years, I don't think physicists are doing themselves any favors by being in denial about it.

42. **Toby Young**
February 18, 2015

Peter,

your essay looks like a winner to me, definitely in the spirit of past winners such as: It From Bit or Bit From It 2013.

Personally, I would have liked to have seen more on the extraordinary interplay in the 80s, starting with Instantons from QFT leading to Donaldson theory, Donaldson invariants, simplified using Seiberg–Witten gauge theory, but I loved what you put in all the same.

43. **Maurice Carid**
February 18, 2015

Peter:

> But maybe a non-crackpot such (Grand Unified) claim would be new…

Yeah, but this hasn't this claim already been made by Frenkel in the
quote of your paper? He calls it "grand unified theory
of mathematics" but he includes quantum field theory so
I guess he means the same?

> I think some of the ideas about the relationship of QFT and number theory are new

You mean the three sentences after Frenkel's quote dealing with
adele rings and the sentence
"In a hazy analogy…" further down the page?
I hold a PhD in physics but never heard about "adele rings". I just asked
a fellow mathematician and he said "yeah that's something from number
theory, but I'd had to look it up".
I fear this doesn't cut the following requirement from the contest guidelines:

"Accessible to a diverse, well-educated but non-specialist audience…"

What is new in your essay seems to be accessible only to specialists
in number theory.

44. **S**
February 18, 2015

Hi Peter,

I enjoyed the essay and look forward to its final form. One thing I would like to see better addressed is just what a "grand unifying theory of mathematics and physics" would even look like. Not in its specifics, but what such a beast even IS. For example, Tegmark might say that his "Multiverse IV" is just such a theory. I imagine you would not find it so, but I don't think your article is clear enough about what the words even mean to say why not (or, perhaps, why). It focuses mostly on specific mathematical and physical objects or theories.

Another question that comes to mind comes from the fact that mathematics is far larger than those things that turn out to be important in physics. SO(3) is an important Lie group in physics, for example; if SO(73) is, I'm not aware of it, but nobody would be too shocked if SO(73) turned out to have some at least moderately interesting mathematical properties (I'm thinking along the lines of 1729 / Ramanujan), or even to be really important in some far-future mathematical theory. Physics thus seems irreducibly more concrete, and any "grand unified theory" of physics and math seems (to me, right now) like it will have to fall quite a bit short of explaining a lot of interesting features of mathematics just by virtue of its being at most coequal with physics.

I also fear you may come close to dancing with a category error; but it's a speculative essay about a very interesting and fun thing to think about, one that might be fruitful, and it doesn't claim to be rigorous at all; so I think this is pretty forgivable.

Thanks for posting.

45. **verruckte**
February 18, 2015

One of the questions that I've always been fascinated with is : Is there 'more' in mathematics than in physics, in the following sense — Is there a mapping between everything provable in mathematics and some facet of the 'real' world of physical laws. Whether there is or is not such a mapping seems to me to be a key feature of a unified theory.
I don't know whether it would be more mysterious if there weren't such mapping or if there were, but either way it seems fundamental to me.

46. **Jim Beyer**
February 18, 2015

Interesting Essay.

FWIW, I am not a physicist or a mathematician and found many of the pronouncements descriptive and believable, but over my head. I don't really know what the target audience is for this, but how many outside the area really even know what a Lie Group is?

Two points of interest (to me anyway) arose from this essay. The first is the assertion that experimental evidence has been elusive for the past few decades, so we really need either mathematical path finding or perhaps, some GR-type "deep thinking" to get off the plateau we are stuck on. The essay seems to argue for the former.

Which brings me to my second point. I risk getting into the String Theory issue here, but isn't that precisely an example of mathematical path finding NOT working? Hasn't String Theory been driven/seduced by the beauty and elegance of the math? Even if one is more supportive of the String Theory issue, one can see the risk of exploring an area of mathematics in the hopes of furthering our understanding of physics, but which has nothing to do with how our world works or functions at all. String Theory has been wandering in a box canyon for 30+ years, due in some part to periodic revelations of mathematical elegance.

So, to me, the essay has pushed me to believe the next step forward will be from some kind of "deep thought" insight, like which Einstein achieved to give us GR. Maybe mathematics will get lucky, but there are obviously risks involved.

Finally, it would seem to be that mathematics is completely abstract but limited (by our own intellects) whereas the physical world is somewhat less abstract and likely somewhat less limited. So neither field encompasses the other. We seem to be near some kind of boundary that we can't quite surmount. My gut tells me the deep thinker will best the mathematical explorer.

I also couldn't figure out the HTML stuff…..

47. **Peter Woit**
February 18, 2015

Jim Beyer,

The "string theory is elegant math" claim is endlessly repeated by everyone, and it seems to be hopeless to get most people to understand the problem with it. "string theory" encompasses a wide range of different things, some of which are elegant math and some of which very much aren't. The efforts to use string theory to unify physics are now based on postulating an infinity of ugly possibilities, the antithesis of elegant math.

There's lots of elegant math that has no relationship to fundamental physics, I'm not arguing at all that one just needs to look for elegant math. One is looking for elegant math that has explanatory power about physics. The essay points out past examples of this in the past and argues there will be more in the future. String theory just isn't especially relevant.

48. **Aaron Sheldon**
February 18, 2015

There is a typo in the first sentence of section 8.

Overall a pleasant summary of very beautiful topic, the study of symmetries.

In the introduction it would be helpful to clarify the problem that is meant in the statement "grand unified theory of physics and mathematics".

Do you mean strictly looking for a theory that has both QM and GR as the limiting cases?

Or is this a more ambitious program of looking for a single theory from which the results of any experiment can be derived at least in principle?

The former being a reasonable expectation of mathematics and physics, while the latter might be fundamentally forbidden within the context of mathematical logic (i.e. could the latter goal be shown to be equivalent to the halting problem? If you had a theory that predicted everything then could it predict when any algorithm halts?).

49. **Radioactive**
February 19, 2015

So you think actual experiments like Planck/Bicep/LHC2 are just hype but some fuzzy hope that number theory is going to help with fundamental physics is a solid path?

I don't deny that there are some problems with fundamental theoretical physics research, part of the reason I left the field and the reason I read this blog, but not knowing enough math and paying too much attention to experimental results are not problems I ever observed. Quite the opposite in fact.

The essay is supposed to be about the surprising unity of math and physics but reads more like an essay on the surprising unity of math and math.

50. **Erik**
February 19, 2015

Dear Peter,

You might be interested in checking out this contribution to the essay contest: http://arxiv.org/pdf/1502.04794.pdf

51. **Yatima**
February 19, 2015

@Jim Beyer

"Finally, it would seem to be that mathematics is completely abstract but limited (by our own intellects) whereas the physical world is somewhat less abstract and likely somewhat less limited."

I would say it is the other way around. In Mathematics, you 1) Select objects that allow some form of arrangement 2) Posit invariants over these arrangements 3) Select a Logic (itself a subject and part of of Mathematics) 4) See where the Logic leads you, trying to steer clear of breakdowns (logical contradictions)

Given that humans explore the above structure, exploration is necessarily limited to symbolic computation by Turing machines. So far, this has not been an area of concern or we can work around the hang-ups nicely (Uncomputable number found? Just call it \Omega and press on)

The physical world seems to implement a particular structure that is amenable to explorations of the above kind. The universe can be described by a finite substructure of itself, which is nice! Why is this so and whether this description has some remarkable property (e.g. it may an "island in the space of consistent theories", not need any "arbitrary values" or may be the only use in need of some "highest order structure") are of course open questions.

I sure hope it has remarkable properties. Getting some arbitrary ooze out of all the work would be a let-down.

52. **Stuart**
February 19, 2015

Most mathematicians are of the opinion that deep down at the fundamental level of nature there is just numbers nothing else but numbers.This is totally mistaken since mathematics by definition is an empirical science. It born out of observations and experiments on reality. Differential geometry and its other forms are born from the properties of space-time. By making more profound studies of the physical properties of space-time new mathematics arises.This approach led Newton to discover calculus. If one on the other hand tries to start with abstract mathematics and hopes to explain reality one ends up with String Theory. A theory with no predictive power nor a connection with reality.

53. **Igor**
February 19, 2015

Stuart, can you cite a modern and respectable mathematician who expressed the view that "deep down at the fundamental level of nature there is just numbers nothing else but numbers"? Numbers are only elements of a very particular mathematical structure, that of a field, and there are much more algebraic structures which are richer our even prettier than "numbers". Why should nature be in a fundamental level a particular mathematical structure, be it a field or anything else? Also, you can construct alternative mathematics using alternative logic (fuzzy or quantum logics for example). What kind of mathematics is nature made off if any at all?

Now, the view that "mathematics by definition is an empirical science. It born out of observations and experiments on reality" is a very naive and simplistic one of mathematics. It may be true that historically mathematics grew out from empirical observations, but mathematical truth is completely independent from physical experiments, and you do not even need to be a platonist to see this. I do not think that Grothendieck ever needed directly an experimental result to produce any discovery in algebraic geometry.

54. **Igor**
February 19, 2015

This idea of a unified theory of mathematics and physics seem very presumptuous to me, to say the least. Even if a better understanding of the mathematical structure of the Standard Model, as discussed by Peter in his text, or of a theory of quantum gravity based on string theory, as defended by Michael Rio in his own essay (1502.04794v1), can produce new non-trivial applications of sophisticated pieces of mathematics, motivate new conjectures, new insights to the Langlands program &c., there will still exists many other mathematical theories outside such 'unification' that, nevertheless, mathematicians still regards as interesting. So is this a *really* unification of mathematics?

For example, the Greeks could very well consider the theory of statics of Archimedes as an unification of physics and mathematics (indeed, they not even separated physics, mathematics and philosophy at all), since it is an application of Euclidean geometry, which is basically the whole of Greek mathematics, to describe physical configurations.

I think that the most interesting part of Peter's essay is the relation of number theory and QFT, but which could very well be much more developed. Well, maybe in another opportunity!

PS: All this talk remembers me of Gregory W. Moore's http://www.physics.rutgers.edu/~gmoore/PhysicalMathematicsAndFuture.pdf

55. **Peter Woit**
February 19, 2015

Stuart,
"If one on the other hand tries to start with abstract mathematics and hopes to explain reality one ends up with String Theory."
You really can't blame string theory on the mathematicians. It was invented by physicists in the late sixties who had little interest in mathematics, pursued by physicists during the seventies and early eighties who had little interest in mathematics, became popular when someone influential decided it was a promising physical idea about unification (yes, he happens to also have done work with great mathematical significance), and string theory unification is now based on a physical idea (the landscape) which is completely mathematically empty.

Erik,

I saw that. It's a good example of what I don't have in mind: the idea that some piece of abstract mathematics applied to a conjectural framework with no known connection to fundamental physics is the way forward. I try to make clear that what I have in mind is mathematics applied to a deeper understanding of the specific QFT that has been successful. I don't think the idea that applying some abstract math will tell you what M-theory is and show how to do unification is at all a promising one. Lots of effort has gone in that direction in the last twenty years, with nothing to show for it.

Radioactive,
Actually, as far as telling us anything about fundamental physics (as opposed to dust), BICEP2 IS just hype. Despite the endless claims of the last ten years about how Planck data would tell us about fundamental physics, I'm having trouble seeing how it has changed anything in our understanding of physical laws. About LHC2, one can hope for the best, but despite the hype, I think the most physicists feel that the odds now are that it will not see anything unexpected.

To put the reason for interest in number theory in a language that physicists might find more palatable, the claim is just that progress in fundamental physics has often come in the past from a better understnding of symmetries and how to exploit them. Mathematicians know a lot about symmetries that has not yet found application in physics (representation theory is a large field), and the Langlands program is currently one of the most active areas in mathematics where new work is being done on the exploitation of symmetries.

56. **Peter Woit**
February 19, 2015

Igor,

If you haven't looked at the latest version of the essay, see material I've added at the beginning of the concluding section which addresses the "unification of mathematics" question. But yes, the essay is intended to be somewhat presumptuous and provocative.

I do hope to someday get something serious written about qft and number theory, but that's a big project, and I think our understanding is still very fragmentary.

57. **verruckte**
February 19, 2015

"The universe can be described by a finite substructure of itself, which is nice!"

I don't think that's been determined yet, without the word 'partially' in there before 'described'. Can it be, though? I think that it's a very interesting question. I personally think the answer is 'No, it can't be'. I suppose if physical reality is actually infinite in extent, then it sort of follows that it could contain another arbitrarily large subset, but I still wonder. What does it mean to describe something completely? Don't you essentially have to make an actual copy, and thus break the no-cloning quantum theory constraint?

It is interesting to note, though, that what we think of as mathematics is being performed by a bunch of ionic charges skittering around in a lump of water and protein. If math really is 'larger' than physical reality, which I gather most of you think, it makes me doubtful that we would ever be able to apprehend it fully with our lumps of protein.

58. **Radioactive**
February 20, 2015

I suppose you and I have different outlooks. I am still willing to wait for the results of experiments, overhyped or not, null or not, because they provide grist to the mill of high quality theoretical physics. Whatever the right theory of fundamental physics at high energy scales, there is no guarantee that it will be mathematically elegant but it certainly will predict the results of experiments.

Speaking of things that have been overhyped, I have heard uncountable times how advanced representation theory/topology/number theory/something else under the mathematical sun is going to lead to a new understanding of fundamental physics. This essay is speculation that the Langlands program is going to help fundamental physics because it will help us unify everything back to the one holy mathematical Object. It sounds like ancient philosophy instead of natural science. The "unreasonable effectiveness of mathematics" itself is overhyped and you are helping to build it.

59. **Peter Woit**
February 20, 2015

Radioactive,

If theorists want to sit on their hands and wait for new experimental results that may be a long time coming (as in, after they're dead…) they can do that. One problem with this tactic is that their colleagues may decide to stop hiring more theorists, and there is some data indicating that is happening, see

http://www.physics.utoronto.ca/~poppitz/Jobs94-08.pdf

60. **Radioactive**
February 20, 2015

If there isn't any good reason to hire theorists then why hire them? It isn't a choice between becoming a hep-th postdoc and working in a coal mine. Perhaps fewer garbage papers on the arxiv per day would be good for the field.

Since Anglo-Saxon studies and Abstract Topology departements continue to exist in universities I doubt we'll ever see a complete extinction of mathemathical physicists, though there may be fewer of them, which is not a great loss.

61. **failafail with extra hubris**
February 20, 2015

"Speaking of things that have been overhyped, I have heard uncountable times how advanced representation theory/topology/number theory/something else under the mathematical sun is going to lead to a new understanding of fundamental physics."

Yes, Herr Stark, I agree! The work of Hermann Weyl belongs more to representation theory, topology, and number theory than physics. I mean, really- a gauge theory? Pauli has already shown these structures to be as unphysical as Koenig's spin structure idea.

We should focus on physics of immediate impact in defense and industry- Indeed, Herr Stark, any new physics will manifest through your famous shifts in ultracold atoms. As to whatever Bardeen, Einstein, Oppenheimer, Noether and Weyl are erestwhile up to right now, I'm sure none of it will ever pan out. I mean, really, Herr Stark, who cares about understanding the fractional quantum hall effect? Topological order, edge effects?

What we need is still more experiment. Physics should just be all experimentalists, really- no need to even come up with models to verify! Who needs models, let's just run experiments! Then, something actually interesting comes up in those experiments, we can start developing the mathematical physics required to understand the new physical phenomena. We will simply call some of the mathematical physicists back from the coal mines.

62. **Jim Beyer**
February 24, 2015

Well, I like the new essay better.

It is probably human nature to think one's own post had something to do with your changes, I have no idea if that's the case, but I like that you'd subtly distanced yourself from the String Theory antics of the past 30+ years. That's probably a good thing.

Your point about Einstein's insight on GR being helped by Riemannian
geometry was interesting as well.

I sort of wish I could see the old essay, but that might be a chore. I will suffer my personal hallucinations as to what was actually changed…

63. **Abdelmalek Abdesselam**
February 27, 2015

@Peter

Nice essay! I also think there are interesting things to discover by combining number theory and QFT. The connection between the function field (over C) case of the Langlands program and QFT, is by now well established. However for number fields the situation seems rather unclear. There are some intriguing observations though regarding this hypothetical NT/QFT connection. For instance the Weil distribution whose positivity implies the Riemann Hypothesis looks a lot like the (multiplicatively translation-invariant) two point function of a Euclidean QFT. This was pointed out in a paper by Burnol: http://arxiv.org/abs/math/9809119
Also, Connes' trace formula in http://arxiv.org/abs/math/9811068
involves taking a limit of removing both UV and IR cut-offs just as in the usual approach for constructing a QFT model. Clearly the Weil distribution has to do with the action of rescaling group R^*, but the question is: on what?
A possible connection to such an action on QFTs, namely the renormalization group, was considered in this article by Leichtnam: http://arxiv.org/abs/math/0603576
Having studied Euclidean QFT over both R which is the usual setting, and over Q_p, I can say that the definitions and basic properties are very natural in both of these settings and they parallel each other in a very nice way. For instance, a good theory of probability measures on spaces of distributions require a nuclear topological vector space. Over R it is S(R^d) which is countably Hilbert. Over it is S(Q_p^d)
which is not metrizable. These two spaces are in some sense at the opposite ends of the spectrum ofthe general notion of nuclear space due to Grothendieck. All the good theorems like Bochner-Minlos (for constructing free boson models) or the Levy continuity, hold for these two extreme examples. In fact the theory over p-adics
is simpler than over R and therefore offers a useful testing ground of ideas for constructing QFTs rigorously. I explained that in my short "essay"
http://arxiv.org/abs/1311.4897

February 27, 2015

Abdelmalek,
Thanks for the interesting comments!

This Week’s Hype

February 20, 2015
Categories: This Week's Hype

A quarter-century or so ago, one of common arguments for string theory research was that it was “the only game in town”, in the sense that it was the only possible way to get a unified theory. For instance, back in 1987 David Gross had this to say:

> So I think the real reason why people have got attracted to it is because there is no other game in town. All other approaches of constructing grand unified theories, which were more conservative to begin with, and only gradually became more and more radical, have failed, and this game hasn’t failed yet.

As years went on and string theory unification went nowhere, this often was replaced by a new “only game in town” argument, that string theory was the only possible quantum theory of gravity. This argument got strong disagreement from people pursuing Loop Quantum Gravity or any number of other ideas.

This week, Quanta magazine has a new version of the argument, reporting that “Researchers are demonstrating that, in certain contexts, string theory is the only consistent theory of quantum gravity. Might this make it true?” The new argument (based on this and this) seems to be that string theory is the only possible theory of quantum gravity because if you look at a certain class of CFTs (based on orbifolds by permutation groups) and invoke the AdS/CFT conjecture for AdS3/CFT2, the 3d gravity theory in the large N limit would have a density of states more characteristic of string theory than a conventional particle theory.

The most obvious problem here is that it is in 3 space-time dimensions, where there are no physical gravitational degrees of freedom. The S-matrix of quantum gravity is exactly calculable in flat 3d space: it’s zero. There’s a very long history of studying 3d quantum gravity, as a toy model without gravitons, but with just topological degrees of freedom. For more about this, see for instance Steve Carlip’s 1998 book on 3d quantum gravity, which works out a large number of different ways of quantizing 3d gravity (not including string theory). One problem with the argument that string theory is the only way to quantize gravity because it is the only way that works in 3d is that, as Carlip shows, there’s a long list of other completely different ways to do this (all arguably not that relevant to the problem since none have gravitons). This is also quite different than the usual argument that string theory is needed to quantize gravity, which is based on the occurrence of a spin 2 graviton in the spectrum of the string theory.

Ignoring the obvious problem of no gravitons and being in the wrong dimension, there are other problems with the argument, for instance the claim that looking at permutation orbifolds tells you about all CFTs, or the claim that a large density of states at high energy means you have to have a string theory. The article quotes Matt Strassler about this:

> But these aren’t really proofs; these are arguments. They are calculations, but there are weasel words in certain places… And just finding a stringy density of states — I don’t know if there’s a proof in that … This is just one property.

Carlo Rovelli sums up the issue with using this to hype string theory and excuse its failures:

> They should try to solve the problems of their theory, which are many, instead of trying to score points by preaching around that they are ‘the only game in town.’

I haven’t followed closely work on AdS3/CFT2, but it is a quite interesting topic, although not because it promises a proof of the “universality” of string theory. Chern-Simons theory is based on a very similar relation between a topological 3d qft and 2d CFTs, and there we have some idea what is going on, although many fascinating questions remain. One might hope that AdS3/CFT2 provides a context where one could understand things using some ideas from the Chern-Simons context. This is what Witten did back in 2007 in his paper Three-Dimensional Gravity Revisited (I wrote about this before the paper here). My understanding is that problems with Witten’s proposal later surfaced, I’d be curious to hear from an expert on the latest state of that (perhaps Witten can write a “Three-Dimensional Gravity Revisited Revisited” paper).

There are a lot of wonderful questions still not understood about this story, but I don’t see that using it to argue that string theory is the “only game in town” does anything other than throw one more thing on the pile of outrageous hype generated by string theory partisans over the last 30 years.

Update: There’s been a change to the Quanta article, adding to the quote from Lee Smolin, who is making much the same point I was making in this posting:

> “And even in that case , there have existed for a long time counterexamples to the string universality conjecture, in the form of completely worked out formulations of quantum gravity which have nothing to do with string theory.” (String theorists argue that these particular 2+1 gravity theories differ from quantum gravity in the real world in an important way.)

This whole thing really is very strange: on the one hand string theorists are arguing that only string theory can give you quantum gravity, based on an argument in 2+1 d. When you point out to them that there are well-known counterexamples to their argument in 2+1 d, they say “well, things are different in 2+1d than in other dimensions”. Just bizarre…

Comments

1. **Natalie Wolchover**
   February 20, 2015

   Peter,

   Thanks for responding to my piece with your hallmark spirit. 🙂 A couple of minor points: I’m not sure whether you’re calling the article itself “hype” or claims presented therein, but I would like to note that most of the points you raise about the limitations of this research are explored in the piece. I would also note that you’ve curated your excerpts a tad misleadingly. Strassler’s quote began “It’s clear that these papers are an interesting attempt.” Carlip, whom you mentioned, also had a mildly positive take. Most experts I spoke to (even some LQG theorists) consider these papers worth taking seriously. No one is anywhere near claiming that string universality is proven, of course. But it seems reasonable to call these consistency conditions “evidence” — a new kind of evidence, possibly, and certainly not of the smoking gun variety.

   I also think it’s worth pointing out that there are a couple of papers discussed in the story that go beyond 3D gravity. The most significant is Maldacena and colleagues’ from last summer: http://arxiv.org/pdf/1407.5597.pdf.

   Always a pleasure.

   Natalie

2. **andrew**
   February 20, 2015

   Peter, what exactly is the “only game in town” claim? Is it something like:

.
If I begin with a set of desiderata including
* Low-energy limit is general relativity in 3+1
* Low-energy limit is QFT/QM
* Lorentz invariance
* Unitarity
I would (if I could do the math etc) find a unique solution: string theory. What is the full list of desiderata?
.
If it were proven, it would be quite compelling, but not the final word (eg Lorentz could be broken at a small level in nature).

3. **Peter Woit**
February 20, 2015

Hi Natalie,
Sorry not to make it clear, but the "hype" reference was to the claims physicists are making, not the article. You do quote appropriately skeptical voices. Just thought I'd add some context though about how 3d is different….

About ignoring the Maldacena et al 4d reference, that just seemed to be a completely different topic and sort of calculation, one I'm not familiar with and don't have time to become well-enough informed to write about it. Taking a quick look I see that even they don't make any strong claims for their result:

"We should mention the grand dream of deriving the most general weakly coupled consistent theory of gravity. It is quite likely that the only such theory is a string-like theory, broadly defined. We are certainly very far away from this dream, but hopefully our simple observation about three-point functions could be useful."

4. **Peter Woit**
February 20, 2015

Andrew,
Some string theorists would like to try this style of argument, there are a variety of sets of hypotheses you could imagine. See my previous quote though, where Maldacena et al acknowledge "we are certainly very far away from this dream" and I think that's accurate.

The problem with No-Go theorems (here string theorists are hoping for a No-Go theorem about alternatives to string theory) is that very often someone finds a way around them. They can be very helpful at focusing attention on precisely what assumptions lead to an obstruction to doing something, giving ideas about what needs to be done to get around the obstruction. In this case though, I think one is so far away from anything one could reasonably call a No-Go theorem that it's just hype to make claims about one. In particular, arguments about 3d quantum gravity are just pretty much irrelevant to the topic.

5. **guest**
February 20, 2015

The strength of the proof is inverse to how many assumptions they make.

6. **Anonyrat**
February 20, 2015

February 21, 2015

Natalie Wolchover,

Maybe you can explain why the Maldacena, Zhiboedov 2011 paper provides "evidence that string theories are the only quantum gravity theories with a particular feature that reproduce general relativity at large scales." as the article claims?

On the contrary this paper as I see it provides evidence of Vasiliev's HS theories by confirming the famous HS_AdS$_4$/Free_O(N)_vector_model correspondence of Klebanov-Polyakov (http://arxiv.org/abs/hep-th/0210114).

But maybe I'm missing something.

On the other hand if your aim was to claim that a Supersymmetric version of HS_AdS4$_4$ is a limit of String theory you should have mentioned in addition the accompanying papers that make this claim i.e. in this case http://arxiv.org/abs/1207.4485. Otherwise the above statement in your article is meaningless and confusing.

But again maybe I'm missing something so I would be grateful if you can elaborate on this statement of your article.

8. **Carl**
February 21, 2015

The quote "the only game in town" is exceptionally apt. It's most associated with con man "Canada Bill" Jones, master of the Three Card Monte, who ironically was himself addicted to gambling and lost his money to better professionals as fast as he took from marks. Supposedly, on being advised by a friend that the Faro game he was losing money at was rigged, he replied "I know, but it's the only game in town!".

9. **Peter Woit**
February 21, 2015

Carl,
The weird thing is that many string theory proponents are well aware of the origin of "only game in town", but use this anyway. See for instance

http://www.math.columbia.edu/~woit/wordpress/?p=1917

10. **BMc**
February 22, 2015

For many years, it was regarded as a hallmark of a successful theory of quantum gravity that it should automatically exclude spacetimes that are known, on general grounds, to be unphysical. For example, it simply should not work on Goedel's famous spacetime. Indeed, if somebody came up with a theory of quantum gravity that *demanded* that spacetime must be globally hyperbolic, as all realistic spacetimes are, that would be counted as strong evidence in its favour. String theorists used to argue like this: in the heady days of 1985, some of us thought that [at least] the internal manifold could have only a tiny number of geometries, and that was [rightly] hailed as strong evidence in favour of string theory.

If the correct theory of quantum gravity only works on globally hyperbolic spacetimes, then it won't work at all on AdS. Conversely, a theory that works spectacularly well on unphysical spacetimes like AdS, indeed that is the only game in town there….. well, that is pretty powerful evidence that it is *not* the correct theory of quantum gravity. Yes, I know that things like gauge theories work quite well on AdS, but we don't look to gauge theories to select our spacetimes for us.

So the conclusion here should be precisely the opposite of the one being drawn.

Well, I don't know whether I really believe all that. But it shows how tricky, and perhaps how futile, this sort of argument can be……

11. **Aleksandar Mikovic**
February 23, 2015

Andrew,
Even with a short list of desiderata for a QG theory (well-defined theory, semiclassical limit is GR + QFT), string theory is not a unique solution, because the spin-cube models (categorical generalizations of spin-foam models) also satisfy the list. However, the complete list of conditions must include a generalization of the QM formalism to the whole universe (no external observes, the meaning of the measurement and the wave-function collapse in quantum cosmology, the role of time).

12. **Natalie Wolchover**
February 23, 2015

Giotis,

There's no doubt that the sentence in question is very vague and probably confusing to an expert. As the paper was explained to me, Zhiboedov and Maldacena considered a class of AdS4 theories with higher spin symmetry; when they deformed these theories in a way that made the higher spin states heavy, the only theories that ended up looking like GR in the right limits were string theories. So the "particular feature" would be heavy higher spin states, as opposed to massless higher spin states, which of course our universe does not have. Hope that helps.

13. **Giotis**
February 23, 2015

Natalie Wolchover,

Thanks for the answer.

I think I understand now what have happened.

Are you sure you have referenced the correct paper?

From your description I understand that the correct paper is

http://arxiv.org/abs/1204.3882

Check the motivational introduction in appendix G and the relevant conjecture.

14. **Robert Delbourgo**
February 24, 2015

I have another game, but nobody wants to play it! Oh well, that is the fate of alternative approaches against the string/brane/susy juggernaut and one must just accept it. That is life.

15. **smtx**
February 24, 2015

The S-matrix cannot be zero, it is a unitary matrix, it must be the identity. When Einstein invented special relativity, SR survived on its own merits. It didn't matter if anyone wanted to play Einstein's game, or stick to the juggernaut of the luminiferous ether. Whatever new game anyone wishes to offer today will have to prove itself on its own merits.

16. **si**
March 1, 2015

Regarding experimental "confirmation" of the String theory, there will be a Gordon Research Conference in June. Its title is "String Theory & Cosmology (New Ideas Meet New Experimental Data)". I'm rather interested to see what the new experimental data are.

17. **Peter Woit**
March 1, 2015

si,
Thanks. More about this here
http://www.grc.org/programs.aspx?id=16938
I see the participants are going to explain about
"Testing String Theory Through Observational Cosmology"
Wonder what new "test of string theory" they've got?

Once they're finished in Hong Kong, many of them will fly to Aspen to discuss the same topics
http://www.aspenphys.org/physicists/summer/program/currentworkshops.html

Quick Links

February 25, 2015
Categories: Uncategorized

- The LHC is getting close to the point where it can be restarted with a 6.5 TeV beam energy. Latest news here, schedule here. Plan is for a sector test late next week (beam in part of the machine), beam in the whole machine March 23. First physics run May 18th.
- Next week there will be a conference in Venice devoted to neutrinos, blogging going on here.
- There may be some progress on the Mochizuki/abc front. Ivan Fesenko has written up some notes that try and put Mochizuki's ideas in context with some other more conventional parts of mathematics. The week after next will see a workshop in Kyoto, with lectures from Go Yamashita on the abc proof. Another recent survey talk by Mochizuki is here.
- The latest AMS Notices has a series of articles about the life and work of Arthur Wightman, one of the main figures in the effort to make rigorous sense of quantum field theory.
- In my essay about math and physics, I mentioned the Atiyah-Bott work on the moduli space of solutions to the Yang-Mills equation in the case of Riemann surfaces. This has an intriguing analog to the function field case, which was discussed already by Atiyah and Bott. Dennis Gaitsgory has a new paper out that touches on this in the context of his proof (with Jacob Lurie) of the Weil Tamagawa number 1 conjecture for function fields (see here). The new paper has the footnote: "The contents of this paper are joint work with J. Lurie, who chose not to sign it as author."
- Returning to physics, Princeton University Press announced that Frank Wilczek will edit a Princeton Companion to Physics, modeled on the wonderful Princeton Companion to Mathematics, which was edited by Tim Gowers. Publication is planned for 2018.
- Caltech hosted a workshop the past couple days, inaugurating the Walter Burke Institute for Theoretical Physics. Hopefully they're well-funded enough to put videos or slides online. John Preskill's remarks at a celebration of the event are available here. He gives some principles for doing science that I very much agree with. In recent years I've become especially aware of the importance of his first principle: "We learn by teaching", since I've been learning a lot that way. As the trend grows towards institutes modeled on the IAS and prestigious positions that involve no teaching, I think this needs to be kept in mind.

  I also agree with his last principle: "Nature is subtle", and found very interesting his comments on the holographic principle:

  > Perhaps there is no greater illustration of Nature's subtlety than what we call the holographic principle. This principle says that, in a sense, all the information that is stored in this room, or any room, is really encoded entirely and with perfect accuracy on the boundary of the room, on its walls, ceiling and floor. Things just don't seem that way, and if we underestimate the subtlety of Nature we'll conclude that it can't possibly be true. But unless our current ideas about the quantum theory of gravity are on the wrong track, it really is true. It's just that the holographic encoding of information on the boundary of the room is extremely complex and we don't really understand in detail how to decode it. At least not yet.
  >
  > This holographic principle, arguably the deepest idea about physics to emerge in my lifetime, is still mysterious. How can we make progress toward understanding it well enough to explain it to freshmen?

  From what I can tell, the problem is not that it can't be explained to freshmen, but that it can't be explained precisely to anyone, since it is very poorly understood. The AdS/CFT conjecture is now older than some of my current students, with a literature of more than 10,000 papers, but taking a look recently (see here) at what should be a toy model case (AdS3/CFT2) reminded me just how little seems to be truly understood. This is a quite odd and I think historically unprecedented situation.

- Somewhat related to the holography question, for anyone interested in condensed matter physics, I recommend taking a look at Ross McKenzie's blog Condensed Concepts. He discusses some of the issues related to attempts to use holography in condensed matter. He also has a recent paper (with Nandan Pakhira) showing a violation of a bound suggested by holographic arguments.

Update: On the multiverse mania front, tomorrow Science Friday is hosting Sean Carroll to continue his war against falsifiability and the conventional understanding of science, joined by Seth Lloyd to help promote the multiverse. Perhaps it should be "Pseudo-science Friday"?

Update: Michael Harris's book now has a blog, which promises to discuss topics that didn't make it into the book.

Update (March 7): Beam is back in the LHC (well, at least in a part of it). There was a successful test today, sending beam into one sector in one direction, two in the other, see here.

Comments

1. **gadfly**
   February 25, 2015

   I'm very empirically driven and not an expert at all on quantum gravity, can anybody summarize or point me to a good summary of why the holographic principle, in spite of having no apparent empirical justification, is held in such high regard?

   This is not intended to be hostile in any way, I'm just genuinely curious.

2. **Peter Woit**
   February 25, 2015

   gadfly,
   I think there are two main sources of physical interest in this, since it (adS/CFT) seems to non-trivially relate two different quantum theories:

   1. strong coupling on one side gets related to weak coupling on the other. So, for systems where you don't understand the strong coupling theory (for instance string theory on the adS side, QCD or some condensed matter system on the CFT side), this promises to turn your problem into a weakly coupled one you can understand (e.g. a gauge theory on the CFT side, a weakly coupled gravity theory on the adS side). If this really works, it becomes a powerful calculational method for theories we otherwise know little about.

   2. Gravity theories on the adS side get related to more conventional field theories on the CFT side. This promises to make sense of quantum gravity.

   You'll need an expert to explain exactly what the state is of understanding about when this works and how this works exactly (i.e. what exactly are the two dual theories, and what exactly is the mapping between them). One problem for the non-experts is to sort out what's hype and what's a solid result (I'm guessing Preskill's "all information in the room is in the walls" business isn't on the "solid result" side….). My recently quick attempts to understand what was known in the AdS3/CFT2 case didn't get me far, which surprised me since we know a lot in that case about both sides of the correspondence (2d CFTs, 3d gravity theory).

3. **Ben R**

February 25, 2015

The idea of gravitational holography originally came from the Bekenstein entropy bound, which is convincing because it doesn't depend on any particular theory of quantum gravity but only on the same sort of quasiclassical argument that gave us Hawking radiation. Take a look at gr-qc/9310026 and hep-th/9409089 (which predate AdS/CFT). The latter even has pictures showing how the projection onto the boundary is supposed to work.

4. **Art Brown**
February 25, 2015

Re "We learn by teaching", it's notable that the three examples Dr. Preskill referenced, Einstein, Schockley, and Bardeen, did not. Teach, that is. RIP, Bell Labs.

5. **Douglas Natelson**
February 25, 2015

Art Brown: Well, Bardeen did at UIUC after Bell Labs, but your point is taken.

6. **RogerP**
February 26, 2015

"From what I can tell, the problem is not that it can't be explained to freshmen, but that it can't be explained precisely to anyone, since it is very poorly understood."

"What can be said at all can be said clearly." – Ludwig Wittgenstein –

7. **Alex**
February 26, 2015

On the topic of the holographic principle being held in such high regard, I have a naive question. What is the difference between the holographic principle and specifying the physics via boundary conditions? "all information in the room is in the walls" seems like an obvious quote given that the fundamental field equations are second order and hence are uniquely specified by giving the values of the fields on the boundary of the region?

8. **Peter Woit**
February 26, 2015

Alex,
These are quantum field theories, not classical field theories. And, again, the real interest here is in the fact that strong coupling in the bulk theory is getting related to weak coupling in the boundary theory, and vice versa, allowing access to information about strongly coupled theories.

9. **Alex**
February 26, 2015

Peter,

I acknowledge that relating strongly coupled theories to weakly coupled ones definitely seems like a result but now I'm confused by your statement: "These are quantum field theories, not classical field theories". Are you suggesting there's some sort of fundamental difference between solving a quantum field theory by specifying boundary conditions as opposed to an analogous classical field theory?

10. **Peter Woit**
February 26, 2015

Alex,
Yes, the whole question of boundary conditions is very different in QFT, and the AdS/CFT story does not seem to be the conventional one about specifying boundary conditions. But I'd love to hear from someone expert who could tell us more about exactly what AdS/CFT does say (or at least provide references).

11. **gadfly**
February 26, 2015

Peter,

Thanks, that was informative. I've only heard bad results about actual applications (for instance, I heard that AdS/CFT or something closely related can be used to get a theory of quark gluon plasmas, but with the fine print being that it is the worst such theory), have there been any cases where it has been exploited with undeniable success?

12. **Bernhard**
February 26, 2015

I read Sean Carrol's piece again. Nothing I haven't read before but still deeply disturbing. I suppose one should just ignore this sort of thing. It could be laughable it it weren't so sad:

"The truth is the opposite. Whether or not we can observe them directly, the entities involved in these theories are either real or they are not. Refusing to contemplate their possible existence on the grounds of some a-priori principle, even though they might play a crucial role in how the world works, is as non-scientific as it gets."

Is someone really refusing "to contemplate the possible existence" of a multiverse (who?) or is and others selling this as a serious scientific idea that deserves acceptance (and applause) based on nothing? He is completely misleading people here so to appear that people are being stubborn and blind to this great revolution whereas he and other geniuses are being so open minded. It reminds me that Feynman once said: "with an open mind I do not mean an empty mind!"

13. **Peter Woit**
February 26, 2015

gadfly,
I'm really the wrong person to answer that question. From what I've seen, the most detailed understanding is available in the case of AdS5/CFT4, relating N=4 SUSY Yang-Mills to supergravity and superstring theory. The interest there is that weakly coupled strings and gravity, which you can compute with, tell you about strongly coupled SUSY Yang-Mills. The applications to the quark gluon plasma involve making this work for the non-SUSY case, and it is there that I think the trouble arises and you no longer have a controlled approximation method.

Bernhard,
Sean keeps attacking the straw man who "refuses to contemplate" the multiverse, not acknowledging that serious multiverse critics do contemplate it, just don't see any conventional scientific evidence for it, or any plausible path to getting any. If there's no way to get such conventional scientific evidence, then contemplating the multiverse is much like contemplating the existence of angels and supreme beings. Nothing wrong with that, but it's just not science.

14. **Anonyrat**
February 26, 2015

" The AdS/CFT conjecture is now older than some of my current students….This is a quite odd and I think historically unprecedented situation."

The closest recent thing I can think of is renormalization theory – from Steukelberg (1943), Schwinger, Feynman (1948-49) – to Wilson (1971) — 28 years, enough interval for the birth to PhD of a physicist.

There is a big difference with AdS/CFT, of course, that even when ill-understood, renormalization theory was known to work in the physical world.

15. **gadfly**
February 26, 2015

Why is Sean Carroll so committed to the multiverse?

16. **Peter Woit**
February 26, 2015

gadfly,
He long ago wrote a paper about how the multiverse would explain the arrow of time problem, and that had a lot to do with his first book. I have no idea how he got into that, it was at a time that the multiverse started to be a hot topic among string theorists.

It has always mystified me why he's running simultaneous campaigns for the multiverse and against religion. I would have thought that if you were intensely devoted to upholding science and rationality against religion, you'd be inclined to stay away from the parts of science that, at best, skate on the edge of what is science.

17. **student**
February 26, 2015

The introduction of arXiv:0912.0959 provides a fairly concise introduction to basic aspects of the AdS_3/CFT_2 correspondence and references to earlier reviews. Holography in this case is the correspondence between type IIB string theory on AdS_3 x S^3 x M and the CFT with target space Sym^N M where M = K3 or T^4 and N is taken to be large. Early checks of the duality included comparisons of the moduli spaces, (BPS/protected) spectra, and symmetries. More recent progress (circa 1999) is the matching of 3-point functions of BPS operators between the CFT and supergravity dual. The equality of the 3-point functions is explained by a very non-trivial non-renormalization theorem.
One of the difficulties is that the dual string theory is not at the symmetric product orbifold point in the CFT moduli space. That is why many of the early checks compute quantities that are (covariantly) constant over the CFT moduli space. Going beyond protected quantities, the "toy model case (AdS3/CFT2)" is perhaps less developed than some of its higher dimensional cousins. For example the anomalous dimension of the non-BPS Konishi operator in N=4 SYM in the large N limit can be computed for all values of the t'Hooft coupling using spin chains and integrability.

18. **Jon**
February 27, 2015

Peter,

I think there is a link between Sean Carroll's commitment to the multiverse and his campaign against religion. The multiverse is often seen as a counter argument to the idea that the fine tuning of physical constants provide evidence for God.

I'm pretty sure I've heard him use this argument in the past in debates against theists.

19. **Peter Woit**
February 27, 2015

student,
What I'm wondering about is not the kind of very specific duality conjecture you mention, but the philosophy that this duality phenomenon is general, that (for instance) to every CFT2 you'll get a gravity theory on AdS3. That's what is being discussed in the Quanta article, or in Preskill's claim about the boundary of a real room. What's the exact conjecture there, what's the evidence for it, and what's the state of understanding of why it might be true?

Also, how much recent progress is there? You refer to recent progress from 1999, but that's now a very long time ago…

Jon,
Yes, but my point was more about his war against falsifiability, since that's conventionally the first argument you make against the hypothesis of a deity (it's unfalsifiable). The problem with "the multiverse did it" as an explanation of fine-tuning is again falsifiability. If you don't have conventional scientific evidence for it, it's the same sort of explanation as "the big guy upstairs did it".

20. **Jim Harbough**
February 27, 2015

I read his blog (as well as many others). Sean loves Everett's MWI and is almost fanatical about it. It strikes me that he is now focused on cosmological philosophical questions and less on being a physicist.

21. **Bernd**
February 27, 2015

The violation of the holographic duality bound is based on DMFT calculations, which is a bit like string theory for strongly correlated fermions in the sense that it is somtimes sold as "the only game in town". Nobody knows how accurate these methods really are.

22. **Bill**
February 27, 2015

Speaking about duality: http://arxiv.org/abs/1502.07719

23. **Chris W.**
February 27, 2015

Both the multiverse adherents and the theists would have something if they could say that their favored explanation "explains fine-tuning [or whatever] in precisely this way [insert details here], and if you don't believe me *you can check it using these methods [insert details here]*."

Of course, they can't do that. The theists don't really care, because their agenda is apologetics for a faith, which is a nearly 2000-year-old practice originally directed at Roman overlords. The multiverse adherents have a somewhat different problem. They're asserting that certain features of the observed universe are simply accidental, with no explanation in physical laws. The trouble is that they can't point to *actually existing* alternative instances (of a universe) where those features differ or are missing. All they can do is conjecture that such instances exist, and then resort to the last refuge of scoundrels: "You can't prove that they don't exist!" The argument thus degenerates into another form of apologetics.

24. **Peter Woit**
February 27, 2015

Bill,
What that paper is doing looks like the attempts to get "string theory" out of the strong coupling expansion in lattice gauge theory that were very popular when I was a grad student in the early 80s (work of people like Polyakov and Migdal). The problem with this is two-fold:

1. You get some sum over a lattice version of surfaces, with certain weights, and you can call this "string theory" if you want, but it has no known relationship to what you normally call "string theory", the continuum quantization of the vibrating string.

2. To recover continuum gauge theory, which is asymptotically free, you want weakly coupled gauge fields at short distances. Here, you've got a strong coupling expansion, which is about not g=0, but g=infinity, with no way of getting to the physical g=0.

Anyway, I haven't read the whole paper, but I don't see any new idea that gets around those old problems (or even any claim that what the author does gets around those problems). Unless I'm missing something the claim by the author to have the first explicit gauge-string duality is completely misleading, since this sort of relation between gauge theory and sums over surface has been well known since the late 70s, and is also well-known to not give you the kind of duality between gauge theory and a physical string theory that you are looking for.

25. **hopffiber**
February 27, 2015

Peter,
>Also, how much recent progress is there? You refer to recent progress from 1999, but that's now a very long time ago…

I'm sure you know some of this, but every rational 2d CFT is proven to have a holographic dual theory of CS type, which can also be described as a topological string theory. This is thought of as a simpler sector of the full AdS3/CFT2 duality, where non-rational 2d CFTs are thought to be dual to (non-topological) string theories in AdS3. There is plenty of observations supporting this, but no real proof, but this understanding is for sure more recent than 1999.

And of course there is continuously a lot of evidence for higher-dimensional specific cases of AdS/CFT produced all the time, through techniques like integrability, localization, entanglement entropy and so on. Of course the general case is very hard to study, so investigating "simple" examples is the best we can do. But the fact that a lot of examples do work in non-trivial ways do point to some degree of generality, at least to me.

26. **Mark**
February 27, 2015

Peter, here are two references that do what you want. They provide evidence that large-N CFTs with a gap in the spectrum of operator dimensions is dual to semiclassical gravity in AdS:
http://arxiv.org/pdf/0907.0151.pdf
http://arxiv.org/pdf/1403.6829v2.pdf

27. **Giotis**
February 28, 2015

Especially for AdS_3 I'm not sure I understand the point of the discussion.

The fact that every consistent theory of QG in AdS_3 is a CFT_2 is ancient history. It was proven back in 1986 by Brown-Henneaux in the celebrated paper

"Central Charges in the Canonical Realization of Asymptotical Symmetries: An Example from Three-Dimensional Gravity".

Specifically they showed that in AdS_3 the asymptotic symmetry is generated by a Virasoro algebra.

28. **Shantanu**
February 28, 2015

Peter and others to me, looking at the agenda of previous neutrino telescopes in venice workshops. experimental neutrino physics seems to be like experimental incarnation of string theory. Just as string theory makes no contact with experiment, experimental neutrino physics seem makes no contact with theory or any BSM physics, despite bold claims that it is first evidence for physics beyond standard model.

29. **Jeff M**
February 28, 2015

Pardon the ignorance of a mathematician, but I'm kind of curious about the whole AdS/CFT thing. I mean AdS has negative cosmological constant, and the universe has positive cosmological constant, no? So whatever the proposed duality is (and it is conjectured, not proved), what the hell does it have to do with the actual universe? Pretty, yes, if someone can actually prove it, but physics?

30. **Peter Woit**
February 28, 2015

Jeff M,
There's no claim that AdS/CFT itself has anything to say about the physical case of our universe. There is a hope that it might inspire finding a similar duality that would apply (see "dS/CFT duality"), but, like for many questions about generalizations of AdS/CFT, I've never understood exactly what the state is of the search for such a theory.

31. **bitboy**
March 1, 2015

Some thoughts on the arguments/comments by Sean Carroll and Seth Lloyd in the NPR segment:
– Comments on falsifiability of string theory were disingenuous to say the least:
– Contrary to what SC and SL stated, most folks that claim that string theory is not falsifiable don't do so because the experiments are out of reach(Do they really think so many people that use the word "falsifiable" are so ignorant about such things?) but because there are _no_ real proposed experiments that can validate or invalidate string theory("validate" in the sense of an experiment that can confirm some unique prediction of ST).
– Sorry, "GR falls out of string theory" is not a valid argument.
– They both seem to think that scientists should do science and leave philosophy to the philosophers and that physicists use "science should be falsifiable" as a catchphrase. Apparently these two physicists are the exception to this rule and are sophisticated enough in the philosophy of science to have the right to admonish other physicists in their use of philosophical ideas.
– Sean Carroll states that "The lesson here is scientists should respect the field of the philosophy of science". I guess they should do this by trashing certain parts of that field, like the idea of falsifiability. 🙂

32. **martibal**
March 2, 2015

Peter, a bit off topic but since you mention it and this is something I always wonder: is it possible in a few words to explain why there is no dS/CFT theory ? Is it just a technical difficulty, or there is a deep reason for which the A in AdS is important ?

33. **Peter Woit**
March 2, 2015

martibal,
Maybe someone else has a good answer. My problem is that I don't really understand why AdS/CFT, so no idea about why no dS/CFT. Many of the general arguments about the ubiquity of holography seem to apply to either dS or AdS.

34. **fg**
March 2, 2015

A rather intriguing statement I have heard about the AdS5/CFT4 correspondence is that the fifth dimension in AdS5 in a sense encodes the virtuality/off-shellness. In the CFT in 4 dimensions, there are loop corrections that correspond to the possibility of having virtual excitations (e.g. a quark that fluctuates momentarily into a quark+gluon state). In the AdS5 side of the correspondence, weak coupling corresponds to a purely classical theory that has no quantum fluctuations. The statement was that, for some specific observables, one can relate rather precisely the 5th coordinatein AdS5 to the virtuality of the modes that would be running in the loops in the QFT side of things.

35. **MathPhys**
March 2, 2015

On a different matter, I have just realized that Tullio Regge, one of the most original theoretical physicists in the 20th century, has passed away in October 2014. He was 83, and I don't think that this was widely announced outside the Italian Physics community.

His observation in 1957, at the age of 26, that scattering amplitudes in non-relativistic quantum mechanics are controlled by poles in the complex angular momentum plane led in 1967 to the Veneziano amplitude and from there to almost everything discussed in this blog.

36. **Peter Woit**
March 2, 2015

fg,
I've also heard it claimed that one could think of the 5th dimension in terms of the renormalization group flow. Again, I've never seen a precise statement.

37. **S**
March 2, 2015

@martibal,

I'm certainly no expert on AdS/CFT, but as I understand it, the geometric setting for the theory is an asymptotically hyperbolic manifold: take a compact manifold-with-boundary \bar{M} and put a metric g on the interior (M) such that g blows up to second-order. Then for any defining function f of the boundary (f is zero precisely on the boundary and df is nonvanishing there), f^2g is a metric on the whole manifold-with-boundary. We can choose different functions f, and so restricting f^2g to the boundary, we induce a conformal class of metrics there (but not a well-defined Riemannian metric). Hence the *conformal* in the CFT. The interior metric can then be expanded in a well-defined way in powers of the defining function, where the coefficients are determined by the conformal geometry of the boundary, say N.

The problem is that the curvature of the interior metric is asymptotically -|df|^2, where this norm is taken in the metric f^2g. Thus, we can have negative-curvature metrics on the interior, or maybe asymptotically flat ones, but we can't have positive-curvature ones.

This I *think* is the reason, but I don't claim to know a lot about Lorentzian geometry, or (goodness knows) the AdS/CFT conjecture.

38. **S**
March 3, 2015

(I should have noted that in order to have the above-mentioned expansion, the interior metric g must be Einstein — hardly a small point).

39. **matthew foster**
March 3, 2015

My recollection is that the idea behind the connection with AdS and the RG picture is that AdS encodes the conformal group geometrically. I.e. the conformal group for the boundary theory is generated by SO(d+1,1) (for a Euclidean theory), and these appear as Killing vector fields which encode isometries of the AdS metric. Then it is natural to view the RG as a propagation through the space(time), say by following a one-parameter family of diffeomorphisms generated by the dilation operator, as you move away from the boundary theory. But I'm not sure if this is precisely how it works in practice, i.e. N = 4 SUSY Yang-Mills. In this (hand-waving) version it's a very pretty idea that isn't obviously tied to string theory.

40. **Sam**
March 5, 2015

Peter,

Why does nobody say anything about the almost one year delay in the announcement of the Lucasian chair occupant? It is a rather curious situation for such a prestigious professorship.

Sam

41. **Ross McKenzie**
March 6, 2015

Bernd commented

“The violation of the holographic duality bound is based on DMFT calculations, which is a bit like string theory for strongly correlated fermions in the sense that it is somtimes sold as “the only game in town”. Nobody knows how accurate these methods really are.”

I disagree. My detailed response is here.

GR100

March 7, 2015
Categories: Uncategorized

I hadn't thought until recently about the fact that this year is the 100th anniversary of Einstein's discovery of the field equations of general relativity, so there will be quite a few events taking place commemorating this (for a list of some, see here). This week's Science magazine has a special issue on the topic. It includes news stories about LIGO and gravitational waves, new tests of the equivalence principle, and possible tests of GR from observations of the black hole at the center of our galaxy.

There's also a review of a book from a few years ago about Einstein's search for a unified theory, Einstein's Unification by Jeroen van Dongen. The review addresses something I mentioned in my recent essay about mathematics and physics, that the development of GR provides a good example of a successful theory coming out of not just experiment and "physical intuition", but motivated also by the serious use of deep mathematical ideas. According to the review:

> Einstein employed two strategies in this search : either starting from a mathematically attractive candidate and then checking the physics or starting from a physically sensible candidate and then checking the mathematics. Although Einstein scholars disagree about which of these two strategies brought the decisive breakthrough of November 1915, they all acknowledge that both played an essential role in the work leading up to it. In hindsight, however, Einstein maintained that his success with general relativity had been due solely to the mathematical strategy. It is no coincidence that this is the approach he adopted in his search for a unified field theory.

Besides the fact that Einstein said so, other evidence for the primacy of the mathematical strategy in this case is the simultaneously successful work by mathematician David Hilbert, who was definitely pursuing the mathematical strategy.

While I think there's an excellent argument that a mathematical approach was crucial in Einstein's discovery of the field equations, the later history this book deals with also shows the dangers this can lead to. Einstein spent much of the rest of his life on a fruitless attempt to get a unified theory by pursuing the same mathematics he had so much success with in the case of GR. It's a good idea to keep in mind both examples. On the one hand, trying out some new deep mathematical ideas can lead to success, on a time scale of a few years. On the other, if you've spent 30 years pursuing a mathematical framework that has gone nowhere, maybe you should do something else. A lesson that Einstein's successors at the IAS might want to keep in mind…

The story about new tests of the equivalence principle contains the usual nonsense about testing "string theory predictions":

> Using beryllium and titanium, they found gravitational and inertial mass equal to one part in 10 trillion, as they reported in Physical Review Letters in 2008. That's not quite precise enough to test string theory predictions.

That "string theory predicts violations of the equivalence principle" is what used to be called a "factoid", something not true repeated so often that it becomes a fact. It seems though that usage has changed, with "factoid" now often being used to refer to something true. A new word is needed.

Update: See here for an article by Michel Janssen and Jurgen Renn discussing in detail the question of the "mathematical" versus "physical" strategies in Einstein's discovery of the GR field equations.

Comments

1. **M**
   March 7, 2015

   Experimentalist: "how can I use BRST cohomology to proof that the AdS/CFT duality prediction of genus one string correction to beryllium inertial masses is not an artefact of gauge fixing the superconformal symmetry of the D5-BPS black hole background?"

   String theorist: "What is beryllium?"

2. **Chris W.**
   March 7, 2015

   I wonder how much of the Science special issue will remain available online as full text. It deserves to remain available that way indefinitely.

3. **Chris W.**
   March 7, 2015

   Based on the above excerpt, I find it interesting that the book review seems to gloss over a historical viewpoint which I thought was more or less standard, namely that Einstein was struggling to find a precise formulation of geodesic deviation, presumably without knowing at the start what that notion was.

   To put it another way, if one senses that gravity in some sense breaks the rigid metric structure of spacetime as understood in special relativity, but that that metric structure must be preserved as a limiting case, one needs an appropriate mathematical framework to consider such things. Riemannian geometry turned out to be precisely that framework. The *new* physical realization that objects moving solely under the influence of gravity were following essentially inertial trajectories drove this search for a framework.

   The problem later on was that Einstein was unable to identify such a *key* physical realization that could drive and guide a similar search for the mathematical structure of a unified theory. We are arguably in a similar position today, despite having vastly more mathematical resources at our disposal. Some would argue that the age of such key physical realizations has past, and so we can only grope furiously through the mathematical possibilities with some past successes to guide us (we hope).

4. **Oldster**
   March 7, 2015

   Perhaps what Einstein lacked during that last 30 years was a contact with a physical intuition in his mathematics that was as fruitful as the Equivalence Principle was for GR, eventually leading to Riemannian Geometry as the framework for GR. That may also be why Banesh Hoffman lamented the failure of Weyl's original 1918 unified field theory to succeed at unifying gravitation and electromagnetism, because gauge invariance is such a seemingly reasonable idea, and leads to beautiful theories as well …

5. **Chris W.**
   March 7, 2015

PS on my last comment: I really should have said "…*especially with* vastly more mathematical resources at our disposal.". The increased size of the search space for appropriate mathematical structures makes the need for the right kind of physical guidance all the more crucial.

(Note, by the way, that the obtuse identification of mathematically formulated physical theory with mathematical theory doesn't help matters at all. This is about more than just the question of relative mathematical rigor.)

6. **lun**
   March 8, 2015

   In general, string theory does predict a violation of the equivalence principle in some regime, since Newton's constant couples to a scalar field (the dilaton), which generically mixes with other scalar fields.
   If Galileo threw such scalar fields off the tower of pisa with a normal weight, they would not fall at the same rate.
   The magnitude of this violation is of course completely undetermined (and things like Moduli Stabilization are supposed to make it as tiny as possible), but it is worth keeping in mind.

7. **Peter Woit**
   March 8, 2015

   lun,
   If the magnitude is completely undetermined, there is no prediction. It's also true that some string theorists, when pressed for an example of a prediction of string theory, have argued for "no violation of the equivalence principle" as a prediction, see for example
   http://www.math.columbia.edu/~woit/wordpress/?p=151
   http://www.math.columbia.edu/~woit/wordpress/?p=559

   This is a typical example of a "string theory prediction", no actual prediction, with claims from string theorists of evidence for string theory if you see something or if you don't.

8. **lun**
   March 8, 2015

   Peter, the "reference" you give in the second link is, to put it very mildly, not up to standard of scientific literature, and the second link has very little to do with the equivalence principle (It is relatively easy to incorporate the variation of the fine structure constant into GR, just add a scalar field coupled to the photon with a VEV varying in time in the FRW metric).

   Of course what you are saying about the lack of a quantitative prediction is right, especially since string theorists have invented really ingenious ways of making this prediction irrelevant for any conceivable experiment.
   Nevertheless, since the driving principle which drove Einstein to develop his mathematics is the EP, it is worth keeping in mind that in string theory the geometrization of gravity is most likely a property of the EFT in certan vacua, not a fundamental principle of the full theory. Quite a few string theorists never even thought about it.

9. **Martin S.**
   March 9, 2015

   > A new word is needed.
   mystification

10. **EFT**
    March 9, 2015

    @ lun,

    "…in string theory the geometrization of gravity is most likely a property of the EFT in certain vacua"
    What does EFT stand for ?
    Thanks!

11. **Peter Woit**
    March 9, 2015

    "EFT" is a conventional acronym for "Effective Field Theory".

12. **Zathras**
    March 9, 2015

    "The review addresses something I mentioned in my recent essay about mathematics and physics, that the development of GR provides a good example of a successful theory coming out of not just experiment and "physical intuition", but motivated also by the serious use of deep mathematical ideas."

    Some would say it is the only such example.

13. **John**
    March 9, 2015

    I read the article about LIGO and GR waves. It was filled with words like 'certainty'. Reminds me of SUS and the LHC back in the mid 2000's. So what happens if nor waves are found by LIGO?

14. **Peter Woit**
    March 9, 2015

    John,
    The SUSY story is quite different. There's strong indirect experimental evidence for gravitational waves (the pulsars), none for SUSY. The theoretical arguments for gravitational waves are much stronger also (it's hard to come up with a theory without them, whereas the simplest theories are ones without SUSY).

    It will be interesting if nothing is seen. I'd guess that at first the suspicion would fall on the astrophysics, that the modeling of production of gravitational waves is wrong, or the frequency of events that generate gravitational wave was wrong. But sooner or later it would become clear if there was a major problem with GR, and that would be quite revolutionary.

15. **Yatima**
March 9, 2015

> “Some would say it is the only such example.”

Regrettably, “some” got a bad case of Gruppenpest and were never heard of again.

16. **srp**
March 9, 2015

I was hoping somebody would use the anniversary to officially retire the “ball rolling on a rubber sheet” pseudo-explanation which is extremely confusing if you try to think about it at all.

17. **Peter Orland**
March 9, 2015

srp,

The usual TIME-LIFE picture of a ball on a curved static rubber sheet is not even a pseudo-explanation. The main effect of gravity is that the rubber sheet is being sucked into energy (mass). The curvature of the rubber sheet is a small correction.

18. **Shantanu**
March 10, 2015

John, there are no guaranteed astrophysical sources in the frequency range of advanced-LIGO/VIRGO. So if nothing is seen, the blame will be on astrophysical sources. Note that CMB polarization experiments also now on hot on the heal of this
and could be lucky if nature chooses a value of r within sensitivity range of upcoming experiments.

19. **WLM**
March 11, 2015

A couple of useful references for a modern study of the fundamental mathematics of General Relativity (as opposed to various black-hole solutions and AdS correspondences):

David B. Malament, Topics in the Foundations of General Relativity and Newtonian Gravitational Theory. University of Chicago Press, 2012

R. K. Sachs and H. Wu, General Relativity for Mathematicians. Springer-Verlag, 1977

These are (copyrighted) books, not papers or summaries. Although versions can be found online, they are worth their purchase price. (Although I was a student of David Malament at UCI, I have no financial ties to any of the above authors).

Spring Break

March 11, 2015
Categories: Uncategorized

I'm heading off soon on spring break, planning on traveling to Scandinavia and hoping to see a solar eclipse. There hasn't been much news recently from the math and physics worlds, and it's unlikely I'll be blogging until I get back (around the 24th), so will turn off comments while away.

Comments

1. **Johan**
   March 12, 2015

   Svalbard or Faroe islands? In any case, enjoy your trip!

2. **Peter Woit**
   March 12, 2015

   Hi Johan,
   Thanks! Will be going to the Faroe islands. Would love someday to get to Svalbard, but not this time…

Back from Break

March 24, 2015
Categories: Multiverse Mania

Clouds cleared about 15 minutes too late at Torshavn in the Faroe Islands, so totality was behind a cloud, but still an impressive sight. And the Faroe Islands are quite a remarkable place to visit. Some recent news:

- The plan has been to inject a beam into the LHC this week, leading to a news item in the UK Daily Express about how Scientists at Large Hadron Collider hope to make contact with PARALLEL UNIVERSE in days. This nonsense comes to us courtesy of this paper published in Physics Letters B.
- Unfortunately the machine checkout going on at the LHC has identified a problem that may delay contact with the PARALLEL UNIVERSE for a little while. Looks like no beam this week, for details see this from CERN. Some news is put out here, details of discussions of the problem here.
- Also on the parallel universe front, Quanta magazine has an interview with Weinberg. About the multiverse, he repeats some of the arguments for it, but also says:

  > I am not a proponent of the idea that our Big Bang universe is just part of a larger multiverse.

  About string theory, the LHC and SUSY, the exchange went:

  > **If the LHC finds no evidence for supersymmetry, what happens to string theory?**
  > Damned if I know!

  Weinberg went on to respond to the issue of the testability of string theory by discussing the possible measurement of primordial B-modes, without mentioning that string theory makes no predictions at all about this.

- Quanta magazine keeps putting out some of the best coverage of math and physics available. See for instance Natalie Wolchover on penguins (although also read Tommaso Dorigo and Adam Falkowski) and Erica Klarreich on moonshine.
- Jess Riedel has a wonderful blog posting about the subtleties of the classical limit in quantum mechanics. Textbooks like to claim this is explained by just taking the hbar goes to zero limit of a path integral, but that doesn't really provide an explanation, for reasons clearly laid out by Riedel.
- Nominations are open for this year's Breakthrough Prizes, see here. There will be $3 million prizes in physics and mathematics, as well as $100,000 "New Horizons Prize" for younger researchers, up to 3 each in both math and physics. For more, see here.

Update: Sabine Hossenfelder performs the public service of reading the "PARALLEL UNIVERSES" paper and explaining what is going on here.

Update: This year's Abel Prize went to John Nash and Louis Nirenberg. Nature News has a story here. The award to Nash was for his work on PDEs and the Nash embedding theorem. He already has an Economics Nobel, for his work on game theory. This surely makes him the first person to win not-quite-Nobels in two completely different fields.

Update: Also at Nature, news about the LHC problem.

Comments

1. **Justin**
   March 24, 2015

   You beat me to posting about the moonshine Quanta article. I was going to link it to you as soon as you got back, as I knew it would be in line with your interests. Are you as excited about this research as I am?

2. **David Roberts**
   March 25, 2015

   The arXiv version of the Phys. Lett. B paper is here

3. **Bee**
   March 25, 2015

   Hi Peter,

   I just posted a rant about the parallel nonsense: http://backreaction.blogspot.com/2015/03/no-lhc-will-not-make-contact-with.html

   Best,

   Sabine

4. **momerathe**
   March 25, 2015

   I wouldn't get too wound up about the Daily Express – it's not really considered a serious source of news; more a soapbox for whatever the proprietor's latest racist or paranoid conspiracy theory is.

5. **Anna**
   March 25, 2015

   The parallel universe hype has been all over the media here in the UK – not just the Daily Express, even reaching the Metro. Another example of 'Churnalism' (the article appears to originate with physics.org) and poor scientific reporting. Unfortunately, it is being reported as being CERN's primary objective – with the inevitable reaction from the public ('money wasted by those delusional boffins').

6. **piscator**
   March 25, 2015

   The comments on the Quanta magazine article are depressing, as people take turns to explain how Weinberg doesn't know what science is.

7. **Peter Woit**
March 25, 2015

Justin,

In my case, the right word is more "intrigued". This is one topic I wish I knew more about, once I catch up on other things, hope to learn some more about it.

8. **SteveB**
March 25, 2015

Is it just me or does everyone see that Tommaso Dorrigo's articles and everyone else's articles on Science 2.0 are newly blocked? Firefox tells me "Access denied". The site appears to want me to login as if I were an author of a blog — which I am not. I have enjoyed Tommaso's articles for some years now and would miss them.

9. **Peter Lund**
March 25, 2015

> This surely makes him the first person to win not-quite-Nobels in two completely different fields.

http://en.wikipedia.org/wiki/Herbert_A._Simon

10. **Peter Shor**
March 25, 2015

Peter Lund: Awfully close, but doesn't a not-quite-Nobel prize have to be awarded in a Scandinavian country?

11. **Narad**
March 25, 2015

> This nonsense comes to us courtesy of this paper published in Physics Letters B.

As a brief aside from the substantive comments, I can't help but be dismayed that – at this late date – Elsevier is completely incompetent at generating HTML from such material, even though they're obviously throwing an algorithm at it, which appears to specialize in *hopelessly breaking things* (e.g., Eq. [1]; the rendering of the $\sim 10^{19}$ GeV" in the original in the introduction is something to behold, as someone or something had to explicitly change the font of the "GeV," which was missed in Table 1).

I generally have to go to campus to snarf papers (this one is OA), so I'm used to the amateurish typesetting in the PDFs (Eqs. [25] and [28] are in close competition), but this takes the cake. And PDF is so Not Mobilly Enough.

Gah. I hope the rant won't be received too poorly; I'm back to reading, where I belong.

12. **Thomas Larsson**
March 26, 2015

Linus Pauling won two unrelated quite-Nobel prizes, chemistry and peace.

13. **MB**
March 26, 2015

"The mass of this remnant is found to be greater than the energy scale at which experiments were performed at the LHC. We propose this as a possible explanation for the absence of black holes at the LHC."

Hmm let me see here…

P(BH | not seen at LHC) = P(not seen at LHC | BH) P(BH prior) / (P(not seen at LHC | BH) P(BH prior) + P(not seen at LHC | no BH) P(no BH prior))
~ 1.0 * P(BH prior) / (1.0 * P(BH prior) + 1.0 * P(no BH prior))
= P(BH prior).

Yep, completely useless.

14. **Geoff**
March 26, 2015

In the Freeman Dyson spirit of "It's better to be wrong than vague", I've read seemingly serious proposals from supposedly sober physicists that quantum computations would be done in parallel universes. Perhaps it is best that alleged parallel universes are discovered at the LHC. I don't think The Onion is creative enough to come up with a headline reading "Parallel Universes Discovered at NSA".

15. **Adw**
March 26, 2015

Re: the earlier GR100 post—

If it should happen that, even with more sensitive detectors, no gravitational waves are observed, would some sort of graviton extinction occurring in interstellar space be a possible explanation—or is it basically a given that nothing could plausibly scatter gravitational waves at classical length scales enough to cause a null result?

16. **paddy**
March 26, 2015

To Adw (and please pitch in folk who know better than I):
(a) do not confuse graviton detection with gravitational wave detection, and
(b) unless said energy is beam-like, scattering is not extinction.

17. **Nathalie**
March 27, 2015

There is no Nobel Prize in economy. If someone says that there is, you should tell him or her: sorry, you can't reverse time – Nobel died already in 1896 and the "Bank of Sweden Prize" in economy was created around 1969! Scientists should make accurate statements and not get carried away by incorrect statements in the press.

18. **imho**
March 27, 2015

Hmmm…

What are the ramifications of this article that claims to rule out extensions to the standard model that require significant interation between dark matter particles. Isn't this contrary to the whole "dark matter particles are supersymmetric partners" idea?

19. **Shantanu**
March 28, 2015

Peter, check out Cliff Burgess recent talk
https://cds.cern.ch/record/2002541?ln=en

20. **Dom**
March 28, 2015

On the subject of the LHC, I hope that this isn't something that has been linked many times before LHC Configurable Monitors

21. **M**
March 30, 2015

The End (of string theory) is Near:
http://arxiv.org/pdf/1503.08130.pdf

22. **Peter Woit**
March 30, 2015

M,
Quite the opposite, that paper shows that string theory research should be the highest priority for mankind, crucial for the survival of the species (as long as possible…).

23. **bugannoyer**
March 30, 2015

From Dr Sen's paper, the solution to the vacuum-instability apocalypse is to send spaceships out to 10^10 light years, where they will be carried out of causal connection with the nucleating vacuum:

"In our universe the horizon size is of the order of 1010 light years. This means that by sending out space-ships we can reach and establish civilizations on dierent worlds situated within a radius of about 10^10 light years from us today"

And:

"The cost of this endeavour is clearly going to be high"

And concludes that we need to research the vacuum parameters to best allocate resources:

"In the context of string theory this means that we need to identify the correct minimum of the potential that describes the phase in which we live and then compute the probability of decay of this phase by standard techniques."

Perhaps he could help us get a start on funding by donating a modest portion of the Milner prize? Or is it too much to hope that this is just all an early start on Wednesday?

24. **Radioactive**
March 31, 2015

Wilczek has an article about physics in the next 100 years, http://arxiv.org/abs/1503.07735 , much of which could have probably been written 30 years ago. But he still has 70 to go.

25. **Thomas Larsson**
March 31, 2015

Radioactive, it was written 14 years ago:
http://arxiv.org/abs/hep-ph/0101187

26. **Thomas Larsson**
March 31, 2015

"5.5.Produce the New Particles!
Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, there must be several accessible to the LHC."

– From Wilczek's future summary above.

27. **Radioactive**
March 31, 2015

Well in that he says "I expect that in ten to fifteen years we will know a lot more", and now's he's revising his estimate from O(10) to O(100) years. As far as parameter tuning BSM papers I've seen a lot worse 😉

28. **CU Phil**
March 31, 2015

Peter,

Thought you might be interested in this special issue of Philosophia Mathematica on "Mathematical Depth." It came out of a conference on the topic involving mathematicians, philosophers & historians of mathematics, and a physicist or two. Links to videos of the talks are here: https://www.youtube.com/playlist?list=PLQw7KTnzkpXfGo93vo3kQk7_jA_HgwbnC

and the foreword to the special issue itself here: http://philmat.oxfordjournals.org/content/early/2015/02/27/philmat.nkv003.full

29. **Peter Woit**
March 31, 2015

CUPhil,

Thanks! That is very interesting. It's very hard to figure out exactly what "Mathematical Depth" is, but I think it's a very real and important characteristic of some ideas.

30. **Chris W.**
April 2, 2015

On that Weinberg interview, some might find it interesting to compare his responses with his essay (book chapter) "Against Philosophy" in *Dreams of a Final Theory* (1993). I found this PDF online.

Also see this review of his new book, *To Explain the World*.

31. **Socrates**
April 3, 2015

There has been so much interest in the lay press regarding Fuwa, Wiseman et. al's papers regarding nonlocal wavefunction collapse and EPR steering, but very little discussion in the online physics community.

http://arxiv.org/abs/1412.8178
http://arxiv.org/abs/1412.7790
http://www.nature.com/ncomms/2015/150324/ncomms7665/full/ncomms7665.html

Off-topic, but interesting?

Thanks

32. **Yatima**
April 4, 2015

Off-topic, but interesting?

As I see it, yes: "QM works exactly as expected."

Various News

March 31, 2015
Categories: Uncategorized

Some news from all over:

- The problem with a short in the LHC seems to have been resolved (one can follow progress here), looks like they'll be ready to inject a beam in a few days. Also looks like they're not likely to spend their Easter Sunday doing this, so, maybe it will be next Monday?
- Cambridge has finally gotten around to choosing a new Lucasian professor (the last two were Michael Green and Stephen Hawking). Michael Cates will take the position July 1.
- Grothendieck's death last year was sad to hear about, but a positive result is that the Grothendieck Circle is back in the business of making available resources concerning his work. There's a comment at the top of the website that

  > With the agreement of Grothendieck's family, the work of the Circle to bring Grothendieck's unique story and writings to the public has resumed.

- There was a workshop this past month devoted to Mochizuki's work, but I haven't found anyone who knows what happened there. Minhyong Kim has taken to trying to write about Mochizuki's ideas on MathOverflow, see here.
- The Toronto Star has a long article about Langlands.
- At the KITP this week a new program on quantum gravity is starting. This month's Scientific American has a Joe Polchinski cover story on Burning Rings of Fire. Maybe some of the KITP talks will be enlightening, but the small amount of time I've spent trying to follow the past two years of debate on this has just left me mystified, struggling to see how the very general framework people seem to be working in can possibly lead to a resolution of the questions they're concerned with.
- Frank Wilczek has a speculative article about Physics in 100 years. A commenter here suggests comparing it to Wilczek's version of nearly fifteen years ago. The last fifteen years have not been kind to Wilczek's hopes for vindication of SUSY or SUSY GUTs, but he's not giving up yet. It will be interesting to see what his reaction will be if the next fifteen years are equally discouraging.

  I do very much like one thing in the new version, the section about possible unification of ideas of quantization and of symmetry, where he speculates:

  > Quantization and fundamental symmetry will not appear as separate principles, but as two aspects of a deeper unity.

  That's pretty much one of the main motivations of the book I'm writing (see here).

Update: There are rumors going around tonight that there's been a hoax perpetrated on the arXiv, something like the Sokal hoax. This has to do with an hep-th posting entitled Riding Gravity Away from Doomsday, which has appeared under the name of a very prominent string theorist, Ashoke Sen, winner of the $3 million Milner Fundamental Physics Prize. What I'm hearing is that no one can believe that Sen could possibly have seriously written something this silly, so it must be some sort of hoax. Speculation is that the hoax could have been carried out to make the hep-th moderators look bad, by showing that they'll agree to anything, no matter how absurd, if it invokes the Landscape and the multiverse. Some think that Sen's account must have been hacked and then used to post the nonsense paper, others think that Sen himself is behind the hoax, having had enough of the Landscape business. I'll update this as more information becomes available.

Update: At least some papers on the arXiv still are serious.

Update: Beams are back in the LHC, successfully circulated at 450 GeV on Easter Sunday (live blog here). Next step, ramp up to 6.5 TeV.

   March 31, 2015

   I think maybe Tuesday. Monday is a big holiday in Europe – Easter Monday.

2. **MB**
   April 1, 2015

   Yaay for the LHC getting fixed so easily!

   My opinion on the Sen piece FWIW: Honestly I don't get the hoopla about it. I'm not sure it's anything like Sokal. First of all it's an "essay" for some random competition, not a journal paper. Second, supposing the typical eternally inflating multiverse paradigm is true I can't spot any obvious flaw in Sen's (or the author's if it really wasn't Sen) reasoning, which follows as an almost trivial consequence of the assumptions. Please correct me if I'm wrong. The essential message is to spread the human race out so as to avoid vacuum decay bubbles as much as possible. He does some very crude dimensional analysis in support of this that doesn't go very far in terms of building a concrete model. If there is silliness in this it seems to stem from the starting assumptions, not anything in the essay itself.

   So: silly premise? Yes, if you think the eternally inflating multiverse is silly (as I do).
   Absurd title? Definitely. Pure, shameless click-bait.
   Sokal-esque hoax? Not convinced.
   Worth getting worked up about? Nah. Nothing to see here. Move along. If he tries to get it published in Nature or promoted as some major breakthrough then maybe start an outcry…

   April 1, 2015

   April Fools' Day?

4. **anon**
   April 1, 2015

   Seconding MB…

   If Sen's account was hacked I doubt this would last more than a minute on the arXiv. He is not a sarcastic person and tends to be kind and differential to other's work, even when he doesn't find it so useful. So I doubt this is a hoax. My guess is that it is what it appears to be: a lightweight, fun article intended for general readers.

Why he decided this would be appropriate for posting on the arXiv I don't know. Perhaps he just wanted it to be available to general readers on the internet.

5. **Bobito**
   April 1, 2015

   Text such as: "The situation looks pretty bleak, particularly since we have no control on when and where such a doomsday bubble may form! Nevertheless there is a course of action that could save some of our descendants from this catastrophe. The essential idea is simple; we must spread out as fast as possible, establishing civilizations on dfferent worlds in different parts of the universe, so that even if some of us are hit by the catastrophe, the others may survive."

   is either a joke, or the worst kind of crackpot crap. Let's not pretend that it's respectable to write things like this. It isn't. No real physicist would write this. As far as know, travel to "other worlds" is a physical impossibility, and always will be. It's all fine and good to oversimplify, but it is dishonest and irresponsible, especially in a popular essay, to claim as a solution something simply ridiculous.

   I think it has to be a joke. The joke is to see if he wins the contest submitting complete garbage.

6. **Aquiles**
   April 1, 2015

   To understand Sen's paper, use Occam's razor !

   There is a trivial interpretation: today is April 1st ….

7. **Maurice Carid**
   April 1, 2015

   Ha, ha. All you commentators were successfully
   sent into April by Peter.
   Truly funny April fools' day joke, Peter ;-).

8. **Radioactive**
   April 1, 2015

   Sen's article is in hep-th instead of pop-ph, I'm sure it will be moved. It's just some kind of popular, quasi sci-fi essay (not paper) for a general audience. Lighten up.

9. **Anonymous**

17. **David**
    April 2, 2015

    Peter,

    What do you make of this paper?

    http://arxiv.org/pdf/1504.00056v1.pdf

18. **Peter Woit**
    April 2, 2015

    David,
    I gather the claim is that in some approximation, in some class of string vacua, you can't get a positive CC 4d spacetime. The subject of "string vacua" is an infinitely complex one, I don't see that this changes the situation much. Their conclusion I guess is that many arguments about string vacua "should be viewed with caution", and on this I can't disagree with them…

19. **z**
    April 2, 2015

    It's interesting you have Langlands right after Mochizuki, who was quite fed up with Langlands program.

20. **srp**
    April 3, 2015

    The Star article on Langlands is pretty entertaining. He sounds like quite an interesting character.

21. **physics grad**
    April 5, 2015

    6.5 GeV is unlikely to be interesting… I believe you mean 6.5 TeV! 🙂

22. **Peter Woit**
    April 5, 2015

    Thanks physics grad, fixed.
    I keep making that mistake…

23. **Manjil Saikia**
    April 6, 2015

    Prof. Sen has given an update on his website about this: http://www.hri.res.in/~sen/

24. **Peter Woit**
    April 6, 2015

    Manjil Sikia,

    Thanks! It's interesting to see that Sen denies any connection to eternal inflation and the multiverse, and yet devotes the concluding section to arguing for investigation of the string theory landscape. I guess this is logically consistent, but it gives up on "statistical predictions", and, going forward, I don't see any plausible argument that you could ever use the string theory landscape to predict anything.

25. **jonnie**
    April 7, 2015

    The Sen paper seems to mirror the plot of Schild's Ladder by Greg Egan, some of the hardest of hard sci-fi.

    http://en.wikipedia.org/wiki/Schild%27s_Ladder

    I loved it, but actual physicists may be angered by it, I don't know 🙂

26. **MB**
    April 7, 2015

    jonnie,

    Actual physicist here who thinks Schild's Ladder was pretty darn good. Much better, in fact, than the vast majority of sci-fi (confession: I do like Star Trek, though for sentimental reasons more than anything). I'll grant it's certainly not to everyone's taste, but I think you'd have to be stubbornly, boringly hard-nosed to be unwilling to suspend disbelief over Egan's departures from reality as we know it (or speculate it to be). He at least goes to extraordinary lengths to ensure the internal consistency of his fictional universes.

27. **Mitchell Porter**
    April 7, 2015

    I wonder if he's serious in proposing that this scheme to delay extinction via vacuum decay, through a crash program of cosmic fecundity and settlement, offers an important incentive to study the string landscape. That is the sort of thought you see in impassioned Internet discussions by transhumanists at their most extreme, who often don't understand why our whole civilization isn't already mobilized around some Promethean agenda like "ending death". I have personally had at least one discussion with someone anxious to know if string theoretic cosmology could allow "information processing" to continue forever.

28. **Chris W.**
    April 7, 2015

    Such speculations (and obsessions) make the plot of the film *Interstellar* seem conservative by comparison, to put it politely.

29. **MB**
April 7, 2015

Mitchell Porter,

My reading was that you only need a doubling time just faster than the vacuum decay rate, so in ordinary terms you don't need anything like a "crash program of cosmic fecundity and settlement" (though I love the phrase — thanks!).

Fun speculations aside, I don't understand how anyone can really worry about these things. I mean, even if we were all very confident string theory was a complete, consistent and unique theory of physical phenomena *and* we had the whole landscape mapped out, who's to say that one of our fundamental assumptions isn't slightly wrong? Maybe nature doesn't *admit* a complete, consistent and unique theory. Maybe in a hundred billion years God comes in, says "nice experiment that one, moving on" and everything vanishes in a puff of thought. Who's to say? In the infinite future there is an infinite amount of time for things to go wrong. You have to assign literally zero prior probability to anything you want to avoid. Not good Bayesianity.

Chris W.,

Nah. String landscape/multiverse doesn't predict anything so exotic as closed timelike curves. Only random configurations of chaotic events which, on casual inspection, *look* like closed timelike curves. 😉

30. **Zimriel**
April 8, 2015

Not that I want to start a flamewar here but "travel to other worlds" isn't impossible. It's *impractical*. Those are different adjectives.

31. **Parth**
April 9, 2015

The essay posted under the name Ashoke Sen is actually by Ashoke Sen.
He clarifies his essay in his website:
http://www.hri.res.in/~sen/

32. **JG**
April 9, 2015

haha, I was amazed at that anyone could make a comparison to the "Sokal Hoax" for this innocent and fun little essay.

Come on Peter Woit – you have not too bad standards, the update about the Sen publication was well below what is expected

News of the Multiverse

April 8, 2015
Categories: Multiverse Mania

Just about ten years ago, my April 1 posting here was a fantasy about the Stanford ITP getting major funding from the Templeton Foundation, using it to fund a program on the multiverse, and renaming themselves the Stanford Templeton Research Institute for Nature, God and Science. The last part hasn't yet come true yet, but I just noticed the announcement last year of a $878K Inflation, the Multiverse, and Holography grant from Templeton to the SITP, the third part of "A three component Templeton Initiative at the Stanford Institute for Theoretical Physics."

To get some idea of the scale of this funding, note that the entire NSF budget for theoretical HEP is about $12 million (the DOE spends about $50-60 million, but that supports groups at the labs, as well as computational hardware, and is decreasing). The Templeton Foundation has an endowment of over $3 billion (growing rapidly), and pays out over $100 million in grants/year (also growing rapidly). I don't think my skills as a fantasist are good enough to imagine what this means for ten years from now in the future.

In other multiverse news, the Literary Review of Canada has published a review by David Orrell of the recent Unger/Smolin book, and an exchange of letters between him and Matthew Kleban. I wrote something about the book here, and I'm in many ways not very sympathetic to the point of view of Orrell and Unger/Smolin, especially about the role of mathematics in physics.

I'm more on Kleban's side about mathematics, but the way he paints multiverse studies as the latest scientific descendant of the mathematics-driven successes of physics of the past is highly problematic. While this is a point of view favored at Stanford and at Templeton (Kleban has a $175,000 grant from them), I don't think it's a defensible one. Kleban's arguments are

- More to the point is the string landscape, a relatively concrete structure believed to follow from the mathematics of string theory.

Here "relatively" is a weasel word (relative to what?), masking the fact that we don't at all know what the structure of the string landscape is.

- contrary to Unger and Smolin's assertions, recent work indicates that current or near-future cosmological observations – specifically, the detection of positive spatial curvature – would falsify the landscape (if it is false).

The situation with the measurement of spatial curvature is that recent Planck results give |Omega_K| less than 0.005 and the expectation is that it is zero to a much higher accuracy than that, way beyond anything measurable (this is considered one of the main arguments for inflation). This "prediction" isn't "recent". Susskind's book on the multiverse ten years ago gave this one bit of sign information as the only prediction of the multiverse (see here). Shortly thereafter some authors were arguing that you could get positive curvature from the string landscape (see here). I have no idea if they're right, but in a recent paper Kleban himself writes about this:

> Positive curvature would probably not completely end discussion about a multiverse but it would be very bad news for the eternal inflation/CDL bubble nucleation framework.

and I think Orrell has it right that

> I would be interested to see if the detection of positive spatial curvature actually falsified the theory – wouldn't it just adapt?

- Furthermore, the theory can be used to predict the signatures of cosmic bubble collisions: violent events where two previously separate "universes" collide.

There's no evidence at all for such "signatures", and I don't think there's any plausible argument for why they'll appear in new data given that they haven't been seen yet (I wrote here about Kleban's Columbia talk about this). Final data from Planck on polarization are expected soon, but this is so implausible that I'm not sure Planck will even bother to look.

The problem with this kind of "testable prediction" is that it's much like my claiming that my theory that the universe is controlled by a giant turtle is testable and predictive, since if you saw a big picture of a turtle in the CMB, that would be strong evidence for my theory. There was a reason Popper went on about falsifiability…

- the standard model of particle physics combined with Einstein's theory of general relativity – two of the most well-established theories in physics – predict a large landscape quite similar to that of string theory.

This one brings back the "string wars" era, since I haven't heard anyone trying to use it (based on this) since 2007. Whenever people make a "string theory is just like the standard model" argument I'm never sure what to respond. How do you argue with someone trying to claim that the most successful physical theory ever, by far, is "quite similar" to a theory that has had zero success? It's kind of like trying to argue with someone who wants to tell you that black is white, because they're both kinds of grey. Surely they're not serious?

In this case, sure, if you put the standard model on a complicated space-time background, added lots of fluxes, etc. to the background, maybe you could turn it into as useless a theory as string theory. This doesn't mean it's "quite similar".

Update: Just noticed another recent essay about the multiverse, Marcelo Gleiser's examination of whether Fairies live in the multiverse.

Comments

1. **JG**
   April 8, 2015

   I think you should give the Templeton Foundation a break, they wouldn't need to fund bright young scientists if democracy worked better – it doesn't, the majority of the population don't care that bright young scientists have to go into IT, Finance etc rather than pursue a career in academic research.

   These Templeton funded students/researchers are not stupid people, they must learn a lot of advanced physics to come up to expert level on the multiverse question – and I am sure they are allowed to conclude it is not a workable idea, and I am sure the Templeton Foundation would be delighted if their funding was responsible for rigorous arguments explaining why the multiverse is a bad idea, just as much as they would be delighted with strong arguments supporting the idea.

   Are you worried that these people aren't doing "proper" physics?

2. **Peter Woit**
   April 8, 2015

JG,

If you pay closer attention, you'll notice that I'm not criticizing the Templeton Foundation, I'm just reporting what is going on (by the way, I've attended events sponsored by them, and recently wrote an essay for an essay competition they fund). They're free to do what they want with their money, but I'm also free to comment (if I had $3 billion I'd stop blogging and instead spend my time giving grants to people with my point of view). There are definitely problems with DOE/NSF funding and how their panels work, as well as the problem of Templeton's fondness for mixing religion and science. No source of money is problem-free. In some cases (e.g. the Simons Foundation) I actually agree more with their choices of how to spend money than I do with the DOE/NSF peer-reviewed choices.

But I think people need to be aware of the changes going on. The shift from public funding to funding by wealthy donors is very real and there should be awareness that this is happening, who the donors are, and what their agenda is. When you see lots of activity going on in the field related to the multiverse, you should keep in mind that there may be more to the story of why it is happening than "physicists are excited about the multiverse" .

3. **JG**
April 8, 2015

Ah, my bad understanding of the situation.

Templeton are giving the money to established academics, NOT young students and researchers.

Ok, yes you should call them out, and continue to do it, it is a very valuable service.

Sorry I must have been thinking about some other private funding agencies who actually are doing something useful.

4. **nicola**
April 9, 2015

Fairies surely live in the multiverse although they are most likely higher dimensional – my guess is M5 branes.

5. **Jim Baggott**
April 9, 2015

Peter,
I have a favour to ask. I think it's time that opponents of what I call 'fairy-tale' physics dropped arguments based on Popper's criterion of falsifiability. Popper published these ideas in his book *The Logic of Scientific Discovery* in 1934, and I think it's fair to say that the literature on the philosophy of science has moved on since then. Few contemporary philosophers have many good words to say about it.

I've just posted an article on this theme on my new website (!) – see http://www.jimbaggott.com/articles/against-falsifiability/

6. **Steve Bergman**
April 9, 2015

I thought the Planck polarization results were finally released a couple of months ago, on Feb 5. Am I in error?

7. **Lee Smolin**
April 9, 2015

Dear Peter,

I am glad to see the issues raised by Mangabeira Unger and myself getting discussed. But re Kleban's remarks, "contrary to Unger and Smolin's assertions…", let me note that the prediction of eternal inflation of slightly negative spatial curvature is discussed in our book on page 460. I explain why this is a genuine prediction of eternal inflation but conclude, "However, this will be difficult to confirm or falsify with near-future observations because it will require a great deal of precision to distinguish this from vanishing curvature."

Thanks,

Lee

8. **Bernhard**
April 9, 2015

Is there any comprehensive document where all these alleged multiverse "predictions" can be found? These bubble collisions are what keeps popping up, but there seems to be little hope there. Anyway, not that I believe the proponents have anything compelling, but it would be educational to see a list.

9. **Peter Woit**
April 9, 2015

Steve Bergman,
Some polarization results were released, especially ones related to the BICEP2 claims. But if you look at the public Planck results page, you'll see that of the 28 2105 results papers listed, 8 are still "in preparation". The page says "Additional 2015 products will be released near the end of March 2015", yet another deadline they haven't made, don't know what the latest is. As far as I know there's nothing in the 20 released papers about even looking for bubble collision signatures, I have no ideas if that will be somewhere in the 8 still to come.

Lee,
Thanks for pointing that out. I think you're being too kind though. It seems to me that the generic prediction of inflationary scenarios, including any bubble universe ones, is that there is no conceivably measurable spatial curvature, and thus that spatial curvature observations will never tell you anything about bubble universes.

Bernhard,
I think Kleban's list is pretty comprehensive, which is why I bothered to write about it. As far as I know, no one has put together a list of all the claims made about "bubble collisions". Claims about the possibility of seeing such things get lots of play in the media, with never any followup when someone looks at the data and sees nothing.

10. **David Orrell**
April 9, 2015

Interesting that multiverse theory is being funded by money from investment firms. Not sure if they will turn out to be as good at picking scientific winners as they are at picking stocks. I have posted an article on this:
https://futureofeverything.wordpress.com/2015/04/09/funding-other-universes/

11. **bhr**
April 9, 2015

Correct me if I'm wrong but the $878K is spread out over three years according to the link to the project description. This might make the comparison with the NSF/DOE numbers a bit less scary.

That comes out to just under $300K/year. I'm a bit confused about where it's going. According to the link, this will fund one postdoc, 2-3 peoples' summer salaries, and a workshop. I would have guessed that only adds up to about half the total award.

12. **Peter Woit**
April 9, 2015

bhr,
I think the numbers roughly add up, you may be underestimating what people get paid. I'd guess very roughly $100 K would go to summer salaries, $100 K for postdoc salary + benefits +overhead, $100 K for visitors + workshops + public lecture.

Note that this is supposedly only one of three Templeton grants to the SITP. One of the others is this
http://www.templeton.org/what-we-fund/grants/quantum-gravity-frontiers
which is for $600K, so $200K this year. I don't know what the third grant is, but
there's at least $500K this year. For comparison, the same people also have an NSF grant
http://www.nsf.gov/awardsearch/showAward?AWD_ID=1316699
$1 million for ~~3 years~~ (*correction, I'm told this is for two years*), which presumably covers another month of summer salary, more postdocs and grad students.

It seems likely that they're now taking in ~~significantly more~~ *about the same* from Templeton than from the NSF.

It also seems to me that some of the newer Templeton grants like this one are structured to be very much like NSF grants, with the standard summer salary/postdoc package (although it looks like they're not now supporting students). The Stanford Templeton postdoc is a conventional condensed matter theory postdoc, indistinguishable from NSF ones, see the ad here
http://web.stanford.edu/group/sitp/CondensedMatter/postdocpositions.html

Templeton has always favored giving grants to the most prestigious universities around. It may be that in the future the most prominent theory research groups will be getting their funding more from Templeton than from the NSF/DOE.

13. **Missleaded layman**
April 9, 2015

Is a a big picture of a turtle in the CMB a requirement for the giant turtle controlled universe theory, I mean, if no such picture is found in the CMB data, would that rule the theory out?

14. **Peter Woit**
April 9, 2015

Missleaded layman,

Certainly not! My giant turtle theory works equally well with a turtle who likes his image spread over the sky, and one who doesn't.
But the point is that I can answer the criticism that my theory is empty and makes no distinctive predictions. There is a distinctive prediction: "if the image of a giant animal shows up in the CMB, it will be the image of a turtle". And I think it's undeniable that if and when a convincing turtle image shows up in the CMB, that will give good reason for taking the turtle theory seriously.

15. **Missleaded layman**
April 9, 2015

Thank you. I started to search the web for multiverse related topics after reading an unsatisfactory book about multiverse theory targeted at laymen earlier this year, and eventually came across your blog. And for sure I'll be back seeking your point of view frequently!

16. **vmarko**
April 9, 2015

"it's undeniable that if and when a convincing turtle image shows up in the CMB, that will give good reason for taking the turtle theory seriously."

I think we should take the turtle theory seriously already now. Namely, in addition to the prediction of turtle image in the CMB, there are theoretical reasons as well — it naturally explains why there are no unicorns in the observable universe, and why the world is flat. Not to mention the explanation-through-randomness for the values of the fundamental coupling constants, which is equally good as in inflation+antropic principle+string theory.

17. **emile**
April 9, 2015

Ironically, in the multiverse, there must be a few universes out there with a picture of a Giant Turtle in their CMB.

18. **paddy**
April 9, 2015

…and one in which it is turtles all the way down.

19. **N**
April 9, 2015

I like the Turtle Approach.
As many turtles, so many universes.
And everybody happy, even the Templetones.

Amen.

20. **JG**
April 9, 2015

For people waiting for Planck's final say on bubble universe collisions and turtles I think the paper to watch for is

"Planck 2015 results. XVI. Isotropy and statistics of the CMB"

Still "In prep" as of this posting

21. **DrDave**
April 9, 2015

Nice acronym.

22. **former mathematician**
April 9, 2015

From Rebecca Goldstein's "Plato at the Googleplex": "It's not turtles all the way down, but rather reasons, logoi, all the way down."

23. **ateixeira**
April 10, 2015

@Peter why do you say that the standard model is "the most successful physical theory ever". In terms of sucess I think that GR is at least as good as the SM. Or is it because the range of application of the standard model (either be it theoretical or practical) is far greater than the range of application of GR?

Now that I think of it I think it is safe to say that Condensed Matter Physics may be even more successful than the SM and GR together (again in a theoretical and practical level)

More in line with the main focus of your post I'd say that this situation of research funding being more and more dependent from private donors is kind a return to the old days of gentleman science where patrons were responsible for providing the means of subsistence of influential scientists. This of course has two problems in my view. In the first place it may happen, as you already alluded, that these modern day patrons pay for the kind of research they want to see and lastly young researchers can be drawn to this highly visible and profitable fields of research hindering progress in other worthy areas (like condensed matter for instance).

24. **Low Math, Meekly Interacting**
April 10, 2015

I'm really encouraged to hear that someone, even in the guise of reductio ad absurdum, is putting the Fairy Question out there in the public discourse. My daughter is captivated by and obsessed with all things Tinkerbell. I don't know how to tell her Tink isn't real. I dread that conversation more than the one about the Easter Bunny, or even Santa. Now it occurs to me I don't have to disabuse her of anything. Thank you, Multiverse! It's also comforting to realize there's a copy of me somewhere that's totally pumped to have The Talk about sex and menstruation. The gifts you bestow are truly infinite!

25. **Shantanu**
April 11, 2015

atexeira, Unfortunately even these private foundations such as templeton (or Fox)
also mainly fund fad topics (and probably topics already funded by NSF/DOE etc)
There is still a fundamental problem that people who work on non-mainstream ideas
or independent research find it very hard to get funding or jobs. (Again I don't want
to go into which topics are these or examples of such people in this post.)

26. **Anthony Reynolds**
April 11, 2015

In Orrel's comments, he states at least twice that "if we take time seriously", then follows some conclusion. I don't know what it means to take time seriously, or to take it lightly, for that matter. To be taken seriously is not a possible attribute of time. I would say that statement is "not even wrong." I haven't read Unger and Smolin's book, but some of Smolin's writing that I have read (not all of it) suffers from the same problem. At least his more wild speculations.

27. **Anthony Reynolds**
April 12, 2015

Jim Baggot,

Regarding your wish to get rid of "falsifiability." In Chapter 1 of your book "Farewell to Reality," you put forward the "Testability Principle" as part of the demarcation problem. But it seems that this principle includes both 'verifiability' and 'falsifiability' at some level. Neither of these works all the time, but together, with some notions of how to interpret the tests gets you what you want. Indeed, you state

> While this is not quite falsifiability, it certainly has some of its flavor. So, while perhaps Popper's falsifiability notion should not be our sole criteria, it certainly should be an element of the solution to demarcation.

28. **Anthony Reynolds**
April 12, 2015

Sorry, my cut and paste failed me. It should be:

Indeed you state

> A theory that continually fails repeated tests is a failed theory.

While this is not quite falsifiability, it certainly has some of its flavor. So, while perhaps Popper's falsifiability notion should not be our sole criteria, it certainly should be an element of the solution to demarcation.

29. **Jim Baggott**

April 14, 2015

Anthony Reynolds,
Peter's blog is probably not the best place to have a discussion about this. Have a look at the article I posted on my website (the link is in my earlier post). I have it on authority from a highly respected academic philosopher that I am, at heart, a Popperian. That's OK by me, but it doesn't make my point any less valid. We need to accept that the business of accepting or rejecting theories is all rather fuzzy, and doesn't lend itself to easy, black-or-white demarcation. To continue to construct arguments based on falsifiability alone simply plays into the hands of the fairy-tale physicists, I think.

An approach to theory development based on mathematical (rather than physical) logic and intuition is perfectly valid and has been enormously successful in the past. Obvious examples are general relativity, Dirac's relativistic wave equation for the electron, and even the Higgs mechanism. But, whether by accident or design, all these examples predicted or at least hinted at effects that might be discernible in empirical reality: the perihelion of Mercury and the bending of starlight, the positron, the masses of the W/Z bosons and the existence of the Higgs boson.

The criticism of 'fairy-tale' physics is that in many cases there are simply no empirical references; no tests. And where 'predictions' are made, these are so loose, adjustable or negotiable that taking the trouble to establish the empirical facts takes us no further forward. Some philosophers use the term 'progressive' to describe a theory that allows us to make scientific progress in this sense and, it seems to me, 'testability' is an adequate criterion to help us to understand what it means for a theory to be progressive.

For sure, a theory that is 'testable' is also in principle 'falsifiable', but these two terms are not synonymous. Is Newtonian mechanics false? Arguably no, it's not – it still holds good within its domain of applicability, which is why we still teach it in schools and colleges. Falsifying a theory can be really difficult – philosophers reference something called the Duhem-Quine thesis: when a prediction is not upheld by empirical data this could mean the theory is false or it could mean that any one of a number of approximations or 'auxiliary hypotheses' required to make the prediction are invalid, but the data don't tell us which. A test is a test.

30. **David Orrell**
April 14, 2015

Anthony,
You say that "To be taken seriously is not a possible attribute of time" so to assert that it can be taken seriously or not, as Unger and Smolin do in their book, and I do in the review, makes no sense.
Being taken seriously is not a fundamental attribute of time, any more than it is a fundamental attribute of the multiverse. It refers to the attitudes of people. One of the main arguments in Unger and Smolin's book is that some scientific approaches take time as a given, while others invest more energy in exploring its attributes and see it as playing a more active role – in the authors' words, they take it more seriously. It would be a shame to write off their approach based on what looks like a case of semantic confusion.

31. **gadfly**
April 14, 2015

"I'm in many ways not very sympathetic to the point of view of Orrell and Unger/Smolin, especially about the role of mathematics in physics. "

I think spending time with complex systems (plasmas, proteins, shockwaves in materials, glasses, ecological and economic systems) would rapidly disabuse you of the notion that mathematics is anything more than the scientific equivalent of democracy: that is to say, a mediocre and tragically limited way of doing things, but vastly superior to any of its competitors. There was a very good article in IEEE about the reasonable ineffectiveness of mathematics recently which establishes this point pretty well.

32. **David Orrell**
April 15, 2015

Further to gadfly's comment, apparently there is a NOVA show on this evening about this topic of the effectiveness of math: http://www.pbs.org/wgbh/nova/physics/great-math-mystery.html

33. **gadfly**
April 15, 2015

That NOVA looks amazing, thanks for sharing!

34. **Lee Smolin**
April 16, 2015

Dear Anthony,

"Taking time seriously" is of course just a slogan , which is shorthand for "investigate and test scientific hypothesis which incorporate a notion of physical time which has one or more of the following attributes":

-Laws are not timeless, but evolve, according to some specific dynamical mechanism, which has testible consequences.

-The arrows of time have their origin in a fundamental irreversibility or time assymmetry, of the fundamental theory, out of which the standard, time irreversible laws are emergent.

-The fundamental laws refer to an objective distinction between the past, present and future, not available within a block universe interpretation of GR.

-At the fundamental or quantum gravity level, the refoliation invariance of GR is replaced by dependence on a global slicing as in shape dynamics.

The conceptual and philosophical analyses of my recent book with Mangabeira Unger have value to the extent that they suggests new hypotheses like these which may be developed and tested-because they make falsifiable (or if you prefer, testable) predictions.

Here are some papers which propose and develop such ideas:

–Marina Cortes, Henriques Gomes and Lee Smolin, Time asymmetric extensions of general relativity, gr-qc. arXiv:1503.06085.

LHC News

April 9, 2015
Categories: Uncategorized

The LHC has just ramped up for the first time to 6.5 TeV, and has a probe beam circulating in one direction, the highest energy protons humans have ever accelerated. You can follow what's happening here.

The BBC has gotten very excited about this whole LHC thing.

Update: Now it's two beams at 6.5 TeV. They just need to be careful to avoid beam collisions until the press event is organized…

Update: Maybe they weren't careful enough. The Monday morning beam commissioning reports "Possibly first collisions". No confirmation of this from the experiments, or officially from CERN.

Comments

1. **Gus Bici**
   April 9, 2015

   6.5 is large. 13 is gross. LHC to be renamed GHC?

2. **Peter Woit**
   April 9, 2015

   Gus,
   Luckily, it's only 6.5/beam, 13 for two of them.

3. **Los Ranchos**
   April 9, 2015

   I think its wrong not to be excited about the LHC, whatever motivations or theories got it advertised, sold and done.

4. **Bernhard**
   April 10, 2015

   Los Ranchos,

   Sure, but not that much. Kids are watching, you know…

5. **Low Math, Meekly Interacting**
   April 10, 2015

   Think about it: there's a pocket universe in which it makes perfect sense.

6. **EFT**
   April 10, 2015

   Could this level of energy provide a definitive test for the simplest MSSM model?
   Thanks

7. **Peter Woit**
   April 10, 2015

   EFT,
   Depends what you mean by simplest. In the simplest pictures of what SUSY models are supposed to do, evidence should have turned up at LEP and the Tevatron.

   I've already written a huge amount about SUSY and the LHC, and that will be the big story during the coming year so will be discussed extensively here. Right now though, no news, so it's off-topic for this posting.

8. **EDBM**
   April 11, 2015

   A rare caption of an excitation of the BBC field! I suppose it has long since decayed to a ground state…

9. **srp**
   April 11, 2015

   The real-time LHC data page is oddly compelling. They have a nice documentation page to help you understand each element, too. On three visits to the page at widely separated times, the same beam always had the higher intensity of the two–wonder if that's a design spec, or just the way it turned out due to normal manufacturing or operating variance.

10. **Justin**
    April 12, 2015

    Woit,

    I would like to clarify exactly your view on what one might expect from the LHC. If I'm not mistaken, you do not expect to see any fundamental deviation from the standard model because the standard model may turn out to be a basic fundamental description, one that we need to understand better. Is that more or less correct?

11. **Thomas Larsson**
April 13, 2015

Justin,
The most striking results from LHC 1 are clearly that the Higgs mass is at the brink of instability and that no BSM physics has shown up. As emphasized e.g. in arxiv:1307.3536 or arxiv:1407.2122, the near-criticality of the Higgs mass means there is really no need for any new physics at all until close to the Planck scale. This may even be thought of as a principle – the principle of living dangerously.

12. **Michael Shain**
April 13, 2015

The authors of arxiv:1307.3536 (Investigating the near-criticality of the Higgs boson)
in their conclusion seem to favour the multiverse :
"an explanation of near-criticality almost necessarily requires the existence of an underlying statistical system. This drives us towards the multiverse as the most convincing framework in which one can address the issue."

So is the discovery of the mass of the Higgs proof of the existence of the Multiverse?

13. **Thomas Larsson**
April 13, 2015

Personally I don't believe in the multiverse, but would rather expect that near-criticality is a reflection of a symmetry principle. This is in analogy with the situation in statistical physics, where critical exponents satisfy certain thermodynamic inequalities as equalities, due to an underlying scale symmetry.

Be that as it is. The striking experimental facts are that all kinds of BSM physics have been disfavored by the LHC, and that the Higgs is balancing at the edge of instability. It must mean something.

14. **Peter Woit**
April 13, 2015

All,
Please, there are too many postings on this blog about the multiverse, no need to infect the ones that aren't with the topic.

Justin,
I expect that by far the most likely result from the LHC will be continued confirmation of the Standard Model (and I suspect that's also most people's expectation). Personally I think the most likely place to look for deviations from the Standard Model is the Higgs sector, and the LHC has a long career ahead of it studying the Higgs. It would be wonderful if the LHC sees something that violates the Standard Model, we desperately need a hint from experiment about how to do better. I just don't know of any proposed new physics to be found at the LHC that has any compelling theoretical or experimental evidence to support it.

15. **srp**
April 16, 2015

"Beam lost due to losses in the usual position…" 4/17 03:41:29

Is that normal ramp-down or a repeated teething problem? It says there was a "protection dump" and lists the data as part of a "post mortem" which sounds less than propitious. I'm sure they'll get the bugs worked out but it must get nerve-wracking over there.

16. **KenW**
May 4, 2015

Your reply to Justin is disheartening. If a long career exploring the Higgs is what awaits the LHC, I fear that there will never be a more capable collider. People – governments – want significant new physics. Of course, results are results. But the high costs associated with these machines make it difficult to go further by this means, at least without spectacular news. Are there truly no lower cost options?

17. **Peter Woit**
May 4, 2015

KenW,

It was always clear that one problem with overselling the LHC, as a machine that would discover extra dimensions, black holes, supersymmetry, etc., was that there would be a price to be paid in terms of credibility. If the LHC turns up nothing beyond the SM, that is going to make the case for a higher energy machine more difficult to make. If the LHC turns up unusual Higgs behavior, and the case for a higher energy machine to study it is made difficult because the public and decision makers think "but what about those extra dimensions, black holes, etc?" that would be a shame.

My impression is that current studies of a larger machine than the LHC are still at a preliminary stage, with nobody talking about realistic cost estimates, so it's unclear what the financial feasibility of these ideas is. If a larger machine can mostly be financed at current CERN budget levels, it's a realistic possibility. If much higher budget levels are necessary, that seems unlikely. While the US, Japan or China could do such a project, there's zero probability in the US, and I have no idea about Japan or China.

I'm surprised there hasn't been more discussion of the HE-LHC idea (reusing the LHC tunnel for a machine with twice the energy), since I would have thought the cost of that would be much more likely to be affordable than the more ambitious VHE-LHC ideas which would require a new, much larger, tunnel and infrastructure.

I should make it clear that personally I think that, if technologically realistic, any of these higher energy accelerator ideas are worth the money and I hope at least one will be pursued. These are expensive machines, but affordable on the scale of the resources available to the countries involved, and more worthwhile than a lot of other things that are being funded.

The Lady Gaga of French Mathematicians Comes Stateside, and Other News

April 15, 2015
Categories: Uncategorized

Cédric Villani is in town today, giving a talk at the French consulate. He'll discuss his book, recently translated into English (I wrote a bit about it here). Yesterday, despite the lack of suitable bread and cheese, he was in Princeton, where he gave a public lecture at the IAS. The New Yorker has a story about him by Thomas Lin, entitled The Lady Gaga of French Mathematicians Comes Stateside.

If you're not listening to Villani tonight, you could be watching a PBS Nova program on mathematics, The Great Math Mystery. Among the mathematicians interviewed will be my colleague Dusa McDuff. As for the question on the PBS site:

> Is math a human invention or the discovery of the language of the universe?

the answer is the latter.

What some mathematicians might consider the "Great Math Mystery" is whether Mochizuki really has a proof of the abc conjecture. There finally will be the topic of a workshop involving experts in the field, to be held this December in Oxford. Still no paper from Go Yamashita about this, but here you can find some photographs of the boards from his talks in Kyoto last month. Mochizuki himself has a new paper, inspired by conversations with Fesenko.

Also in New York this week, Bjorn Poonen will be speaking on Thursday. His topic is a heuristic argument that there is a finite bound on the rank of elliptic curves. For notes from a talk of his about this last year, see here.

Update: The Villani IAS talk is available here.

Update: At David Mumford's blog he has a long and very interesting posting about the state of mathematical research publishing.

Update: One more piece of math news. Dan Rockmore has set up a public version of his Concinnitas Project, which lets people post, with explanation, a picture of their choice of a "most beautiful mathematical expression". See here for details.

Comments

1. **Interested**
   April 15, 2015

   Will the Villani IAS lecture be posted on their website afterwards?

2. **PointedRemark**
   April 15, 2015

   Fesenko's impressive survey of IUT,
   https://www.maths.nottingham.ac.uk/personal/ibf/notesoniut.pdf
   cited in the last line of the "here" link above, ends with this pointed and invaluable remark:

   An opinion of R. Langlands on current trends about supporting long-term fundamental research work can be heard during the 52nd minute of his video lecture [20]. Some roots of the decline of support to long-term fundamental work, such as the shortsighted race to higher number of publications and higher citation index, which often results in pressure to produce short-term work that consists essentially of minor improvements to known results, originate from causes external to the mathematical community. To do well in their academic career, young researchers are very often pushed to go along this path which typically implies a very narrow specialisation. The latter leads to the emphasise on technical perfection as opposite to innovation and on presentation rather than the substance of work. Following this path eventually makes it more difficult to think broader, to learn new areas, to develop in more directions. Lack of inventiveness, more widely spread imitation, fear to stand alone in scientific endeavour, fear to look too far away are associated issues. Some roots, such as the unnecessarily strong emphasis on concrete applications, originate from within the mathematical community. Changes are needed.

   There is an issue about attitudes of number theorists towards the study of IUT and their unusually sluggish response. Reasons for this are related to the topics discussed in the third paragraph of 3.3 and in the previous paragraph. It seems that the number theory community is suffering from the problems listed there even more than other mathematical communities.

3. **Interested**
   April 15, 2015

   Never mind, Villani's talk has already been posted:
   https://video.ias.edu/villani-publiclecture-2015

4. **Peter Woit**
   April 15, 2015

   PointedRemark,
   I think Langland's point is excellent and quite important, but I'm not convinced it's relevant to the IUT/Mochizuki story. Here the question is not why people aren't being inventive and developing their own long-term research projects, but why they're not signing on to Mochizuki's, which is different. This has a very high profile in the math research community, everyone in the field knows about it and has looked at it. My interpretation of what has happened is that a lot of experts have just decided that this claimed proof is not yet in a state where it can be evaluated by the usual methods and the methods used are not obviously convincing enough to be worth the time needed to try and figure out how to use them. Given this, it's quite reasonable to decide to not spend one's time on IUT, but to instead work on ones own ideas and wait until either Mochizuki/Yamashita/someone else puts out a comprehensible version of the arguments. Mochizuki's own reports on what is being done to check the proof aren't inspiring confidence.

   I think sooner or later though, enough people will put enough time into this for it to become clear what the value of the ideas is. Some day we'll know whether or not there's really a proof of abc and powerful new methods there, but in the meantime I don't think people can be criticized for not finding this convincing and not wanting to abandon work on their own ideas in favor of working on Mochizuki's.

5. **vmarko**
   April 15, 2015

   Hi Peter,

   "Is math a human invention or the discovery of the language of the universe? [T]he answer is the latter."

   Risking that this might be off-topic, I nevertheless need to ask something about this. It seems that you have a very strong opinion, and I am curious why? For example, how do you rate, say, the axiom of choice — is it a part of the language of the universe, or not? Note that if you say "yes" I'll ask you further about the Banach-Tarski paradox (which seems anything but to hold in our universe), while if you say "no" I'll ask you about the lack of power of the ZF without C, and the fact that most mathematicians today prefer ZFC over ZF, despite it not being the language of the universe (by assumption).

   Or as another example, take the distributive law (of propositional logic) and note that it fails in the context of quantum mechanics (as discussed, say, in the Wikipedia article on quantum logic). If math is the discovered language of the universe, does distributive law hold or not? If not, how many theorems in standard math would go down the drain because their proofs rely on it?

   There is also the question regarding Brouwer's intuitionistic logic versus Hilbert's formalist logic (discussed here) — which one is the correct language of the universe? I as suspicious that it can't be both, so…

   It seems to me that these examples suggest that math (being mostly built on top of some particular logic and some paricular set theory) is a language that sometimes nicely describes the real world, and sometimes less so, depending on the adopted axioms. This makes it more a human invention than a discovery of some property of nature, since otherwise issues like Brouwer-Hilbert controversy could be resolved experimentally. I am really curious to hear how do you deal with these issues, from your POV.

   Best, 🙂
   Marko

6. **Peter Woit**
   April 15, 2015

   Marko,
   Sorry, this really is off-topic. In my essay I tried to explain my point of view. The question is a completely ill-defined one, and people can use it for inspiration to discuss all sorts of topics. Questions about the fundamentals of mathematics (or physics) in terms of logic happen to be ones that have always left me cold, so I've neither the knowledge nor the interest to carry on my half of an intelligible debate about the issues you raise.

7. **Douglas J. Keenan**
   April 16, 2015

   Last month, *The Observer* (which is the Sunday version of *The Guardian*) had a 2000-word article "Cédric Villani: 'Mathematics is about progress and adventure and emotion' ". The article focuses on Villani's book *Birth of a Theorem*.

8. **gadfly**
   April 16, 2015

   Speaking of the research climate for fundamental mathematics, what is the research climate like for pure mathematics in general? Obviously they've never needed huge grants (in general anyway) but I've always wondered how hard it is to become a research professor in a subject* which is so controversial.

   *I do realize this probably varies from subtopic to subtopic within pure mathematics.

9. **Peter Woit**
   April 16, 2015

   gadfly,
   I don't think pure math is controversial, quite the opposite. Few people are interested or care one way or the other about it.

   Academic math departments have a mix of pure and applied, and the pure component is in some sense mostly funded by the teaching mission: there are lots of students out there who need to learn calculus, etc. This is what most pure mathematicians are being mostly funded to do. The number of purely research positions, e.g. at research institutes, is a small part of the overall number of positions.

   Like most of academia and the rest of society, there's been a trend to a star system where some people do very well, most people not so much. So, people with permanent positions at major research universities are doing quite well and have good environments for their research, but such positions are hard to get (and, like Langlands one might worry this makes people risk-averse). Not so hard to get some kind of position, but often these are poorly paid adjunct positions, in which carrying on research can be quite difficult.

10. **Jeff M**
    April 16, 2015

    Peter and gadfly,

    As an academic mathematician I'll put my two cents in. Peter has it basically right. Math (pure or applied) is significantly easier than physics, in that lots of students need calculus, and not many need basic physics. At my university, we have 32 full time mathematicians (this includes math ed and statistics, if you take just math folks it's 16). There are 5 physics professors. That said, getting an academic position in math is hard. When we have an opening, we'll get 3 or 4 hundred applicants, most over qualified. I'm not at a research one school, you're expected to do research but you teach 3 classes a semester. Our last hire has a Ph.D. from Cornell and a research postdoc at Rochester, and he was happy to get the job. Most of our adjuncts are honestly not Ph.D. mathematicians, that end of the job market actually gets covered in large part by jobs at community colleges and such, brutal, but at least with job security and vaguely reasonable pay. Not that there aren't some Ph.D. adjuncts in math, just nothing as bad as physics, or art. And math, like physics, has an out, you can go work on wall street and make 10 times what I do.

11. **EFT**
    April 17, 2015

    I must be missing something, but I would very much like to know why Cédric Villani is called "the lady gaga of french mathematicians".
    Thanks.

12. **Peter Woit**

April 17, 2015

EFT,
Probably like most people, the little I know about Lady Gaga is that she is a celebrity who favors flamboyant dress. I'd guess that's the analogy in someone's mind that the article's author is referring to.

13. **Zimriel**
April 17, 2015

"a heuristic argument that there is a finite bound on the rank of elliptic curves"

Oh my. Is he gunning for the Birch and Swinnerton-Dyer Conjecture?

14. **Peter Woit**
April 17, 2015

Zimriel,
I don't think Poonen's heuristic argument really addresses Birch Swinnerton-Dyer. Even if you prove no elliptic curves of arbitrarily high rank, you still have to prove BSD for curves up to some finite rank, and that's completely open.

15. **David Roberts**
April 17, 2015

@Zimriel,

there are still infinitely many curves of rank greater than, say 18, (and conjecturally, only finitely many above 22 or so) so there's no hope of just enumerating the rank greater than 1 curves, and using Bhargava-style results on density (100% curves blah blah) to get BS-D.

16. **Art Brown**
April 19, 2015

Columbia was certainly well-represented on the Nova program (I counted 3 reps), even if Dr. Tegmark got the bulk of the airtime. Does someone there know somebody at PBS?

Flashy graphics and hip engineers didn't rescue this program from boredom, imho. One bet they missed: instead of rhapsodizing about the universality of gravity, explain that most folks are currently doubling down on the theory, invoking unobserved dark matter to explain discrepant galactic motions, in direct analogy to the Uranus orbit discrepancy leading to the discovery of Neptune. (Rather fewer are betting that the correct analogy is to the Mercury orbit discrepancy.)

17. **Obs**
April 19, 2015

EFT, the New Yorker article just says "Villani has been called the Lady Gaga of French mathematicians" which it probably got from one of the many earlier articles that says the same thing. However, a bit of Googling indicates that it comes from Villani himself in an interview with Télérama in 2011, where he comments on the attention in French media after he won the Fields metal; a lot of focus on his clothing style, little on what he actually did or on fellow French winner Ngô Bảo Châu: "Je suis un peu la Lady Gaga des mathématiques."

18. **EFT**
April 20, 2015

Peter & Obs,
Thank you very much for the clarifications.

19. **gadfly**
April 20, 2015

I finally watched the nova program. The Tegmark section caused me to laugh out loud. The point where he implied that nature was contained in its entirety in the standard model and that this somehow furnished his argument that math and nature are one and the same reconfirmed my view of him as a nigh unparalleled munchkin.

It is obvious that the standard model doesn't actually describe the vast majority of reality… right?

20. **Peter Woit**
April 20, 2015

gadfly,
I haven't watched the Nova program yet (it's on the DVR…) but while I disagree with Tegmark about a lot of things, it sounds like this isn't one of them. The Standard Model + GR is an amazingly successful and comprehensive fundamental theory, and the connections between these theories and mathematics are very deep.

There is a big difference though between being a successful fundamental theory and "describing reality". A fundamental theory is just not relevant for understanding most of science, not to mention things besides science.

21. **gadfly**
April 20, 2015

Peter,

Intriguing. The SM+GR does indeed have a far more mathematical character than say, the statistical mechanics of classical liquids. But I have always heard that GR and QFT contain a relatively small amount of pure mathematics; a dash of continuous group theory in the latter and a bit more than a dash of differential geometry in the former. Is this true?

What do you make of the alternative viewpoint that more exotic mathematics is a result of poor intuition? We have a poor intuition of subatomic, high energy systems, and a poor intuition of black holes and cosmological scales, so we need a more subtle and complex language to describe them; in some regards, it is a form of packaging ignorance. You can find sophisticated mathematics elsewhere in physics where there is a breakdown of intuition; people have tried to use topological techniques to study the configuration spaces of biomolecular systems, for instance.

22. **Chris W.**
April 20, 2015

gadfly,
Speaking of reliance on intuition versus mathematical formalization, see [this fortuitous post] from Steve Hsu.

One can argue that the breakdown of intuition is inevitable; science can't help but advance into realms where intuition is not helpful, and worse yet, can never really be developed. Extreme combinatorial complexity might be one such realm. In such realms the human mind needs powerful aids.

23. **Peter Woit**
April 21, 2015

gadfly,
No, it's simply not true at all. SM + GR contain a huge amount of deep, non-trivial mathematics.
Mathematics is a language that can be of great use in situations where our intuition fails us, but typically it is not sophisticated mathematics that is of use, but more basic mathematical ideas. What's amazing about SM + GR is that deep mathematical ideas are precisely what is needed to state the theory.

April 21, 2015

Peter, I learned of your site after finding John Baez's site (or series of postings), around 2003-4. I was pretty down on "string theory" at the time, having been unconvinced by the semi-popular version that all particles are some kind of violin strings. So your site, and the books by you and Smolin were refreshing. (I am less down on ST now, despite the untestable part, but at least things have moved beyond the guitar and violin metaphors. Also, ST no longer seems to be the 800-lb gorilla. Perhaps I am wrong in terms of who is being hired, but certainly the shine has come off it a bit in the past 15 years. The AdS-QFT thing is really intriguing, and two of the most interesting talks I've been to at Stanford have been by Lenny Susskind!)

It seems to me that the category/topos and representation theory aspects of physics are central, though not always necessary for "shut up and calculate" work, and that these involve some of the deepest aspects of work done by Grothendieck, Serre, Mac Lane, and others. (Maybe my connection to computers and programming theory have influenced my interest in type theory, category theory, and "topology via logic" points of view, which are along the lines of "algebraic geometry" a la Grothendieck, Lawvere, Abramsky, and others.)

I'm just a retired physicist who did some fun work for Intel in the 70s and 80s and who took Jim Hartle's GR class in 1973. (Wish I'd learned more…seems black hole horizons are a lot more confusing than I seemed to think back then! As the current slogan goes, it's not the singularity at the center that is interesting, but the event horizon.)

BTW, some of the most invigorating stuff back then was in analysis and point set topology (mostly class notes, but Kelly and Dugundji were often used). Utterly unconnected with physics, to me at that time, but I keep coming back to it again and again. And it of course relates to quantum theory in interesting ways–lattices, von Neumann algebras, even intuitionistic logic.

Thank you for your site.

–Tim May, California

April 24, 2015

LadyGaga is famous for her outrageous costumes, esp her shoes, but she seems to have tamed it down some now that she is engaged/married. She does have a very good singing voice and is trained.

Her greatest accomplishment is getting everyone to call her 'Lady Gaga' and be known across the globe.

Things Have Changed

April 24, 2015
Categories: Uncategorized

I've been busy with other things, but after taking a look today at various new things related to quantum gravity, I was struck by how much things have changed sociologically in that subject over the last few years. Back in the days of the "string wars", debates about quantum gravity were fiercely polarized. Oversimplifying and caricaturing the situation a bit, the two sides of the quantum gravity debate were:

- Those interested in loop quantum gravity as well as other more exotic attempts to reformulate the problem of quantum gravity. These people just considered pure quantum gravity and devoted a lot of effort to analyzing the deep conceptual issues that arise. They sometimes considered highly speculative hypotheses, trying out abandoning the usual basic axioms, for instance replacing fundamental axioms of quantum mechanics. Lee Smolin was an influential figure, and the Perimeter Institute a major center for this research.
- String theorists, who argued that the appearance of spin-two massless mode in the quantized string spectrum showed that string theory was the only way to understand quantum gravity. They claimed that they had a single, very specific and highly technical mathematical structure to study, which obeyed the conventional quantum theory axioms. Their efforts were devoted to specific computations in this theory, and they seemed to regard the other side of the debate as woolly thinkers, caught up in meaningless ill-defined philosophical speculation. The KITP at Santa Barbara, led by David Gross and Joe Polchinski, was a major center for this side of the debate.

These days, things have changed. If you're at Perimeter, prominent activities include:

- This week's conference on a very technical issue in string theory, superstring perturbation theory.
- This month's course of lectures on Explorations in String Theory.
- The next public lecture will feature Amanda Peet promoting string theory. Peet has been one of the more ferocious partisans of the string wars. The text advertising her public talk a few years back at the Center for Inquiry in Toronto warned attendees who might consider "parrotting of critical views by outsiders like Lee Smolin."

On the other hand, it you're in Santa Barbara these days, you might be participating in a KITP conference on Quantum Gravity Foundations. This is featuring very little about the technical issues in superstring theory being discussed at Perimeter, but a lot of discussion of deep conceptual issues in quantum gravity. There's also a lot of willingness to throw out standard axioms of physics, maybe even quantum mechanics. They're even letting Carlo Rovelli talk.

The sort of speculation going on at the KITP is featured on the cover of this month's Scientific American, and this week Quanta magazine will be publishing a series of pieces on something related, the "ER=EPR" conjecture. There's debate whether anyone really understands this and whether it is consistent with standard quantum mechanics. It also features a diagram that people call the "octopus" diagram. Back in the day it was Lee Smolin who was getting grief for an "octopus" diagram (see here), yet another way in which things have changed.

For a more balanced view of quantum gravity issues, you might want to spend your time in France, where the IHES recently hosted an interesting series of surveys of the subject (see here), and the Quantum Gravity in Paris conference featured more specialized talks. In the category of quantum gravity topics I wish I had more time to learn about, Kirill Krasnov's talk was presumably related to this recent work, which looks intriguing.

Comments

1. **Noboru Nakanishi**
   April 24, 2015

   I believe that the most natural unification of Einstein gravity and quantum field theory is the (non-perturbative) operator formalism of quantum Einstein gravity. I don't understand why people wish to neglect this fact.

2. **Dave Miller in Sacramento**
   April 25, 2015

   Peter,

   Over the decades, I've had similar musings to the firewall and ER=EPR ideas: for example, I remember around 1980 a discussion with Subhash Gupta when we were both at SLAC about the fact that black holes never actually quite form (classically, it takes an infinite amount of coordinate time, but in that amount of coordinate time, Hawking radiation wipes out the black hole); I always assumed something like the firewall had to exist.

   But I (and as far as I know Subhash) never got beyond such musings.

   So, I hope all this leads to wild successes.

   But, my "gut feeling," alas, is that you have to be Einstein for such qualitative musings to lead to a revolution in understanding.

   So, what's your gut feeling about all this — the firewall, ER=EPR, etc.?

   Dave Miller in Sacramento

3. **Peter Woit**
   April 25, 2015

   Dave Miller,
   I've always been dubious that very general speculation about gravity/space/time/black holes, etc., is going to go anywhere. I tried to give the example of Krasnov's work as the kind of thing that seems more promising. The big problem of quantum gravity to me seems to be the relation of space-time degrees of freedom and the internal degrees of freedom of the standard model. The best argument for string theory vs. LQG was always that string theory would explain this relation.

   These days, prominent string theorists seem to have just given up on the problem, and adopted a version of Smolin's call for "seers", but on steroids. The world has always been full of people with ideas about how they are going to revolutionize physics,
   ideas which are far too vague and speculative to ever go anywhere. What's weird is that some of the most prominent figures in the theoretical physics community are now headed down this route (one example of recent years is Verlinde and "entropic" gravity). I'm loathe to specifically criticize "firewalls" or "entangled particles = wormholes" too much since I don't know exactly what these people are doing (I've spent enough time looking at it though to decide that my time was better spent on other things).

One thing that is clear though is that, unless it actually achieves something, putting this on the cover of Scientific American, or otherwise giving it a lot of publicity, is not a great idea. More hype is not what this subject needs.

4. **Dave Miller in Sacramento**
April 25, 2015

Peter,

Thanks — I suspect you're right: perhaps a lot of physicists (and I'm not excluding myself) are overly beguiled by the thought of being Einstein thinking deep thoughts while working in the Swiss Patent Office.

You wrote:
>The big problem of quantum gravity to me seems to be the relation of space-time degrees of freedom and the internal degrees of freedom of the standard model.

Are you acquainted with the "problem of time" in quantum gravity? It seems to me the solution probably lies in an integrated theory where the standard-model degrees of freedom act as "clocks" to make time determinate: of course, I have no idea how to actually do this, alas.

I'll look into Krasnov's work as you suggest. Like you, I am old enough to remember when "real" physics meant doing calculations that had, in principle, experimentally testable predictions.

I suppose the best counter-argument to your and my pessimism is that, if enough people muse over various oddities and loose threads in existing theories, perhaps one of them actually will end up being Einstein sitting in the Patent Office.

Anyway, it has been interesting watching the "string wars" and all the rest, even if it is hard to see how it has advanced physics. Thanks for keeping us up to date on what is going on.

Dave

5. **Neil**
April 25, 2015

I am glad to see Asymptotic Safety first in the list of alternatives in Nicolai's survey, rather than at the bottom where it usually is. But perhaps that was just alphabetic. I thought after the remarkable prediction of the Higgs mass by AS, it would have gotten far more attention. Perhaps it is just that non-perturbative theory is so difficult.

6. **Tom**
April 25, 2015

The type of ideas discussed by Krasnov, that is GR as YM. have been around for more than 30 years. The classic one is McDowell-Mansouri SO(4,1) gravity, PRL 38, 739 (1977), reformulated by Stelle and West in PRD 21, 1466 (1980) in a way that connects YM with Einstein-Cartan and (anti)de Sitter. Very interesting, but did not lead to anything better than good old GR except for giving a moral raison d'etre for the cosmological constant…

7. **Peter Shor**
April 25, 2015

I think that a symptom of what is wrong with string theory right now is that nobody is saying "ER=EPR makes absolutely no sense. It isn't compatible with our understanding of general relativity, and it isn't compatible with our understanding of quantum mechanics. Please explain to me how this makes any sense."

Compare this with the mathematicians' treatment of Mochizuki's claim of a proof of the ABC conjecture. Or, if you want a mathematician of the stature of "EP=EPR", the treatment of Connes' idea about how to prove the Riemann hypothesis. In these two cases, we get a healthy amount of skepticism.

8. **David Roberts**
April 25, 2015

> Einstein thinking deep thoughts while working in the Swiss Patent Office.

and then (fast-forwarding a few years) he had to go and learn the then-hardcore-pure-mathematics now known as semi-Riemannian geometry to properly formulate a working theory to get gravity in the picture, with actual predictive power. Having a nice idea like the equivalence principle is not enough.

9. **jd**
April 26, 2015

I hope to hear opinions on the paper by Saini and Stojkovic, Radiation from a Collapsing Object is Manifestly Unitary, PRL114, 111301(2015).

10. **Dave Miller in Sacramento**
April 26, 2015

jd,

Bee Hossenfelder has a critical discussion (including some heated back-and-forth in the comments with one of the authors) of the paper.

The bottom line seems to be that:
a) The paper was over-hyped in the media
b) If you assume no singularity forms, the paper proves no information loss occurs
c) Everyone already knew b) anyway

In any case, as I recall, Hawking actually agreed that no information loss occurred some time ago (vide Lenny Susskind's book), though of course that does not necessarily settle the issue.

My own suspicion is that the horizon never technically forms because of Hawking evaporation (technically, you can only be sure of the horizon at standard coordinate time equals infinity); however, quantum effects should "smear out" the horizon and… well, I'm unclear on how that quantum smearing affects everything.

Dave

11. **martibal**

April 26, 2015

@Franck: well, since Connes name has been mentioned in the discussion (in another context though), let me answer that if there is at least one approach where the relation between the space-time degrees of freedom and the standard model degrees of freedom are addressed, this is precisely Connes noncommutative geometry. It can be summarized as saying: the standard model is a gravity theory, but gravity on a slightly non-commutative version of space-time. This is off topic and I already had a long exchange on that topic in the comments of a previous post, so I do not want to discuss it here, just recall that even though it is not hyped in the hep-th community, it exists and has been through recent interesting developments.

12. **Lee Smolin**
April 26, 2015

Dear Tom,

I partly agree, but there are three important aspects of gravity expressed in connection variables that MacDowell and Mansouri and Kelle and West missed. These are the fact that general relativity in 3+1 dimensions can be understood as a constrained topological field theory and that when doing so there is a redundancy in the equations of motion that can be removed by making the theory depend just on the chiral half of the spacetime connection. That is you can write a topological field theory for the chiral left handed SU(2) left space time connection, and constrain the action in the simplest possible way and find that general relativity emerges.

The third fact is that the action is most directly expressed as a function, not of the metric, and not of the frame fields, but of a self-dual two form. (The constraints that I mentioned yield the frame field as an integration constant.)

When one combines these three insights one has the Plebanski action, (whose Hamiltonian formulation was discovered by Ashtekar), which was also rediscovered by Capovilla, Dell and Jacobson. This action is not just polynomial, it is cubic in the fields, making it the simplest possible action that GR can have. The important work of Kirill Krasnov extends and deepens these insights.

These insights are also at the heart of loop quantum gravity and spin foam models. Non-trivial results are possible for a non-perturbative quantization because the action is that of a diffeomorphism invariant gauge theory with a cubic action, closely related to topological field theory.

Macdowell-Mansouri and Stelle-West build on a different insight, that (in the modern language) you can relate GR to a broken topological field theory of the deSitter or anti-deSitter group. This is compatible with the Plebanski formulation and can be incorporated into it.

Indeed by combining these insights there emerged also a connection with Chern-Simons theory induced in 3 dimensional boundaries such as horizons; and this led to an understanding of the role of the cosmological constant in quantum gravity, as an infrared cutoff that is imposed as a quantum deformation of the chiral SU(2).

Thanks,

Lee

13. **Mark**
April 26, 2015

Peter Shor,

I'd be really curious why you think "ER=EPR makes absolutely no sense". My understanding is that it gives a geometric description of states in QG (very entangled black holes) that had no prior understanding. It is an extension of the AdS/CFT description of the eternal BH/thermofield double, and you can argue for it starting from Ryu-Takanayagi (Section 1 of http://arxiv.org/pdf/1412.8483.pdf). These may not be overwhelming evidence, but why is the idea nonsense?

14. **vmarko**
April 26, 2015

Dear Lee and Tom,

The Plebanski action is indeed polynomial and cubic, but the action proposed by Krasnov is neither, due to the presence of the square root in the action (2) (also obvious in (20) in his paper). I don't really see the benefit of this for the spinfoam models. In particular, the absence of the tetrad fields makes it hard to couple fermionic matter later on, just like in the Plebanski case.

There is also the approach based on the Poincare 2-group (I'm shamelessly advertising myself here… see arXiv:1110.4694), with the constrained BFCG action — also polynomial and cubic, similar in structure to Plebanski in that it has a topological sector plus the simplicity constraint. Its advantage is that tetrad fields are explicitly present in the topological sector, which allows for the straightforward coupling of fermions. Also, the constraint has a much more transparent geometric interpretation. Finally, if one adds the cosmological constant term, one can show that the MacDowell-Mansouri action can be recovered as a second-order theory from this action (by substituting one of the algebraic equations of motion back into the action).

IMO, there are many reformulations of GR action in terms of various variables, from the historic ones (Palatini, Einstein-Cartan) to these modern ones (including the teleparallel gravity, both historic models and the recent Baez-Wise version). Each reformulation has certain appeal and benefits, as well as drawbacks. Krasnov's approach is certainly interesting, but I honestly don't see why it deserves so much hype. What problem does it solve, that other proposed actions don't? And is that solution worth the price of the nonpolynomial simplicity constraint?

Best, 🙂
Marko

15. **Guest**
April 26, 2015

Well said, Peter Shor. What I find quite entertaining is that Lenny Susskind – who jointly proposed this ER=EPR is obviously completely unconvinced by it and he doesn't try to hide that very much. I kind of expect him at any moment to say "Oh, I can't do this anymore. We all know it's not right."

16. **EFT**
April 26, 2015

Dear Peter and Lee,

I have read with great joy Peter's book "Not Even Wrong" as well as Lee's book "The Trouble with Physics".
Do you think that this change is a sign that theoretical physics is slowly becoming healthy again (using Lee's words) and that this will take physics out of its present crisis

and lead it back to the exciting and glorious years of the past centuries?

Thanks,

17. **Peter Woit**
April 26, 2015

EFT,
Personally I don't think theoretical physics is getting healthier. The changes in recent years have been a mixed bag. One positive development is that there's a lot more skepticism in the physics community about string theory, with the issues that Lee and I were raising moving from a marginalized point of view to a rather conventional one among physicists. This potentially creates space for people to work on other ideas. Unfortunately, there has been a backlash against sophisticated mathematical approaches, with too many physicists believing that it was mathematics that led string theorists astray. As a counterpoint, such mathematical research remains alive, partly due to significant funding from Jim Simons.

Among string theorists themselves, a sizable number have basically given up on conventional science, using the multiverse as an excuse to make string theory immune to challenge from experiment. Many if not most have moved on to studying other topics, from condensed matter physics to the kind of quantum gravity going on at the KITP. I have no expertise on the condensed matter stuff, but as indicated here I'm skeptical about the quantum gravity ideas and how they are being pursued. This seems to bring together the worst of the string theory fondness for hype and the worst of the long tradition of empty quasi-philosophical speculation.

18. **Peter Shor**
April 26, 2015

@Mark: Why does ER=EPR make no sense to me? Because general relativity is a well-defined theory of gravity without entanglement, and wormholes are created by curved space (possibly with negative energy density), not by information. And because quantum mechanics is a perfectly well-defined theory without general relativity, and entanglement is perfectly well-behaved without invoking wormholes.

19. **Mark**
April 26, 2015

@Peter Shor: Thanks for your answer. I don't think they wanted to explain entanglement or ER bridges, which are well understood. They just say that in QG there are some states (e.g. two very entangled BHs) that can be described in another (dual) way involving an ER bridge. While the original description is certainly fine (the wave function of the two BHs is entangled), the other description they are proposing is more geometrical and may help in calculations/thought experiments.

I'm at risk of repeating myself, but take the most concrete manifestation of EPR=ER: 1. Two CFTs in a thermofield double state. There's no gravity, but there's entanglement. 2. Take the eternal BH in AdS, the two asymptotic regions are connected by an ER bridge. By CFT/AdS 1. and 2. are equivalent descriptions of the same thing, so EPR=ER. (I acknowledge that this isn't a perfect example, because 1. was not a QG state, but I wanted to give a setup, where there are calculations that support the picture.)

20. **Peter Shor**
April 27, 2015

@Mark

Let me quote from Maldacena and Susskind's paper:

> Suppose that we take a large number of particles, entangled
> into separate Bell pairs, and separate them in the same way as the mini-black holes. When we collapse each side to form two distant black holes, the two black holes will be entangled. We make the conjecture that they will also be connected by an Einstein-Rosen bridge.

And I repeat: with our current understanding of entanglement (which I think is very good), it cannot generate ER bridges, even in the interior of black holes where it's not falsifiable. You might as well conjecture that unicorns live in the interior of black holes. That's not falsifiable, either.

21. **Peter Woit**
April 27, 2015

To add my own less well-informed take on this to Peter Shor's, perhaps someone can point me to something I'm missing here (which I surely am):

I understand very well exactly what an entangled pair of particles is, both mathematically and physically. I also understand (less well and less exactly) the AdS/CFT duality conjecture, as a conjecture relating two well-defined theories (supergravity on AdS and N=4 SUSY on the boundary). When people however announce that they are conjecturing some duality between the simple, well-understood entangled particle system and a complicated gravitational system (e.g. a wormhole), I immediately get lost, because I can't figure out exactly what the gravitational system is or how the mapping is supposed to go. When I try and read about this, all I find are vague general statements about holography and such, so I soon give up.

It's possible one can get somewhere interesting by following this kind of highly speculative line of thinking, but I don't see this happening. It seems to me that people are going to credulous people in the press like K.C. Cole to promote vague speculation, long before getting to the point of having a well-defined idea that can be evaluated sensibly in some way or other (of course all of this is completely unmoored from experiment, but it would be nice if it weren't also unmoored from the parts of theoretical physics we understand).

22. **Mark**
April 27, 2015

@Peter Shor

It's true that using particle scattering you can't see behind the horizon, so there could well be unicorns there. But people have thought of other (more subtle) observables that probe the interior. Take this paper: http://arxiv.org/pdf/1303.1080.pdf

The time evolution of entanglement entropy after a quantum quench (known in 2d CFT from the work of Calabrese-Cardy) is reproduced by the Ryu-Takanayagi surface going through the ER bridge. (It's a very special situation, but also concrete. Maybe the same results can be produced without an ER bridge, but the ER bridge is consistent with the field theory knowledge.)

Hong Liu from the CTP also worked on probing the geometry behind the horizon. You can ask him, if you're unhappy with my imperfect explanations.

23. **Guest**
April 27, 2015

The best bit about ER=EPR is that apparently now “a particle is a black hole”. Honestly! Lenny Susskind said it. If a crank had said it, it would have been dismissed.

24. **Matthew Foster**
April 27, 2015

I can’t say much for the quantum gravity side of things, but I would certainly advocate against a backlash to sophisticated mathematical methods (esp those developed alongside, entangled with the first phase of string theory ending in the 80s) . 1+1-D Conformal field theory has been enormously important in statistical physics and condensed matter; much of this structure grew out of quantum gravity and string-related research. E.g., key results on the structure of affine Lie algebras by Gepner and Witten. 1+1-D CFT underlies the deepest formulations of the fractional quantum Hall effect via Moore and Read’s construction of many-body wavefunctions from conformal blocks, and the understanding of edge states as CFTs (Wen). That’s the clearest application of WZW/Chern-Simons holography to a real well-studied experimental system (5/2 state, which may well harbor non-abelian Ising anyons).

If you are a field theorist working anywhere in quantum physics except unification and quantum gravity, I think you can profitably view much of string theory (1st quantized) as an elaborate self-consistent construction exercised within the framework of conventional quantum field theory. Much of the mathematics that we are now employing in condensed matter has already been field-tested there, and partially translated from the language of mathematicians into a form that one can use to compute things with. I.e. I’m happy to use results from conformal embedding theory, but I’m glad I didn’t have to prove their validity! If string theorists decide to stop doing this job of importing mathematics, I’m afraid us condensed matter theorists will have to do it ourselves. That means more time spent not working on calculations not “immediately” to experiment, or even perhaps concrete models. I’m not sure our funding agencies will approve…

25. **Shantanu**
April 27, 2015

Peter, this is also the first time Ed witten has given a conference (or any technical talk)
at PI. Earlier he has given a public lecture there a decade back

26. **gadfly**
April 27, 2015

EFT,

Theoretical physics as a whole is pretty healthy, but the subfields concentrating on gravity, high energy particles, and cosmology will remain in their current languid circumstances until more experiments probe those regions, since theorists are impotent and helpless without actual empirical data. This isn’t a cultural problem, since pragmatism will beat idealism if there are good experiments, sooner or later.

27. **Peter Woit**
April 27, 2015

Matthew Foster,
Thanks. 1+1 d CFT is an amazing subject, both in terms of mathematics and physics. It’s not really string theory, but string theory research brought a lot of attention and progress to the subject. Unfortunately the CFT in AdS/CFT is a different one, and the concentration of the subject on that topic hasn’t led to the same kind of progress.

gadfly,
Cosmology has lots of data, so does HEP, the problem is that theorists are fond of trying to answer questions not addressed by any data, and often such that it is unclear whether there ever will be data. It’s worth noticing that pure mathematics is a subject that has managed to keep making great progress, even in the absence of any data. Theorists should pay attention to how mathematicians do it. One thing they don’t do is promote ill-defined ideas…

28. **Chris W.**
April 27, 2015

> It’s worth noticing that pure mathematics is a subject that has managed to keep making great progress, **even in the absence of any data**.

Isn’t that possibility inherent in pure mathematics? It’s not about the physical world and in a strict sense isn’t empirical. The only “data” it might need, if any, are the results of calculations, enumeration of cases, etc., that raise interesting mathematical questions.

29. **Peter Woit**
April 27, 2015

Chris W.,
Yes, pure mathematics has always been pursued mostly independent of any data. My point is that mathematicians have over the centuries developed effective ways of making progress based purely on the internal logic of the problems they pursue. This is what theoretical physicists are also trying to do in areas like quantum gravity.

One of the most basic parts of the method of pure mathematics is an insistence that you need to pay close attention to exactly what it is you understand, and exactly what claims you are trying to make. If you don’t, you’ll get lost very quickly. I’ve never had any luck arguing with physicists that if they’re not going to have any data, they need to behave more like mathematicians. In general they’re convinced that making precise statements is a waste of time that will just slow them down, but I think they should give this a try. Couldn’t hurt…

30. **Justin**
April 27, 2015

Peter,

I know it is off topic, but April is almost over and I was hoping that you would write a blog entry commemorating the 100th anniversary of Noether’s Theorem which was discovered in April 1915.

Best Wishes

31. **Peter Woit**
April 27, 2015

Justin,
Sorry, but I’ve just spent much of the last three years writing a book about how to do symmetry arguments in quantum theory without using Noether’s theorem, for a blog entry about this, see
http://www.math.columbia.edu/~woit/wordpress/?p=7146
So, I’m the wrong person for this.

Noether was a great mathematician, and Noether's theorem is a great result, central to understanding symmetry in the Lagrangian formalism. But, these days I'm quite wrapped up in the Hamiltonian formalism…

32. **Dave Miller in Sacramento**
April 28, 2015

On the issue of quantum gravity/information loss in black holes/firewalls, etc., I just ran across this preprint by Hawking from early last year in which he argues that no event horizon ever actually forms and that therefore there is no need for a "firewall." The paper has no math at all (!); nonetheless, I am unsure what to make of it.

Peter, I cannot find that you have mentioned this: do you (or anyone else) know what to make of it?

Dave

33. **chethan krishnan**
April 28, 2015

@ Matthew Foster

Great to know that there is real appreciation for the work of string theorists from a working Condensed Matter physicist. I have seen ego-based nonsense from both sides, but this is rare.

Cool, awesome, etc.

34. **Thomas Larsson**
April 28, 2015

Matthew Foster,

Nobody has denied that the application of CFT to statistical systems is a huge success, and I have argued for 25 years that BPZ deserve a Nobel prize for this. At the same time, the limitation is very obvious in this context.

Since the string world sheet is a unobservable target manifold, in HEP you might argue that infinite conformal symmetry is so special that it must be Nature's choice. In statphys it is the base manifold that is 2D, and we know that there are 3D systems as well, and that these are both more experimentally relevant and much more complex.

When I was a postdoc I heard a joke about Polyakov's response to "Good morning": "Yes, it is a good morning, nobody has solved the 3D Ising model yet". I have no idea how much truth there is to this joke, though.

35. **Peter Shor**
April 28, 2015

@Dave
I expect that even Hawking sees this paper as not an actual resolution of the black hole paradox, but as a proposal for a high-level description of what such a resolution should look like.

36. **Jeff M**
April 28, 2015

Pardon my ignorance, as a mathematician I'm kind of confused by Hawking's paper. Not the paper, I understand his argument, more or less. And off the top of my head, I'm guessing he's right about firewalls not existing. But why exactly is ADS/CFT supposed to be useful? I mean ADS/CFT applies in universes with negative cosmological constant, which is not the case in our universe. And it's only a conjecture. I certainly understand why ADS/CFT is an interesting conjecture, but it seems to me that in order to make it relevant at the very least someone should come up with a version that applies in the actual universe, even if it's still only a conjecture. Am I missing something?

37. **Peter Woit**
April 28, 2015

Jeff M,
This whole story is based on the idea that some version of an AdS/CFT type holography is supposed to explain the black hole information paradox. Ten years ago the people involved in this were claiming that holography solved the black hole information paradox, now they've changed their mind, and their arguing about whether/how it does. Part of the problem here is that you don't know why AdS/CFT holography works, much less how something analogous is supposed to work in this different setup.

38. **Jeff M**
April 28, 2015

Thanks Peter. Personally, I was never really convinced losing unitarity was that big a deal. Not a big fan of determinism 🙂

39. **Peter Shor**
April 28, 2015

@Jeff M: I think the big problem with losing unitarity is that we have no idea how to generalize QFT to a reasonable non-unitary theory.

So assuming the real theory is unitary is kind of like looking for your keys under the streetlight. You suspect that the keys aren't under it, but you also know that if they're not, you are *never* going to find them.

40. **Vladimir**
April 28, 2015

Dr. Woit,

I've heard Susskind claim that not only does ER=EPR for (maximally entangled?) black holes, but also for elementary particles. Do you know what he means by this? How can wormholes connect two entangled particles if the entangled particles are prepared at low energies?

Thanks.

41. **Matthew Foster**
April 28, 2015

@ Jeff M

AdS/CFT might be useful and interesting if it helps us say things about CFTs. That's the context in which there is non-string theory interest in high energy physics, since you could view the gravity dual of N=4 SUSY Yang-Mills as a calculational tool for studying the strong-coupling regime of this theory. How you get from this very special theory to non-conformally invariant standard model physics is not obvious, since the question is how much infrared physics comes in. (And that's assuming the conjecture works for this special theory). But similar questions arise in connecting lattice models to CFTs and massive integrable QFTs, which do indeed work in suitable contexts. E.g. the E8 spectrum of the massive transverse field Ising model.

Some condensed matter physicists are also interested in AdS/CFT, if it might shed light on CFTs in more than 1 spatial dimension or stat physics models in more than 2D. Without studying the current state of the subject I can't say much, but my impression is that the precise correspondence is not well-established for other (e.g. non-gauge) theories. Nevertheless, one might hope that some general results about CFTs that do not follow simply from global conformal invariance could be obtained this way, such as the Ryu/Takayanagi formula for entanglement entropy.

One curious aspect of AdS/CFT is that the gravity side at weak coupling is classical and generically non-integrable, meaning you get dissipation (and presumably, chaos and thermalization). One expects these to emerge in an isolated quantum many particle theory when driven far from equilibrium (e.g. following a global quantum quench), so long as the system is not integrable. But in general we don't know a way to derive such "non-unitarity" from QFT. For disordered quantum systems such as the problem of Anderson (de)localization, we know how to obtain effective non-unitary theories that correctly capture the "chaotic" aspects of such systems, e.g. wavefunction multifractality. These can be non-unitary CFTs, which admittedly are harder to find and make sense of (since they are beyond Peter Shor's streetlight), but there are a few well-understood examples.

42. **Peter Woit**
April 28, 2015

Vladimir,
I have no idea. One problem with this whole subject is that listening to people like Susskind, it's sometimes very hard to tell the difference between when they have a reasonably well-defined idea and when they don't, so you don't know what to ignore and what to pay attention to.

43. **Jeff m**
April 28, 2015

@peter shor. Thanks, nice to know my intuition isn't completely crazy 😉

44. **chethan krishnan**
April 28, 2015

@JeffM

In AdS, black holes *still* have the same theoretical problems as in flat space. So it is conceivable that we are not throwing the baby out with the bathwater by working with AdS instead of flat space, even though AdS is possibly substantially more tractable, due to AdS/CFT.

Note also that since the universe is accelerating, real world black holes are not actually flat space black holes either! For astrophysical questions, this doesn't matter. AdS/CFT deals with fundamental (as opposed to astrophysical) aspects of black holes, and needs the asymptotic boundary in a crucial way, but I think it is still instructive, at least if black hole physics is dominated by the (parametrically at least) near horizon region.

45. **Moshe**
April 28, 2015

Matthew Foster: Your last paragraph got my attention, could you please provide an entry point to the literature on these non-unitary CFTs relevant to (many-body?) localization?

Thanks,

Moshe Rozali

46. **matthew foster**
April 29, 2015

@ Moshe

The non-unitary CFTs of which I speak describe critical delocalization, as occurs at a non-interacting Anderson metal-insulator transition. There are different examples under different levels of control. E.g.,

1) "Exactly solved" 2D critical states: Dirac fermions coupled to random abelian or non-abelian vector potentials. Critical properties like wavefunction multifractal exponents are known exactly, from 1+1-D CFT. (Non-interacting, so energy is a parameter and the post-disorder-averaged theory is 2+0-D). These are affine Lie algebras, e.g. Sp(2n)_k, U(n)_k, SO(2n)_k. For positive integer n,k these are unitary, but one needs to take the limit n->0 at the end to get results relevant to disorder physics ("replica trick"). There's a better-defined version (the SUSY trick), but you get the same results. These have also been checked numerically. First papers were by Ludwig, Fisher, Shankar, Grinstein and by Nersesyan, Tsvelik, Wenger in 94. We review these in our recent papers on 3D topological superconductors, since these models turn out to be relevant to surface states.

2) Anderson metal-insulator transition in 2+\epsilon. Perturbative RG results via the epsilon expansion. Same kinds of data can be extracted.

3) Plateau transition of the integer quantum Hall effect. Extensive numerics spanning 20 years, and many indications that the underlying theory is conformally invariant, but no one knows what that theory is yet analytically (as far as I know). Martin Zirnbauer and Ilya Gruzberg are among the people who've worked extensively on this problem.

Both 2) and 3) are reviewed in Evers and Mirlin, Anderson Transitions, RMP 2008.

As for the interacting problem (e.g. MBL), obviously I wouldn't expect space-time conformal invariance because the disorder is non-dynamical. In some situations, however, you can graft interactions into the non-interacting theory and determine stability, and perhaps even identify nearby interacting, critically delocalized fixed points (scale invariant separately both time and space.) This happens e.g. in the unitary metal-insulator transition with long-ranged Coulomb interactions in d = 2 + \epsilon, and also in class AIII topological superconductor surface states in a certain regime (e.g. here).

47. **Moshe**
April 29, 2015

Thanks Matthew!

48. **S**
May 3, 2015

[comment moved from inappropriate post to more appropriate one]

Not strictly on topic, Peter, so delete if you wish, but consider it a request for the future — do you have any thoughts on this stuff? It's hard for me to tell if it's the same as the ER=EPR material that was discussed in part I, and which you already addressed in an earlier post. Thanks!

https://www.quantamagazine.org/20150428-how-quantum-pairs-stitch-space-time/

49. **Peter Shor**
May 3, 2015

@S: No, that's not about ER=EPR. It's about research which is much more plausible than that (that's not setting a very high bar …).

50. **Peter Woit**
May 3, 2015

S,
I moved your comment to here. That topic is very relevant to the general theme of the posting: 15 years ago this kind of attempt to explain quantum gravity as "information" would have been the kind of thing the string theory community would have little time for. Things have changed.

I don't understand though exactly what these people are doing so won't comment on it specifically. In general I'm skeptical about this sort of thing. There's a long tradition of attempts to derive fundamental physics from simple-minded models of 0s and 1s, it's a favorite idea of a wide range of people from crackpots to great scientists. As far as I can tell it has never gone anywhere, and the mathematical ideas that have been successful in fundamental physics are ones of a very different nature. On the other hand, an infinite dimensional Clifford algebra acting on qubits maybe is closer to fundamental physics.

One thing to note about the Ouellette Quanta article is that I don't think she mentions that her husband has just been coauthor of a paper on the precise topic she is writing about, see
http://arxiv.org/abs/1504.06632

51. **matthew foster**
May 6, 2015

From my limited knowledge, my impression is that one fundamental limitation of AdS/CFT schemes seems to be the lack of an algebraic structure that can determine the "data" of the CFT. In 1+1-D CFT, the differential equations satisfied by correlation functions derive from specializing the generic Verma module to descendants of an appropriate primary field. At least for a rational CFT the spectrum is determined by the algebra. Of course the conformal group is finite in d > 2 and it's not clear to me what if any connection one has between local QFTs and "central extensions" of higher dimensional loop algebras (analogs of Kac-Moody).

If the CFT is in some general sense "non-integrable," then it makes sense that the crucial data (scaling dimensions, OPE coefficients) cannot be exactly computed via some machine, algebraic or holographic. But one might hope that correlation functions beyond the trivial ones (four point and higher) are determined, if one can input the necessary data obtained elsewhere (epsilon expansion, numerics…). Do we know if this is the case? From conversations I've had with experts, I have the impression that these correlators might be less universal than in 1+1-D CFT. Then one needs to understand how to classify different holographic duals. Naively I would expect that has something to do with the additional space used for compactification on the gravity side, which is usually not discussed in applications to condensed matter…

52. **Thomas Larsson**
May 6, 2015

Matthew,

The higher-dimensional analogs of affine algebras can not arise in QFT. Gauge anomalies in Yang-Mills theory in 3+1D are proportional to the third Casimir, but the Kac-Moody extension is proportional to the second. Hence the multi-dimensional affine extension requires that we go beyond QFT.

As you noted, the conformal group is finite-dimensional when d \geq 3, but the Virasoro algebra also arises as an extension of the diffeomorphism algebra on the circle. As such it has a direct generalization to higher dimensions, but the extension is not central except when d=1.

At least in statistical physics there is strong reasons to expect universality to hold, both from experiments and from theoretical considerations (4-epsilon expansion).

53. **Matthew Foster**
May 6, 2015

@ Thomas Larsson,

Thanks–I'm not an expert on the anomaly structure in QCD so your comment is very helpful. But I wonder if there might be connections between affine algebras and non-gauge theories. A trivial observation is that you get a loop algebra as the commutation relations of spins on any lattice, when expressed in terms of momentum modes. Obviously that doesn't help you understand anything about a particular Hamiltonian. But I wonder if non-trivial extensions can give rise to interesting representations that might "exactly solve" some the low-energy sector of some (artificial but non-trivial) quantum spin models. Locality would be the hard thing to achieve I would guess, but there are useful non-local spin models that arise as mean field approximations in condensed matter or in cavity QED type schemes.

54. **Moshe**
May 6, 2015

Matthew, there is a large body of work on the questions you are raising, and this is probably not the best place for this discussion. Briefly, it is true that the higher dimensional CFTs in AdS/CFT are not integtable, but one perspective is that this is what makes them interesting. For example there is recent effort to quantify quantum chaos using this framework, for which genericity arguments are more powerful than algebraic structures. As you expect from a quantum chaotic system, for generic observables there isn't a closed form expression, or a convergent series expansion. Another comment is that AdS/CFT is no longer a good name for the subject, since most of the work has to do with massive deformations of CFTs and other non-CFTs, so this is really duality relating continuum QFT to gravitational theories.

55. **Matthew Foster**
May 7, 2015

@ Moshe

Now I'm intrigued! Can you give a reference or two for the application to quantum chaos?

Best,
matt

56. **moshe**
May 7, 2015

Look at recent papers by Douglas Stanford and Steve Shenker, especially a very recent one with Juan Maldacena. This is pretty technical and not completely digested yet, but hopefully some of it will be useful.

57. **moshe**
May 7, 2015

I should also mention that Alexi Kitaev has been working on very similar ideas. There are various talks on the Internet (one in KITP in their ongoing entanglement program), but none of it is published as far as I know.

58. **Matthew Foster**
May 11, 2015

Thanks Moshe!

Dreams of a Final (or Better) Theory

May 1, 2015
Categories: Multiverse Mania

John Horgan has an interesting interview with Steven Weinberg here. Weinberg isn't very optimistic about possible progress these days:

> **Horgan**: In 1995 you told me that it's a "terrible time for particle physics." Are you feeling any better about your field now? Are there any particular advances that give you hope?
>
> **Weinberg**: I'm not much more cheerful.
> …
> **Horgan**: Do you still believe in the attainability of a "final theory" of physics, one that ends what you called "the ancient search for those principles that cannot be explained in terms of deeper principles"?
>
> **Weinberg**: I still expect there to be a final theory, but I'm less confident that humans will discover it in this century.

When asked about when string theory should be abandoned as a dead end he ignores that part of the question:

> **Horgan**: In your new book, To Explain the World, you write that "scientific theories cannot be deduced by purely mathematical reasoning." Doesn't that principle apply to string theory? At what point, if ever, should string theory be abandoned as a dead end?
>
> **Weinberg**: String theory may be inspired by mathematical reasoning, but not deduced, and certainly not confirmed.

He defends the multiverse with

> Further, if we find some future theory that does make successful predictions about a lot of things, which turn out to be true rather than false, and if that theory also predicts the existence of a multiverse, then we should take that prediction seriously even though it can't be tested directly.

which is true enough, but doesn't address the fact that there is no such theory. The string theory landscape "prediction" of a multiverse is exactly the opposite sort of thing, not a corollary of successful predictions, but something being invoked as an excuse for failure to make predictions about anything at all.

For something more substantive, I recommend Alessandro Strumia's theory summary for Moriond 2015. It has a lot of interesting commentary about a range of phenomenological topics. On the multiverse and anthropics he takes a quite different point of view than Weinberg:

> Nobody talked about anthropics at Moriond 2015. This has an anthropic interpretation: Moriond is not in California. Clearly, social factors are playing a role, as always when experiments cannot set the issue. On one side, `having discovered the multiverse' is physically indistinguishable from `having pursued a failed unification program', but sounds much better. On the other side, future physicists could consider us as crazy for not having immediately accepted anthropic arguments.

He discusses "naturalness" extensively, including explaining why anthropics is no solution, since it doesn't explain an unnaturally small Higgs mass.

Comments

1. **Bernhard**
   May 1, 2015

   "Further, if we find some future theory that does make successful predictions about a lot of things, which turn out to be true rather than false, and if that theory also predicts the existence of whatever" , than yes, I would also take "whatever" seriously.

   About Moriond, I think there is also another reason. This is one of the most important conferences for HEP experimentalists. I guess talking about this embarrassing multiverse businesses is something better left for more stringy-focused conferences or at least for a conference where not too many people doing real science are around.

2. **JG**
   May 1, 2015

   "Weinberg isn't very optimistic about possible progress these days:"

   What about you?

3. **gadfly**
   May 1, 2015

   No good data -> No progress. I think we can safely say that the limits of what we can know about so called "fundamental" theories have been reached for the foreseeable future.

4. **Jacques**
   May 2, 2015

   Humans will discover the final theory this century. There is a good probability that the final theory is a theory that explains why there is only gravity and the standard model.

   The research options in this segment are not exhausted yet. There is an anthropic reason for it (-: this research segment is not attractive for researchers, as it promises few – or even no – novel particles or effects.

   The scenario might be the following: once the LHC will have shown to everybody that there is no BSM physics, the search for a final theory will be rapid, because on the one hand, the research options are not exhausted, and on the other hand, the options are not legion.

5. **Yatima**
   May 2, 2015

In other news Quanta Magazine has the second installment of the "looking at entanglement while thinking about spacetime" series: How Quantum Pairs Stitch Space-Time, which is hard to understand but which leads to Arxiv 1306.2164: "A Practical Introduction to Tensor Networks: Matrix Product States and Projected Entangled Pair States".

6. **TOE**
May 2, 2015

"The string theory landscape "prediction" of a multiverse is exactly the opposite sort of thing, not a corollary of successful predictions, but something being invoked as an excuse for failure to make predictions about anything at all."
Right, this is highly suggestive of the "sickness" of a theory. In fact many different theories of quantum gravity presently produce a multiverse. See https://indico.math.cnrs.fr/getFile.py/access?resId=4&materialId=slides&confId=782
page 21. (Very importantly, this list puts the string landscape into perspective).

7. **Bee**
May 2, 2015

It isn't true that finding a multiverse is the same as having failed at unification. It means you haven't succeeded in finding sufficiently many assumptions (axioms/constraints) that give you a unique unification. That isn't the same thing. String theory can well have the one unification they are looking for, just that they haven't found it.

I've explaint that in great detail elsewhere, but it really isn't so difficult to see that every theory has a multiverse if it's underspecified for exactly the reason that Weinberg points out: You cannot deduce a theory on purely mathematical reasoning. You need a set of postulates, and if you don't have sufficiently many, you get an ambiguous result, that's it. In the end, all these postulates must be emprically motivated (not counting mathematical consistency itself).

8. **Eduardo Lira**
May 2, 2015

How much did human beings know about SR in the last years of the 19th century? Zero, right? And about GR? Zero again. What about QM, not to mention QFT? Or the SM? All ridiculous questions, aren't they?

Well, considering such antecedents, and with another 85 years to go before this century's end it's quite absurd that someone (be it on this side of ST and the MV or the other) dares to assert that humankind has hit a dead end in the foreseeable future concerning the search for a "final theory" of physics. Nature's complexity is fully independent of human impatience. Or a physicist's wish to find definite answers during his or her lifetime.

9. **Art Brown**
May 2, 2015

So we're running out of water, Brooklyn is moving here *en masse* , and our physics is getting dis'ed by old Europe. Just another perfect day…

10. **JG**
May 2, 2015

My question wasn't rhetorical

What do think about possible progress?

11. **Peter Woit**
May 2, 2015

JG,
I'm not particularly optimistic, in some ways now even more pessimistic than ten years ago. Back then I would never have believed that multiverse nonsense would be so influential, and I hoped the LHC would discover something unexpected about the Higgs mechanism.

On the other hand, there's a much wider understanding that the string theory/SUSY paradigm hasn't worked out, and this may lead to more openness to looking for other ideas. There's a wide variety of activity in mathematics related to physics, and this may lead somewhere. I have no idea though on what time scale…

12. **Mesmar Djehha, alias EFT**
May 3, 2015

Dear Peter,
When you say "There's a wide variety of activity in mathematics related to physics, and this may lead somewhere. I have no idea though on what time scale…"
what if the time scale becomes longer than the one already taken by string theory, would you still believe that advanced mathematics would lead to a breakthrough in physics?
Thank you.

13. **Peter Woit**
May 3, 2015

Mesmar Djehha,
I don't think the problem with string theory is the time scale for progress, but the sign of the derivative. As more and more has been learned about string theory, it has become more and more clear that ideas for how to get unification out of it and connect to the standard model don't work (i.e. are empty, they answer no questions about the standard model).

On the other hand, my own personal experience is that as I have learned more and more mathematics, I see more evidence for deep connections between physics and mathematics. Maybe this is a mirage that will dissipate as more is learned about these subjects, maybe not.

Progress doesn't happen linearly, but in jumps when people have good ideas. The question is evaluating the prospects for good ideas solving certain problems. I'd claim the probability of finding a compelling string theory explanation for the SM has been decreasing for a long time, with the "landscape" just the claim that it has hit zero, but that's alright. I don't see any evidence of a comparable phenomenon if you try and evaluate prospects for the use of advanced mathematics in physics.

14. **Theo Nieuwenhuizen**
May 3, 2015

String theory is a consistent framework to consider questions about quantum field theory. Various insights are gained from it. It has drawbacks due to its ad-hoc

assumptions like the string nature of particles, extra dimensions etc. It has failed to recover, let alone to improve, the standard model. So the program is a failure for physics, but it can be a subject for mathematical physics.
The multiverse is a poor way of escaping to admit the failure, it is a clear sort of cheating since its claims lie out of the domain for which the theory was formulated. Incredible that people believe this fallacy.
Moreover, if we accept the multiverse, we must give up on falsifiability, but why then still do any science at all? We do have to keep separating science from religion. It is amazing to see that so many people who don't accept God do accept the multiverse. Humans do need religion, but why such an obviously failed one?

15. **Steve**
May 4, 2015

When I read Weinberg's comment about taking multiverses seriously I thought of his surprisingly sympathetic treatment of many worlds in his text "Lectures on Quantum Mechanics". He certainly doesn't endorse many worlds, but he gives it several pages of careful thought. Maybe he's thinking that kind of multiverse?

16. **Chris W.**
May 4, 2015

Steve,
I think Weinberg certainly appreciates the distinction, but he is trying to give careful consideration to both. In *Dreams of a Final Theory* he warns against dismissing a possible way forward in physics on the grounds that it seems unacceptable on *a priori* philosophical grounds.

Of course, that begs the question of why the multiverse should still be considered a possible way forward…

17. **MikeS**
May 5, 2015

A final theory this century?

A final theory, one assumes, has to be so logically compelling and self-consistent that things could be no other way. I would suggest we have a difficult conceiving how such a theory might even be framed, which rather gives serious difficulty in finding what it actually is.

Something looking similar to the Standard Model is far too arbitrary to fit the bill. General Relativity, with its geometric elegance, may give a mere glimmer of what such a theory might look like – but then again maybe not.

18. **JFD**
May 5, 2015

Peter,
I find it hard to believe that you recommend Strummia's comments as "more substantive". I'll bet that it is only because the comments reinforce your preconceived biases. He clearly says "In my opinion.." and then, amazingly, "The most likely outcome should have been…" as if he has special insight into the laws of Nature. There is not much of substance there.
There is a demonstrable need for the weak scale (quark and gauge boson masses) and the QCD scale (the nucleon mass) to essentially overlap – this produces the complex nuclei and atoms that we see. It is a valid scientific question whether this is a consequence of Nature having a unique ground state which luckily has this property, or a multitude of ground states sufficient to invoke anthropic selection. This may be difficult to settle any time soon, but it will not be decided by mere opinions.
I enjoy your BS detector, which is great for puncturing a lot of the hype that is out there. But "Naturalness" has been the dominant form of hype for decades, and has made clear predictions that have so far failed. Lets hope that the LHC offers us a reasonably definitive answer – finding "natural" new physics would be awesome. But if naturalness fails, it provides extra motivation to continue to explore theories with multiple ground states.

19. **Peter Woit**
May 5, 2015

JFD,

Not sure if it qualifies as more than an opinion, but to me it seems there are no solid arguments about what Higgs mass is likely or unlikely, and that seems to put me in agreement with Strumia. This is often stated as a "measure problem", but it seems to me worse than that: you don't even know what space the measure you can't calculate is a measure on (what's the space of theories you are putting a measure on?)

Sure, maybe a better theory has many vacua with different physics, but this postulate isn't worth anything unless it manages to explain something, not just provide an excuse. I think what Strumia was reacting against was the point of view pushed by Arkani-Hamed that the only two possible outcomes from the LHC are vindicating one of two ideas ("naturalness" or "multiverse"), both of which are popular, but neither of which actually explains much at all.
Glad you enjoy the BS detector!

20. **Just Another Reader**
May 11, 2015

"… if we find some future theory that does make successful predictions about a lot of things, which turn out to be true rather than false, and if that theory also predicts the existence of a multiverse…"
You go on to say that he "doesn't address the fact that there is no such theory". But would you not agree that your criticism arises as a result of a misread of what Weinberg said. He said "*if* we find…"—a conditional that surely concedes there is no theory at present. So perhaps your criticism of the Weinberg is, in this case, unfair. Or rather unneeded.

21. **Peter Woit**
May 11, 2015

Just Another Reader,

I don't think it's a misreading, note that I describe what Weinberg says as "true enough". The conditional "if" though evades addressing the difficult question, which Horgan was explicitly asking, of evaluating claims being made about the "string landscape", in favor of saying something obvious about a hypothetical circumstance that is not the case.

I'd be very curious to hear Weinberg address explicitly the "dead end" question: does our current best research indicate that the string landscape is an indication of failure and that the subject is at a dead end, or are there serious indications it's a plausible picture of reality that is our "best hope for a unified theory" as string theorists often claim these days?

Einstein’s Dice and Schrödinger’s Cat

May 2, 2015
Categories: Book Reviews

I’ve written a review for the Wall Street Journal of Paul Halpern’s new book
Einstein’s Dice and Schrödinger’s Cat (It’s here, unfortunately now behind a paywall).
I liked the book quite a bit, and learned many things about some history I already thought I knew well. The most dramatic section of the book is the story of the 1947 trouble between Schrodinger and Einstein caused by Schrödinger’s publicity campaign for a supposed breakthrough in the search for a unified theory, and Halpern writes about that here
.

The title of the book emphasizes their misgivings about the probabilistic interpretation of quantum mechanics, and describes how Schrödinger’s cat arose out of discussions with Einstein. More of the book though is actually about their efforts to generalize GR and find a unified geometrical theory of gravity and electromagnetism. This began almost as soon as the field equations for GR were in place (1915). The book’s stories of media hype for bad ideas, involving physicists given rock-star academic positions at institutes set up for them make clear that some contemporary problems go back much further than I’d ever realized.

Einstein’s later work is, for good reason, dismissed as misguided, since it ignored quantum theory. He and Schrödinger did however have good reasons for skepticism about the Copenhagen interpretation of quantum mechanics. The measurement problem has turned out to be a very subtle one, with the cat experiment a very good way of making clear the problem. Their enthusiasm for ideas about unification that weren’t working was also way ahead of their time…

Update: For some other reviews of the book, see Jennifer Ouellette in the New York Times, and Denis Weaire in Physics World.

Comments

1. **cthulhu**
   May 2, 2015

   Have to add this one to my list…FYI, if you search with Google for the exact title of a WSJ article, you get a link that bypasses the paywall.

2. **Peter Woit**
   May 2, 2015

   cthulhu,
   Thanks. It does seem that the Google link behaves differently.

3. **Richard Gaylord**
   May 3, 2015

   this is IMO a really terrible book unless you’re into reading about the randiness of Einstein and Schrodinger. the scientific content is close to zero. it was a major dissappointment to me since i thought his “The Great Beyond” was quite good.

4. **Peter Woit**
   May 3, 2015

   Richard Gaylord,

   I strongly disagree. There’s relatively little in the book about Einstein’s romantic life, and Schrodinger’s is a significant part of the story, since one of the main reasons he ended up in Dublin instead of Oxford or Princeton is that he essentially had two wives.

   It’s true there’s little in the book about the details of the generalizations of GR that Einstein and Schrodinger were working on. That’s a very technical subject, and those ideas don’t seem to go anywhere, so it’s not an unreasonable choice to not focus on it.

5. **john McAllison**
   May 3, 2015

   Peter,

   in your review you say:

   “While most of their colleagues were moving on to the study of such quantum-field theories, the two of them resisted, feeling to different degrees that such theories were likely inherently flawed.”

   I can’t help feeling that this sounds a little like you with your attitude towards String Theory 😉 Nowadays, any respectable graduate course in HEP will include this.

6. **Peter Woit**
   May 3, 2015

   John McAllison,
   I think there are a few obvious differences between me and Einstein/Schrodinger (as well as between QED and string theory…).

7. **Kenneth Vatz**
   May 3, 2015

   First I read the review in today’s Times Book Review by the “popular science” writer, Jennifer Ouellette, who says there is little that’s new in the book. Then I read your review in the WSJ (by Googling it, as described), and decided I would get it.

   But what really influenced me, as a lay reader, to ignore Ouellette altogether was this excerpt from the end of her review:

   “Mainstream physics left [Einstein] behind as the Standard Model of particle physics took shape, and the mathematical approaches once explored by Einstein and Schrödinger have long since given way to string theory and loop quantum gravity, two of the most promising candidates for quantum gravity.”

I’m not sure if Ouellette reads your blog.

8. **Peter Woit**
May 3, 2015

Kenneth Vatz,
I’ve added a link to the New York Times review and to one at Physics World.

I don’t actually disagree all that much with Ouellette’s review. It’s a fact that much of the story of Einstein and Schrodinger is “well-traveled historical ground”, and it’s very hard for anyone to come up with a new take on it. Halpern’s decision to focus on their interactions in their later years is a new take, and that’s where he has new material. For the rest of the story, there are many other better sources, ones it’s hard for anyone to compete with.

I’m pretty sure Ouellette has heard of my point of view on string theory (maybe she was even in the audience when Sean Carroll and I debated this once..). Saying that the failed ideas of Einstein and Schrodinger have been replaced by string theory etc. doesn’t necessarily make much of a positive claim for string theory, even with the “promising”. If you read Halpern’s book, you’ll see that he also probably has a more positive take on string theory than I do.

9. **Anonymous**
May 4, 2015

My understanding of Einstein’s motivations (which might well be wrong) is that he was trying to obtain a theory from which quantum mechanics would naturally emerge, and so “quantization” would not be the starting point of such a theory.

From the standard biography by Pais :

“He was looking for a unified field theory, but to him that concept meant something different from what it meant and means to everyone else. He demanded that the theory shall be strictly causal that it shall unify gravitation and electromagnetism, that the particles of physics shall emerge as special solutions of the general field equations, and that the quantum postulates shall be a consequence of the general field quations.”
[p. 465 in the OUP edition]

In addition, he had a favoured mathematical idea for reaching this end : overdetermination of systems of partial differential equations [mentioned in Pais].

From another (excellent) articulation of Einstein’s position :

https://www.marxists.org/reference/archive/einstein/works/1940s/reply.htm

“Assuming the success of efforts to accomplish a complete physical description, the statistical quantum theory would, within the framework of future physics, take an approximately analogous position to the statistical mechanics within the framework of classical mechanics. I am rather firmly convinced that the development of theoretical physics will be of this type; but the path will be lengthy and difficult.”

So he had a fairly clear and not entirely unreasonable notion of what he was looking for, and how he would go about it. It’s just that he didn’t succeed.

And neither String Theory, nor Loop Quantum Gravity are – in this sense – attempts towards fulfilling Einstein’s “dream”.

I can stand corrected on anything I’ve said here.

10. **Phil Harmsworth**
May 4, 2015

Richard Gaylord,
If you’re interested in the technical details, the Pais biography of Einstein provides an overview.

Pais also explains that, far from ‘ignoring quantum theory’, as Peter stated, Einstein initially thought it was possible to derive its features without invoking probabilities at a fundamental level. As Pais makes clear, to some extent he wavered in this conviction towards the end of his life.

11. **Richard Gaylord**
May 4, 2015

sorry for sendingg so many comments but i wanted to add the following:

Einstein quote: “I consider it quite possible that physics cannot be based on the field concept, that is, on continuous structures. Then nothing remains of my entire castle in the sky, including the theory of gravitation, but also nothing of the rest of modern physics.” (In a letter to a friend in 1954, the year before he died.)

and to get a good understanding of Einstein’s research program in his post GR period, see the book “Einstein’s Unification”.

Also, recently there have been a number of very interesting articles on arXiv (history and philosphy of physics) describing Einstein’s methodology in seeking a cosmological model based on GR.

finally, i’d like to read a discussion of the causal net approach to spacetime proposed by Raphael Sorkin and taken up (without attribution) and modified by Stephen Wolfram who considers the concept of spacetime itself to be misguided.

12. **Michael Gogins**
May 4, 2015

I found the Peter Woit review absorbing and it interested me in the book.

Regards,
Mike

13. **Oldster**
May 4, 2015

Anonymous: I think you covered your points pretty well. I was never sure what Einstein thought overdetermined PDE’s would quantize however. Somehow, I got the impression he might have been thinking more about quantization of charge or such there, but that’s merely my speculation, not something I recall him writing down. But the quote you gave from Pais may be consistent with that …

14. **Cormac**
May 7, 2015

Good review Peter, well written and interesting. Given their kerfuffle concerning the possible theft of ideas in the 1940s, I find it surprising that Einstein never pointed out that the Schroedinger cat paradox was an extension of his gunpowder argument, outlined in a letter to Schroedinger…does the author touch on this?

I hope the author mentions that Schrodeinger wrote two excellent early books on GR and cosmology, this is not widely known.
Fun fact. Did you know that Schroedinger published a short paper on relativistic cosmology way back in 1918, asking this: why not put the cosmic constant on the RHS of the field equations? And why a constant, might it not be a variable? [Yes, he really did suggest this. Einstein's reply was that, if constant, putting the cc on the RHS made no difference (not quite true): if not constant, one would have to hypothesize a time variation and he had "no wish to enter this thicket of hypotheses" !
Such little titbits make historical books interesting..

First Collisions of Run 2

May 5, 2015
Categories: Experimental HEP News

This morning in Geneva saw the first collisions in the revamped LHC, there's an event display from ATLAS here, CMS here.

These collisions are just at the injection energy of 450 GeV/beam, but over the past few weeks beams have been successfully ramped up (without intentional collisions, although see page 23 here) to the planned 6.5 TeV/beam. 6.5 TeV beams have been accelerated not just with probe intensity, but with nominal bunch intensity and squeeze. They are roughly halfway through a planned 8 week beam commissioning process and on schedule, with stable beams for physics collisions still planned for around June 1. For quite a while now, 6.5 TeV/beam collisions have been possible, but no word yet on when this is planned for, I assume there will be some sort of media event at that time.

Update: Something about this from CERN here.

The Admiral of the String Theory Wars

May 7, 2015
Categories: Uncategorized

The science magazine *Nautilus* this month has a profile of me, under the title [The Admiral of the String Theory Wars](). The writer, Bob Henderson, spent a lot of time talking to me and other people around here, including attending my class. I think he did a very good job of handling the complex topic of the debate over string theory, not so easily done in the context of this kind of personal story. Then again, I guess I would think that since he was mainly hearing my point of view, others may see this very differently…

Talking to Henderson brought back memories of a lot of the very odd things that happened during this period, now nearly ten years ago. I also recently realized that this week is the 10th anniversary of the date on which I sent off the final version of "Not Even Wrong" to the publisher (it then went to copy editing, was published a year later). Looking back at it now, I don't see much that I'd change. The earliest version of the manuscript written around 2003 didn't discuss the landscape and multiverse business, which only really got going in 2004. By 2005 I did add a chapter on this, but at the time thought doing this might be a bit unfair to string theorists. Surely they were all aware this was obvious nonsense and would quickly themselves put a stop to it. I was very wrong about that and, oddly, it's over this argument (where I would have thought my point of view was uncontroversial) that I've gotten the most grief from certain prominent string theorists (e.g. Polchinski).

For the latest in the string wars, you can watch last night's Perimeter Institute [public lecture by Amanda Peet](). It was a promotional effort that reminded me a lot of the kind of thing you see on late night TV, with an inspirational speaker selling a product to a rapt studio audience. The main selling points for string theory were that it "would blow your mind", that branes explain black hole entropy (the Strominger/Vafa calculations of 20 years ago), and that the world is a hologram (Maldacena from nearly 20 years ago).

After the talk the first question read to her was the obvious one about testing these ideas experimentally. Remarkably, she claimed that string theory was testable, that published work of 10 years ago showed that it could be tested at accelerators, and so far it had passed the tests. What she was referring to was one of the weirder stories of the string wars. At the time Jacques Distler and collaborators wrote a paper entitled *Falsifying String Theory Through WW Scattering*, which I discussed [here](). They also wrote to the Wall Street Journal about this (see [here]()). A few months later their paper was accepted by Physical Review Letters, with their claims about string theory removed, I assume at the insistence of a referee (see [here]()). In a spectacular display of chutzpah, when the PRL paper appeared, the authors had their institutions put out press releases claiming that "Physicists Develop Test for String Theory" (see [here]()), exactly the claim that PRL would not let them make in print. It's this claim that Peet is now using to mislead the public at Perimeter. I think it's their responsibility to look into this and issue a public correction. Or do they really feel that it is all right for their public lecture series to be used to mislead the public about science?

Update: I see that the Nautilus piece is part of [an issue on "Error"](), which also includes interesting articles about the [OPERA superluminal neutrino story]() and about [Vladimir Voevodsky]().

Update: I probably should have included the relevant question and answer exchange with Peet, here it is:

> **Q**: Any predictions or comments on how and when string theory might be able to be proven experimentally?
>
> **A**:… there are experiments that can be done, this is published work that has been around for almost ten years now, that you can do experiments in nature in the lab without having to invent equipment that you haven't invented yet that would test whether or not the assumptions of string theory are true or false. So far none of those experiments has shown a red flag that says string theory is wrong.

Update: Ethan Siegel has a [blog entry]() and [live-blogging about the Peet talk](). He was hoping that Peet would discuss some sort of connection between string theory and observable physics, didn't hear any (he seems to have missed the bogus claim about the LHC). Siegel gives an argument that string theory is in principle falsifiable, since it predicts space-time supersymmetry superpartners, although with no prediction for the mass scale. I've never heard this before, and I don't know of any argument that such superpartners must appear in the spectrum of a string theory.

   May 7, 2015

   About "It's this claim that Peet is now using to mislead the public at Perimeter".

   To be honest, at the question session at 1.07.50, she says that "the **assumptions** of ST are falsifiable".

   That statement is in fact true because we can in principle test the assumptions of any theory if only we had enough energy to test the Planck scale. So, that statement while true is completely useless. The point is not about assumptions but about any falsifiable predictions (that was the question from somebody from twitter). In particular the LHC-predictions (I suppose). I often hear/read from string theorists that they confuse assumptions with predictions. Maybe one should make it clear once and for all that the assumption that particles are extended objects is not a prediction?

   She then refers to that PRL paper but still talks about the ST assumptions. In fact she is not answering the question.

   Too bad there wasn't, in the audience, any expert in the field to point out that she is in fact manipulating/misleading the public. Because indeed her answer sounds as if so far ST fulfilled all the experimental tests. But in fact there were no experimental tests of ST so far – to do that you need a prediction first. She "forgot" to add that so far ST made no predictions but merely succeeded in fitting the already obtained experimental results. She also forgot to add that there are so many compactification schemes in ST that they can fit (almost) whatever they want.

May 7, 2015

Be very wary when advocates claim the "science is settled" or that "xx% of the 'experts' have 'consensus' "

re the Nautilus interview in which
"He [Woit] is called an 'incompetent, power-thirsty … moron' and a 'stuttering crackpot-in-chief ' " ,
Falling back onto ad hominem attacks is a sure sign of scoundrels who have no data to justify their beliefs or opinions. You'll find this behavior in almost every human endeavor (public policy, economics, science, medicine, etc).

5. **KenW**
May 7, 2015

I've known and worked for a lot of admirals – some good and some not. Henderson seems pretty fair, so I wonder if this is a case where the editor wrote the title rather than the author. It seems like a dose of God Particle sensationalism. As for Dr. Peet, she is a gifted lecturer for a lay audience. She sounds very confident about her subject. She sounds as though she is presenting settled history.

6. **Anon**
May 7, 2015

Peter, You have been mentioned on page 8 of the pdf (slides) of the talk Where is Susy? by Howard Baer at Pheno 2015.

Where's Where is SUSY? — https://indico.cern.ch/event/364031/session/35/contribution/182

7. **Peter Woit**
May 7, 2015

Anon,
Thanks. The arguments he's objecting to though (about how massive gluinos and squarks can be and not violate naturalness) are from Arkani-Hamed and others, I was just reporting them…

8. **Bernhard**
May 7, 2015

nicola,

If we could reach the Planck scale there would still be no unambiguous way to test ST because non-perturbative ST is unknown (see the FAQ). In any case, this is an really old discussion, one that I'm sure Peter is not exactly dying to moderate…

9. **Peter Woit**
May 7, 2015

nicola,

Besides the point Bernhard makes about this, if you look at the links where I discussed the Distler et al paper the main point was that the assumptions they claim to test are standard QFT assumptions, not assumptions that have anything to do with strings or string theory. That's why PRL made them remove the claims about string theory from the paper.

That paper was clearly written exactly to provide someone like Peet the argument she made. But it's a fact that PRL would not allow that argument to be published, and her claim that it is in a published paper is provably false. Again, I think it's the responsibility of Perimeter to take some action to correct the false information put out in their public lecture.

10. **CIP**

Admiral or the admirable kid who pointed out the Emperor's unclothed state?

11. **Thomas Larsson**
May 8, 2015

String theory is not completely void of predictive power. In fact, I have used string theory to make a [falsifiable but confirmed prediction about the LHC](). I'm particularly proud that I already in 2007 could predict that poor Lubos would lose his experimental-susy-by-2006 bet.

12. **Mesmar Djehha**
May 8, 2015

In my opinion, Bob Henderson's article could be a beautiful epilogue to any new edition of Peter's book "' Not Even Wrong".

13. **nicola**
May 8, 2015

Bernhard,

at Planck scale you would surely test the ST basic assumptions e.g. if particles are indeed stringy. Testing the dynamics and its consequences is another thing.
I am trying to return to old discussions.

Peter,

I perfectly understand what you say. However she seems to refer to the assumptions, not predictions. Maybe she means predictions all the time but says assumptions or maybe she does it on purpose.

14. **Bernhard**
May 8, 2015

nicola,

The point is falsifiability. Of course, if would see stringy behavior at the Planck scale this would certainly be strong evidence for string theory. But since you don't know the theory non-perturbative behavior not observing it does NOT falsify the theory because stringy behavior is not a necessity. The point is that string theory would still be immune to this test, just as it is immune to the non-SUSY at the LHC test.

"I am trying to return to old discussions. "
A time-machine to travel to 10 years ago is probably your best option.

15. **Peter Woit**
May 8, 2015

nicola,
She is making the same argument as the Distler et al paper which claims to derive "predictions" of string theory testable at the LHC based on "string theory assumptions" about high energy behavior, and explicitly referring to the paper, vetted as a "published" paper. Again, the problem here is that this claim about string theory was removed in the published version since it the "assumptions" are qft assumptions not string theory assumptions.

About the "string theory predicts you see strings at high energy" argument, it's not the one she is making. If you look at the Nautilus article, you'll see that Kleban tries to make it, but Michael Dine, a string theorist expert on this, disagrees.

18. **Chris Oakley**
May 9, 2015

Sir (I suppose I have to address you like that now you're an Admiral),

Mr. Henderson needs to be congratulated on not mentioning he-who-shall-not-be-named by name, although I see the name crops up in the comment section. Speaking as one of the early followers of the blog (a select group of – according to he-who-shall-not-named – anti-science crackpot losers), I would say that the article is pretty fair, and I am glad that he pointed out the considerable mission creep that has resulted in your blog being one of the prime sources of fundamental physics news irrespective of your views on String Theory. I suppose that there are lot of String Theorists out there who do not appreciate the considerable amount of unpaid work that goes into it, but I do.

19. **Edgar**
May 9, 2015

"A few months later their paper was accepted by Physical Review Letters, with their claims about string theory removed, I assume at the insistence of a referee."

It is pretty obvious the change in title refers to a large class of possible 'new physics' scenarios at the LHC, not a request from a referee. (This also had to do with the re-doing of the analysis.) The beauty of the relationship discussed in the paper (originally studied by Adams et al. and others in the context of QCD) is rooted in the UV/IR connection: bounds on EFT coefs. that may be derived assuming basic properties of the high-energy theory. For instance, claims have appeared in the literature, e.g. breaking of Lorentz invariance and quantum gravity, which may be then confronted with data (even if somehow hidden in direct low-energy experiments, e.g. due to new symmetries such as SUSY). The existence of a light Higgs changes the tone of the paper, but the premises remain.
The search for UV/IR connections is key to relate measurements we can perform to theories for which we may not have direct access to. This is even more transparent in cosmology, e.g. 1502.07304. Unfortunately you seem to have failed to appreciate the basic idea(s).

20. **Peter Woit**
May 9, 2015

"Edgar",
So, your claim is that the change in title and wording of the paper was because the reaction from the journal was that the "we have found a way to test string theory at the LHC" was too modest? That's very funny. And your claim that the problem here is that I'm just too ignorant to appreciate the significance of this work does bring back the glory days of the string theory wars. As does the hiding behind anonymity to make arguments you're too embarrassed to attach your name to…

It seems your point of view is that the real problem here is my raising this issue, not Amanda Peet's telling the public that Distler et al shows that the LHC can test string theory (as well as claiming that it already has done this, successfully). Do you have any problem with her doing that?

21. **Guest from Norway**
May 9, 2015

Thanks to Woit for his blog. I have read the blog for many years now. Here is a voice from Norway that you may find nice😊

https://m.youtube.com/watch?v=eCuE7UOP9gw

22. **Edgar**
May 9, 2015

listen to what she says regarding this point, carefully:

http://www.youtube.com/watch?v=MlDd2HtFfPU&t=68m0s

"experiments […] that would test whether or not the assumptions of string theory are true or false"

This is factually correct. The case of Lorentz invariance for example has been raised many times when the subject of Quantum Gravity has been brought upon, e.g.1106.1417 .
The type of sum rules derived by Distler et al. (and others) does this precisely.

Again, there are measurements (in cosmology) of various kinds which may open a window to physics at high energies, e.g. 1109.0292.

I think this is a more fruitful discussion that nitpicking some specific wording. Unfortunately you stop when the fun/physics begins!

Didn't occur to you the paper by Distler et al. may have been submitted for the first time with its given title already?

23. **Peter Woit**
May 9, 2015

Edgar,

For more context, here's the question that Peet was asked, followed by the relevant extract from her answer. She is clearly referring to the Distler et al claims that string theory can be tested at the LHC, and claiming that so far it has passed the tests.

Q: Any predictions or comments on how and when string theory might be able to be proven experimentally?

A:… there are experiments that can be done, this is published work that has been around for almost ten years now, that you can do experiments in nature in the lab without having to invent equipment that you haven't invented yet that would test whether or not the assumptions of string theory are true or false. So far none of those experiments has shown a red flag that says string theory is wrong.

Do you really think that is an honest answer to the question? If it isn't, why are you writing here to criticize my complaint about it, rather than criticizing her behavior. Is it honest to tell the public that the LHC has successfully tested string theory?

"Factually correct" is dishonest weaseling. It would be factually correct to say that the LHC has tested the "assumptions" of string theory, having in mind that string theory assumes usual mathematical axioms. That was the problem with the Distler et al paper (and press releases). Their assumptions were standard QFT assumptions, having nothing to do with string theory (the day someone finds a violation of Lorentz invariance, do you really believe the reaction of string theorists will be to abandon string theory rather than look at string theory models that can accomodate this?).

You're correct that I don't know the details of the publication process of that paper. It sounds like you do and maybe you can enlighten us on what happened between the May and October versions, although your suggestion that the authors changed the title in order to strengthen the claims of the paper doesn't really pass the laugh test. All I do know is that the preprint carried the bogus title, which I wrote about, the final published version had it removed, then the authors put out press releases using it.

24. **Dundee**
May 9, 2015

You seem to be too focused on small players in string theory while sparing the big names. In addition you do not report on positive developments such as the workshop that took place at the Simons center this week with diverse topics. One should keep a positive attitude and not to be critical most of the time.

25. **Peter Woit**
May 9, 2015

Dundee,
I think I've done more than my part as far as offending big names in string theory…

Happy when there's something positive to report, I'm afraid I can't agree about the Simons Center talks (other than the Seiberg one, which was much the same as similar talks of his I've discussed here before).

26. **Dundee**
May 10, 2015

Peter: To spend half a post about a talk by Amanda Peet is pointless. Her work for the last ten years have little impact on the string community and as such her talk does not represent them. It is clear that you did not listen to the Simons meeting talks, but only glanced at the titles. Some of the talks like those of Damour and Sunayev, among others, show that there are still serious people who do excellent work without making noise.

27. **Peter Woit**
May 10, 2015

Dundee,
I wasn't discussing Amanda Peet's own work, but her high profile public talk. You say her public talk doesn't represent the string theory community, but she was specifically chosen by Perimeter for this purpose (presumably with the participation of the string theorists at Perimeter and who advise Perimeter). Will any string theorists join me in complaining to the people at Perimeter who made this choice, and asking that the institution post a correction concerning the bogus claims she made in her talk? I've been considering doing this, but it shouldn't be me, it is string theorists who should be contacting them.

There's by now a long tradition of fanatics from the string theory community getting a lot of attention for ridiculous claims for the theory. I can't think of one example of a string theorist ever publicly raising an objection to any of this.

The Simons Center talks you mention weren't ones I found compelling, but, tastes differ.

28. **Tammie Lee Haynes**
May 11, 2015

Dear Dr Woit.

The String Theorists at Perimeter may be unaware of what Dr. Peet stated.
Even if they were in attendance, their attention may have been distracted at the time she made her remarkable claims.

In fairness to them, I suggest you let them know of the problem, before criticizing them for not correcting it.

29. **Yi-Zen Chu**
May 11, 2015

Thank you for linking to the article on Vladimir Voevodsky, Peter.

This resonated with me because it is a scientific issue I've always been concerned about — how careful theoretical physicists are in their own work, and how much effort is actually put into checking each other's work. As with most human behavior, I believe the incentives need to be there to encourage this sort of scrupulousness. However, the terrible academic job market, declining government support for fundamental research, pressure to publish O[10] papers every year, and the (usually) sub-par refereeing process in journals, all point towards the lack of such an incentive structure.

Voevodsky himself has responded by advocating the use of a "proof assistant". I'm curious, how else has the Mathematics community at large responded? Are there any adjustments being made?

What about theoretical physics? I often wonder if any established theorists share my concern? (I am currently a mere postdoc and have no power whatsoever.) Much more importantly, is there any concrete effort exerted at all to maintain a high standard of intellectual inquiry in theoretical physics?

30. **Peter Woit**
May 11, 2015

Yi-Zen Chu,
I don't personally know anyone in mathematics now using a "proof assistant" in their work (or at least if they are I'm not aware that they're doing this). It is a huge effort to put a proof in a form that a computer can check, and I'm not even sure that it is possible for lots of areas of mathematics research. One question that came to mind when reading the Voevodsky article was whether the work of his that had an error was actually of the sort that a "proof assistant" could have been used to catch it.

Questions of the reliability of the theoretical physics literature I think are quite different, since there rarely is anything with the level of rigor of a "proof", so even in principle a "proof assistant" would be of no use.

31. **Peter Woit**
May 11, 2015

Tammie Lee Haynes,

The string theorists at Perimeter know Amanda Peet well, so I doubt are surprised she would do this kind of thing. If I thought there was any chance they or Perimeter would do anything about this, I would pursue the matter with them, but there are limits to how much time I want to waste on this, and writing the blog entry probably already went over the limit.

This blog is very widely read by string theorists, so quite a few now know about the Peet issue. If they care about the credibility of their field, they are the ones who should be doing something.

32. **Jeff M**
May 11, 2015

Yi Zen and Peter,

Let me put my 2 cents in as a mathematician on the proof/refereeing question. First, Peter is right most proofs are essentially impossible to check via computer, and I'm guessing they will be for quite some time. There are exceptions, like Hales proof of the Kepler conjecture. But that's a very special case, and the proof would be impossible without computers, it's nothing resembling a "normal" proof. As for refereeing, I think it varies, a lot. I think most people take it seriously, but it's easy enough to miss things. A recent paper of mine had a mistake, not in any of the important parts, just a minor calculation at the end. My co-author and I missed it, basically out of lazy stupidity, we were done with all the big stuff and weren't paying attention. I'm guessing the referee missed it for the same reason. In that case it didn't matter, just meant that our estimate for the shortest geodesic was 2.3 and it should have been 2.4. But bigger mistakes have happened. Theres a well known case from the 70's, where a big time paper was published proving that the bottom of the spectrum of the Laplacian on surfaces was 1/4 (big big deal) – only thing was, it's not true. Caught pretty quickly. But it happens. And I know of people taking advantage of this. I remember a conversation with Peter Sarnak about some people who were claiming a big result, and he read the preprint and explained to them it was incorrect. So did several other people. They still claimed it was right, and kept sending it to journals until someone finally published it.

I am the monarch of the sea,
A critic of the theory stringy,
Whose praise Nautilus loudly chants…

I rule over all the landscapes
that give multiple answers freely,
And find them most unseemly..

34. **Yi-Zen Chu**
May 11, 2015

Thanks for the response, Peter.

My questions were meant to be of a more general nature, not just specifically about whether mathematicians are now using a "proof assistant"/computer to check their logic. Perhaps let me give 2 basic examples, to illustrate what I was getting at. It's very common, nowadays, for theoretical physics papers to contain multiple authors. Most journals do not require authors to describe who contributed what to the research itself. The question here is, do the authors of a given paper even cross-check each other's work? When physicists write "reviews" of a particular sub-field, they probably do not check — and perhaps do not even read thoroughly! — the papers they cite. How reliable then is the body of work we call theoretical physics, especially given the current climate of an over-saturated job market?

I believe Voevodsky himself, in the article you linked, raised issues of similar spirit — the temptation of publishing a sloppy proof because of the fear of competition, and the consequence of having students learn from their advisers that doing so is alright, etc. I thought this latter point regarding students learning what is OK to do is quite a good one; academia is strongly driven by internal social dynamics and what students assimilate as the "norm" is going to set the climate, and therefore the intellectual standards, for the next generation of scientists.

Jeff M — I was told referees in Mathematics actually step through the proofs in a given paper, so once it passes peer review there is high chance the results are correct? This is one of the reasons why I've always held mathematicians in high intellectual regard. Your final story has tarnished that image slightly…

35. **Jeff M**
May 11, 2015

Sorry to tarnish the image, but it does happen. Not often. If you referee something you are supposed to go through it carefully, and if you cannot confirm it you should ask the editor to get the author(s) to explain. Most things in any good math journal are essentially correct, as in the major results are correct. And anything that isn't correct is discovered quite quickly, unless it's very obscure. So you can assume most everything you see in good math journals is OK. Physics is different, "correct" should mean "agrees with experiment" and "is mathematically consistent" which is the best you'll ever do. Peter's issue, and Lee Smolin's, and all sorts of other people at this point, is that "correct" no longer has anything to do with the first, and often not the second either. Well, perhaps that's not quite fair to string theory, it "agrees with experiment" in the sense that some version of it agrees with any experiment you care to do, in any universe you happen to live in 🙂

36. **Peter Woit**
May 11, 2015

Yi-Zen (and others),
Sorry, but enough about this. It seems you want to discuss an immense topic (problems with the physics literature and scientific literature in general) that has nothing at all to do with the topic of this posting.

37. **paddy**
May 11, 2015

Tho the discussion was off topic….twas also interesting to us listeners.

38. **Peter Woit**
May 11, 2015

paddy,
Unfortunately not interesting enough this late this evening to the person who would have to sensibly moderate such a discussion…

39. **Peter**
May 12, 2015

@Yi-Zen Chu
The "sloppiness" in higher category theory is of conceptually different nature than the one in theoretical physics. For an example of the kind of things done by a "proof assistant" you can check Carlos Simpson's paper math/0506471 ("Explaining Gabriel-Zisman localization to the computer"). But the topic of "stability" of results in math and how deep you have to go into someone else's proof, etc. is huge.

40. **Jeff M**
May 12, 2015

Sorry to go off topic Peter, will be a good boy from now on…

About That Smoking Gun…

May 13, 2015
Categories: Multiverse Mania

Aeon magazine has just published a long piece on the current state of cosmology by Ross Andersen. One focus is on Paul Steinhardt and his claims that the popular multiverse/eternal inflation scenario doesn't explain what it is supposed to, and is compatible with almost any experimental result. The BICEP2 fiasco, where multiverse proponents first claimed a "smoking gun" vindication from B-modes, then went on to claim that no B-modes was just as good for their theory once they disappeared, is the main topic of the article (for a previous posting about this, see here).

> That's why Steinhardt was surprised to see inflationary theorists clinking glasses when BICEP2 announced a high swirls figure. 'They declared victory,' he told me. 'They said it was smoking-gun proof! Just what they expected!'
>
> But then a few months passed and BICEP2's interpretation started to look wobbly. In June, Linde told New Scientist that he didn't like the way BICEP2's swirls were being treated as a smoking gun for inflation. In July, Guth made similar statements to the Washington Post. Steinhardt was furious. He thought it was flip-flopping. He began to wonder if any data would disturb the serene certainty of inflationary theorists. 'It was Andre Linde who used the "smoking gun" language in the first place,' he told me. 'Now he says it doesn't make a difference what BICEP2 says. How can it be that not seeing gravitational waves is fine, and then seeing them is a smoking gun, and then not seeing them is fine again?'

Steinhardt explains that the underlying problem is that the underlying problem is an inherently untestable paradigm, compatible with anything:

> The theory's weaknesses can be explained away with the same glib shrug that accompanies the retort: 'God just made it that way.'
>
> A dominant, infinitely flexible multiverse theory could make it easy not to strain for the next leap forward. It could lead to a chilling effect on new ideas in cosmology, or worse, a creative crisis. Steinhardt thinks we're already there. 'Andre Linde has become associated with eternal inflation because he thinks the multiverse is a good idea,' he told me. 'But I invented it, too, and I think it's a horrible idea. It's an emperor's new clothes story. Except in that story, it's a child who points out that the Emperor has no clothes. In this case, it's the tailors themselves telling us that the theory is not testable. It's Guth and Linde.'

His hope for how the subject will get saved from itself is with help from philosophers:

> 'The outside community isn't recognising the problem,' he said. 'This whole BICEP2 thing has made some people more aware of it. It's been nice to have that aired out. But most people give us too much respect. They think we know what we're doing. They take too seriously these voices that say inflation is established theory.'
>
> I asked him who might help. What cavalry was he calling for?
>
> 'I wish the philosophers would get involved,' he said.

That might help, but I think other ideas are needed…

Comments

1. **Theo Nieuwenhuizen**
   May 13, 2015

   I can't help for longing for the 1930's, even if it was before my time. People were very cautious with new claims. Pauli felt bad for proposing a new particle – the neutrino.
   Nowadays, if you don't propose a whole new sector of the standard model (SuSy, mirror matter, …) you won't be taken serious. Better proclaim smoking-gun inflation or even multiverses (= undecipherable verses).

   What do we really have? Just the standard model particles, with the stable ones being protons, electrons, photons, neutrinos. In the 1930s one would have tried to construct a Universe from that. And one would have hunted the bears-on-the-road like neutrino free-streaming, that seems to be a road block (but is not).

   Great times. I bet we will be forced to return to this level of modesty. And have to wonder how we could get it so wrong.

2. **Jim Given**
   May 13, 2015

   The philosophers of science have already told us everything we need to know:
   Every domain of Big Science needs a "governing narrative" to provide a basis for discussion and to evaluate research priorities. Such a narrative, a Big Theory, is constructed so as to be non-falsifiable. to provide continuity. So attempts to directly overturn Big Theories, whether Freud's in psychology, Chomsky's in linguistics, or inflationary cosmology in this case; are futile. What must happen is for funders and research directors to conclude the dominant Big Theory is no longer a productive source of interesting research directions; and for bright young theorists to work on other paradigms and find success. Perhaps future historians of science will conclude we are already well into this phase. But Big Theories never fail; those with a lifelong vested interest in them retire or die and are replaced by theorists with a different perspective. (This is all vintage Imre Lakatos.)
   *** May you live in interesting times. ***

3. **Michael Gogins**
   May 13, 2015

   Jim Given: I think it's a little more complex, and a great deal more interesting, than that. Think about Einstein and entanglement. He hated its implication of irreducible indeterminacy because it conflicted with what you are calling a "governing narrative," which for Einstein was the idea that natural law is deterministic and local. To fight this spooky implication, Einstein, Podolsky, and Rosen wrote a paper which has become extremely influential and productive, even though it is wrong.

   I guess there's a saying of some sort lurking in there: "wrong enough to be useful" or something like that.

   Anyway, scientists of different views are, in my judgment, at least the good ones, involved in something more like a dialectic than a die-off.

   Also, I think the final arbiters of how this all works are the scientists themselves, not philosophers. The scientists have implicit philosophies, which I call "the philosophy of scientists" as opposed to "the philosophy of science," which are usually pretty vague and not formulated to the standards of philosophical papers, but on the other hand, the empirical successes of science warrant that there is something important going on in "the philosophy of scientists."

4. **Syksy Räsänen**
May 13, 2015

Steinhardt is disingeniously conflating eternal inflation and inflation. Inflation is not necessarily eternal (many models, including ones consistent with the data, such as Higgs inflation, do not lead to eternal inflation), and does not in any way imply the multiverse. It's true that some inflationary theorists are promoting the chain of inference inflation -> eternal inflation -> multiverse. But the criticism should be directed towards the theorists, not inflationary theory. Instead, Steinhardt is adopting this false chain of reasoning to promote his own competing ideas.

PS. The first person to suggest inflation as a solution to the horizon problem was not Guth, but Kazanas: http://adsabs.harvard.edu/doi/10.1086/183361

5. **Thomas Larsson**
May 13, 2015

Theo, I think the situation today may be quite similar to the 1930s. At that time people had discovered that QM was incompatible with electromagnetics, and many people apparantly thought that the only way to solve that problem was to postulate new physics – I have seen claims that Oppenheimer thought so. Alas, we all know that the solution was not new physics, but a new way to look at old physics – renormalization. Perhaps there is a lesson there for our time, when everything but SM + GR looks increasingly unlikely.

6. **JG**
May 13, 2015

The role of philosophers belongs to pre-1950s and even much earlier when not many scientists took cosmological models serious.

Since then we have a remarkably good *scientific* cosmological model – people should (re-)read Weinberg's The First Three Minutes from 1977(!) to remind just how good a scientific theory we have even without Inflation, Dark Matter/Energy and other more recent theoretical suggestions. (Weinberg updated the book in 1993, before the accelerating expansion had been discovered but he discussed many of the other newer ideas)

None of these additions since the late 1970s are of a philosophical nature, they are deep mathematically constructed ideas that require a high degree of understanding of a lot of known physics.

Philosophers can only muddy the waters, we need brilliant mathematical/physical insights building on a solid understanding of the existing theory. We may even already have discovered the true model.

7. **Art Brown**
May 13, 2015

It's a pity the article didn't include any responses from Linde and/or Guth, given Steinhardt's statements about them.

8. **Dave Miller in Sacramento**
May 13, 2015

Perhaps someone more knowledgeable than I can let me know if my impression of inflation is close to the mark:

My impression is that inflation is an interesting idea, which might explain some interesting features of the universe (large-scale homogeneity, near flatness, etc.), which is consistent with existing cosmological data, and which perhaps has a little bit of observational data that supports it but that is inconclusive.

Is that pretty much it?

Incidentally, I was at SLAC when Guth did his initial inflation work there, and I went to hear one of Alan's early talks on the subject: it sounded interesting and still sounds interesting (the Big Bang as the ultimate beginning was always a bit dodgy), but I am curious as to whether it can ever be confirmed or disproven.

Dave Miller in Sacramento.

Such a narrative, a Big Theory, is constructed so as to be non-falsifiable. to provide continuity.

Except… a lot of those "governing narratives" *have* been falsified: the geocentric theory, the immutability of species, the absoluteness of space and time, the immovability of the continents, etc.

So… the philosophical theory you mention has in fact itself been falsified!

Dave

10. **Neil**
May 13, 2015

Send in the philosophers? I doubt that would help from what I have read so far (see Richard Dawid's book on "post-empiricism".) The multiverse, like free will, offers philosophers a dream subject–something that can be debated endlessly without fear of ever reaching resolution.

11. **Aleksandar Mikovic**
May 14, 2015

The obvious solution to the multiverse problem is to find a quantum gravity theory different from string theory, such that it allows inflation. One example is loop quantum cosmology.

12. **Syksy Räsänen**
May 14, 2015

Dave Miller in Sacramento:

The major success of inflation is not explaining the spatial homogeneity, isotropy and flatness of the background (although the last was not obvious at the time inflation was proposed), but accounting in detail for the perturbations in terms of quantum fluctuations, first discussed by Mukhanov and Chibisov.

The perturbation calculation is non-trivial, and it correctly predicted that the primordial perturbations are a) close to scale-invariant, b) dominantly scalar, c) adiabatic, d) statistically homogeneous and isotropic and e) Gaussian. These are real predictions, made before the observations were in. No other proposal has been able to account for them as well as inflation, even after the fact.

So there is a lot of support for inflation. Whether one regards inflation as proven is a matter of taste. There are hundreds of inflationary models (many of which differ from one or more of predictions given above), and I would prefer to have more understanding of the physics, or observation of the wavelength dependence of the gravitational waves (see below), before saying that we know that inflation occurred.

As for the smoking gun, the BICEP2 results were misrepresented from the beginning as "first direct evidence of cosmic inflation", because there was a lot of evidence already, and gravitational waves are not more direct than scalar perturbations. The simplest models of inflation predict a relationship between the amplitude of the scalar perturbations, amplitude of the gravitational waves and the wavelength-dependence of the gravitational wave amplitude. I think that could be called a 'smoking gun', in the sense that if it was measured, I think we could say that inflation happened, even without further understanding of the models.

Please note that even if something is a smoking gun (definite evidence for A), not finding it does not imply that A is not correct.

13. **Alex**
May 14, 2015

@Syksy Räsänen

"The simplest models of inflation predict a relationship between the amplitude of the scalar perturbations, amplitude of the gravitational waves and the wavelength-dependence of the gravitational wave amplitude. I think that could be called a 'smoking gun', in the sense that if it was measured, I think we could say that inflation happened, even without further understanding of the models."

But a parameter was measured, and it was found to conflict with the simplest models of inflation. Yet, all this measurement has done was to constrain which models of inflation could possibly work. Therefore I really don't think this could reasonably be called a smoking gun. Again, all it did was to rule out models of inflation that could not possibly be true.

14. **Alex**
May 14, 2015

@Syksy Räsänen

I've put a very rough argument together to put this idea that this observation would be a "smoking gun" on a slightly more objective footing.

I think its reasonable to assume that an observation being a "smoking gun" means that this observation must carry some kind of information about the theory we are trying to evaluate. Namely whether it be true or false. The key parameter we're measuring here would be the scalar-to-tensor ratio denoted by r. The measurement of r should tell us whether our theory is true or false. Denote these outcomes by \omega_r. \omega_r = 0 or 1 for false and true. They key question here is what is the probability that our theory (inflation) is false given some observation of r. I think its quite reasonable to assume (given the above discussion) that P(\omega_r = 0) ~ \epsilon, where \epsilon is a very small number, approaching zero. This quantifying the fact that no matter what value of r we observe, inflation is correct. Hence, P(\omega_r = 1) ~ 1 – \epsilon.

What is the information given by this measurement which you characterize as being of the "smoking gun" nature. The information entropy is E(I(\omega_r)) = -\sum_{\omega_r}(P(\omega_r)log(P(\omega_r))) = -\epsilon*log(\epsilon) – (1-\epsilon)*log(1-\epsilon) ~ 0.

Hence, no real information is conveyed given you characterization of this experiment. Hence we do not have a smoking gun.

15. **Syksy Räsänen**
May 14, 2015

Alex:

1. BICEP2 only claimed to have measured the amplitude of gravitational waves, not the dependence of the amplitude on wavenumber. So even if correct, their results would not have been what I called a smoking gun above.

2. The BICEP2 results, if correct, would not have been in conflict with the simplest models of inflation, though there was some tension. See http://arxiv.org/abs/1405.1390 (though their accounting of the tension is a bit simplistic).

3. Let us not confuse the concepts "smoking gun" and "test". A is a test for X, if X implies A. Proving A does not prove X, but disproving A disproves X.

A is a smoking gun for X, if A implies X. Proving A proves X, but disproving A does not disprove X.

Seeing gravitational waves that satisfy the consistency condition I referred to above can, in my view, be regarded as a smoking gun for inflation, because it relates three independent, non-trivial, quantities in a way that no other theory has (as far as I know) has been able to reproduce.

However, it cannot be regarded as a test, because even if the relation holds, the gravitational wave amplitude depends on the model (and can be below the sensitivity of near-future experiments), and there are many models of inflation in which the relation does not hold.

16. **Alex**
May 14, 2015

Syksy Räsänen:

I'm sorry I think I read part of your comment too quickly. Yes, I agree with point 1) above.

But as for this part:

"However, it cannot be regarded as a test, […] and there are many models of inflation in which the relation does not hold."

Am I reading this right? You're saying that one of the reasons it can't be regarded as a test is *because* there are many models of inflation in which this relationship between wave number and amplitude doesn't hold anyway?

17. **RM**
May 14, 2015

I think philosophers would be of help to Steinhardt – one of the basic lessons one learns in philosophy is that if A implies B, then Not A does not imply Not B.

18. **Alex**
May 14, 2015

Syksy Räsänen:

To sum up:

The alternative test you are proposing seems to be on the same footing as the amplitude measured by BICEP2 in terms of its ability to determine the validity of inflationary theory. If there is a specific relationship between wave number and amplitude, inflation is right. If there isn't this specific relationship, inflation is right. The problem isn't with your test, its with inflationary theory itself, its not uniquely defined.

Also, I disagree with your description of the "smoking gun" term. If an experiment is going to provide me with conclusive evidence that a theory is correct, there ought to be an experimental outcome that would prove the theory incorrect. In other words, the experimental outcome should give actual information (see my above post).

I think we're probably going to have to agree to disagree.

Cheers

19. **Syksy Räsänen**
May 14, 2015

Unlike Steinhardt claims, there's nothing extraordinary about the situation with regard to gravitational waves. This distinction of test vs. smoking gun is common to all cases where there are several models whose predictions overlap in the area where predictions have been made, but which have different predictions outside.

For example, consider direct detection experiments of dark matter, sensitive to a certain range of mass and interaction cross section. If events are seen that are consistent with dark matter (so that they are consistent with other observations, and backgrounds, systematics etc. are ruled out), this can be regarded as a smoking gun. If they are not seen, this does not rule out dark matter, because its mass and cross section may be out of the range probed by the experiment. This does not mean that the experiment does not give us information about dark matter (it narrows the possibilities).

20. **Andre**
May 14, 2015

Steinhardt criticizes inflation, because if this theory is confirmed, then his own work on the cyclic universe will remain useless. All simple.

21. **Peter Woit**
May 14, 2015

Andre,
Surely his own work is a motivation, but I think it's not unreasonable for him to argue that it's not a fair scientific competition between ideas when one side gets to claim victory no matter what the experiments say. If you take a look at the reaction after the BICEP2 results were announced, see
http://www.nature.com/news/gravitational-wave-finding-causes-spring-cleaning-in-physics-1.14910
you had
1. "Paul Steinhardt, a theoretical physicist at Princeton University in New Jersey and an originator of the cyclic theory, agrees that — if the BICEP2 findings are confirmed — his theory is now dead"
although he did say he would look for a cyclic model that would agree with BICEP2.
2. Linde on the other hand, reacting to incompatibility of BICEP2 with popular string inflation schemes: "There is no need to discard string theory, it is just a normal process of learning which versions of the theory are better,"

22. **Alex**
May 14, 2015

Syksy Räsänen:

IF you are already convinced inflation (or dark matter) indeed happened then yes these experiments provide information in the form of narrowing down which specific parameter values in the theory are true.

But I maintain that these tests provide no information as to whether the theory of inflation itself (for any parameter value) is true. There will always be a parameter value to fit ANY observation. So we can't "say that inflation happened" based on the results of BICEP2 or the experiment you proposed. But if we assume inflation happened then we can say which version of it happened based on the results of these experiments.

Ok, the prosecution rests.

23. **Dave Miller in Sacramento**
May 14, 2015

Alex and Syksy,

Thanks for your informative back-and-forth on inflation.

Sysksy, you wrote:

> The major success of inflation is… accounting in detail for the perturbations in terms of quantum fluctuations, first discussed by Mukhanov and Chibisov.
>
> …it correctly predicted that the primordial perturbations are a) close to scale-invariant, b) dominantly scalar, c) adiabatic, d) statistically homogeneous and isotropic and e) Gaussian….
>
> … There are hundreds of inflationary models (many of which differ from one or more of predictions given above)

That was sort of my impression, and it strikes me as suggestive, but very, very far from conclusive. After all,, isotropy and Gaussian distributions are, for example, rather common features of phenomena in the real world!

Having known Alan when he started working on inflation, I have a vested interest in hoping that it is eventually proven to be true: kinda cool to be able to say "I was there when…" (Similarly, I knew Schwarz, Polchinski, and Susskind when I was a student, so it would be kinda cool for me if string theory works out.)

But… when there are, as you say, "hundreds of inflationary models" that give different results… well, if the theories of Planck, Rutherford, Bohr, et al. had been that rubbery, I think they would have been a good deal less convincing.

Thanks again for the back-and-forth.

Dave

24. **srp**
May 14, 2015

Clearly a smoking gun and a crucial test are not the same things, as Syksy points out. A smoking gun in the suspect's hand would be powerful evidence of the suspect's guilt, but the absence of the smoking gun would not be enough to exonerate him. It is perfectly logical to posit such "one-way" tests that are not crucial but could still clinch the truth of a theory if they were passed. (In the same way, we might rule out a suspect if a test turned out one way but not convict him if it turned out the other way, e.g. if we see him far away from the victim on a video time-stamped at the time the crime occurred he's in the clear, but failing to find such a video wouldn't make him guilty.)

On the other hand, if we theorized that the murderer must come from a vaguely defined set of over one million people and claimed that our theory was useful only because a smoking gun might turn up in one of their hands, we might not be hired back as consulting detectives.

25. **Art Brown**
May 17, 2015

Syksy Räsänen,
Thanks for the reference to the illuminating Audren et al. analysis of the tension between BICEP2's original paper and Planck. I realize this topic is now Overtaken By Events, but:
1) Can you elaborate a bit on your comment that "their accounting of the tension was a bit simplistic"?
2) What am I to make of the conclusion in BICEP2's original release (1403.3985v1, 2, & 3): "These high values of r are in apparent tension with previous indirect limits based on temperature limits …"?
Thanks again.

26. **Calvin Marshall**
May 19, 2015

Dr. Woit,

As I understand it from Vilenkin's book 'Many Worlds in One', the mechanism for eternal inflation is a scalar field: areas of false vacuum decaying into areas of true vacuum. But as Alexander Vilenkin notes in 'Many Worlds in One', there is no direct evidence for the existence of scalar fields in nature: "Another important question is whether or not such scalar fields really exist in nature. Unfortunately, we don't know. There is no direct evidence for their existence." (p. 61). Reading this as a layman, this is what I take away: no scalar fields, no eternal inflation. There's no direct evidence for scalar fields, therefore there's no direct evidence eternal inflation. Is this a correct understanding?

Thank you,
Calvin Marshall

27. **Peter Woit**
May 19, 2015

Calvin Marshall,
We do now have evidence for a scalar field, the Higgs field. It's very unclear though whether the Higgs field can be used to give you inflation. The models cosmologists mostly work with use a postulated scalar field to drive inflation, one which has no other observable effects.

28. **Syksy Räsänen**
May 20, 2015

Art Brown:

1) In the paper, the authors find the confidence levels for Planck and BICEP2 separately and look at their overlap. They say that since the overlap is in the region between one and two sigma, there is no significant tension.

It would be more appropriate to do one or more of the following: 1) ask the Bayesian question of what is the likelihood of the BICEP2 observations given the Planck observations (assuming the simplest inflation model), 2) consider the goodness-of-fit of the model to the full dataset, or 3) see how much the fit is improved by the addition of new parameters.

All this, of course, assuming the (wrong) interpretation of the B-modes as being due to gravitational waves.

2) The part you quote is correct: the results were "in apparent tension" (which is different from conflict). For caveats in that BICEP2 statement of tension, see the abstract of the Audren et al paper.

29. **Syksy Räsänen**
May 20, 2015

Art Brown:

I realised now that your question is probably related to the title of the Audren et al paper, "BICEP2 and Planck are not in tension". I would say that their analysis shows that the tension is not as large as some thought (with the caveats above), not as saying that there is no tension, but this is a matter of taste.

30. **Art Brown**
May 20, 2015

Syksy Räsänen, Thank you very much for the additional explanation. On a separate note, I see you have updated your cosmology notes and look forward to having a go at them.

31. **Syksy Räsänen**
May 21, 2015

Art Brown:

Let me know of any typos!

32. **Hank Bolden**
June 6, 2015

In the New York Times dated June 5, 2015:

"Crisis at the Edge of Physics" DO physicists need empirical evidence to confirm their theories?

http://www.nytimes.com/2015/06/07/opinion/a-crisis-at-the-edge-of-physics.html

Contested Boundaries

May 13, 2015
Categories: Uncategorized

Apologies for too much recent posting here about the tired topic of the string wars. I hope to soon make amends by writing about something new I learned about geometric Langlands.

The summer 2015 issue of *Perspectives in Science* has an excellent article about the debate over string theory entitled [Contested Boundaries: The String Theory Debates and Ideologies of Science]() (also available [here]()), by Sophie Ritson and Kristian Camilleri. It deals with the debate from a point of view bringing together aspects of history, philosophy and sociology, while staying away from the technical aspects of the controversy.

The article has an interesting take on the debate, not taking sides as to who is right or wrong, but examining what the central issues have been and the ways people involved have chosen to make their case. One point made that I'd never thought of is that while this debate concerns an issue that comes up often, that of the boundary of what is science and what isn't, here the usual roles are reversed:

> In most scientific controversies in which we find scientists engaging in boundary work, the boundary dispute is generally over whether an unorthodox or minority view or approach should be regarded as science, pseudoscience, or pathological science. UFOology, parapsychology, intelligent design, and cold fusion all represent cases of this sort. The "ideological attempts to define science," as Gieryn explains, are largely motivated by the desire "to justify and protect the authority of science by offering principled demarcations from poachers or impostors" (Gieryn 1999, p. 26). However, in the case of string theory, it is the dominant research program in a well-established field of science that has been forced to defend its credentials as "scientific" (Taylor 1996, pp. 177–9).
>
> This presents an intriguing departure from most studied episodes of boundary work. String theory currently enjoys a privileged status by virtue of being the dominant paradigm within theoretical physics. Yet string theorists have found themselves forced to defend the scientific legitimacy of their research against charges that it has degenerated into a form of "metaphysics," "non-science," or "bad science." In doing so, string theorists have attempted to "loosen" the methodological definition of science, while critics try to impose a stricter definition.

The emphasis of the article is on the string theory debate, not the multiverse, and I'm (accurately) quoted as defending string theory as "scientific". When I wrote about this in my book back in 2002-3, I had no idea that multiverse pseudo-science would take hold among prominent theorists, a situation that raises issues I never thought would come up (the sort of thing Steinhardt is hoping for help with from the philosophers, see the last posting). The parts of the book about the "is it science?" question are ones I would write differently today, based on both recent history and new things I've learned about the philosophy of science.

Comments

   May 13, 2015

   Mention of boundaries brings to mind Turing's view on them:
   "Science is a differential equation. Religion is a boundary condition"

2. **Jim Beyer**
   May 14, 2015

   This was covered at a basic level on NPR's Science Friday:

   [Should These Scientific Ideas Be Retired?]()

   I think it is significant (and troubling) because even Ufologists, etc. don't dispute the validity of the scientific method; they just report results/findings which are not reproducible. I find John Mack more credible (as a researcher) than some string theorists….

3. **Marc**
   May 14, 2015

   Peter– you are quoted as saying "At the moment [string theory] is a theory which cannot be falsified by any conceivable experimental result." Suppose the 100 TeV collider discovers extra dimensions — ten of them. Would the knowledge that space-time is at least fourteen-dimensional rule out superstring theory? Or, perhaps more reasonably, suppose extra Z's are discovered that show that the gauge group of nature has at least rank 10 (or some large number). Would this rule out heterotic string theory? Yeah, these are extreme, and rather ridiculous, but they are "conceivable"…

4. **Peter Woit**
   May 14, 2015

   Marc,
   "conceivable" is perhaps an overly strong word, I think with that statement I was trying to be provocative, not precise. A better wording might have been "plausibly conceivable". And I wasn't just referring to heterotic string models, but to more general possibilities.

   But, honestly, it is extremely difficult to come up with actual experimental results that one couldn't somehow explain by a complicated string theory model. First of all, the examples you give assume a certain theoretical interpretation of some experimental result, with experiment not directly measuring number of dimensions or rank of gauge group. Trying to think of experimental results that would have that interpretation, I suspect alternate explanations would be possible. Even given airtight evidence for one of those theoretical interpretations, it's unclear to me that one really can't find some kind of string model with those properties. For a while there was an active research program of trying to characterize the "swampland", qft theories that could not come from string theory. Typically though, claims to identify such a QFT were quickly met by someone coming up with a string theory construction, see for example
   https://golem.ph.utexas.edu/~distler/blog/archives/000651.html

   So, the claim I had in mind was really: think of anything you can plausibly imagine turning up in a plot from an LHC experiment in the next few years and find an example that would cause string theorists to abandon string theory. I can't think of anything like that.

5. **Peter Woit**
   May 14, 2015

   After more thought, a quite precise version of the claim I had in mind that Marc refers to would be:

“No one working on an LHC experiment has ever run a Monte-Carlo for some scenario, such that if data matched the Monte-Carlo, that would cause string theorists to abandon string theory.”

6. **JG**
May 14, 2015

article available at mitpressjournals.org for non-subscribers

7. **Peter Woit**
May 14, 2015

JG,
Thanks. I’ve now put both links in the posting, hopefully people will be able to get access to one or the other of them.

8. **Anonyrat**
May 14, 2015

“No one working on an LHC experiment has ever run a Monte-Carlo for some scenario, such that if data matched the Monte-Carlo, that would cause string theorists to abandon string theory.”

Much sharper, but could use further sharpening in my opinion. For instance, the string theorists’ riposte could be – “Nor have they run a Monte-Carlo that would cause physicists to abandon QFT. Abandon SUSY, the Standard Model, etc., yes, but not QFT”.

I know you’ve previously dealt with this kind of objection, so just saying….

9. **Peter Woit**
May 14, 2015

Anonyrat,

I’m sure many if not most theorists would happily abandon the Standard Model given a proven violation of it, and much of the LHC effort is looking for that, surely with Monte-Carlo simulation of possibilities. In some sense LHC research is mainly an effort to falsify the SM, and my point was just that no one is even trying to falsify string theory.

Better to not reopen the question of the appropriate definition of falsifiability though, it’s a thorny subject discussed here often, and it seems highly unlikely anyone will have anything new and insightful on the topic.

10. **al**
May 15, 2015

It’s a pity that Roger Penrose (Roads to Reality) is not mentioned.
Also a glance towards the financial aspects might have been useful in discussing sociology: doing theoretical physics is the cheapest way to do (natural) science, and it’s a bonus if the work is never refuted. Advertising nowadays often promotes ‘prestige’ that is not to be judged by grossly material standards.

Next Week's Hype

May 14, 2015
Categories: This Week's Hype

I know I should be coming up with material on different topics here, but the multiverse stuff sometimes is just too hard to ignore.

Next week's Comicpalooza in Houston will feature string theorist Gerald Cleaver. His blurb tells us that:

> His EUCOS team conducts long-term systematic computer-based studies of global phenomenology of parameter spaces of the string landscape of around 10,500 possible string-derived universes and its theorized multiverse realization.

A local paper has a news story: Physicist to discuss multiverse theory at comic convention. According to the article:

> Cleaver is a physicist and early universe cosmologist at Baylor University whose area of expertise is string theories, or the concept that there are not one but multiple universes in existence…
>
> Cleaver said when the multiverse theory was first investigated scientifically in the 1980s, the formulas made it look like a string, hence the name, but was later revised to be more spherical or bubble-like. Some call the universes "bubbleverses" as a result….
>
> Cleaver said there are four levels of universes with ours being in the first and most simple level. The second level has its forces and can contain that of the first. The third has its own and can contain the first two and likewise with the fourth level.
>
> String theory remains just that – a theory. Cleaver, however, feels scientists are close to proving the theory. It could be a matter of a few days or a few years but he and others like him press on with the belief that reality is bigger and much stranger than fiction.

According to his website, besides the string landscape,

> Cleaver is also interested in the general concept of multiverse, not just the string/M-derived class. In his spare time he is writing a book on philosophical and theological implications of a multiverse and has contributed related chapters in associated books…
>
> Cleaver is also a member of the XP4 division of Icarus Interstellar, a non-profit organization created by his Ph.D. graduate Dr. Richard Obousy. Members of XP4 are exploring advanced propulsion systems and energy generation concepts for interstellar spacecraft, including possible string/M-theory realization of the Alcubierre effect.

For Cleaver's views on theology and the multiverse, see his articles here. Last fall he gave a talk to students at Baylor explaining that

> a multiverse is the likely natural mechanism through which the God of infinitudes grants inherent freedom to a spatially and/or temporally infinite creation. In other words, the multiverse is God's means of indeterminacy in action.

Update: Keeping up with the hype is getting to be beyond my powers. Just this morning there's:

- The idea that "string theory allows time travel at the LHC" has been revived, reported on here, and Morgan Freeman has it on Through the Wormhole. This first appeared back in 2011, discussed here then.
  By the way, the same site has convincing evidence for time travel, reporting earlier this year that Large Hadron Collider Predecessor May Be Four Times Larger, Much More Powerful.
- Nova has something about yet another paper describing how we're going to observe the multiverse through bubble collisions. The paper at least admits the obvious, that if such things were observable, almost surely we would have already seen them:

  > a certain amount of tuning must be applied in order to construct models that produce signatures that are possibly observable but not yet ruled out by data.

   10,500? Not 10^500?
   What a relief!

3. **phil fogle**
   May 15, 2015

   Ok , we know there are nutters in the world, but can someone please come up with a counterexample???

4. **Guest**
   May 15, 2015

   They wrote: "String theory remains just that – a theory". They should have written: "String theory remains just that – a hypothesis".q

5. **S**
   May 15, 2015

   This seems like a piece that might interest you, Peter, especially toward the end (although the whole article is interesting). It's unclear what the attitude of the reviewer or writer toward what they're saying is:

   http://www.firstthings.com/article/2015/06/a-new-era

"Increasingly, one finds science lapping over its seawalls. Indeed, in some areas, the boundary between science and speculation has been entirely washed away. Science began with philosophical speculation twenty-five centuries ago, and it seems likely that it will end in the same place."

6. **Richard E.**
   May 15, 2015

   You have to sign a statement of faith to work at Baylor, so presumably the religious spin is less of a surprise in this case.

7. **Theo Nieuwenhuizen**
   May 15, 2015

   String theory is no more than a consistent quantum model. I don't understand why we should believe any of this, knowing that string theory does not reproduce the standard model of elementary particles. This hyping is just a cover up for its complete failure to connect to the things that do exist. I don't mind string theologists. But they should choose words like: "As a string theologist I am convinced that …"

8. **Jon Awbrey**
   May 15, 2015

   G-strings?

   Where "G" is for *Genesis*, of course.

9. **Peter Woit**
   May 15, 2015

   Theo,
   I think you're being very unfair to theologians (or theologists), by trying to associate them with Cleaver's string landscape stuff.

   Richard E.
   Seems to me that the theology is the part of Cleaver's work that actually makes some sort of sense. If God is going to be in the business of making universes, why shouldn't he make lots of them? On the other hand, I do think Baylor should be concerned about the landscape pseudo-science and public promotion of it…

   By the way, this reminded me of Amanda Peet's Perimeter lecture, which probably could have been improved by adding some God into it. There was a live blog during that lecture which included some Perimeter physicists going on about how wonderful it was, one of whom (Tibra Ali) was a Cleaver postdoc. Perhaps Cleaver can be Perimeter's next public event.

10. **Nobody**
    May 15, 2015

    According to Aquinas, God knows all possible universes, so maybe Tegmark et al _should_ be considered theologians.

11. **Theo Nieuwenhuizen**
    May 15, 2015

    Dear Peter, if string theologists declare themselves as such, this will not much improve my respect for them. For others it would clarify why they make the claims they make.

12. **Mr. Roarke**
    May 15, 2015

    String Theory, Multiverse, God… the Neapolitan ice cream of Fantasy Island.

13. **KenW**
    May 15, 2015

    Comicpalooza looks like quite the ticket. Jackie Earle Haley alone is worth the price of admission. But you get Henry Winkler, too.

14. **Noboru Nakanishi**
    May 15, 2015

    String theory is a theory of everything except for the truth.

15. **Al**
    May 15, 2015

    I don't know what we gain by drawing attention to seeming crackpots like Cleaver with his theological justifications for multiverse. There are plenty of proper scientists working on string theory landscape who deserve to be criticized on scientific grounds.

16. **Narad**
    May 16, 2015

    > If [G-d] is going to be in the business of making universes, why shouldn't he make lots of them?

    I suspect that *that* phrasing instantiates the heresy of G-d as demiurge, but somebody would have to check with Guy Consolmagno.

17. **Yatima**
    May 16, 2015

    Cleaver said there are four levels of universes with ours being in the first and most simple level. The second level has its forces and can contain that of the first. The third has its own and can contain the first two and likewise with the fourth level.

    More evidence that the War on Drugs is an utter failure.

18. **adrian**

May 16, 2015

dear all,
i believe it is a bit unfair to associate the work of Dr. Cleaver with the work of the rest of the strings theorists. These things just catch the media attention, but this is NOT what string theorist do. As you all know, we have this website called arXiv.org, where one can see what string and other theorist work on.
Also, we have this website called inspire.net, where you can check that the work of Dr. Clever in the last few years and on the string landscape, have not had a big impact in the community. Again, it is my impression that what the media says or reflects is not the reality of the string theorists.

Also, it is, clearly a bit unfair to write opinions about the talk and its contents–before–the talk happened.

Just wanted to get the thing straight. This is not the reality, nor the main interest of most of the string theorist, who, by the way, are working on different aspects of quantum field theory.

thanks

19. **Peter Woit**
May 16, 2015

Adrian,
The research program Cleaver is pursuing is the sort of thing lots of prominent string theorists were promoting as the "String Vacuum Project", see
http://www.physics.rutgers.edu/~mrd/SVP-v2.ps
The only difference is that most of them seem to have realized (but never admitted publicly) that this was nonsense and given up on it. It's still as far as I know a respected part of the "string phenomenology" business.

It is true that most good string theorists have long ago given up on "string phenomenology" as hopeless, but they still publicly often promote the claim that "string theory is our best hope for unification". And Cleaver's pseudo-science about the multiverse and string theory is now firmly mainstream.

As far as outreach efforts go, I don't see a lot of difference between what Cleaver is doing, the Amanda Peet/Perimeter "Lego" performance, and any number of books by prominent string theorists about how wonderful the multiverse is.

20. **adrian**
May 16, 2015

dear Peter,
thanks for your reply. As you may have guessed, I work on string theory. Allow me to disagree with some of the things you wrote and agree with others.

–I heard about the project you mentioned lead by Douglas and Kane. When I heard about it via some european physicists, my reaction was positive. I see the whole idea as a 'taxonomic' effort. A classificatory effort—in this case of Calabi-Yau 3-folds. In my experience, these efforts are worthwhile.

We learnt a lot of geometry [even useful to mathematicians sometimes] thanks to projects based on pure taxonomy. Good examples are papers lead by Gauntlett, Waldram, Martelli, Sparks, classifying AdS-vacua of type II and eleven dimensional supergravities. More recent works by Tomassiello and collaborators, Papadopoulos and collaborators, etc.

These are just examples, but you and your readers are probably aware that this is precise and correct science. Some people like me have used these papers to learn about QFTs. Now, will the same go for the project you linked? Obviously, i do not know.
But is not a bad idea to classify geometries. Do you agree?

I may be a bit allergic to the wording about the 'landscape and particle Physics" but any educated physicists knows that there is not much of Physics—for the moment– in there.
I see it as a project in geometry, with the hope that it might illuminate some Physics beyond the Standard Model….but that is a hope, close to the opinion.

–I do not see "string phenomenology" as a waste of time. I see it as a way people learn about geometry. See papers, for example, by Schaffer-Nameki and collaborators. This is serious and correct science. Will it have impact or find a place in Physics beyond the Standard Model? I do not know. I am a bit pessimistic, but that is an 'opinion'.

I agree with you that some statements have been over claimed in the past [and probably in the present]. But that is not Physics or science. It is the press together with some not-so-careful attitude of scientist. One should not forget, they are humans, so a bit of ego is expected to appear. I think that for example, all the physicists i mentioned above, are doing correct, not-overclaimed, precise studies. I think you will agree.

–About the talk of Amanda Peet in Perimeter and your comparison with Cleaver's forthcoming one. I cannot give you my opinion, I did not hear Cleaver's talk. I do not think I will be able to hear it [will it be recorded and linked?].

In any case. Let me tell you what I saw in Peet's talk: She talked–in a popular style– about topics that are well established. Mostly, black holes and the calculation of their entropies. These are very precise computations in CFT and in gravity. She said nothing that was technically wrong. Same goes for her description of AdS/CFT. One may or may not like her style, her choice of topics and the wording she used. But I do not think she said anything technically wrong. You feel it was a bit over claimed? me too. But is hard in a talk of those characteristics to be completely clear about what we observe and what we do not observe. It is hard—and this I know for experience– not to talk as if we are describing "the truth". I honestly do not think she gave a bad talk, I do not think she was dishonest. One can of course pick three or four phrases where the 'stringer in her' does not clarify "this is not observed in Nature". In summary, I believe that Peet's talk was correct.

–Finally and to close the disagreements; you wrote
"And Cleaver's pseudo-science about the multiverse and string theory is now firmly mainstream."

But, it is mainstream in the press, not in the ArxiV. Do you agree?

Physics is decided in the ArXiv [i mean, the papers posted there], these seminars, the labs and on what physicists work on. I understand and share your worry about all this press attention. I do agree it is not beneficial for young people, I see it in my early courses, talented kids that want to learn about M-theory before learning the oscillator. One just needs to call their attention to some obvious facts, they understand.

All right, too long comment, your readers are already gone, your attention cannot be bothered any more. Apologies

21. **Klaus**
May 16, 2015

@adrian, @Peter,

since about 8 years, every morning, the first thing I look at is http://arxiv.org/list/hep-th/recent . You are right to distinguish what happens in the press from what happens on arxiv. The press mainstream is about "multiverse", "unfied theory" etc. The term multiverse appears in 151 abstracts in hep-th; many well-known physicists appear as authors, but this is indeed a small number.

The arxiv/hep-th mainstream differs from the press mainstream in many other topics: it is rarely about "unfied theory", rarely about "theory of everything", rarely about "comparison with experiment", rarely about the "standard model". And when hep-th is about these topics, it is usually about approaches that are NOT from string theorists. Try by yourself.

Not only is the reality of string theory in the arxiv different from in the press; in a sense, hep-th is even more disappointing: string theorists in the arxiv do not seem to work on the topics they tell about in the press or in popular talks.

Hept-th shows clearly that people working on string theory have given up both on unification and on comparison with experiments. Also impressive is the lack of string theorists working on the foundations or on the principles of string theory. As a group, string theorists have effectively given up determining the spectrum of elementary particles, given up deducing the forces of nature, and given up calculating fundamental constants.

I might be wrong, and I am open to be corrected; but since many years, hep-th does NOT provide good advertizing or encouragement for string theory as a theory of everything.

22. **adrian**
May 17, 2015

dear Klaus, dear readers,
I must have lots of free time, that I am responding to comments. I will try to stop, as the thing is addictive. First of all, I wish to thank Klaus and Peter for the non-agressive character of their comments. I would immediately retreat to the usual silence if people started being aggressive pointlessly. In this way of discussing, one can may be learn something from other people. Let me take some minutes of your attention to give my opinion or views on Klaus' comments.
I will copy Klaus' comment above and try to elaborate on my view on it.

Klaus

"The term multiverse appears in 151 abstracts in hep-th; many well-known physicists appear as authors, but this is indeed a small number."

Yes, the number is small. I think the topic is immature—needs many developments in the mathematics to occur. It is unclear if it will ever give something useful for Physics.
These reasons, I think, scare away most stringers. Some people, of course, decide to explore the landscape of string theory. Please, appreciate that this is an interesting geometrical problem.

Klaus

" string theorists in the arxiv do not seem to work on the topics they tell about in the press or in popular talks."

This, I believe is due to the fact that the topic one is presently woking on is not yet 'mature' in our minds. It is unclear what its implications are. It would be incorrect that I give a popular talk discussing my latest paper dealing with geometries dual to 2-d CFTs. The significance of the paper and the topic is still unclear in my broad picture of Physics. I cannot tell these things in a talk for people without mathematical instruction. This is for my technical seminars. Do we agree? I believe this is the main reason behind for this correct observation by Klaus.

Klaus

"Hept-th shows clearly that people working on string theory have given up both on unification and on comparison with experiments. Also impressive is the lack of string theorists working on the foundations or on the principles of string theory. As a group, string theorists have effectively given up determining the spectrum of elementary particles, given up deducing the forces of nature, and given up calculating fundamental constants.
"
Many comments to make. I believe that what is described above is nearly correct.
Some people will disagree and with reason, since they attempt to make contact with experiments [for example, those working on the quark gluon plasma, cosmology, some beyond the standard model]. But, may I suggest that this disconnection with the experiment is due to the fact that, may be, the string theory is not yet ready to calculate some of these things Klaus wants to calculate. You may suggest that it will never be. I do not know for sure, but you do not know that either. I just think—and this is clear to me–that the theory has the potential to calculate those things. But certainly is not at the level of technical development to do so. For example, it is unclear how to compute the precise values of certain constants in Nature. But you will surely agree that it is not an in-principle impossibility.

To be fair, some other things have been calculated, like spectra and correlators in different QFTs [not in the standard model] that can be checked as soon as the Lattice field theory progresses a bit on the technical side. I think, given the interest that practising physicists show on this, the topic should not be disregarded.

What Klaus is asking, would be like asking a stringer of the early 1990's to deal with the strong coupling regime in Yang-Mills field theory. It is 2015 and we can with good confidence say sure things about field theories that are related to YM after many [MANY] deformations of the theory. Still, we believe that the path covered is on the correct track. Since we saw similar deformations in Lattice field theory [there, it goes under the name of 'strong coupling expansion']. All these developments thanks to the remarkable proposal by Maldacena in 1997.

Sorry that I digressed. My point is that sometimes the theory is not ready to produce what the physicist want it to produce. Sometimes a theory cannot produce it. People who have studied the theory of strings, surely feel the remarkable beauty and power of the theory. This gives some confidence on the above projects. Of course, this is a feeling. Might be wrong. Another feeling, due to the amazing consistency of the theory is that, may be, it is actually a deep branch of mathematics that we are working on.

Finally, Klaus wrote:
"I might be wrong, and I am open to be corrected; but since many years, hep-th does NOT provide good advertizing or encouragement for string theory as a theory of everything.
"
You are correct, in my view. There are people who would disagree. People who seriously work on string phenomenology, either in Spain, Germany and many other places. Once again, let us make a distinction between what physicists say or want or wish and what the theory of strings actually gives. The arXiv is a good thermometer, what people work on is what the theory is actually giving. As you know this should be averaged over time. Apologies that I insist, but I am pretty sure that the theory of strings have taught physicists a LOT about the general structure of quantum field theory, illuminating aspects that were completely obscure in theories like QCD, the Electroweak theory, etc. So, in my opinion, it is worth to have an open mind. One may learn lot thanks to the theory of strings.

To close this comment. Some reader may want to investigate some of the claims in this post–those related to the useful role of string theory to learn about QFT. I suggest to read the different sets of lectures that Matthew Strassler gave in Trieste 2000, TASI 2001, TASI 2005. Of course, there are many more, I can write upon request, but these are good places where to start.

Thanks again for your patience, apologies for the unreadable post.

23. **Peter Woit**
May 17, 2015

Adrian and Klaus,
Thanks to both of you for the thoughtful comments.

My perception I think is consistent with both of yours. Theorists have mostly abandoned work on connecting string theory unification to experiment, as well as on the problem of really understanding "what string theory is" at a fundamental level. They've done this for the excellent reason that there are no good ideas around about these topics, so no way to make progress. Better then to do other things, which is what they are doing.

The problem I see though is that instead of acknowledging what doesn't work, many if not most string theorists just repeat the same failed ideology, and allow that to govern what research topics are pursued. The first part of the ideology is that there is some sort of single 11-dimensonal M-theory that will solve the problem of fundamentals and explain known facts about dualities. The second part of the ideology is that string theory explains unification but actually checking this is hopeless, because of the string landscape. Most string theorists don't give public promotional talks, but they do invoke this ideology if asked, and those that do give public talks heavily promote the two ideologies. The Amanda Peet lecture was a good example: it was a sales pitch, not a scientific talk, and when someone asked the obvious question about the product not working, she answered by making completely untrue claims for the product: "tested at the LHC!!".

The hep-th literature is depressing to look at these days, I think for the reason that theorists still insist on following the "hot topic", and the choice by leaders of the field of "hot topic" remains constrained by the requirement that it be consistent with the governing ideologies. Maybe some day this will lead to something new and some real progress, but I fear this will take a very long time.

24. **These Binary Trees**
May 17, 2015

Physics will always be philosophy's subservient niece-turned-mistress, messily slurring her strange words like Edison's talking dolls.

" … at comic convention. "

At least at an appropriate place.

26. **adrian**
May 20, 2015

Dear Peter,
I would like to comment on something you wrote a couple of days ago, in the comments o your post. You wrote:

"The hep-th literature is depressing to look at these days, I think for the reason that theorists still insist on following the "hot topic", and the choice by leaders of the field of "hot topic" remains constrained by the requirement that it be consistent with the governing ideologies. Maybe some day this will lead to something new and some real progress, but I fear this will take a very long time
"
My comment is the following; it is easy from the outside to criticize. Just like the person who watches football criticizes the ones in the field, sometimes with acidity, many times in very unfair ways.
I think that your comment goes on a similar line. I would add, if you believe it is so depressive, may be you should start publishing papers, not following the hot topics, with good ideas that young people will follow and things will improve over all.

Both of us know that it is not easy. We both know that people do the very best they can. In the case of the string theorist—that I know close enough, they belong to the most 'pure' scientist you can find. They do not cheat, they act honestly, they calculate and write doing their very best effort. We all know that this is not necessarily the case in all other areas of knowledge.
So, to finish, I believe that comments like the one above are quite unhappy and unfair.
Do not take this as a personal attack. It is not. I do know that what you wrote is not a personal attack to any stringer in particular. But I believe that comments in this tone create on lay-people the impression of a dishonest community. The stringers might be misguided [I do not think it is the case, but that an opinion], but certainly, they are not lazy or dishonest or anything like that. Quite the opposite I would say.
thanks

27. **Peter Woit**
May 20, 2015

Adrian,

I wasn't accusing string theorists of being lazy and dishonest, in any case I would never generalize about qualities of groups of people, that's not something I do. About dishonesty, I'm afraid I have to say that over the years I have definitely run into some dishonest string theorists, although they're a small minority of the field.

The criticism of the faddishness of particle theory was meant seriously, but it's a sociological rather than personal criticism. I've written about it extensively, on the blog and in my book, and I think it's a problem that many people are aware of and would agree with me about. Faddishness is an aspect of any human endeavor, but I've had enough experience in two different but related academic fields (math and physics) to see that the problem is a lot more serious in particle theory, as well as to see from the situation in mathematics that it doesn't have to be that way.

I completely understand the appeal of working on topics where there is a lot of activity going on, and that there are a wide range of reasons to do this, some good, some less so. I just think it really is a fact that the range of topics discussed on hep-th at any time is relatively narrow, something quite understandable when major progress is in the works, something discouraging to watch when it isn't.

Personally, most of my recent effort has gone into the book I've been writing, which is almost done. One aspect of writing the book is that it has made even more clear to me where there are some basic questions that are not well understood. I have a list of ideas about such things to work on once I finish the book, hopefully some day one or more of those will bear fruit and I'll write about it. But even if they don't, that doesn't change the actual nature of the current state of hep-th, which I think can only be honestly described as discouraging.

Lurie and Categorifying the Fourier Transform

May 18, 2015
Categories: Langlands

Before I turn to the main topic of this posting, a lecture by Jacob Lurie, I'd like to point to something else involving him, a comment and posting at Mathematics Without Apologies, a blog you should be following anyway. On the topic of the usefulness of "proof assistants", I liked Lurie's point that a major problem with this is:

> Working in a formal system, more or less by definition, means that you can't ignore steps which are routine and focus attention on the ones that contain the fundamental ideas.

But if you want to discuss this, it should be over there, the topic of this posting is something very different.

Last week I noticed that Lurie had given a talk at Harvard on "Categorifying Fourier Theory", which is available here. I enjoyed watching it, ending up quite intrigued by the abstract picture he was painting, but rather discouraged by the lack of any example that would give insight into what it might be useful for. Neglecting to mention the example that explains why an abstract theorem is useful is unfortunately all-too-common practice among mathematicians. Perhaps in this case with Dick Gross, Jean-Pierre Serre and John Tate in the front row, he felt it unnecessary. Luckily though, he gave the same talk recently in Arizona, and there (in the question session) did give a fascinating motivating example.

His starting point was the Fourier transform, which one can generalize to any abelian group G, and think of as identifying complex functions on G with complex functions on the dual (or character) group G^. The standard Fourier transform is the case G=G^=**R**, Fourier series are the case G=U(1), G^=**Z**. He then went on to discuss two levels of abstraction, or categorification of this. The first identifies a representation of G on a vector space V with a function from G^ to vector spaces (the isotypic decomposition of the representation). The second identifies representations of G on categories with representations of G^ on categories.

It was this equivalence of representations on categories that was his main result, for which in Arizona he gave the example of G the group of invertible Laurent series. The idea is that this group can be identified with its dual group G^ (in some sense as algebraic groups), using the Weil symbol (for a definition and context, see here). Lurie's claim that was new to me was that the equivalence in this case is essentially the GL(1) version of the general local geometric Langlands conjecture, which is supposed to be an equivalence of two representations on categories, for more general (non-abelian) groups G.

At least for me, understanding of some sophisticated mathematical phenomenon really starts when I understand the simplest example of the phenomenon. For the number field case of Langlands theory, my initial efforts to understand the subject didn't lead anywhere until I realized that maybe it was best to first think about the local version, which was a statement about representation theory that I could make some sense of. I was hopeful that thinking about the simplest case of that, the abelian case, would give great insight, found though that the Abelian case is already quite non-trivial (local class field theory). For the geometric Langlands case, I found that the discussion of the local version in Edward Frenkel's book was very helpful, but I always wondered about the abelian case. Now I'm hopeful that the abelian story is something that although I've never seen it, is well-understood, and that a helpful reader will point me to a reference.

Another reason for being interested in this particular topic is that it has some connection to the relationship between Langlands theory and QFT that first got me interested in all of this. Back in 1987 Witten wrote some fascinating papers giving an abstract formulation of free fermion theories on Riemann surfaces (see here and here) with tantalizing connections to what later became geometric Langlands. In this work the group of invertible Laurent series and the Weil symbol play a central role. There was also later work by Takhtajan on this, see here and here. I wonder why the most recent version of the last reference deletes the material on the multiplicative group case, which is the one Lurie mentions.

Comments

1. **Marty Weissman**
   May 19, 2015

   The abelian case of geometric Langlands is geometric class field theory. Serre's text on algebraic groups and class fields is the standard reference. But there are many expositions! See http://mathoverflow.net/questions/73054/a-reference-for-geometric-class-field-theory for links.

2. **Peter Woit**
   May 19, 2015

   Thanks Marty,
   What I'm curious about is something that should be much simpler, the local case, and just for the group GL(1,C). Lurie's argument seems to indicate that this case follows from his very general, very simple construction. Also, he's claiming an equivalence of group actions on categories, and I'd like to know more about what that means here (as opposed to just a usual Langlands correspondence of representations).

3. **Justin**
   May 19, 2015

   Peter,

   I've never understood what this langlands QFT connection is supposed to have anything to do with new physics. Is this purely a mathematical interest, or is there potential for a new stimulating insight into fundamental physics?

4. **Peter Woit**
   May 19, 2015

   Justin,
   Personally I believe the connections between qft and the representation theory point of view on number theory (e.g. Langlands theory) indicate a deep unity that if better understood may lead to new insights in fundamental physics, for more, see
   ww.math.columbia.edu/~woit/mathphys.pdf

   But that's a far off goal, and the question I'm asking here is a purely mathematical one, I was just pointing out the tantalizing connection to QFT.

5. **David Ben-Zvi**
   May 19, 2015

   Thanks for the links Peter! I haven't yet watched the videos, which sound great, but here's some perspective on the story. First of all the local geometric Langlands conjecture is (roughly speaking) an equivalence of two-categories, one associated to G and one associated to the dual group G^. This is completely natural from the physics — a four-dimensional topological field theory (such as twisted N=4 super Yang Mills) should attach a 2-category to a closed 1-manifold, in this case the circle, so that an equivalence of field theories (S-duality) gives an equivalence of 2-categories. Roughly speaking, following Frenkel-Gaitsgory, one side is the 2-category of categorical representations of the loop group, and the other is the 2-category of sheaves of categories over the stack of Langlands parameters — very roughly, modules over the tensor category of quasicoherent sheaves on the space of Langlands paramters. In the abelian case, geometric Langlands is captured by Cartier duality (algebraic Pontrjagin duality, i.e. Fourier transform) — this goes back at least to Laumon's work on Fourier transforms and that of Rothstein. There they work in the global setting, using the self-duality of the Jacobian, but this has a well-known local origin, the Contou-Carrere Cartier self-duality of invertible Laurent series (or of its quotient by invertible Taylor series, i.e., the abelian affine Grassmannian). This is what Jacob is generalizing I believe, though I need to find out what the precise statement is. Sadly as with most things in this subject it's hard to find introductory references.

6. **David Ben-Zvi**
   May 19, 2015

   In any case let's work out the GL_1 case in the simpler Betti form (the Betti Geometric Langlands conjecture is a new modified form of the usual de Rham one which, unlike its predecessor, really is a TFT, an algebraic model of Kapustin-Witten's – to appear). On both sides we're not dealing with any old two-categories, but with monoidal categories (the 2-categories being the collection of their module categories). On the automorphic side this is the "categorical group algebra" of the group K^* of Laurent series — i.e. the monoidal category built so that its module categories are simply categories with an action of the group. This means (in the Betti version) local systems on K^* with convolution (in the de Rham case this is replaced with D-modules). But K^* splits as a product of two contractible pieces (the infinite dimensional vector space of monic Taylor series and its dual, the formal group of K/O) which don't affect the category, and then Z (counting degree of leading term) and C^* (the coefficient of the leading term). So we need to describe local systems on Z x C^*, with convolution. Sheaves on Z are the same as representations of the dual multiplicative group C^*, ie quasicoherent sheaves on pt/C^*. The Mellin transform (multiplicative Fourier transform) identifies local systems on C^* (ie reps of pi_1 = Z) with quasicoherent sheaves on the dual torus C^* (labeling monodromies). So we have an equivalence of monoidal categories betweek Loc(K^*) with convolution and QCoh(C^* x pt/C^*) with tensor product, hence of their 2-categories of module categories. Now note the latter is C^*/C^*= C^* local systems on the punctured disc — i.e., the space of Langlands parameters (it's fun to work this out for general tori to not get confused between the group and its dual). This is the (Betti) local geometric class field theory (the de Rham version involves the stack of rank one connections on the punctured disc, which is more painful).

7. **David Ben-Zvi**
   May 19, 2015

   As an illustration of Betti vs de Rham by the way it's useful to look at how we can think of sheaves on C^*. In the Betti version, local systems=reps of pi_1=modules for group algebra of pi_1=quasicoherent sheaves on the dual C^*. In the de Rham case, D-modules on C^*= modules for C[z,z^-1] adjoined z d/dz = (by Mellin transform) modules for C[s] (s corresponding to z d/dz) adjoined t, t^-1 (corresponding to z) which acts on s as shift by integers. In other words we have difference modules on the dual C, which are the same as Z-equivariant quasicoherent sheaves on C. ANALYTICALLY these would be the same as sheaves on the quotient C/Z= C^*, but algebraically the two categories are very different. However, they both contain the same "basic objects of interest", the "eigensheaves" (rank one local systems with various monodromies) and things finitely constructed out of them (finite rank local systems=flat connections). Thus the two theories are different ways to "integrate" the same basic objects. The claim is the kind of objects seen by Kapustin-Witten are closer to the former than the latter.

8. **Peter Woit**
   May 20, 2015

   Thanks David!

   That's very helpful. It would be great if someone would write this sort of thing up in detail. I'm still quite curious how one might understand the picture you're explaining in terms of Lurie's "categorification" of Pontryagin duality.

9. **John Baez**
   May 20, 2015

   Peter wrote: " I'm still quite curious how one might understand the picture you're explaining in terms of Lurie's "categorification" of Pontryagin duality."

   I can't tell what level of understanding you're at and what you're wondering about, so I'll assume this remark means Ben-Zvi's story is not screaming out *categorification* to you, as it is to me.

   The point is that sheaves are like functions, but functions on a space form a set, while sheaves form a category. It's good to draw up a big "analogy chart" with two columns, at left listing things you can do with the set of complex-valued functions on a space (or abelian group), at right the corresponding things you can do with the category of sheaves over that space. Most fundamentally, you can add and multiply functions on a space, and you can convolve functions on a group. All these operations have analogues for sheaves! Think about the analogue of the "group algebra" over in the right column. The fun starts when you get to the Fourier transform.

10. **Peter Woit**
    May 20, 2015

    John,
    Thanks for the further comments elucidating Ben-Zvi. I do see the general "categorification" going on here, I'm afraid I wasn't very clear about what I still don't see. It's really about this specific example, how the identification given by the Weil pairing and the general story about group actions on categories told by Lurie ends up giving the equivalence between the things David describes. I suppose I just need to think carefully about the hints he provides…

Various News

May 19, 2015
Categories: Uncategorized

- First test collisions at 6.5 TeV/beam at the LHC are tentatively scheduled for Thursday morning.
- At CERN today there's a workshop about the Higgs Machine Learning Challenge.
- Also on the topic of LHC data analysis news, Tommaso Dorigo announces the award of a grant for the AMVA4NewPhysics project.
- Sabine Hossenfelder has a review, slideshow and discussion of the Dawid book on "String theory and the scientific method" (which I wrote about here and here). Much of the discussion is about the "No Alternatives" argument, but at this point I don't even see how it applies here. The Landscape shows that string theory unification is a failed program, which rules it out. As for whether "gravitation is due to the spin two massless mode of a superstring" is the only alternative, these days my impression is that many prominent theorists are pursuing alternatives, that gravity is supposed to be an "emergent" phenomenon coming from something else.
- For those sticking to the 1984 point of view though, there's a workshop on some interesting mathematics that's part of that story (super geometry, super moduli spaces) going on at the Simons Center.
- Last week on Jeopardy (see here), no one got this question:

  > Nima Arkani-Hamed is using this number dimension, the next one beyond time, to rock the physics world.

  I wouldn't have either…

- For a bit of mathematics history, you might want to read Beilinson on Gelfand's seminar.
- Natalie Wolchover at Quanta keeps on coming up with interesting physics stories not seen anywhere else, last week covering news about ultra-high energy cosmic rays.

Update: Successful test with first collisions at 13 TeV this morning at the LHC, see here.

   May 19, 2015

   Thanks for the link. I found the no alternatives argument to be the least convincing one. Anyway, I think it's good some philosopher is trying to make sense of this mess 🙂

2. **Egon**
   May 19, 2015

   It seems that the Jeopardy answer must be referring to the following paper:
   http://arxiv.org/abs/hep-th/0104005

   The paper is from 2001, though, so it's hard to see how it could still be 'rocking the physics world.'

3. **Chillin**
   May 19, 2015

   I'm staying with the 1984 viewpoint.

4. **Tommaso Dorigo**
   May 20, 2015

   Hello Peter,

   thank you for highlighting my grant. I literally spent four months of my life on writing it, but the chances of success with this kind of EU projects are very small, so I must have been lucky anyway.

   Since no good deed goes unpunished, I will ask you the courtesy to advertise the PhD positions we will open, in a few months 😉

   Cheers,
   T.

5. **PAC**
   May 20, 2015

   Goodness, the Soviet Union as portrayed by Beilinson sounds like sheer heaven, from today's perspective. No soulless consumerism, no politics-as-spectacle, no globalized noise. And respect for the austere beauty of mathematics and art.

   Very far from a complete picture obviously, but a much-needed one.

6. **AHS**
   May 21, 2015

   Thanks for Beilinson's little write-up. Some very nice insight. Cheers

Egon,

As opposed to thinking about what was "'*rocking*' the physics world" back in 2001, the Jeopardy production staff was instead hoping that you would be drawn to thinking about what was "'*rocking*' the music world" back in 1966 to 1975; that is, to associate the word '*rock*' (or, more precisely, the phrase '*rock and roll*'), with the word '*dimension*' so as to bring you to thinking about the R&B/Pop/Soul vocal group "The 5th Dimension". I know you're given perhaps all of three seconds to try to put this all together, but it's a perfect example of the wacky way that Jeopardy likes to bury clues within 'the answer' so as to guide you to the correct 'question' response on their game show.

-Nick

May 21, 2015

> so as to bring you to thinking about the R&B/Pop/Soul vocal group "The 5th Dimension"

Yah, I figured that out, but it seems very oddly placed as the only third question in as bland a category as "physical science." True obscurantism in this vein would have realized that The 5th Dimension made a lot of bread by covering Laura Nyro songs, including two from *Eli and the* ***Thirteenth*** *Confession*.

Thanks N. Interesting is perhaps an understatement.

12. **Robert Barton**
May 27, 2015

Jeopardy is pretty straight forward, and its questions are written to be answered by non-specialists. Time is the fourth dimension(common knowledge). So one more. It's meant to be that simple. You don't have to know who Arkani is and 99.9% of people don't. His name is a kind of red herring. They could have substituted a whole bunch of names for his. Jeopardy does not reference physics papers. The music group idea is probably correct because they use "rocked" which seems a weird verb choice otherwise. So if you got it by the music group that's impressive lateral thinking but it would only serve to reinforce the easy answer.

John Nash 1928-2015

May 24, 2015
Categories: Obituaries

I was sorry to hear this morning that John Nash and his wife Alicia died yesterday in a car crash (news story here). They were in a taxi on the New Jersey Turnpike, heading home from the airport after a trip to Norway where Nash was awarded the Abel Prize.

Nash's mathematical career was cut short by the onset of mental illness, which he then struggled with for many years. Sylvia Nasar's A Beautiful Mind is a wonderful biography, doing a great job of accurately portraying Nash's life, including the role of the mathematics community in its various parts. The movie version is another story, especially in the way it shows Nash's mathematical achievements as somehow being due to his delusions, when what really happened is that the onset of delusional thinking is what made it no longer possible for him to continue doing research at the highest level.

During the years I was a graduate student in Princeton, Nash was often to be seen, especially in the mathematics/physics library, and I talked to him a few times. The first time was when he stopped me one day, told me he had seen my name on the physics department picture board, and was curious about the origin of my last name. While I had heard stories about Nash, that he was mentally ill, spent his time writing delusional things on the hallway blackboards, he seemed fine to me. This was a period (early 1980s) when he had stopped writing on the blackboards and was successfully dealing with the illness. I was very glad to see how later on he was able to lead a more normal life and enjoy the recognition he deserved.

Update: The New York Times has an excellent long obituary of Nash this morning, presumably mostly prepared before his death.

   May 24, 2015

   This tragedy reminds me that we are all human, even though we all tend to lose touch with reality and forget what it means.

2. **Neil**
   May 24, 2015

   Are we sure that his blackboard scribblings were delusional? I mean his real ones, not the ones in the movie. Did anyone write them down?

3. **Peter Woit**
   May 24, 2015

   Neil,
   The blackboard writings were mostly before my time (I got there in 1979). I'm sure people read them and tried to make sense of them, never heard of anyone saying that they had been insightful as opposed to delusional. Nash himself may be the best source about this, I recall reading somewhere comments from him about what was going on in his mind during those years and what he thought about it from his later, non-delusional point of view.
   There's no question though that he was ill during this period, and the effects of this disease in terms of delusional thinking are well-known.

4. **Dan**
   May 24, 2015

   Sad to hear about their passing. On a happier tangent, regarding the NYT obituaries, here is an interesting article where one of their writing staff explains the somewhat weird process by which they write "advance" obits, including interviewing the "pre-dead" subjects…

5. **David Derbes**
   May 25, 2015

   Nash and obituaries.
   I was an undergraduate 1970-74 at Princeton and knew Nash a very little, again mostly from extremely brief interactions with him at Fine-Jadwin (the math and physics buildings are connected, and the library is on the ground floor/basement with holdings for both.) Back then one could smoke in the building, and I would occasionally bum a light or a smoke from him (never the other way.) The writings on the blackboard were typically done overnight and usually involved very large numbers raised to very large exponents. I wish I'd taken pictures of them. I had a few courses at 8:00 and was greeted by new results frequently. Now and then in the middle of the night my lab partner Mark Johnston and I would see him at the Computer Center (it was the only time we could get on; Mark wrote the Fortran code to analyze our lab data.) My friend Danny Rohrlich, now at the Technion I think, the nephew of Fritz Rohrlich and himself now a physicist, double majored in physics and psychology. He had, I think, pretty normal conversations with Nash when nobody else could. I had two very brief and memorable interactions with Nash after graduation. I went to my 10th reunion in 1984, and leaving Monday morning to go visit a friend in New York, got off the dinky to wait for the train, suddenly realized that I didn't know when the next train was. I went into the station to look for a schedule, and saw a man with his back to me. I walked up to him and said, Pardon me, do you know when the next train to New York is? He turned around; it was Nash! "No," he said. Four years later I was on a NSF sponsored teacher summer school at Princeton, when walking up the stairs towards Blair Arch, there was Nash! I said, "Hello, Prof. Nash." He turned and smiled. "Hello," he said. He was clearly much, much better. I said, truthfully, "I used to see you around Fine when I was an undergraduate. You look great!" And he said, "I'm feeling good." It was really wonderful. Something happened between 1984 and 1988. I don't know what, but the difference was night and day. Nash always liked libraries (Fine-Jadwin, and the main library, Firestone in particular) and trains. My classmates referred to him as the Ghost or the Library Crazy Man. He always wore red Keds.

   Obituaries: Every big newspaper keeps a large file cabinet (or probably now, its electronic equivalent) called the morgue. Newsworthy people get a file and interesting articles and other snippets go into the morgue, to be pulled out when the time comes to write their obituary. That's why they could put Nash's obit together rapidly. Feynman's NYT obit is really good, and appeared the next day. (I learned about this from a friend whose family owned the New Orleans newspaper. His father offered me the use of the morgue to do some high school research into a politician running for governor. Pre-internet.)

6. **Matt Grayson**
   May 25, 2015

   In 1979, on a Fine Hall blackboard, I saw a list of towns and a claim that 2^(zip code)-1 was prime… He was a ghost then – Russell Crowe perfectly captured the distant look in his eyes. I visited Princeton in 1987, and it was wonderful to see Nash's improvement.

   I'd forgotten the Keds!

7. **David Derbes**
May 25, 2015

I forgot to mention that Nash's late night notes were often in the form of a letter, typically from Moses to Brezhnev, or other unlikely world leaders. I think Kruschev also figured in the correspondence, as did famous mathematicians, many of whom I had not then heard of.

May 25, 2015

Ave atque vale.

9. **Jeff M**
May 26, 2015

My Nash story, told to me by one of my professors in grad school. He was an undergrad at MIT when Nash was there, Paul Cohen was there at the same time. They would get into pissing contests in the math lounge, each trying to prove he was smarter than the other. So my prof Al would hang around since they would start discussing something and scribbling away on blackboards and Al said he learned a lot watching them. In any case Nash knew Al to say hi to, and one day he comes up to him and hands him an offprint of one of his papers. Al takes it, says thank you, and then opens it up. On the inside of the cover was a very elaborately drawn and calligraphed "interstellar drivers license" valid everywhere in the galaxy, made out to Al Vasquez, and marked as being "valid in perpetuity." Al was kind of confused, this was before Nash had his public break. Later, when Nash was hospitalized, he contacted Al through one of the MIT profs to let him know that despite the fact that the license he gave him was good forever, Nash was going to have to revoke it. Needless to say Al still has the license.

10. **Cormac O'Raifeartaigh**
May 26, 2015

My Dad met him a few times at IAS and always said that "he didn't seem any stranger than anyone else there"!

11. **Nathalie**
May 26, 2015

What kind of Nobel Prize did Nash get?

There is no Nobel Prize in mathematics and the one in economy is the The State Bank of Sweden Prize created 3/4 of century after Nobel had passed away.

12. **Casey Leedom**
May 26, 2015

Nathalie, "… he shared the 1994 Nobel Memorial Prize in Economic Sciences with game theorists Reinhard Selten and John Harsanyi."

http://en.wikipedia.org/wiki/John_Forbes_Nash,_Jr.

13. **Peter Woit**
May 27, 2015

Casey Leedom,
Nathalie is just referring to, as Wikipedia notes, the fact that the prize Nash got is technically the "Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel, commonly (and misleadingly) referred to as the Nobel Prize in Economics". The Abel prize is also not a Nobel prize, although set up to be in some ways equivalent. At the time Nash got the Abel, I commented here
http://www.math.columbia.edu/~woit/wordpress/?p=7613
that "This surely makes him the first person to win not-quite-Nobels in two completely different fields.", but that was challenged here
http://www.math.columbia.edu/~woit/wordpress/?p=7613&cpage=1#comment-217775

14. **Kieron**
May 27, 2015

[Something I shared with my friends when I heard, on Facebook. – kieron]
A profound loss, but also a source of some hope….
— — — — — — — —
John Nash was a great mathematician. He, tragically, was involved in a traffic accident in a taxi on his way back from the airport, with his wife Alicia, after receiving the (Norwegian) Abel Prize for his work on non-linear differential equations and geometric analysis (with Louis Nirenberg). Both John & Alicia were killed, on Saturday, and one might hope they are together now.
Although he is best known for the "Nash equilibrium" (eventually sharing the Nobel prize in Economics as a result) which extends game theory to non-zero-sum contexts and paved the way to real-world economic use, he did mathematically more profound work later, in different fields — after, thankfully, returning to sanity. That range and depth is rare in modern mathematics, which has been increasingly specialized. (I can only think of Terry Tao as someone as wide ranging and recognised, in modern maths.) He was a prodigious talent and, despite Hollywood, his illness was clearly a handicap, not a help or inspiration.
The story of his return from illness, and rebuilding his professional and personal life is touching and heartwarming too. A story that gives us all hope that our troubles will pass and that a bright future exists and is attainable and that help, companionship and support are so important — an indispensable part of humanity.
I met him once, at a colloquium at Princeton in the very early '90's when I was doing work on X Windows at MIT. He seemed sane enough then, and I barely understood the differential geometry he was talking about. 🙂
Check out this rather good obituary at the NYT:
http://www.nytimes.com/…/john-nash-a-beautiful-mind-subject…
Truly A Beautiful Mind. RIP.
– kieron

15. **S. Molnar**
May 27, 2015

I'm not sure what to make of this, but since both Nash and NSA are recurring subjects here, it might be of interest: http://econospeak.blogspot.com/2015/05/john-nash-as-cryptanalyst.html. The blogger is the son of a well-known logician. Speaking of logicians, the Guardian obituary, which is a disappointment, claims Nash was being funny when he said that among mathematicians it is only the logicians who tend not to be sane; the obituarist apparently does not realize that this is a commonplace view.

Not quite OT, since you mentioned it, do we get the Woit name etymology? I have no idea whether you came by it from a long lineage of Woits or whether it's a corruption of an entirely different (Polish?) name.

16. **Peter Woit**
May 27, 2015

S. Molnar,
The name is Latvian (my father was born in Riga), in Latvian, Voits was the family name, spelling changed when they moved to Germany, to agree with German pronunciation.

17. **A. Seibert**
May 28, 2015

I haven't seen the movie recently, but I don't think it attributes Nash's mathematical achievements to his delusions. Granted, it inaccurately shows him as delusional during his mathematical peak, and it links his brilliance and his madness by using the same flashing-numbers special effect for each. But unless I've forgotten scenes where Ed Harris and the other apparitions whisper successful proof strategies in Nash's ear, this merely suggests that both Nash's brilliance and his delusions may stem from his mind's rare openness to unusual ideas and appetite for patterns–which was basically the view expressed by post-recovery Nash and by Nasar's book. That's quite distinct from saying the delusions caused the mathematics. The only mathematics I recall the movie attributing to the delusions was fictitious "code breaking" stuffed into abandoned mailboxes.

His story taught me a lot, there is no words could describe how his Bio influenced lots of people.
At the end nothing could be said except, good bye legend, good bye ghost of Fine Hall.

REST IN PEACE BEAUTIFUL MIND!!!

This Week’s Hype

May 27, 2015
Categories: This Week's Hype

I’m busy with other things, so no possible way I can keep up with the claims about string theory flooding the media for some reason these days. It’s hard enough to find the time to read all of this, much less write something thoughtful about it… One obvious point to make though is that none of it acknowledges the obvious: the widely promoted idea that we can get a unified theory and explain the Standard Model by using a theory of strings has turned out to be an empty one. The result of tens of thousands of papers and more than 30 years of work is that all the evidence is that if you can get something this way that looks at all like the Standard Model, you can get anything. Normally when that happens you simply acknowledge the problem and give up, but for some reason that hasn’t happened. Instead of a description of this straightforward situation, the public gets the following:

- Frank Close describes the situation as

  > In recent years, however, many physicists have developed theories of great mathematical elegance, but which are beyond the reach of empirical falsification, even in principle. The uncomfortable question that arises is whether they can still be regarded as science. Some scientists are proposing that the definition of what is “scientific” be loosened, while others fear that to do so could open the door for pseudo-scientists or charlatans to mislead the public and claim equal space for their views…
  >
  > Is physics moving towards an era in which elegance will suffice and into the domain of theories that are beyond the reach of experimental proof? Or will empirical evidence remain the arbiter of science?

  Close correctly identifies the problematic nature of multiverse pseudo-science, but misses the basic facts about the string theory landscape. This is not a theory of “great mathematical elegance”, quite the opposite, and there is no such thing developed “in recent years”. If you go back 30 years, there were then claims of “elegant” string theory models, but those never worked out. KKLT is the opposite of “elegant”.

- Clifford Johnson takes the Close piece as a starting point to explain his own view. He lacks interest in string unification, thinks that string theory should be thought of as a “method” for solving problems. He doesn’t really explain though why it is a “method” that deserves so much more attention than any number of other methods used in physics. He also doesn’t acknowledge that, besides the huge amount of TOE hype (which he and other string theorists often appear on TV to promote), the hype problem for the string theory “method” may be just as bad. For example, he was quite proud of his efforts to promote string theory as the method to understand heavy-ion physics (see here and here), but that’s something that really hasn’t worked out very well.
- Over at Starts With a Bang, by Sabine Hossenfelder, there’s Will the LHC be able to test String Theory: Definitely maybe. The article actually does a very good job of explaining why the answer is “no”, so I have no idea why the misleading headline. The fact that the AdS/CFT heavy ion predictions haven’t worked out is explained, with the comment that

  > The LHC, thus, has already tested string theory!

  and that this failed, which might be a more accurate headline.

- There’s a long interview with Sean Carroll at the Edge website. He’s quite defensive about the multiverse, claims it’s a prediction of our best theories, and gives his usual characterization of multiverse critics as zealots unable to understand the idea of an indirect test

  > But certain zealous colleagues of mine are saying that because you can’t see the other universes in the multiverse or because you can’t see the little super strings moving around, these theories are not falsifiable and, therefore, should not count as science.

  He’s also defensive about string theory, there the argument is

  > Either we will bring it down to earth and connect it to the world we see or people will lose interest. People cannot maintain this optimistic idea that we’re going to get the right theory of quantum gravity, the theory of everything, if it’s literally decades and decades of people writing down equations and never predicting the experimental outcome of anything. But we’re not there yet. It would be a terrible shame if we gave up on string theory when maybe next year someone will figure out how to bring it in connection to observations, or maybe ten years from now it will happen. This is how science works, and this is it at work.

  The problem here is that it is “literally decades and decades of people writing down equations and never predicting the experimental outcome of anything”, and no matter how many decades of this go on, someone can always argue that “maybe next year”. He’s avoiding the very real issue at the center of things: why hasn’t string theory been held to account for its failures the way any normal speculative scientific idea is supposed to?
  As far as his current interests go, from what he says, he seems to be losing interest in the multiverse, which soon may no longer be a hot topic, and moving into research into complexity and consciousness.

   May 27, 2015

   Dr. Woit – Thank you for continuing to write such interesting, informative articles. Always look forward to the latest showing up in my Twitter feed.

2. **John McVirgo**
   May 27, 2015

   Peter,

   surely you need to be following more closely what top young post docs have to say about String Theory, rather than focusing on the opinions of theoretical physicists much older and possibly ignorant in comparison?

   For example, this is what David Simmons-Duffin has to say:
   http://www.quora.com/Is-it-true-that-many-physicists-are-abandoning-String-Theory

   “Here’s my personal favorite at the moment (Warning: technical jargon — feel free to skip this paragraph). Physicists have recently been able to compute operator dimensions and scattering amplitudes in planar N=4 Super Yang Mills theory nonperturbatively at all values of the ‘t Hooft coupling. These quantities interpolate between 5-loop Feynman diagram calculations at weak coupling (note, these are calculations in QFT, a theory no physicist — even Woit or Smolin — disputes the correctness of) and 10-dimensional supergravity calculations at strong coupling, with full String Theory calculations in between. This is spectacular evidence that N=4 SYM (a close cousin of the theory of quarks) is both a Quantum Field Theory and a String Theory (as conjectured by Maldacena), in a way that can be made quantitatively precise.

I don't know what high energy theorist isn't impressed with 5-loop Feynman diagrams. And if you're impressed with that, you'd better be impressed with all-loop results that agree with 5-loops when Taylor expanded to 5th order.

That kind of result is so impressive that I am convinced without a shadow of a doubt about the merit of studying String Theory. It also shows why String Theory is an inevitable and inextricable part of physics. Gauge theory is real and correct: it describes electrons and photons and W-bosons and quarks and has been verified innumerable times by a variety of experiments. The above evidence shows that some gauge theories literally are String Theories. Given that many scientists would like to understand gauge theory better, it would be totally crazy to abandon String Theory!"

May 27, 2015

and moving into research into complexity and consciousness

This does not bode well as there lies a fertile savannah where the tenure buffaloos of crackpottery congregate, free of the restraints of realistic physics and the theory of computation. At night, the ghostly moonlight of fantasist attributes ascribed to the human mind illuminates their ruminations of ethereal qualia.

4. **vmarko**
May 27, 2015

John McVirgo,

Young post-docs are not a very good opinion gauge, since they are typically still bedazzled by the theories they study (I'm also struggling with that, so…). The first signal of becoming a mature scientist is when one recognizes all the *problems* that the theory has, and starts paying attention to those rather than saying "Oh wow, this can be evaluated to five loops! Wow!".

The serious scientist focuses on what is wrong with their own pet theory, and emphasizes that in public and among peers, so that others may also attack the problems. Putting one's head in the sand doesn't make the problems go away, but only adds to confusion. Senior scientists are aware of these problems (at least they should be), while junior scientists somewhat lack the experience to recognize them as such. Btw, that is why mentoring is so important in academia.

As for the concrete example you quoted, the "planar N=4 Super Yang Mills theory" has a very big symmetry, and nobody should be surprised that something like that can be integrated in some cases. But this is very very far from, say, Standard Model, or any other realistic theory, where a large portion of that symmetry is broken. Saying that it is a "a close cousin of the theory of quarks" is just naive. I often compare such statements to a man who wants to go to the Moon, and who after climbing a tree says "I've made a first step". It's just a lack of perspective.

HTH, 🙂
Marko

5. **Jeff M**
May 27, 2015

Ha, I will refrain from listing all the reasons I think consciousness research is a dead end 🙂 As for "let's study string theory since some gauge theories are string theories" I will point out that generalization is not always a good thing. Also, the fact that you can compute something does not make it interesting, or useful. If only – one of the joys of being a mathematician is working on some problem, realizing you can compute something related to what you want, and at the same time realizing it won't do you a lick of good…

6. **Bee**
May 28, 2015

Peter,

Ethan, who edits the collection, asked me to write a piece on the question. (He also picked the title and changed a few paragraphs here and there.) My first impuls was to say, well, the answer is obviously no. On second thought, I managed to write "no" in 1600 words 😉 To be fair, I find the AdS/CFT approach to strongly coupled matter very interesting, though the applications to strange metals seem better motivated. Besides, I'm trying to remain open-minded. As the saying goes, predictions are difficult, esp about the future. (And I've been told it's wrongly attributed to Niels Bohr, so I won't.)

7. **Peter Woit**
May 28, 2015

Thanks Bee,

I should have made clearer that I think it was a very well-done article, except maybe for the title….

8. **Peter Woit**
May 28, 2015

John McVirgo,
I did write something at that Quora question. Best if people who want to discuss that do it there, although I fear participating in discussions at sites like that is not something I have the time for.

9. **Koray**
May 28, 2015

I think Mr. Carroll's problem is more with Mr. Occam than with Mr. Popper. If I come up with a scientific model that fits the existing data, but inevitably also suggests that there are unicorns that I can never see, should I take the unicorns seriously, or should I doubt that perhaps there's an equally good, yet to be found model that doesn't suggest unicorns?

Unless logicians demonstrate that this is the only mathematical model we can ever find, I'm not comfortable with taking unicorns seriously. Even then, my next move would be to question the foundations of math or its use in physics itself.

10. **Hilbert**

May 28, 2015

I think if there's a theory that fits the data, then successfully predicts the observation of something new, AND also contains a mechanism within itself that generates unicorns that can never been seen, but the mechanism follows from the mathematics and from the principles of the theory, THEN we should take those unobservable unicorns seriously.

11. **Peter Woit**
May 28, 2015

Koray/Hilbert,
I think that what Carroll is doing is trying to shift the argument from actual theories we know about (where the unicorns are a dubious feature) to some hypothetical unknown theory (where the unicorns are a sure thing). At least this zealot isn't very interested in such hypotheticals, happy to admit there's logically some unicorn theory out there which I'd sign on to.
This is a standard move in string theory defenses, to try and discuss some completely successful unknown string theory that string theorists wish existed, not the one that actually does.

12. **Nobody**
May 29, 2015

From Frank Close quotation:
"Some scientists are proposing that the definition of what is "scientific" be loosened… towards an era in which elegance will suffice and into the domain of theories that are beyond the reach of experimental proof? "

Reminds me of the talk about new methods of valuating corporations at the top of a market boom, like the dot.com boom, when "elegant" corporations that had never made a cent were sky high. Could this mean the career ending bust is near?

From Sean Carroll quotation:
"It would be a terrible shame if we gave up on string theory when maybe next year someone will figure out how to bring it in connection to observations, or maybe ten years from now it will happen."

Definition of insanity: doing the same thing over and over again and expecting different results. – Albert Einstein

"moving into research into complexity and consciousness."

Oh no!

13. **zzz**
May 29, 2015

"the next six months will be critical for string theory"

15. **Matthew Foster**
June 3, 2015

Hi Peter Woit and John McVirgo,

It seems to me that you are talking apples and oranges here. The David Simmons-Duffin quote sums up some of the very strange and remarkable results now available for large-n, N=4 Super Yang Mills theory. That's some exotic conformally invariant, in some sense "integrable" QFT that keeps leading to new surprises, from AdS/CFT to the Amplituhedron. It's possible that one can learn some deep aspects of quantum field theory from studying this "exactly solvable" (?) model. The same can be said about many aspects of quantum gravity and string research over the years; sometimes seemingly completely unrealistic models of fundamental physics end up having surprising and testable consequences for effective condensed matter systems–for example, 1+1-D Liouville field theory, which has connections to membrane and glass physics as well as being a toy model of quantum gravity.

Irrespective of the "hype" they use to sell their work, I view the efforts of string theorists from a pragmatic perspective, similar to my view of manned space exploration. Absent the race to put weapons platforms in space that was a big cold war motivation, one might ask what the compelling scientific purpose of manned exploration has been or will be in the near future, beyond useful near-earth orbit missions to deploy and service scientific instruments, satellites, etc. Advocates stress the indirect benefits; perhaps if string theorists were better-acquainted with the mathematics and physics "spin-offs" that have paid off in condensed matter, one could make a better argument than the one to abandon scientific falsifiability. I'm afraid that the latter will just isolate high-energy theory from the rest of science, and probably have a chilling effect on funding.

At the same time, if you acknowledge that unexpected byproducts are a main benefit of a large line of research, one has to evaluate the value of those compared to the investment. I'm curious where you come down on that one, Peter, given your interest in Langlands, CFT, and the mathematical aspects of QFT more generally. Are these less impressive or important than the benefits of further accelerator research, assuming no sparticles or other non-SM physics is found at LHC?

16. **Peter Woit**
June 3, 2015

Matthew Foster,
I don't see any useful way to compare accelerators and pure theory research, they're just two very different things. The HEP experiment people have a very tough job ahead figuring out how to go beyond the LHC. There isn't an obvious best choice, and all choices are expensive. Theorists are not expensive at all on that scale. I don't think moving money from one side to the other can help: diverted theory funding would be too small to solve the problem of the experimenters, diverted experimental

funding I don't think will solve the problems of the theorists (I don't think they are now due to insufficient funding).

I'm obviously all in favor of mathematically based QFT research, which I think one can justify either by "spin-offs" or simply by the argument that deeper understanding is inherently of value. What I see as problematic is selling one narrow part of this research (that related to string theory) by bogus claims that string theory will unify physics, when that's a failed idea. One part of the problem is that if you justify your field by an overhyped idea that doesn't work, as it becomes clear the idea doesn't work, people will pull the plug on your field (already happening: in the US right now very few young theorists can get a job in this area).

The other part of the problem is that this leads to a focus of research into certain narrow areas based purely on the fact that they are connected to the failed program. Sure, N=4 SYM is an interesting model, but there are a huge number of other poorly understood questions at the intersection of qft and math. The Simmons-Duffin quote doesn't seem to recognize this is not the only model out there with a fascinating and not completely understood structure. Instead of more people working on AdS/CFT, justifying themselves by the failed idea of string theory unification, I think we'd be better off if questions not related to AdS/CFT could also get attention. These might seem harder to justify than just invoking string theory and the theory of everything, but making a more honest case is likely to work better in the long run anyway.

17. **Totally off topic**
June 4, 2015

"Liouville field theory, which has connections to membrane and glass physics as well as being a toy model of quantum gravity"

This sounds fascinating. Could you give me a reference on applications of Liouville theory to membrane and glass physics?

18. **Matthew Foster**
June 4, 2015

Hi Totally off topic,

There is a generalized version of Derrida's Random Energy Model (a supersimplified, exactly solvable model of the glass transition) in which many-body energies have logarithmic correlations, instead of being independent as in the original. The partition function can alternatively be thought of as that for a classical particle in a log-correlated random potential. At high temperatures, the particle is "delocalized" throughout the volume, while it tends to get stuck in one of a "few" minima below a freezing transition at which the extensive component of the entropy vanishes. There is yet another interpretation of the model in terms multifractal wavefunctions of disordered Dirac fermions in 2D.

The connection to Liouville is as follows. The partition function is a random variable, and exhibits log-normal fluctuations at low temperatures. This is in contrast to the free energy, which is non-fluctuating (self-averaging) in the thermodynamic limit. You can write a generating functional to calculate moments of the partition function, averaging over potential configurations. The result has the form of Liouville field theory.

In the high temperature phase, you can calculate statistics using scaling dimensions of local (vertex) operators. This fails at low temperatures, however, because the OPE generates higher moment operators from lower ones.
There is a mapping to the KPP equation for non-linear diffusion, in which one keeps the entire infinite tower of moment operators. In the end, the glass transition (or transition for the moments) is encoded in the "velocity selection" of the front solution to KPP, and this allows an exact solution. This part is well-understood and has been checked numerically in various contexts.

The part that I don't understand that well is how to interpret the results in terms of LFT. There are some interesting ideas that the fusion of this infinite tower of operators somehow produces new "macroscopic" operators, and it is the dimensions of these that one is computing with KPP.

This whole business is due to Carpentier and Le Doussal, although the result was actually conjectured earlier by Chamon, Mudry, and Wen, using a schematic mapping to the problem of directed polymers on the Cayley tree.

Try:
"Glass transition of a particle in a random potential, front selection in nonlinear renormalization group, and entropic phenomena in Liouville and sinh-Gordon models"

Carpentier and Le Doussal, PHYSICAL REVIEW E, VOLUME 63, 026110

The Nash Musings

May 28, 2015
Categories: Uncategorized

Since the news of the tragic death recently of John Nash and his wife in an automobile accident last weekend, some of those who were at Princeton during the same time I was (late 70s, early 80s) have been exchanging emails of their memories of Nash from that time. It turns out that two of them, Mark Schneider and Steven Bottone, had transcribed some of Nash's blackboard writings in a notebook. Here's Steve's account of this:

> Back in May 1979, just after our general examination, Mark Schneider and I decided we would write down some of the writings that Nash left on the blackboards around Jadwin. Mark sat in a wheeled desk chair with a steno notebook in hand and I wheeled him from board to board as he transcribed the musings. I believe if we had done this even six months earlier we would have had a lot more interesting samples of Nash's writings, but I think he was already starting to tail off on his output by May 1979. As far as I know, we were the only Princetonians who thought of compiling any of this. I have made a PDF out of the musings.

Since I suspect quite a few people are curious about these blackboard writings (including me, they mostly had ended by the time I got to Princeton in late 1979), Mark and Steve have allowed me to make the pdf available, see the link above. Mark points out that they didn't actually see Nash writing these, so his authorship is an assumption. Steve notes that the handwriting was distinctive, and that the general assumption was that Nash was the author.

Update: Princeton has now made available publicly Nash's graduate school records, see here.

Comments

1. **Luca Signorelli**
   May 28, 2015

   Wow. It's stuff out of a Philip K. Dick late novel, like "Valis".

2. **andrew**
   May 28, 2015

   I'm not sure I'm comfortable reading his blackboard notes – I presume he wrote them when he was unwell. The notes might gratify a crass curiosity about his mental illness (e.g. "just how nuts was he?"), but what can we actually learn about Nash or mental illness from them?

3. **Peter Woit**
   May 28, 2015

   Andrew,
   Nash wrote them to communicate with others, I don't think his privacy is being invaded by reproducing them. Yes, he was ill, and they are symptoms of his illness, which they give some insight into. One might legitimately take the attitude this is none of our business, or also legitimately I think, instead want to understand more about what he was going through.

4. **andrew**
   May 28, 2015

   Peter. In a thorough biographical piece about Nash, the notes might help to form a complete understanding of his state of mind, but without that context they aren't particularly valuable, and, in my opinion, are in slighlty bad taste.

5. **Luca Signorelli**
   May 28, 2015

   Andrew I strongly disagree about the bad taste. As Peter said, they're attempts to communicate with the public, not private writings. And the biography and ilness of Nash are well known to the public.

6. **Peter Woit**
   May 28, 2015

   andrew,
   I would think that anyone interested enough to read these things would have some interest in understanding Nash and his state of mind. I do recommend again to anyone with such an interest to read the Sylvia Nasar biography, which is quite good (and evidently includes some other samples of this kind of writing by Nash).

7. **andrew**
   May 28, 2015

   Peter, we can agree to disagree. I will continue to enjoy reading your blog. All the best.

8. **S. Molnar**
   May 28, 2015

   I believe the Nasar biography contains not just other examples of the blackboard writings, but some from this set. As far as I know, Nash did not object to this, and it's my understanding that he and his wife were active to some degree in publicizing mental health issues (someone can correct me if I'm mistaken on either count). It seems to me that there are two reasons for suppressing this material: general privacy concerns, which I believe Nash himself did not see as a problem, and a sense that there is something shameful about them, which I feel is akin to blaming the victim. I don't doubt Andrew's sincerity and good intentions, but I'm not convinced his prescription is applicable here. I freely admit to being less than well-informed on this particular case, but I don't see the difference between hiding the public writings of someone who is mentally ill and, say, hiding the evidence of partial paralysis of someone, possibly a president, who suffered from polio.

9. **Peter Woit**
   May 28, 2015

   S. Molnar,
   I believe these were one of the sources Sylvia Nasar had access to, so that's why some of them are in her book.

10. **Jim Conant**
May 28, 2015

I don't think these are in bad taste. If they were accompanied by snarky or derisive commentary, that would be a different story. Not only do these give some insight into Nash's condition, but I also think they read like found poetry.

11. **Oyster Boy**
May 29, 2015

Let me just put it this way… I wish there were a better record of a period in my life when my perceptions were not shared by others who were in a better position to define "reality". And I wish there was less stigma surrounding talking about it openly. To sweep the unsettling bits under the rug is more a disservice than to allow them broader display in the light of day.

For those who knew me before and after, respect was never diminished. And I later achieved an even higher level of general public respect. It was only the strangers, and the social protocol of not talking about it that made me realize how real the stigma was. Do not hide it away. Promote candid conversation and awareness.

12. **Roger**
May 29, 2015

If you are concerned about Nash's privacy, then you must surely object to Nasar's unauthorized biography of him. It had a lot of dubious and privacy-invading allegations against Nash.

13. **Mark Schneider**
May 30, 2015

There has been enough conversation about the appropriateness of posting this material that I thought it might be helpful if I gave my view on this, since I not only assented to the posting, but was originally motivated to record them.

Let me first relate a parallel story. Both my mother and her best friend, in close sequence, suffered from and ultimately succumbed to dementia, probably Alzheimer's disease. As their rationality was stripped away, there were other aspects of their personalities that remained, made even more visible in the absence of cognitive abilities that we use to mask our true emotions. My "aunt's" deep and authentic kindness remained in her actions and comments, and my mother's ability to be simultaneously gentle but firm remained, expressed in frustrations with my father that I had not really understood when she was well, but which were later confirmed by a close relation after my mother's death. And yes, both of these women exhibited these traits in behaviors that were comical as well as tragic; being able to laugh a bit eased the pain of seeing loved ones slowly leave us, and never diminished our respect for them.

Why did we want to record these writings that were almost certainly the work of John Nash? I won't claim to speak for Steve, but let me go beyond my slim quotation in Sylvia Nasar's book. Yes, many of these writings were funny. But at the same time there was an exceptional ingenuity to them, and perhaps some insights into Nash's personality. It would be easy to look at his brief PhD dissertation and picture him as a brilliant individual who just tossed it off in a couple weeks work in a break from playing Hex. But I suspect the detail work that was evident in his board writings (even in his careful handwriting and layout, which I attempted to reproduce faithfully) was characteristic of the meticulous, time-consuming effort that he put into all of his work, regardless of his health. I recall times when a curious graduate student would erase a word or two of a board writing, only to find it scrupulously restored shortly thereafter. I don't think it is too much of a stretch to argue these are personality insights that are more difficult to obtain from a healthy individual, who is concerned with maintaining public perceptions of casual brilliance. Maybe one could even infer from the persistent theme of world leaders that Nash hoped that his insights could be useful in bettering the globe.

And finally, for those of you who have also followed some of the comments on the NY Times article, there was considerable criticism of the Nobel committee for being slow and hesitant to award the prize to Nash, seeing this as unjustified discrimination against him for an illness over which he had no control. Someone unfamiliar with Nash might think that his condition was akin to folks we may know who suffer from depression, or bipolar disorder, but are largely able to function. But the Nobel committee, I'm sure, worried about the highly public nature of this award, probably the highest intellectual honor in the world. Would having Nash at the ceremony be so destructive as to unfairly detract from the honor for the rest of the awardees? Moreover, would such an award to an individual who has lost a grip on reality be a public relations nightmare for the Nobel prize? I am not suggesting I know the right answer to these questions, but I respect them as being very thorny questions. The content of these board writings might help people understand the difficulties faced both by John Nash and the Nobel committee.

14. **David Derbes**
May 30, 2015

@Roger,

Sylvia Nasar had, I believe, the complete cooperation of Alicia Nash (who comes across in Nasar's biography as a woman of great kindness and strength) and at the least was not opposed by John Nash, who at the time of the biography, seems to have been, to a first or better approximation, his healthy, pre-psychotic self. (I should mention that I responded to a request in the Princeton Alumni Weekly from Nasar and wrote her a letter about my extremely limited knowledge of Nash in the early 1970's. Some of that appears in her book.)

When Nash wrote his blackboards, they were clearly intended to be seen. And after he returned to health, he could certainly have let it be known that he would prefer them to be forgotten. I don't think there is either an invasion of privacy or bad taste here. If we don't know what the phenomenon is, we have no hope of understanding it, perhaps with a hope of lessening its effects on others.

I don't want to name names, but there is (or was; I do not know if he is still alive) in my neighborhood a near-clone of Nash's case, a brilliant and highly respected professor at the University of Chicago who seems to have succumbed to schizophrenia. For years he wandered the streets of Hyde Park aimlessly with an upright umbrella and an increasingly filthy handkerchief held in front of him, singing opera. I think Princeton did enormously better by John Nash than Chicago by its former biology professor. Probably the signal difference was Alicia Nash. I do not know if the Chicago professor had as stalwart a wife (or any wife) as John Nash did. With luck some psychiatrists will learn a little more about this terrifying disease from the Nash record, including the blackboards, and maybe begin to understand it a little better.

15. **John Lowery**
May 30, 2015

Waiting for more information on Nash's reformulation of Einstein's Theory of Relativity. Anyone know more about this as seen in the Daily Mail(UK):
'….The 'Beautiful Mind' mathematician John Forbes Nash Jr. (pictured), who died last week, had told a friend he had discovered a replacement equation for Einstein's theory of relativity. Award-winning mathematician Cédric Villani said Nash had explained the work on Einstein's theory to him three days before his death. Nash and his wife Alicia, 82, were killed in a taxi crash in New Jersey in the US last week…'

16. **Thomas Hannagan**
May 30, 2015

See here for Villani's talk at the Hey Festival:

https://www.hayfestival.com/p-9799-cedric-villani.aspx

The Nash discussion starts at about 45′.
Looks like Nash discussed an equation bearing on general relativity, which he had apparently showed to Einstein in his time, but Villani does in no way mention any "replacement for Einstein's theory of relativity"…

17. **Andy P.**
May 30, 2015

David Derbes : I remember the guy you're talking about from Hyde Park. Over the five years I was in graduate school at Chicago, we frequently encountered him on the street. Twice he freaked out and started screaming obscenities at my children. I remember being very surprised to learn (from a fellow student, later confirmed via internet searches) that he was a professor and not a random homeless person. I have never heard stories about Nash behaving aggressively like that, which is perhaps one of the reasons that Princeton tolerated him more than Chicago tolerates their former faculty member.

18. **Steven Bottone**
May 31, 2015

Hopefully I will only have to use this term once, and I will put it in quotes: I will not conjecture on "mental illness". When (presumably) Nash placed these writings on the blackboards in Jadwin and Fine Halls, he most certainly did so for others to read. For those not familiar with these buildings on the Princeton campus, let me point out these writings appeared on the blackboards that lined the hallways, stretching from floor to ceiling, and in full public view. It is a fair assumption to make that whoever wrote these messages meant for them to be read by all passing by.

As Mark pointed out in a previous comment, these writings were meticulously composed and quite carefully formatted to fit neatly, yet artistically, into the space available. The handwriting was so distinctive that it would be nearly impossible mistake these notes for those of another author. Indeed, we would occasionally see attempts at imitating these writings, but there was no mistaking which of these were authored by the person who has been described as "The Phantom of Fine Hall".

I would say that most of our fellow graduated students were genuinely intrigued by these writings and it was always the case that if I walked by a new contribution I would stop to read it and if I were with others they too would stop to read it. Comments were often of the form as to the meaning of these messages and even if on the surface it appeared that the comment was one of ridicule, there was nevertheless invariably an undertone of awe.

I prefer to look at these writings in the spirit that I think Nash posted them. I think he wrote them for his own amusement, and for the amusement of the rest of us. They are meant to be satirical, usually political, commentary. They are funny. I ask those of our literary friends out there to comment on the content of these writings based on their own merit. Do they show great wit? Is this the work of a great satirist, who actually has an almost unique breadth of knowledge of political history, popular culture, and mathematics? This is how I prefer to view these fascinating musings.

19. **Neil**
June 1, 2015

I find these musings most interesting, but baffling. One cannot dismiss them as ramblings without some context, and Nash did not provide any. But one can do some interpretation based on the time they were written. For example, lon nol almost certainly refers to the Khmer president. It would have been witty, and characteristic, had Nash added the comment "ceci n'est pas un palindrome", so he was clearly not in his best form.

I was disappointed so many comments were political and social commentary, rather than mathematics. I was hoping for the bones of some brilliant conjecture.

20. **Curious Wavefunction**
June 1, 2015

To be honest, that statement by Nash about Ford and Nixon is one of the most insightful statements about American politics of the last thirty years that I have seen.

21. **SeekingSanity**
June 3, 2015

Invading privacy? Come on. These notes were written on public blackboards.

Lets have some perspective here. Yes you can talk about privacy, but these notes hardly cross the line. Especially since the person in question had an biography and indeed a major motion picture on their very private life released to the general public.

There's also a clear public interest element in publishing these. Someone who wrote these was a tenured professor at the institution in question for many years. This can be taken in many ways; 1) It was dangerous to do so, 2) it shows that it was not dangerous, but either way publishing these allows people do debate based on something concrete.

Personally I think it shows just how far academia can tolerate eccentricity, and that's a good thing within reason. Especially as we enter an age of increased careerism and corporatism in higher education. The ability to have a professor like could represent a strength of the traditional academy — though I'm sure many would now be happy to spin it as a weakness.

LHC Run 2

June 2, 2015
Categories: Experimental HEP News

Run 2 of the LHC is about to start with first stable beams scheduled for Wednesday morning, Geneva time). If you're up (I'll be asleep) you can watch [a live webcast], or watch what is going on [here]. The current plan is 3 bunches/beam Wednesday, 13 bunches/beam Friday, and 48 bunches/beam over the weekend.

Tomorrow will also be an [LHCC meeting], which you can also watch live. It will include reports from the experiments, and a status report about the machine which should give the latest details about the planned schedule for ramping up the intensity over the next couple months.

For the best advice about what to look for in coming months, see Jester's summary [here]. First new results may well be about gluinos.

This week there's a workshop going on at Nordita. On Thursday Gordon Kane will explain how [string theory predicts that the LHC will see superpartners soon]. I gather his claim is that gluinos are at 1.5 TeV, just above the Run I limits of around 1.4 TeV, so a sure thing for Run II. Of course, [back in 1997] he was claiming they were at around 250 GeV, just above Run I limits, a sure thing for Run II (but that was the Tevatron…).

Update: Kane has very specific [string theory predictions for Run 2]: gluinos at 1.5 TeV, winos at 620 GeV (+/- 10%). So, I guess string theory is going to finally be tested by the LHC over the next year or so…

Comments

1. **SRV**
   June 2, 2015

   Why does Gordon Kane keep making irresponsible 'predictions' that aren't firm??

2. **Peter Woit**
   June 2, 2015

   SRV,

   Because he can? A more to the point question might be why people keep inviting him to do this. For example, long after publishing the failed Tevatron predictions, Physics Today invited him to do it again, see here
   http://www.math.columbia.edu/~woit/wordpress/?p=3236

3. **gluinos**
   June 2, 2015

   what are the implications to HEP if LHC run 2 finds no gluinos?

4. **Peter Woit**
   June 2, 2015

   gluinos,
   That's a very interesting question that I think we're going to find out the answer to. Gluinos are both easy to see (since strongly interacting), and standard arguments for SUSY (eg "naturalness") don't allow you to push their mass up too high. So, they're the most likely ones to be seen, given standard expectations about SUSY. If they're not seen, likely there will be no superpartners seen.

   Kane is an extreme case, it's quite clear what his reaction is going to be ("gluino mass is just above 2 TeV, will be seen at the HL-LHC"). Much more interesting will be how others react to this situation. Will they just say they believe in SUSY no matter what (John Ellis seems to be planning to go that route), or will the negative experimental results change their attitude about SUSY? Some of them will have to pay off bets they have made about this, perhaps that will have some effect.

5. **Eduardo Lira**
   June 2, 2015

   "First new results may well be about gluinos".

   Dr. Woit,
   I think I remember you wrote in your blog not too long ago that no matter what energy they revved up the LHC to no superpartners would ever appear. Am I missing something?

6. **Mimoune**
   June 2, 2015

   Peter

   I thought you may be like to read this

   https://www.quantamagazine.org/20150527-a-new-theory-to-explain-the-higgs-mass/

7. **Peter Woit**
   June 2, 2015

   Eduardo Lira,
   What I meant is just what Jester was discussing: first new results are likely to be stronger limits on gluinos than the limits from Run 1.

   Mimoune,
   I did see that. I think I agree with Arkani-Hamed: "far-fetched"…

8. **you'll_never_walk_alone**

June 3, 2015

Because of the hierarchy problem, until we find them or reach the highest energy scales, the most probable place for sparticles is always just around the corner. That might be frustrating, but it's how it is.

LHC results should barely impact your preference for SUSY over the SM alone – even with all the LHC results, the simplest SUSY models are much more probable explanations for the smallness of the weak scale than the SM.

Kane's remarks are easy to ridicule, but they're not actually that foolish or silly.

9. **David Roberts**
June 3, 2015

And stable beams are up, with collisions going ahead!

10. **Peter Woit**
June 3, 2015

YNWA,

So, SUSY is a theory for which there is no evidence, which always predicts that it will be vindicated "right around the corner", and when it isn't, that has no negative impact on the idea at all. Somehow Kane has always neglected to explain this.

If you want to make particle theory an object of public ridicule, that argument seems to me an excellent way to do it.

11. **you'll_never_walk_alone**
June 3, 2015

There is enormous evidence for SUSY versus the SM. The SM's generic prediction for the weak-scale is totally wrong, $M_Z \sim M_P$ (of course it can be tuned to get it right though). The LHC results should decrease your belief in SUSY versus the SM, but only by a jot. In order to make SUSY as bad at predicting the weak scale as the SM, you'd have to exclude sparticles up to near the Planck scale. That's simply a reflection of how bad the SM is at predicting the weak scale.

12. **Peter Woit**
June 3, 2015

The SM doesn't predict the weak scale at all, and, by your argument, neither does SUSY.
This reminds me of the argument that, since the SM doesn't predict the CC, but SUSY does, SUSY is much better, even though the prediction is off by some exponentially large factor. To my mind that doesn't count as "enormous evidence" for SUSY vs. the SM, but the opposite.

13. **you'll_never_walk_alone**
June 3, 2015

The SM (interpreted as an effective theory valid up to around the Planck scale) does predict the weak scale – its generic prediction is totally wrong $M_Z \sim M_P$. That's the essence of the hierarchy/fine-tuning/naturalness problem in the SM.

A SUSY model also predicts the weak scale and its generic prediction is much better (its prediction is that $M_Z \sim M_SUSY$, where M_SUSY could be anthing up to the Planck scale.

This comes from a place of respect – you must see that there are good reasons for believing that sparticles are around the corner, even if you don't find them compelling.

14. **Peter Woit**
June 3, 2015

YNWA,
I don't think the SM has anything to do with the Planck scale. You can get a bad prediction by making various assumptions about what is happening at the Planck scale and interpreting the SM in terms of those, but that's a problem for your assumptions about the Planck scale, not for the SM.

I also don't think the arguments for SUSY were good pre-LHC (and wrote a chapter about this in my book many years ago). For fans of these bad arguments, the LHC gave some hope of vindication anyway. That's now pretty much gone, and best that be admitted, not replaced by new "right around the corner" claims.

15. **M**
June 3, 2015

If I remember correctly, around 2000 Gordy was saying that he would have abandoned SUSY if it was not discovered at Tevatron run II.

16. **you'll_never_walk_alone**
June 3, 2015

All right, let's leave it at that. I'll try to read your book sometime.

17. **Anonymous**
June 3, 2015

"A SUSY model also predicts the weak scale and its generic prediction is much better (its prediction is that $M_Z \sim M_SUSY$, where M_SUSY could be anthing up to the Planck scale."

Is there actually a hard argument that it cannot be above the Planck scale (other than that all bets are off at the Planck scale)? If not, your "prediction" is simply that the weak scale is a scale. I find the fact you are trumpeting this as some kind of success hilarious.

The hierarchy problem is a case of one free parameter, when extrapolated over 16 orders of magnitude in energy, taking on a value we do not understand. The Standard Model also has 25 other free parameters with values we do not understand the reasons for, some of which also look suspicious. Increasing the number of free parameters by 100+ in order to sort of account for the value of one parameter does not look like progress.

The SUSY may be always just over the horizon to those who love her truly, but increasingly the rest of us simply won't care. This certainly looks like it will be the case if it doesn't show up in the next couple of years.

18. **gluinos**
June 3, 2015

Peter,

What is the upper limit of Gluino masses that is allowed under naturalness/weak scale hiearchy argument? What is the upper limit of gluino masses LHC Run 2 13TEV can produce and detect? How soon will these results be announced, given LHC Run 2 starts today and its projected luminosity? thanks regards

19. **Peter Woit**
June 3, 2015

gluinos,
The talk by Mike Lamont today said 5-10 inverse fb this year, 1 inverse fb during the initial 50 ns part of the run (early July). So, won't match the amount of 8 GeV data until sometime next year. 1 inverse fb should be about enough to match the previous bounds (1.4 Gev), so that may happen by the end of the summer. I'd guess by sometime next year you'll see 2 GeV bounds.

The problem is that there is no upper limit. If you believed the naturalness argument, we were supposed to have seen these things long ago, at the Tevatron. The people who didn't give up after the Tevatron/LEP and insisted that LHC energies were needed are now all gearing up to argue that nothing at the LHC is still no reason to give up, that what is really needed is a 100 TeV machine.

20. **Tim**
June 3, 2015

Here are my predictions:

September 2015 – Z' boson not discovered at LHC
March 2015 – no sign of gluinos at LHC
Summer 2016 – still no axions seen at LHC
2017-2018 – strong evidence that dark matter particles, whatever they are, are not produced at LHC
2019 – "Theory of Everything" fever finally collapses, Nobel Prize awarded for "Theory of Nothing", which explains why there is probably nothing to see between 1-100 TeV.

21. **you'll_never_walk_alone**
June 3, 2015

To my anonymous critic. You want to know what happens if we permit the SUSY scale, and presumably also the cut-off in the SM, to be greater than the Planck scale (let me call this high scale Λ). In the comparison of SUSY versus the SM, not much changes – the SM predicts that $M_Z \sim \Lambda$, whereas SUSY predicts that $M_Z \sim M_SUSY$, where M_SUSY is anything less than Λ.

The point isn't that SUSY predicts the weak scale spot-on – it doesn't. The point is that a SUSY model's generic prediction is more compatible with what we observe than the SM prediction. The smallness of the weak scale is much more probable in a SUSY theory.

You compare the dim-2 Higgs coupling with the SM's many other unexplained parameters, such as the Yukawas. If we can't explain the Yukawas, who cares if we can't explain the dim-2 coupling? But we don't know any theories that make concrete, correct predictions for the measured Yukawas (without parameter fitting). If we knew of such theories, I'd definietly favor them over the SM (especially if they were supersymmetric).

22. **SRV**
June 3, 2015

Wouldn't you say that supersymmetry is a 'prediction' of string theory?

23. **Peter Woit**
June 3, 2015

SRV,
Personally I have been consistent in claiming that string theory makes no predictions. In the past string theorists have often responded to the "no predictions" claim by saying "string theory predicts supersymmetry". See for example
http://www.math.columbia.edu/~woit/wordpress/?p=3904

Ever since results from the LHC started to come in, you hear this claim a lot less often…

24. **Alex**
June 3, 2015

YNWA,

What experimentally verified predictions does SUSY give that the SM doesn't?

25. **Thomas Larsson**
June 4, 2015

I have realized that I am probably the most successful string phenomenologist on this planet. Not famous or prominent, but successful in the sense that used to count as success in pre-post-modern physics: agreement with experiment. After all, who else has managed to use string theory to make a falsifiable but confirmed prediction about the LHC?

26. **Mesmar Djehha**
June 4, 2015

Given the role supersymmetry plays in modern mathematics, would the nonexistence of supersymmetry modify our view on the relation between physics and mathematics?
Thanks

27. **Anonymous Critic**
June 4, 2015

"The point isn't that SUSY predicts the weak scale spot-on – it doesn't. The point is that a SUSY model's generic prediction is more compatible with what we observe than the SM prediction. The smallness of the weak scale is much more probable in a SUSY theory."

My issue initially was that you described the postdiction that a number is between zero and infinity as being a successful prediction. The fact is that this model is set up entirely to solve this "problem" – the fact that it can accommodate a solution is not then evidence that this model is in any way correct.

I agree with you that there aren't any known models that successfully reduce the number of free parameters from the SM – but this does not mean that such models are not realized in nature. The fact that models designed to solve the hierarchy problem alone continue to not show up in nature should maybe be taken as a sign that what we are doing now is not the right approach. If we continue to make the "just over the horizon" argument, and learn absolutely nothing from experimental results, it will ultimately kill the field.

28. **Peter Woit**
June 4, 2015

Mesmar,
No. The specific supersymmetry algebra that has been conjectured to be relevant for particle physics, to some extent being tested by the LHC, is only one very special example of the general phenomenon of supersymmetry and supersymmetric QFTs. That this specific example isn't relevant to the real world doesn't affect the mathematically interesting aspects of supersymmetry (this example was never especially interesting mathematically). It might even have a positive effect, encouraging people to pay more attention to aspects of supersymmetry that are mathematically interesting, rather than this particular one which just had a failed idea about physics associated with it.

29. **gluinos**
June 5, 2015

Update: Kane has very specific string theory predictions for Run 2: gluinos at 1.5 TeV, winos at 620 GeV (+/- 10%). So, I guess string theory is going to finally be tested by the LHC over the next year or so…

^

do you agree with Kane? What happens Kane's prediction if no gluinos or no winos.

30. **Peter Woit**
June 5, 2015

gluinos,
I can predict with 100% certainty what will happen once Kane's prediction doesn't work out: he'll come up with another prediction. A couple years from now he'll be predicting gluinos just above 2 TeV, too heavy for Run 2, but a sure thing for the HL-LHC.

31. **Egon**
June 5, 2015

If no gluinos or winos, Kane revises his model and makes another prediction. In his paper on G_2-MSSM, he says that the entire sparticle spectrum is determined once you take into account the electroweak symmetry-breaking scale, the Higgs mass, and the gravitino mass (which he calculates approximately), but the details depend on the discrete choice of the 7-dimensional compactification manifold, which changes the hidden sector gauge group and the parameters in the formula for the gravitino mass: http://arxiv.org/abs/1408.1961

At best, the prediction of a 1.5 TeV gluino mass could be considered a test of the very specific string-inspired model that Kane is promoting, which is essentially a particular instantiation of SUSY SU(5), but even within his G_2-MSSM model there is room for adjustment.

32. **John Baez**
June 5, 2015

I've become increasingly suspicious of "naturalness" or "no fine-tuning" arguments. They often seem to amount to saying that dimensionless constants are more likely to be near 1 than enormously large or enormously small.

This might be a fine heuristic when we're completely clueless and desperately need any heuristic we can grab ahold of – but is there any reason to believe it's *true?* Can someone point to a reference where someone enthusiastically and intelligently defends this sort of argument? Or alternatively, attacks it?

33. **David Roberts**
June 5, 2015

The thing I find sad is when people say "look! No free parameters!", when they have chosen a geometry on which to dimensionally reduce (or similar: a choice of non-compact space, a choice of structure group,…). Do they really believe that a moduli space of Calbi-Yau manifolds is different to a parameter space of coupling constants? That a discrete choice of homotopy type of manifold, of isomorphism class of a Lie group is different from a choice of real number?

34. **srp**
June 5, 2015

As a geometry guy don't you realize that geometry always seems more natural than real analysis? Visualization!

35. **Urs Schreiber**
June 6, 2015

@John, regarding naturalness: I thought the discussion by Strassler here wasn't too bad: http://profmattstrassler.com/articles-and-posts/particle-physics-basics/the-hierarchy-problem/naturalness/

@David, regarding free parameters: of course moduli are also parameters, but they are not free parameters, instead they are dynamical fields. While you may start out selecting moduli in string theory just as you select free parameters in field theory, afterwards you are required to check that the values you chose constitute a solution to the theory (background equations of motion+quantum corrections+anomaly cancellation). Notably if you want to assume that the moduli won't evolve away from the values you'd like to consider, then you need to check that they sit in their potential well, hence that they are stabilized. Discussion of moduli stabilization is a huge topic (landscape and all). Beware that the full constraints for consistent choices of moduli in string theory are strong, hence solving them is hard, and accordingly it is in practical approximation rather than in fundamental meaning that glancing through the literature you might get the impression that some people choose their moduli as if they were free parameters.

36. **Urs Schreiber**
June 6, 2015

@John, sorry, forgot to add: a pronounced criticism of the traditional naturalness argument was voiced by Wilson, see p. 10 here http://arxiv.org/abs/hep-lat/0412043

37. **Peter Woit**
June 6, 2015

Urs,
You're neglecting to mention that there's a minor problem with the "moduli are dynamically determined" argument: you don't know what the dynamics are. The "moduli stabilization" story is a very complicated one, and not because you know what the underlying theory is and are having a hard time solving it…

38. **David Roberts**
June 8, 2015

@Urs

Mentioning 'moduli' was a little risky, but I mean the moduli space of *all* CY manifolds. I had hoped mentioning homotopy types makes it clear. Unless changing homotopy type is part of the dynamics (which it may be, who knows) I don't see how picking a homotopy type of manifold (and then of course complex structure etc, which can evolve over time) is not a choice.

39. **Urs Schreiber**
June 9, 2015

@David, yes change of homotopy type (aka topology change) of spacetime is part of the dynamics of string backgrounds, see e.g. the references here: http://ncatlab.org/nlab/show/flop+transition .

But this is tangent to your quarrel about the common usage of the term "free parameters". Consider plain GR. It's free parameters are the gravitational coupling constant, the cosmological constant and the prefactors in front of all higher curvature corrections. What is not called a free parameter of GR is the homotopy type of spacetime (what physicists call "the topology"). Instead, this is part of what it means to have a solution to the theory.

In string theory all those prefactors in the effective Lagrangian are fixed, in M-theory also the global coupling is fixed, you may not choose these parameters freely, their values are fixed by a more fundamental principle. Instead, there is now a richer space of solutions of the theory, which in suitable limits look like some effective field theory with free paraneters. But now all these parameters are actually parameters of the solution space of the UV-completing string theory (its moduli) and hence are dynamical fields.

See also the string theory FAQ http://ncatlab.org/nlab/show/string+theory+FAQ#IsStringTheoryTestable

40. **David Roberts**
June 10, 2015

@Urs

thanks for the clarification. I guess GR is qualitatively different at this point in time in that we have (local) solutions that correspond to measured reality, and one can calculate a solution then go measure how accurate it is.

We aren't yet at the point with string theory that Eddington was at when he measured the effect of gravity on light (if we even get there!) in the sense that it was a new prediction that could make or break GR. I guess it's more like when people predicted the Omega^- based on what we now know as representation theory of the structure group of the gauge bundle, but at the time would have been (for mathematicians) very shaky justification. At that time, Gell-Mann and Ne'eman got lucky, in that they had sniffed out what was going on, and the details filled in later. Now, on the other hand, people have no single idea (rather a giant space of field theories-worth) what specific geometric structure should give what we see at the LHC (the analogue of SU(3), or the Schwarzschild metric), if there even is one, and so are clutching at whatever they can calculate.

Time will tell, perhaps.

41. **Urs Schreiber**
June 10, 2015

@David, your issue about the technical meaning of the technical term "free parameter" has nothing to do with phenomenology, it applies to, say, the Ising model as well as to any other realistic or nonrealistic model, and as such is not qualitatively different in gravity, no, on the contrary, it is precisely the free parameters of Einstein-Yang-Mills-Dirac-Higgs Lagrangians that are meant when people say that string theory has no such. This is a mathematical statement about certain functionals which is entirely independent of any phenomenology. While I doubt here the right place here for the discussion we are having, it's good that you voiced your confusion about this common terminology, because without such basics sorted out, there is no educated assessment of the theories under discussion.

42. **David Roberts**
June 10, 2015

@Urs thanks again for clarifications. I'm not sure my issue is only with 'free parameters', but as you say, perhaps this is better discussed elsewhere.

43. **Tommaso Dorigo**
June 12, 2015

Here's two predictions that Gordy Kane made in August 2011 to me privately (I then blogged about it):

———
I thought it was worthwhile to comment a little on recent LHC searches, since they have led to a number of surprising statements. First consider gluino searches. The results of a search for gluinos are very sensitive to squark masses. Theoretically the only well motivated values for squark masses are very large, tens of TeV, because they are generically predicted in compactified string/M-theories when the associated moduli satisfy cosmological restrictions. Then (a) the gluino production rates are considerably reduced, and (b) the decays or gluinos to 3rd family final states dominate. Existing gluino searches cover this region poorly. The current limit on gluino masses is not above 500 GeV. Whether the squarks are indeed so heavy is not the issue, the point is that if they are the limits on gluino masses are smaller than is often stated. I and others excpect this decay to tops and bottoms is the signature by which gluinos will be found, with masses well below a TeV.

Second, when squarks are heavy the two doublet Higgs sector is an effective single doublet since the heavy partners decouple. There is a single light Higgs boson observable. If the gauge group of the theory is the MSSM one then the Higgs mass is between about 115 and 128 GeV (essentially a function of the parameter tan(beta)). It will not be above that range. It has the SM production rate. The LHC searches are not yet sensitive to this region, and should not yet have seen a signal, so not seeing a signal does not allow any meaningful conclusions about Standard Model or MSSM Higgs bosons.
———

As you see he got one wrong and one right 😉

Cheers,
T.

The West Coast Metric is the Wrong One

June 5, 2015
Categories: Favorite Old Posts

I'm trying to get back to blogging about quantum mechanics slogans, this one is about relativistic quantum mechanics. I'm hoping it will stir up more trouble than [my last East vs. West one](#).

If you're doing calculations in relativistic quantum field theory, you typically handle the Minkowski nature of space-time by introducing an indefinite signature metric, and there are two possible choices:

- Mostly minus signs (for the spatial components), positive sign for the time direction. This is commonly known as the "West Coast metric", I'm guessing because Feynman used it.
- Mostly plus signs (for the spatial components), negative sign for the time direction. This is commonly known as the "East Coast metric", I'm guessing because Schwinger used it.

While I was educated on the East Coast, most courses I took and textbooks I used favored the West Coast metric, and that's very much true of more recent textbooks (I don't know of a recent one using the East Coast convention). When I started on [this project](#) I used the West Coast convention. After a while though, I finally found this conceptually more and more confusing, and switched to the East Coast convention. As time has gone on, I've become more and more convinced that this is the right convention to choose, that the West Coast convention is just a mistake, and a source of conceptual confusion in the subject.

Here are some reasons:

- With the East Coast convention, the treatment of spatial coordinates is just like in the non-relativistic case. In the West Coast convention, as far as space goes, you have decided to work with a negative definite metric, which is a quite misguided thing to do for obvious reasons.
- With the East Coast convention, if you do what you always do to make a QFT well-defined, analytically continue to imaginary time, you end up working with the standard Euclidean metric in four dimensions. In the West Coast version, you end up with a negative definite metric, again a bad idea (thanks to Peter Orland for emphasizing this to me). You could instead do your analytic continuation by analytically continuing all three of the space coordinates, also a really bad idea.
- With the East Coast convention, the Clifford algebra Cliff(3,1) is the algebra of real four by four matrices. In other words, you can choose your gamma-matrices to be real matrices and work with a real spinor representation (the Majorana representation). Going with the West Coast, Cliff(1,3) is the algebra of two by two quaternionic matrices, a confusing thing to work with. Ignoring that, what physicists end up doing is working with gamma matrices that are pure imaginary, which is highly confusing (odd powers of gamma matrices are pure imaginary, even ones real). [According to Figueroa-O'Farrill](#), in this case you are working with:

  > pseudo-Majorana spinors – a nebulous concept best kept undisturbed.

  To be fair, for this problem you can do what he does, and just change the sign in your definition of the Clifford algebra.

- Weinberg's quantum field theory textbook uses the East Coast convention.

One reason this issue came to mind is that I've been trying to understand (not very successfully…) Schwinger's old papers on Euclidean quantum field theory, where he makes some quite interesting claims. Schwinger used the East Coast convention for this, and as explained above, it's only with this convention that you get something sensible after analytic continuation in time. There is very little literature following up on Schwinger's arguments, I'm suspecting partly because in the West Coast convention following Schwinger's arguments becomes virtually impossible.

The problem here is part of a more general problem, that I think most physicists don't appreciate the mathematical concept of "real structure" or complexification. Given any formulas, they're happy to just start using complex numbers, even when the quantities involved are real, with the idea that only at the end, when you get observable numbers, do you need to impose some reality condition. For an example of this, one often finds in qft texts claims that sound very strange to mathematicians, I have in mind especially things like

> The mathematically sophisticated say that the algebra SO(3,1) is isomorphic to SU(2) X SU(2) (Tony Zee, QFT in a nutshell, page 113 first edition).

One problem here is that Zee is using the standard math notation for the Lie group to denote the Lie algebra, an unfortunately common practice. But the real problem is that the two Lie algebras are only isomorphic if you complexify, as real Lie algebras they are quite different. If you have always from the beginning complexified everything, this distinction doesn't make sense to you, but it is often an important one if you want to really understand what is going on in some calculation involving spinors. For another example, there's

> the 3D rotation algebra, which has multiple names so(3)=sl(2,R)=so(1,1)=su(2), due to multiple Lie groups having the same algebra. So we have shown that so(3,1)=su(2) + su(2) (Matthew Schwartz, QFT and the Standard Model, Page 162).

Schwartz properly distinguishes by notation between the group and the Lie algebra, so is in better shape than Zee, but, again, so(3,1)=su(2) + su(2) is only true for complexified Lie algebras. The statement "so(3)=sl(2,R)=so(1,1)=su(2)" suffers from a typo (so(1,1) should be so(2,1)), but again an identification is being made that only makes sense if you have complexified everything. What's really true here is that you have SL(2,R) a double cover of SO(2,1), and sl(2,R)=so(2,1), as well as SU(2) a double cover of SO(3), with su(2)=so(3). But SU(2) is a very different Lie group than SL(2,R) (although they share the complexification SL(2,C)).

So, my modest proposal is that the HEP community should just admit that the West Coast convention was a mistake, and rewrite all the textbooks (Weinberg doesn't have to…).

Update: A commenter tells me there is at least one recent textbook with the right convention, Srednicki's.

Checking some books, I remembered one other intriguing recent choice, that of Michael Dine, who wrote the first half of his book (the QFT part) in the West Coast metric, but the second half (the string theory part) in the East Coast metric.

Update: For those interested in how to translate back and forth between Coasts in the two-spinor notation, I noticed that Dreiner, Haber and Martin have written review papers, with a line in the tex that lets you choose which Coast. See [here](#) and [here](#).

Comments

1. **auxsvr**
   June 5, 2015

   One very common mistake physicists make is that the ladder operators taught in quantum mechanics are elements of su(2), but they're elements of its complexification, as su(2) is a real algebra. This distinction is essential if one needs to study group theory in depth for quantum gravity etc.

2. **Peter Woit**
June 5, 2015

auxsvr,
Yes, that's the same issue I'm talking about. Raising and lowering operators occur in representations of the complexification sl(2,C), not of su(2).

3. **Peter Morgan**
June 5, 2015

The invariant distinction for 4-vectors (in flat Minkowski space) is between space-like definite, light-like, and time-like definite (or semi-definite or indefinite, and with similar distinctions for bivectors and for spinors), so I suppose it's better to formulate geometrical argument in these terms rather than in terms of +0- (or -0+). For the algebra, this is just one of very many sign and factor conventions (anyone for a five-minute argument about 2\pi?); we have no choice but to be clear which conventions we are using and to keep perfect track of them all. But I think signs and factors are the least of my worries when trying to understand other people's notations and formalisms (as you note above, people are not as clear as could be about whether they are working over the real or complex field).

4. **Sudip Paul**
June 5, 2015

Mark Srednicki also uses the mostly plus metric in his QFT textbook. Also I was always confused by this East Coast/West Coast nomenclature. Why can't people simply say mostly plus/mostly minus?

5. **Peter Woit**
June 5, 2015

Sudip Paul,
Thanks, Srednicki's book is one of the ones I don't have, I suppose I should get a copy. Glad to know that there's at least one recent example of the right convention.

Instead of East/West, or mostly plus/mostly minus, how about right/wrong?

6. **Alex**
June 5, 2015

While I agree with your conclusion, I think I should point you to this [preprint] indicating the Pin groups may cause physically-meaningful phenomena…depending on which signature you use…well, neutrinoless beta decay can *only* be described in the East coast metric.

7. **Gandalf**
June 5, 2015

Someone has to defend the "West coast metric" here, it seems. For in that metric, energies p^2 are positive, as they should be! Ok, you have to accept that spatial distances x^2 are negative .. you can't have it all. But who wants to impose a negative energy condition? I rather travel -1000 miles 😉

8. **Al**
June 5, 2015

Interestingly I've never heard of this "West/East Coast" nomenclature. Instead when I studied it, we had "the one that particle physicists use" (mostly minus) and "the one that general relativists use" (mostly plus). If I remember correctly, the mostly plus one stems from Minkowski's geometric formulation of special relativity (introducing imaginary time coordinate), so it's the one in use by relativists.

9. **Al**
June 5, 2015

By the way, that might explain Michael Dine's choice. When string theorists want to emphasize string theory's potential as TOE and connect it to gravity, they use mostly plus ("East Coast") one.

10. **John Baez**
June 5, 2015

I agree that it's better to take spacelike vectors to have v · v > 0, because this convention makes spacetime geometry backwards-compatible with the usual way of describing the geometry of space. This is how I do things in my book *Gauge Fields, Knots and Gravity*.

However, the convention for Clifford algebras requires another decision, as you note. And this decision is lot more interesting to me. Should a vector with v · v = 1 give a square root of 1 in the Clifford algebra, or a square root of -1? Thinking about the relation between Clifford algebras and division algebras, I decided that square roots of -1 were more natural here. You can see the thought process hiding [in here]: starting from the idea of a normed division algebra, you can quickly see that an n-dimensional normed division algebra is the same thing as an n-dimensional representation of a Clifford algebra generated by n-1 anticommuting square roots of -1. Another way to put it is that a skew-adjoint orthogonal matrix – that is, a matrix lying both in the Lie group O(n) and the Lie algebra o(n) – must be a square root of -1.

By contrast, your argument that 2×2 matrices of quaternions and purely imaginary gamma matrices are "confusing" seems based on taste rather than theorems.

(My argument that spacelike vectors should have v · v > 0 is also based on taste – or rather, history: I'm saying this is nice because it's the convention we're used to from ordinary Euclidean and Riemannian geometry. But my argument that square roots of -1 are better than square roots of 1 is based on theorems. The simplest of these theorems, of course, is that taking the real numbers and adjoining a square root of -1 gives a field, the complex numbers, while adjoining a square root of 1 does not.)

11. **Noboru Nakanishi**
June 5, 2015

The use of the words, "East Coast Metric"and "West Coast Metric", is unwelcome; high-energy physicists are not necessarily Americans. I once used the words, "Space-favored Metric" and "Time-favored Metric". The former is more convenient than the latter except in the momentum-space consideration. But it must be emphasized that this is the matter of convenience but not the matter of the right/wrong business.

As was noted by Schwinger (and independently by Nakano), the x of a field operator has no intrinsic metric signature in quantum field theory. People just introduce the Minkowski metric by hand. Similarly, in general relativity, the Einstein equation contains no information about metric signature. One just introduces the Lorenzian metric signature by hand as the boundary condition. From these facts, I proposed that the quantity x should be something living in the space which has no metric; concretely, the space of x should be an affine space. Time should be embedded into this space. I formulated quantum Einstein gravity on this standpoint. One of the consequences of this formulation is that SUSY is a wrong symmetry!

12. **Sudip Paul**
June 5, 2015

Just remembered, Polchinski's two volumes of String Theory are completely in the mostly plus convention.

Btw, you might wanna change the title of this post to "West Coast Metric Considered Harmful." 🙂

13. **Magnema**
June 5, 2015

Personally, I prefer the -+++ convention. However, I do see the following advantage in the +— convention: obviously, when it makes squared spacial intervals negative, it makes squared time intervals positive. Practically speaking, the only paths one cares (that I've seen in my studies of classical GR) are the geodesics of particles, which are timelike curves, thus why would would prefer timelike curves to have positive length.

14. **Peter Woit**
June 6, 2015

John,
I agree that the question of the convention for Clifford algebras is a much more interesting one. I've used both, when I first was teaching representation theory I used the negative one, see
http://www.math.columbia.edu/~woit/notes17.pdf
for pretty much the same reason you mention (that Clifford algebras are generalizations of C, or H, where the generators have square -1). More recently I changed to the positive convention, I forget exactly why. Bourbaki does use the positive convention, and this is the kind of thing they usually put a lot of thought into.

I do think it's not just a matter of taste that if you want to work over the reals with an algebra that is isomorphic to an algebra of real matrices, you should use real matrices, and not introduce an "i" into your calculations (e.g. when thinking about Majorana fermions using a Clifford algebra isomorphic to M(4,R)). It is a very interesting question though whether the right Clifford algebra to think about for Minkowski space is M(4, R) or M(2,H) (which is equivalent to the question of which sign to use), they are two different real Clifford algebras (and as Alex points out, the Pin groups are different). My understanding of Schwinger's argument was that he had a "Euclidean principle", that what you see in Minkowski space is only things that analytically continue from Euclidean space, and this explains why you don't see Majorana fermions (a real spinor representation). I don't know if his argument would change if he was using the opposite convention and the Clifford algebra was M(2,H).

15. **Robert Delbourgo**
June 6, 2015

I guess the metric you choose depends on how you were brought up, which then gets ingrained in your brain. I was brought up as a particle person so use the +— choice. It really does not matter all that much although I do appreciate Peter's arguments for the other choice.

16. **John Fredsted**
June 6, 2015

To mind comes the following passage from the monograph *Clifford Algebras and Spinors*, by Pertti Lounesto:

> Physicists might want to observe that the Clifford algebras Cl(3,1) = Mat(4,R) and Cl(1,3) = Mat(2,H) are not isomorphic as associative algebras, even though both of them have the same complexification M(4,C) …

17. **Ralph**
June 6, 2015

Much as I'm tempted to agree with you, the only really convincing point there is Weinberg.

18. **Mike Duff**
June 6, 2015

Type IIB supergravity is an example of a "bi-coastal" theory: its equations of motion are the same in either east or west conventions. This is because it exhibits a metric reversal symmetry g_ab goes to minus g_ab.

June 6, 2015

I think, the dividing line runs typically between high energy physicists and general relativists. In QFT one usually likes to have timelike orbits of particles to have positive length, while in GR one likes to have the spatial metric to be positive.

20. **Anon**
June 6, 2015

Well, on the "west coast" (mostly minus) side, I'd like to note that even the venerable Wald switches to (+,-,-,-) when discussing spinors in curved spacetime (see the discussion under equation 13.1.18).

21. **Theo Nieuwenhuizen**
June 6, 2015

Einstein was thinking physically rather than mathematically. His Lagrangian has a positive kinetic term with a plus in front (west coast convention, being on the east coast). It is indeed annoying that the physical choice is connected with mathematical inconvenience. But "imaginary time" is indeed imaginary, it has nothing whatsoever to do with physics, even though Penrose may discover "physics" in this mathematical game. So the right choice depends on what you are. Physicists should go to the west coast, other can do what they want. (PS I started out on the east, but realized the betray.)

22. **tt**
June 6, 2015

imaginary time is used in stat mech.
http://en.wikipedia.org/wiki/Imaginary_time

Radioactive,
Don't worry, I'll soon move on from technical pedantry and get back to blogging about less childish topics like theories of everything, the multiverse, etc….

25. **vmarko**
June 6, 2015

I've also never heard of the West/East coast terminology, and I think most people in Europe haven't either. There was always just a particle-physicist signature (+,-,-,-) and the gravity-physicist signature (-,+,+,+).

I was also first educated in the particle-signature fashion, but after started doing research (on GR and QG), I switched to gravity-signature, and never ever looked back. It's much more convenient, for all the reasons Peter mentioned, and then some (raising and lowering indices, discussing spatial hypersurfaces and the Cauchy problem, working with Kaluca-Klein scenarios, canonical quantization, Dirac's analysis of constrained systems, etc).

As for books, note also that the "GR-phonebook" (Misner, Thorne, Wheeler) uses the (-,+,+,+) signature throughout.

As for the energy, I don't quite understand what is the problem — energy can be (and should be chosen to be) positive in either metric, AFAIK. The overall sign of the action is what fixes the sign of energy, and this can be chosen independently of the metric signature. One chooses the ground state to be of minimum potential energy, i.e. the action to have a maximum, which is done by multiplying any given action with -1 if needed. This has nothing to do with the choice of the metric.

26. **Peter Woit**
June 6, 2015

Anon,
Thanks for pointing that out. Looking into it, it seems that Wald is doing this to try and follow Penrose, who I hadn't realized is in the West Coast camp, despite being a relativist. It's striking to see multiple instances of writers changing convention in the middle of a book, something that normally one would very much try hard to avoid. I suspect it is partly because the sign issues get very tricky when dealing with spinors, so authors decide it's just too hard to figure out how to change from one to the other.

27. **Kartik Prabhu**
June 6, 2015

Peter,
* The link to Figueroa-O'Farrill's notes is broken. You need a www. instead of ww. in the URL.
* I think the choice of mostly minus or mostly plus metric when not dealing with spinors, is largely an issue of convenience, nothing to do with positivity of energy or action terms.
* For spinors, the relevant issue is the relative sign choice in the metric and the definition of the Clifford algebra. Different relative signs would give inequivalent spinor representations as already pointed out. I don't know of a good physical argument for choosing one over the other, unless physics some how only cares about the representation of the complexified group in which case either convention is fine.
* As for Wald's switch in metric signature. That is done to use the 2-spinor notation where one wants to identify an abstract index "a" on the tangent space to a pair of spinor indices "AA′". In particular, one wants the metric \eta_ab -> \epsilon_AB \epsilon_A′B′ instead of with a minus sign where \epsilon is a real symplectic 2×2 matrix. Though I am sure this again has to do with a choice of sign for the defining equation of the Clifford algebra.
* But overall as pointed out in the notes by Figueroa-O'Farrill "There is no difference between 3+1 and 1+3—there never is at the level of Spin group" so maybe this point is moot!?

original post

28. **Peter Woit**
June 6, 2015

Kartik,
Thanks, fixed the link.

Ignoring spinors, for standard flat space calculations, clearly you can use either convention if you want to. I still think though that working with a negative definite metric (for space or analytically continued space-time) is always going to be at best confusing, if not worse, and that's what the West Coast convention makes you do. The issue about analytic continuation in QFT seems to me a real one, there's far too little clear discussion of the issue (non-perturbatively), and maybe none in the West Coast convention.

I would have thought you could do two component spinor notation with either convention, and a bit of googling shows that it has been done. See
http://www.niu.edu/spmartin/spinors/
and
http://www.niu.edu/spmartin/TASI11/
for details. These papers evidently include a tex file where you can change a single variable, and get the paper in either convention (I'll add this info to the posting).

Yes, for the spin groups, doesn't matter. The physical significance of the two different Clifford algebras and different Pin groups is still obscure to me.

To say that "physics doesn't depend on the real structure, just the complexification" I'd interpret as a claim that the physical picture for the physics of spinor fields in different real structures is related by analytic continuation. This may or may not be true, it's exactly what I'd like to understand better, but have been finding very little in the literature that addresses this.

29. **Kartik Prabhu**

June 6, 2015

Peter,

Being from a GR background, I agree that it is very convenient to work in the mostly plus signature and being in Chicago I'll skip the East/West dichotomy! 🙂

* I am not sure what significance one should attach to "Wick rotation" or analytic continuation procedures emplyed in textbook QFT. Firstly, those work only in analytic and static/stationary spacetimes, which again from a GR perspective is highly restrictive.

* Yes, one can do 2-component spinor notation in either signature if one wants to carry around the "sigma matrices". Penrose's notation gets rid of the sigma matrices entirely (See: Spinors and Spacetime Vol1 — Penrose & Rindler) and one can write equations like g_ab = \epsilon_AB \epsilon_A′B′ which works only in the mostly minus signature. If using a mostly plus signature this would have a minus sign which is very inconvenient. So this notation by Penrose sacrifices the goodness of the mostly plus metric for the goodness of skipping sigma matrices entirely, which is also the convention Wald uses. I have also seen Bob Geroch use this notation in his lectures. In the http://www.niu.edu/spmartin/spinors/ link that you cite this corresponds to their Eq.2.48 which does have a sign change when changing the metric signature.

* I still don't understand the physical significance (if any) of pinors. As far as I have seen, physics theories only use spinors and the Spin group in which case this sign choice is irrelevant.

* Again, I am pretty skeptical of the importance of analytic continuation to physics in general.

original post

30. **Peter Woit**
June 6, 2015

Kartik,
Thanks for the comments on the two-component formalism.

About analytic continuation, I realize this doesn't work in arbitrary backgrounds, but I do think it's a deep issue in QFT. As far as I've ever been able to tell, there really is no such thing as a rigorous, non-perturbative formulation of QFT that does not use the analytic continuation. Even in the simplest considerations of the free field propagator, you have to add some extra piece of information (how do you integrate through the poles) that is very nicely expressed by the analytic continuation requirement.

Anyway, analytic continuation issues are somewhat of a different topic, but the point here is just that they seem to not have been sorted out for spinors, with the general assumption being one of "only depends on complexification", in the sense of assuming the analytic continuation can be done. Your comment led me to take a look at Penrose (at least to the extent of picking up "Road to Reality"), and I was intrigued to learn that he does use the West Coast metric, but that he also clearly thinks of the question in terms of complexified Minkowski space and analytic continuation. Quite possibly the right way to think about these questions is in terms of twistors.

31. **Kartik Prabhu**
June 6, 2015

* I also think that twistors are in some sense capturing the some part of this issue. I would highly recommend both volumes of Spinors and Spacetime — Penrose & Rindler. They present the formalism in a very clear style.

* Another related annoyance wrt complex vs real forms of groups is that we physicists do not distinguish these in Yang-Mills theory. I have had the hardest time finding a good reference on the issues of group structure, complex vs real forms, Cartan subalgebras… as it relates to Yang-Mills theories.

32. **John Baez**
June 6, 2015

Kartik wrote: "I still don't understand the physical significance (if any) of pinors."

One place they can be important is when you've got a theory where spacetime is non-orientable. Then you need to know how your "spinors" transform under orientation-reversing symmetries – so what you really need is pinors, which are a representation of a double cover of O(p,q) rather than merely SO(p,q).

Here I will not enter into the fact that O(p,q) has up to 8 different double covers! After choosing a sign convention for your Clifford algebras, the Clifford algebra will contain a group Pin(p,q) which is a specific double cover of O(p,q). We can hope that nature will be kind enough to use this one.

I saw Cécile DeWitt-Morette give a talk about this stuff. Once she and her husband Bryce DeWitt both did computations for a free fermion field on a nonorientable spacetime. They got physically different answers! And it turned out the reason was that one was using a pinor representation of Pin(1,n), while the other was using a pinor representation of Pin(n,1).

They wrote a paper about this.

33. **Kartik Prabhu**
June 6, 2015

John,

Thanks for pointing that out and for the link to the DeWitts' paper. I was completely ignoring orientability issues.

In this case, wouldn't one want the universal cover of O(p,q) rather than merely a double cover? If I am remembering correctly for d > 3 the Spin(p,q) group is also the universal cover of the oriented part of SO(p.q). For instance in d=3, I thought the universal cover gave rise to representations like anyons.

original post

34. **Marc Nardmann**
June 6, 2015

More information related to John Baez's remark about double covers of O(p,q) can be found in the following two articles:

1.) Trautman, Andrzej: Double covers of pseudo-orthogonal groups. Clifford analysis and its applications, NATO Science Series 25 (2001), 377-388.

(http://link.springer.com/chapter/10.1007%2F978-94-010-0862-4_32)

For p,q>0, eight inequivalent double covers of O(p,q) are constructed in that article; see §7.2. Trautman says there are precisely 16 inequivalent double covers of O(3,1), but he does not construct explicitly the other 8.

2.) Trautman, Andrzej: On eight kinds of spinors. Acta Physica Polonica B 36 (2005), 121-130. (go to http://www.actaphys.uj.edu.pl/_cur/pl/acta_physica_polonica_b, then browse)

This article ends with the following conclusion: "Physicists have been wise to restrict their attention to the groups Pin(1,3) and Pin(3,1) as these are the only double covers of [the full Lorentz group] that admit faithful irreducible spinorial representations and allow the construction of real invariants and covariant currents."

35. **Lowell**

37. **Tony Smith**
June 7, 2015

John Baez said in his week156 web page (17 Sep 2000):
"… any self-dual irreducible unitary group representation H must admit an antiunitary intertwiner J: H → H with either J^2 = 1 or J^2 = -1.
In the first case H comes from a real representation;
in the second case it comes from a quaternionic representation
…
in Volume 1 of Weinberg's "Quantum Field Theory" …
the CPT operator on the Hilbert space of a spin-j representation of the Poincare group is an antiunitary operator with (CPT)^2 = -1^(2j).
So indeed we do have (CPT)^2 = 1 in the bosonic case, making these representations real,
and (CPT)^2 = -1 in the fermionic case, making these representations quaternionic. …".

Kartik wrote:

> In this case, wouldn't one want the universal cover of O(p,q) rather than merely a double cover?

You're right that we need to carefully think about all these issues rather than merely grabbing a double cover and using that. But part of the problem is that the concept of "universal cover" applies to *connected* Lie groups, and O(p,q) typically has 4 connected components. So, for example, O(3,1) has 4 connected components that contain the elements 1, P, T, and PT respectively. If we restrict attention to the connected component containing the identity, its fundamental group is Z/2 so its universal cover is its double cover, isomorphic to SL(2,C). But things get more complicated when we consider all of O(3,1). It has *different* double covers. All of them become isomorphic when we restrict them to obtain covers of the connected component containing the identity. That is, all restrict to give universal covers of this connected component! I think what's happening is that they are different central extensions of SL(2,C) by the group {1,P,T,PT} = Z/2 × Z/2.

You're right that O(2,1) is very different: here the fundamental group of the connected component containing the identity is Z, not Z/2, so we get anyons.

Here is a discussion at mathoverflow about the related issue of the convention used in defining Clifford algebras. Note that I don't claim to understand the first (and meta) answer there…

42. **Justin**
June 8, 2015

Love this blog post. Do not worry about the detractors. I do feel that this blog is not quite as good as it could be because it focuses way too much on multiverse nonsense. I'd like to see more postings about trying to understand quantum field theory better, and this post is right on target.

43. **Geoff**
June 8, 2015

I have only skimmed the comments so I apologize if I'm repeating something already mentioned more succinctly above. I was under the impression that the most obvious reason for using the mostly plus convention was that at some point one is forced to do violence to General Relativity and cast it into Hamiltonian form thru the ADM decomposition. Although Ted Jacobsen has been voicing valid reasons for not quantizing the metric, it seems that the vast majority of successful quantization schemes have passed thru the Hamiltonian formulation.

A wonderful resource that I've just come across that doesn't appear to be on the ArXiv is an article about spinors by Geroch in the Springer Handbook of Spacetime where he uses the mostly minus convention. I've heard a lecture in which he expressed bewilderment that spinors which were originally used to describe electrons make the proof the Positive Energy Theorem in GR substantially easier. And if every tensor and tensor operation has a counterpart in the spinor formulation, it certainly seems worth learning. It does seem from my quite limited viewpoint that something profound is happening when spinors show up in such an unexpected manner.

Professor Baez – I had always skimmed the descriptions of non-orientable spacetimes as it seemed that they lead to violations in causality. Are there non-orientable spacetimes which preserve a global causal structure or are they merely interesting from a theoretical standpoint?

Professor Lowell Brown – I've quite enjoyed having your textbook as welcome addition to my shelf and was hoping you'd get around to someday writing the second half of the book.

I have always been fascinated by stochastic quantization as it too seems entirely unexpected. For those who know, can you point me in the direction of a reference that might explain its physical relevance or is it simply a trick which also involves complexification?

Does anyone happen to know if Schwinger changed conventions when he left Harvard for UCLA?

Thanks in advance for help anyone can provide.

44. **Lowell Brown**
June 9, 2015

Nope, Schwinger stayed East Coast when he moved to the West Coast.

45. **John Baez**
June 9, 2015

I wrote:

> I think what's happening is that they are different central extensions of SL(2,C) by the group {1,P,T,PT} = Z/2 × Z/2.

Sorry, on second thought that doesn't sound right: even in O(3,1) the transformations T and P don't lie in the center, only 1 and PT are. So, I think we should delete the word "central" here.

46. **Peter Woit**
June 9, 2015

Justin,
Don't worry, I'm quite good at ignoring detractors who I don't think have a case. And I do know when a topic is substantive, attracts an intelligent discussion, and I learn something, will do my best to try to make that happen more often. Sorry about the next posting….

47. **cedric bardot**

> …most physicists don't appreciate the mathematical concept of "real structure"

Well, may be one will have to wait for the experimental discovery of a fundamental Majorana neutrino to expect better awareness about clifford algebras, pin groups and real structures (cf I. Todorov arxiv.org/abs/1106.3197)
On the theoretical side people like A. Connes *et al* and John .W. Barrett may have already paved the way to improve our geometric understanding of the standard model in order to orientate us in the possibly already nontrivial dimensional structure of zeptospace (arxiv.org/abs/hep-th/0608226 and arxiv.org/abs/hep-th/0608221).

48. **nicola**
June 11, 2015

The many-minus convention is far better because the mass-shell constraint has the clear form p^2=m^2 (while in the other you get the awkward minus sign). Moreover the Dirac equation in the many-plus convention would get an additional factor of i – either in front of m or in front of Dirac matrices – which is even more awkward.

That Weinberg uses many-plus convention – well, Landau uses the other one.

Wick rotation is just some other mathematical operation used in calculations. There is no deep Physics behind it. To choose a convention in Physics because Wick rotation looks nice, is beyond me.

Backwards-compatibility is the only reasonable argument. If it weren't for the mass-shell constraint and the Dirac equation it would probably convince me. On the other hand the creator of Python language considers backwards-compatibility as misguided since newer ideas/solutions are better then the older ones and so why constraining yourself with the wrong conventions/habits invented before? Many new languages invented are not backwards-compatible anymore.

49. **Peter Woit**
June 11, 2015

nicola,
1. I don't really see why p^2=-m^2 is a problem.
2. I don't see any i's in the Dirac equation in East coast convention, either in Weinberg (equation 1.1.19), or my current notes (section 45.1, that chapter is a mess now, but I think the signs, factors of i are correct).
3. I don't think Wick rotation is just "some other mathematical operation". QFTs really only are well-defined in imaginary time, it's a fundamental fact about them.

50. **Adam Helfer**
June 11, 2015

As a relativist, I'd like to make some points in favor of the mostly-minus convention. Of course, one really can use either convention — one just has to include minus signs or factors of i in different places. And for certain specific applications (e.g. the ADM formalism or some QFT arguments) it may be technically easier to use the mostly-plus convention. But as a matter of principle — of trying to make the mathematics match most directly the physical foundations — in relativity, I think the mostly-minus convention is to be preferred.

The reason is that proper intervals between timelike-separated events are directly measurable: you just let a clock run along the trajectory whose proper time you want. On the other hand, spacelike proper intervals are by definition acausal concepts. They cannot be measured directly, and working them indirectly tends to be involved.

To some degree, of course, one can measure space-like intervals by means of "rigid rulers," but notice that this is not at all a simple thing: the rulers really serve to define a coordinate system and what one reads off from them are coordinate differences, not invariant intervals. Alternatively, one can infer spacelike separations from systems of timelike measurements. (Note that such measurements are needed to calibrate the system of rigid rulers anyway.)

Also the idealizations involved — and the question of how to correct for deviations from them for real measurements — are much more severe for rulers and space-like measurements than they are for clocks and time-like ones. A clock simply has to be small enough and stable enough that its mechanism is not significantly affected by curvature over its run-time. On the other hand, if one wants to extract physics from a ruler extending over a large enough region that space-time curvature is significant, in general one needs to solve the coupled system of the ruler's internal dynamics and gravity (and one cannot really treat the ruler as rigid).

(As an example, note that GPS works primarily by making time-measurements. Some reference to rulers — Earth-based reference frames — is needed, but the main measurements are temporal. Also interferometers like LIGO essentially measure time-signals, as they compare phase differences for light of a fixed frequency along different space-time paths; the spatial separations are inferred.)

It is true that the mostly-plus convention seems to be the friendlier, less radical departure from Euclidean space. But really the lesson of relativity is that three-space is, except in restricted circumstances, a rather indirect concept of limited physical significance. (I hasten to add that in many circumstances, especially when relativity is not important, it certainly is useful!) However, the everyday concept which most directly generalizes to relativity is not space but time. So my feeling is that the friendliness of the mostly-plus convention is meretricious (as far as the foundations of relativity go), and we get a deeper sense of the geometry of space-time by embracing the perspective implicit in the mostly-minus one.

51. **Adam Helfer**
June 12, 2015

I recently sorted out the relation between the two-spinors of Penrose and Rindler and the usual QFT gamma-matrix/four-spinor formalism. The Penrose and Rindler formalism is entirely self-consistent and does not use gamma-matrices, although they do give a conversion in the notes. However, this conversion does not mesh with the usual QFT conventions; it is better to use another one.

For explicit formulas, see the appendix of http://arxiv.org/abs/1408.2729.

52. **nicola**
June 12, 2015

Peter,

1. If p^2=-m^2 does not look awkward to you then fine. It looks awkward however to many other people.

2. Weinberg's equation 1.1.19 is missing a factor of "-i" next too kinetic term(compared to other textbooks). That factor was incorporated into the definition in 1.1.20 so that the metric in 1.1.21 is as you prefer. However standard textbooks like Landau, Bjorken-Drell or Itzykson-Zuber, leave the -i factor next to the derivative and so the Dirac operator is
D= -i\gamma^{\mu}\partial_{\mu} + m (see e.g. eqn 2-9 in I-Z)
while in Weinberg it is
D= \gamma^{\mu}\partial_{\mu} + m
because the gammas are redefined.

3. Come on Peter, it's just a mathematical trick from complex analysis. That no-one so far has found a better way of defining QFT, well it's still just a trick.

Moreover the Wick rotation plays a role only in QFT. It doesn't play a role in QM or classical theory. Unlike the p^2=-m^2 which appears everywhere where particle dynamics is considered. To me it looks awkward as well as the Dirac equation (without the -i factor).

53. **Peter Woit**
June 12, 2015

nicola,
Changing the space-time signature changes the definition of the gammas. As I tried to point out, one virtue of the conventions I advocate is that you can choose the gammas real. As for the Dirac equation, I think you've just provided another argument for my conventions: Weinberg's Dirac equation with no gammas is simpler than one where you have to use i (and allows you to describe Majorana fields more simply).

Sorry, but I don't think analytic continuation in QFT is just a "trick". I'd claim it's a fundamental insight into the nature of time (and the existence of anti-particles). Yes, you only need this in relativistic quantum field theory, but that's the fundamental theory.

54. **Thomas Larsson**
June 13, 2015

Am I the only one who thinks that the topic of this post qualifies as Not Even Wrong? Much more so than string theory, which by any reasonable metric is just wrong.

Sign conventions are like interpretations of QM – if no experiment can tell them apart, they are all equally right or wrong. But of course it is a bad idea to use several conventions in the same calculation, as the people who claimed to have found a muon anomaly 15 years ago did.

55. **nicola**
June 13, 2015

Peter,

Arguments that you find in favor of many+ convention I find actually against it. Well, I guess that's why we call it a convention.

Many people would prefer to leave that -i factor because together with the derivative it gives the momentum operator and so the Dirac operator admits a very nice form D=gamma p + m. Using Weinberg's approach we have D=i gamma p +m with an unnecessary factor of i only because you want p^2=-m^2.

By the way, another argument in favor of many- convention is the form of the action of the point particle. In many-, the Lagrangian is a square-root of (4-velocity)^2, something manifestly positive. In many+ you have a square-root of -(4-velocity)^2, with an awkward minus.

56. **David**
June 15, 2015

Just as a curiosity,

there is a famous writer of hard science fiction (the one which relies heavily on the science) called Greg Egan. He is a mathematician and is famous because his writings are the hardest science fiction ever.

In a trilogy of books (Orthogonal) he esspeculates with a universe with a Riemmanian metric instead of the Lorentzian of our universe. This creates very strange things, such as in that universe the speed of light varies with the frequency and that the "twin paradox" is upside down (time goes by faster with the twin that remains at home), among many many other things. I have not read the book, this is what I have discovered investigating about it.

This a detailed discussion in Egan's web page, in case you are interested http://gregegan.customer.netspace.net.au/ORTHOGONAL/ORTHOGONAL.html#CC

57. **Jack Morava**
June 21, 2015

I'm sorry to come late to this topic, but I learned only recently
of (IMHO profound) joint work of Graeme Segal and Maxim Kontsevich
on Wick rotation, discussed in a talk

https://www.youtube.com/watch?v=vTvXHL6ZJik

by GS at a birthday conference for MK last June. The key technical
point occurs around 25:00 in the video; in particular it seems
to me to provide convincing evidence that the East Coast convention
is NATURAL in the technical sense of the term.

58. **Peter Woit**
June 21, 2015

Jack,
Thanks a lot. I agree that Segal's work on Wick rotation (which as far as I know he has lectured about, but not really written up), is the deepest thinking about the question around. As you note, for what he's saying to make sense, you need the East Coast metric (he actually very quickly but explicitly says that having 3 minus signs won't work: another way of saying that analytically continuing three directions of space instead of one of time is a bad idea).

59. **Alma**
June 25, 2015

Hi Peter and thanks for a great article!
I'm having an argument with a friend over what Zee did and I'm hoping you can clarify it. Did Zee complexify the SO(3,1) in the book such that his statement is correct contextually, or is the excerpt you are showing simply wrong mathematically and not deducible from the introduction? Thank you very much!

60. **Peter Woit**
June 25, 2015

Alma,
What Zee says would be correct if you complexify the two Lie algebras: what is true is that the complexified Lie algebra of SO(3,1) is the same as the complexified Lie algebra of the product of two copies of SU(2). This is not true for real Lie algebras, which is what the notation he is using refers to (if you ignore the fact that he's using the notation for Lie groups to refer to Lie algebras…) My point was just that for him and Schwartz (and a lot of physicists), there is no difference between a real Lie algebra and its complexification.

The complexification of su(2) is sl(2, C), and of so(3,1) is so(4,C). So, what the "mathematically sophisticated" would really say is
so(4,C)=sl(2,C) + sl(2,C)
When you complexify a real Lie algebra so(p,q), you get something that doesn't depend on the signature (so(q+p,C)), since once you have complexified you can just appropriately put in factors of i to make your inner product the standard one.

A Crisis at the (Western) Edge of Physics

June 9, 2015
Categories: Multiverse Mania

The New York Times had an op-ed piece this weekend by Adam Frank and Marcelo Gleiser, entitled A Crisis at the Edge of Physics. They make some of the usual criticisms of string theory and the multiverse, ending with

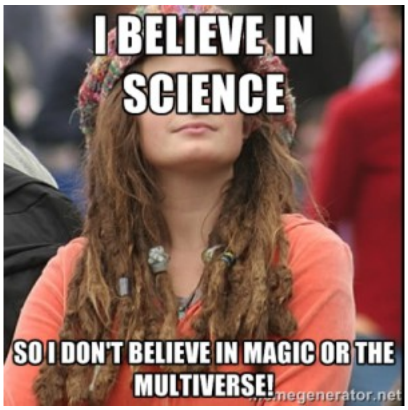
> Are superstrings and the multiverse, painstakingly theorized by hundreds of brilliant scientists, anything more than modern-day epicycles?

I mostly agree, although I don't think they make clear what the real problem is, that these theories predict nothing and explain nothing. In contrast, epicycles were a quite useful, well tested model that was highly predictive and approximately correct. If we had modern day epicycles, that would be a huge advance…

Last Friday in his concluding talk at a Nordita conference on particle physics and cosmology, Michael Turner gave his take on the multiverse:

> Most important discovery since Copernicus?
> Is it science? (not testable)
> Many true believers (left coast) and not enough doubters.

He makes clear his opinion on these questions with this graphic:



and I think this expresses well the majority opinion of the physics community. A major question here is whether the problem of pseudo-scientific multiverse mania is one of the "edge" of physics (the "left edge", as Turner notices and was discussed here), or whether it has infected the center. Some days I'm quite discouraged to see how widespread this is, other days it seems to me that we may finally be getting over this. There's only so long you can get media attention for your empty but easy to understand new "Copernican revolution" before people lose interest and move on to something else. Perhaps we're getting to that point. I think this was the first year that the World Science Festival here in New York didn't have a program promoting the multiverse, and maybe that's a sign of change.

For quite a few years now, there have been few scientific talks trying to use a multiverse to do calculations at serious string theory conferences (see for instance this week's String Pheno 2015, or Strings 2015 later this month), with the multiverse mainly appearing in promotional talks to the public. Maybe the public is finally getting bored and starting to adopt the point of view that Turner's graphic suggests (and that I think the physics community should get behind).

Update: Physics Today has an opinion piece entitled Could the evolution of theoretical physics harm public trust in science? This addresses an issue I don't think some theorists realize the seriousness of. If you start arguing that conventional notions of testability don't matter, this can be a very dangerous thing to do in an environment where public trust in science is an issue. Put differently, if physicists publicly promote the pursuit of speculative ideas in an ideological framework that can never be falsified, they create a real danger of a public perception that science is just one more ideology.

Comments

1. **Jeff M**
   June 9, 2015

   Honestly, epicycles were not "predictive" in any meaningful way. They were just a fancy geometric way of building a table of planetary positions based on past positions. The geometry was there simply because it was clear there had to be some geometric explanation for the positions. But they made no predictions, in the sense that if someone found a new plant, epicycles would tell you nothing about where it should be. Of course, if you want you can consider epicycles to be the correct theory of the solar system, since it's just a change of coordinates.

2. **gadfly**
   June 9, 2015

   I would say homeopathy is worse than multiverse mania, but at least the placebo effect and therapeutic "consultations" actually help people.

3. **Eric Habegger**
   June 9, 2015

   Seriously, is it really necessary to characterize the multiverse mania as a West Coast phenomena? I seem to recall that there is a prominent faculty member at Columbia who has written many books that popularized the whole multiverse idea. The idea of one coast being the fount of misinformation does a disservice to all interested parties and also promotes a "new" source of prejudice that will cause problems down the line. I'm from the West Coast and I've never entertained the multiverse as anything serious.

4. **Peter Woit**
   June 9, 2015

Eric,
Good point about Columbia. There's also someone at MIT… Still though, I think there's a statistically significant effect, was interested to see that Turner shares that perception.

5. **Jeff M**
June 9, 2015

Oh, and BTW, there's a previously unprintable word missing between "I" and "believe" in that great sign 🙂

6. **Jan Galkowski**
June 9, 2015

@Jeff M: "Epicycles". Half in jest, presumably the AIC (or its variants, including Watanabe's WAIC) would penalize the epicycles in comparison to an ellipse for the extra parameters required. An interesting question is whether or not the ellipse would lose in favor of epicycles because of poor observational accuracy, assuming those observational errors were not, at the time, well understood or estimated.

K. P. Burnham, D. R. Anderson, *Model Section and Multimodel Inference*, 2nd edition, Springer, 2002.

S. Konishi, G. Kitagawa, *Information Criteria and Statistical Modeling*, Springer, 2008.

7. **David Roberts**
June 9, 2015

Aren't epicycles really just a Fourier expansion of the apparent motion in the earth's frame of reference? The issue is then a poor choice of coordinates making life hard 🙂

8. **Bee**
June 10, 2015

I'm not sure that this push towards phenomenology is useful at all, and I say that as someone who normally preaches the value of phenomenology. Look, on the one hand there's people who couldn't care less whether their theories are testable at all. That's bad of course. But on the other hand (should I say other coast?) are people who cook up models just because they can be tested with the next experiment, and I can't see there's more value in that. Lisa Randall's talk (at the same conference) was an explicit example for that. That's searching under the lamp post. Does any one really believe a model becomes more plausible because it can soon be testable? No. So why do they do it? Because it will get published and when it doesn't get found one twiddles some parameters and moves the "phenomenology" to next decade's experiments. That's equally sick if you ask me.

9. **chris**
June 10, 2015

Those of you who think epicycles were not predictive should read Keplers Astronomia nova and look at how he got to the Ellipse shape. Peter Woit is spot on with his analysis.

Oh, and I don't believe in science. I wonder who does. I simply accept proven statements about nature as being true. Pictures as the one above are a real disservice to science, putting it on the same footing as religion.

10. **Dom**
June 10, 2015

The word "believe" is natural to use but highly problematic, when challenged I once said I believed in facts and evidence, this was dismissed by the other person as simply "another belief system" as if the alternatives were all equally valid.

11. **Peter**
June 10, 2015

@JeffM
Epicycles are essentially a Fourier expansion.

12. **Peter Woit**
June 10, 2015

Bee,
At least in particle theory, my impression is that the hiring prejudice in favor of phenomenology is now changing, as departments decide that the LHC is not going to provide a lot of new physics. The pressure on "string theorists" to produce something "testable" has now been there for a long time, being met by claims that AdS/CFT is going to solve non-HEP problems. Unclear to me where this is going…

13. **Peter Erwin**
June 10, 2015

Of course the Ptolemaic model was predictive — that was one of its main features, and one of the reasons it stayed popular for centuries: you could use it to predict the future positions of the planets. The idea that a model of the heavens should not just provide a handwaving, semi-metaphorical picture of what was going on, but should make numerical predictions for future observations, was a key achievement.

These weren't terribly *accurate* predictions, and for a long time people weren't very concerned with their inaccuracy. And, of course, the model failed to *explain* a lot of things, and failed to predict things that the Copernican model did (e.g., the phases of Venus).

(It may be worth remembering that Copernicus's heliocentric model *also* had epicycles — indeed, there was one variant that had secondary epicycles attached to the primary epicycles.)

The problem in thinking about Ptolemaic (and Copernican) epicycles as "Fourier expansions" and the like is that they were constrained to have uniform circular motion. If you allow the epicycles to be *elliptical*, with non-uniform motion, then, yes, you can think of them as approximations to actual planetary motion.

14. **al**
June 10, 2015

Copernic's book was published with a preface by Andreas Osiander who took pains to tell everybody that actually heliocentrism si just another way of 'saving appearances.' It was presented as a mathematical hypothesis, a way of doing calculations, not as physics. But in medieval universities two courses were taught: one with the Aristotelian-physical model which was deemed 'true' but known to be descriptively inexact; the other 'untrue' but exact (by the way Ptolemy had the 'equant' (punctum equans) , a point inside an orbit where non uniform movement appeared as uniform).

15. **phil fogle**
June 10, 2015

As a member of the 'public', I constantly see evidence of the undermining of the principle of falsifiability, and HEP seems to be playing a major role.

Almost all my friends have heard about the Higgs field; not one has any idea of its significance. Their minds are full of black holes, holograms and multiverses that they believe are proven facts.

@Gadfly
…actually, I see homeopathy (sorry for being OT) as extremely insideous, as it hijacks the placebo function. Medics should be honest about placebos.

16. **Brian**
June 10, 2015

Funny thing is about the update section, I thought thats what the fuss was about. Science is useful because it allows us to make predictions and test them. It lets us either discover how the world works or at least create a narrative that works, but either way its consistent, rigorous, objective, and sometimes has practical applications. I'm not arguing against religion, superstitions, or odd beliefs, if thats physiologically helpful to you thats all fine, so long as we have an objective way of knowing how the world works that we can use to acquire knowledge free from the subjective views and interests of others. Thats why I found it so unsettling, about a year or two ago when I read a popular science article by someone related to the field. they where saying that it was time to move on to "post empirical science " (what ever that is). Another talking about getting rid of Popper's falsification, the bottom line is the creation of a "science" that does not depend on experiment or verification. It is troubling to hear the words you would expect from a new age woo mister or some incomprehensible post-modernist professor coming from scientists or philosophers of science.

Now to me that seems like giving up what science is in order to save a few careers. The whole argument depends on a lack of imagination, "string theory is right because there is no other game in town" (dubious). I have to ask what makes string theory the only game in town other than it looks fancy and some scientists/mathematicians like it? If science is simply a series of narratives that work, made more plausible by experiments, than any narrative would do in string theories place, since no experiment can be done to confirm it. Even fantastic ones like how the Greeks used to use mythological figures to explain the way the world worked, after all they have the same amount of experimental evidence. In the history of science these mythologies became unsustainable do to the scientific revolution, we could do experiments to come up with better stories, scientific theories. As far as the public is concerned, this is where the power of science comes from, the fact that it explains how the world works and can be demonstrated. Scientists would shot themselves in the foot by arguing that testability needs to go because its not their pet theory that benefits, its the snake oil salesman.

anyway, I say its better to have no theory and science than have a theory and no science.

17. **al**
June 11, 2015

'Postempirical science' is an attempt to shift the burden of proof. Standard science was and still is positivistic: if you make claims you have to point to some evidence. Positivism did not admit any ontological 'known unknowns'. Postempiricists try to argue that you should give them credit as long as they have not been proved wrong. There is an evident shifting of power here as outsiders cannot beat experts at their game.
(actually it was mathematicians in the 19 c. who first claimed the right to consider whatever they pleased as long as it was not obviously self-contradictory; physicists had to point to some external support, but 'mathematical' or 'theoretical' physics tended to erase the distinction)

18. **Nobody**
June 11, 2015

@Peter

"Epicycles are essentially a Fourier expansion."

I think I originated that idea on the Compuserve SciMath forum about 20 years ago and I also believe that it is not true.

But I'm not that smart, so maybe you or someone else can show me how you can get a Keplerian ellipse from a harmonic series of constant speed circles.

19. **Peter Woit**
June 11, 2015

Enough about epicycles please. One problem is that I really know nothing much about them, so can't do a proper moderator's job (e.g. delete misinformation…).

20. **Nathalie**
June 11, 2015

Dear Bee,

You are being unfair to Lisa Randall.
As the great Wolfgang Pauli used to say, when you don't have a theory (as is currently the case for beyond the standard model) you should make "simple" models that can be tested and thus may provide some insight. And that is what Lisa Randall is doing.

Esoteric movements, by not being testable, tend to lead nowhere.

Once you have a theory which starts looking promising it is worth to work on polishing it, in order to understand better its structure.

21. **John Baez**
June 12, 2015

Jeff M wrote:

> Honestly, epicycles were not "predictive" in any meaningful way.

Sure they were! It's true they couldn't predict what would happen to the Solar System if you added a new planet, but Newton's laws couldn't predict anything about chemistry and people don't complain that he didn't invent quantum mechanics.

Anyone who mocks the epicycles Ptolemy's *Almagest* probably hasn't thought about how much better it was than previous models, and how long it took for heliocentric models to exceed its predictive power. Check out Ptolemy's *Almagest*: Fact and Fiction by Richard Fitzpatrick of the physics department of U.T. Austin. Some quotes:

> The standard popular modern criticisms of Ptolemy's model of the solar system are as follows. First, it is generally thought that Ptolemy's thinking was shackled by accepted truths in ancient Greek philosophy (mostly due to Aristotle), which held, amongst other things, that the Earth was stationary, and that celestial bodies were constrained to move uniformly around circular orbits. Second, it is supposed that these mental shackles directly lead Ptolemy to introduce the concept of an epicycle as a sort of kludge to explain the observed retrograde motion of the superior planets without having to admit that this phenomenon was caused by the Earth's motion. Third, it is generally held that Ptolemy's model of the solar system was not particularly accurate, leading later Arabic and medieval European astronomers to add more and more epicycles in order to get better agreement with observations. The final version of the model is alleged to have contained an absurd number of epicycles, and to have essentially collapsed under its own weight, leaving the field clear for Copernicus and his, supposedly, much simpler, and much more accurate, heliocentric model of the solar system.
>
> Needless to say, the popular criticisms of the Almagest that I have just outlined are almost entirely wrong. What I want to do in this talk is to describe what Ptolemy actually did in the Almagest, and to contrast this with the mistaken popular view of what he did.

and:

> The *Almagest* model of the geocentric solar orbit is surprisingly accurate. It can predict the position of the Sun, relative to the stars, to an accuracy of about 1 arc minute. That is, about 1/60 th of a degree.

22. **Kevin Henderson**
June 22, 2015

The general public in America favors ideologies of all sorts. In particular, the majority are in favor of things which scientists either believe or know to be magic (i.e., false). It is unfavorable, economically, at least, at this time to condemn all fantastic ideas based on unrealistic physics. People like to think science fiction is closer than it is.

A View from an Ex-String Theorist

June 9, 2015
Categories: Uncategorized

Every so often I've taken a look at something about theoretical physics on Reddit, generally ending up not spending much time there. One reason was that I realize I'm already spending more of my life than is healthy arguing with people about string theory and the like, so better to avoid a new venue for that. The temptation to respond is strong when one sees someone mischaracterizing one's opinions, but I've generally been able to resist temptation at that site.

Today I happened to come across a really wonderful discussion there though, and wanted to draw attention to it, even though it's from a year ago. It's entitled A View from an Ex-String Theorist and consists of a long piece by someone who has recently left string theory, as well as some answers to questions asked by others. If you want to understand what string theory looks like these days to good theorists who are working on it, read what "No_More_Strings" has to say.

No_More_Strings explains very well the difficult job situation in the field, and the effects this has. With a lot of very smart people and almost no jobs, postdocs are in no position to take the time to try and learn something new that isn't a "hot topic", or try and work on an unpopular idea that might take years to go anywhere. This is a huge part of the story of why this field is in trouble, and the situation seems to have just gotten worse since I wrote about it in my book over 10 years ago.

The suggestion that "string theorists" should stop calling what they do "string theory" is an excellent one. No_More_Strings explains how smart people in the field are not working on string unification, but have moved on to different things with little relation to quantized strings. Giving up the name would be a good first step to allowing people to think of what they are doing in a less narrow way. If you didn't have to start every grant application by explaining that you're motivated by "our best hope for a theory of everything", you might find it easier to work on something quite different, with no relation at all to quantized strings.

I can't quite resist correcting a couple things mentioning me. No, I don't think string theorists are stupid. No, I don't think that Witten "singlehandedly destroyed the study of "real" physics" (the last one isn't the fault of No_More_Strings).

Comments

1. **Amirpouyan**
   June 9, 2015

   If they are not stupid, then why on earth they are insisting on a program that they know (better than anyone else!) has no promising future?!,

2. **Peter Woit**
   June 9, 2015

   Amirpouyan,
   You don't seem to have read or paid any attention to the piece, which explains pretty well that what most "string theorists" are doing (at least the smart ones…) is working on a wide range of topics, of varying degrees of promise for various purposes, most of which have little to do with strings or the supposed use of strings to get a unified theory.

   And, even those who haven't given up on string unification are staying with it not out of stupidity, but out of an honest belief that it's the best idea about unification that they know of, no matter what its problems. Anyone who thinks Witten is stupid is a fool…

   June 9, 2015

   I'm sure we'll hear Lubos' long reply about this tomorrow. Thanks a lot, Peter.

4. **M**
   June 10, 2015

   Gia Dvali has an interesting new understanding of black holes as condensates of gravitons with energy 1/R. If true, this would also mean that black holes are insensitive to UV physics (Einstein general relativity is enough); so computations of black hole entropy in terms of string micro-states would just be way a misunderstanding black holes.

5. **chris**
   June 10, 2015

   I am consistently staggered by some of the insinuations that surface in rants like the one on reddit that you linked to of failed researchers (be it that they didn't land a permanent job or that their research program collapsed).

   .) Why do they always need the collective shoulder-patting of "we are the smartest"?

   .) Why do they believe that their small subfield is so very special in terms of emotional, intellectual and time commitment?

   .) Why do they believe that their particular area is starved of academic positions?

   .) Why do they think they are too "smart" for the "dumb" homework problems or laundry tasks?

   .) And finally, why do they assume that reading fiction loosely related to the theme of research qualify you for anything but a job as librarian?

   I am always reminded of the students that are "bored by classical physics" and the like and jump into quantum field theory in year 2 or so. Never saw a single one of them being successful.

   It's a simple truth that research as a career is highly risky, extremely time consuming, very competitive and very often frustrating, quite independent of the specialization. I would have thought that – especially in good institutions – you get this message very early on and consistently.

6. **Radioactive**
   June 10, 2015

   It's funny that he repeats how smart he is while complaining that all he has ever done is `laundry'. The academic system is designed to select precisely those people who are the best at `laundry' and this guy seems to have indeed been very good at it. But there are many other necessities, besides technical skill, to be a really good scientist like creativity, courage, perseverance and luck.

The canonical example being Einstein, but even the originators of string theory had to toil in obscurity for a decade or so. If you don't have the courage to just do what you're interested in because you are addicted to the praise of your supervisor, you are afraid of losing your position or god forbid, not getting hired at a Top Ten university, or you don't have any ideas that you truly believe in and can make progress on then you are lacking the tools.

It's a shame that the system doesn't allow everyone to just study whatever they want to for as long as they need to (though would that really lead to more insights or just more time for bad ideas?) but as it is this guy had found his level: good technically, not a lot of insight. I have never met a tenured professor who, if you had a really good idea would stop you from working on it, even if it slowed down your output. University is supposed to teach you technical skills that are necessary, but curiosity and creativity are going to make you a great scientist who is doing interesting things. If you don't have those, and are also unwilling to take risks, then working on obscure technical problems is probably the best place for you.

7. **Klaus**
   June 10, 2015

   Sorry, there is no reason to criticise the guy in question. Leave him alone! Yes, you have to take risks to do good research. But you also have to feed your body and later your family. The story of the young man is still happier than that of Lubos Motl, who also left string theory, and now earns his bread writing rants on his blog, for his own fan club. And probably the story is much happier than those of Seiberg or Arkani Hamed, who lure people into the field telling falsities. Everybody takes his choices in his life. Also Motl's decision is a choice. Even the IAS people luring others to join them have taken a choice. Are they happy? They have to decide.

   IMHO, we reduce the talk about human choices, but instead talk about unification, and on how to achieve it.

8. **Radioactive**
   June 10, 2015

   I am not criticizing his decision to leave physics, rather the unsaid assumption that because he is `really smart' boring technical work is beneath him. It's a shame about the job situation but doing the exciting, creative research that he seems to want to do instead of `laundry' would have landed him in exactly the same position. So he didn't have either the guts or the ability.

9. **Peter Woit**
   June 10, 2015

   chris/Radioactive,
   I think you're being too hard on "No_More_Strings". I didn't read his (seems highly likely it's a "he"….) piece as complaining at all. It provides a very accurate take on what the grad student/postdoc system is like in that particular academic field. People who choose to enter it likely have a fairly good idea what they're getting involved in when they start, and reasonably good career prospects for doing something else when they leave (and this is what will happen to almost all of them). More interesting is the significance for the field itself: is this organization of research, this particular set of incentives and pressures, a good way to encourage progress or not?

10. **Radioactive**
    June 10, 2015

    Maybe I am being too harsh but his attitude about `laundry' problems and his repeated assertions about how smart he is are galling. If you don't like it you either quit, as he wisely did, or take a risk and do something interesting. Most people (including me) don't have what it takes to succeed at the latter.

    Regarding the organization of research, have a look at http://www.nature.com/news/the-future-of-the-postdoc-1.17253 . From personal experience I have seen an institute hire half a dozen permanent staff and even more postdocs without increasing the quality of its output. The 'publish or perish' system is often maligned but what is the alternative? Don't publish but keep your job forever? The truth is that boring technical laundry is all that most people can do and the various (also maligned) metrics like citation tracking and impact factors do a reasonable job of measuring quality.

    If there is a problem it is minting too many PhDs like this guy, with technical skill but an inability to drive research themselves who are unlikely to become good scientists. The blame for that is principally on PIs and university administrators who make hiring PhDs and postdocs appealingly cheap. Progress will happen and is happening, it is just harder to distinguish from background noise and perhaps a few bright people are lost to the banking industry.

11. **Jeff M**
    June 10, 2015

    It's fascinating as a mathematician to see this discussion. Math and physics are close, but the job markets have always been very different, since math is a service department and hence universities need a lot more mathematicians. It's not that the job market doesn't suck, it does, but nowhere near as badly as in physics. If you go back to when I was in grad school (late 80s), everyone got an academic job when they got their doctorate. Most of them weren't serious research jobs of course, but you could do some research in most of them. And almost all the jobs were tenure track. It started falling off a cliff the year I got my Ph.D. (great timing on my part), but even so, most of the people I know got jobs, tenure track, just later than they would have, and not in places as good as they were hoping for. My thesis was published in a very very good journal, and when it got seen I actually got asked to apply to a top program – didn't get it, but I did have a shot. If I hadn't have been married, and settled in NYC, and if I could have moved anywhere, I might well have been able to move up to a pretty serious research program. As it is, I have tenure, I enjoy my job, I've done research, and it's been supported. From what I know this is extremely unlike physics.
    Part of the problem is pretty obviously physics should produce many fewer Ph.D.s They're just setting people up for 5 or 10 years of stressful postdocs with almost no chance of a permanent job, and very little opportunity to work on what interests them. Most of them end up doing the laundry, and eventually hating it. An alternative I guess would be not to drop the number of doctorates, but instead just let postdocs do whatever they want. Most still wouldn't get jobs, but they would enjoy what they were doing, and maybe it would drive research in interesting directions.
    One other interesting thing is I really think there is much less laundry in math. Not sure why, maybe it all got done in the 17th Century. No one wants postdocs to sit and do boring stuff for them, it wouldn't help the senior people or the junior people.

12. **Peter Woit**
    June 10, 2015

    Jeff M,
    I also found the contrasts to math quite interesting, including the comments about this and the comments from a mathematician there.
    One thing that struck me is that my experience as a grad student/post doc didn't at all involve a senior person making me work all the time on endless computations. My main memory of the time was of how difficult it was to get a senior person to take any interest at all in what I was doing. I suppose this is just evidence I wasn't doing it right: unless you're an obvious genius, the way to the small chance of a successful career there may very well be finding a senior person who needs this kind of work done, under time pressure, and get it done.
    I also don't see that happening very much in math, where the pressure on young people seems to be more to come up with something oneself, to show that one can do math research oneself at a high level. Part of what is different is the very different job situation.

I often advise young people trying to decide which field to go into that at this point they're more likely to be able to have a career doing work related to deep issues in physics in a math department than in a physics department, and this piece provides more evidence of that. The author's attitude of "I don't do proofs, I do do laundry" I don't really understand.

13. **Jeff M**
June 10, 2015

    Peter,

    You're right about the fact that for young folk in math the thing to do is to show you can do something yourself. Even your thesis. And you never know what it will be. The thing in my thesis that actually got attention was a technical lemma, not the actual result.

14. **Richard E**
June 10, 2015

    The first commenter is spot-on though – "I think the fact that you never really enjoyed learning quantum, E&M, etc was a big warning sign." This person says they didn't much enjoy most of physics, so why am I surprised that their career in physics didn't work out.

    When I am admitting people to grad school a really useful "rule of thumb" is whether the person is more excited about the *idea* of being a physicist than with physics itself — since that is a red flag.

15. **Justin**
June 10, 2015

    Woit,

    I was interested in your comments about advising students. If you're a young student about to enter graduate school with interests in mathematics and physics, and you're having a tough time picking between the two, do you have any advice on how to choose?

16. **Peter Woit**
June 10, 2015

    Justin,
    If you're interested in an academic career after a Ph.D., and find math and physics equally appealing, go to graduate school in math. You're just much more likely to have a chance at a reasonable academic job, and math is intellectually a very healthy subject. If you're interested in the experimental side of physics, that's very different than what mathematicians do. The only way to pursue that is in a physics (or maybe engineering) department. If you're not set on an academic career, but interested in getting a Ph.D and then doing something other than teaching at the college level, then there's no particular reason to necessarily favor math over physics.

17. **condensedmatter**
June 11, 2015

    Peter
    I may add that there is also condensed matter physics, which is a quite healthy subject. There are many interesting problems in theoretical and computational condensed matter physics (and in theoretical chemistry). These problems have usually straightforward connections with experiments. A PhD in these fields can be quite satisfactory for students with interest in the theory side. The job market does not seem terrible, at least in Europe, so that academic or research career is a difficult but still reasonable option.
    P.S. Peter, your blog is a fantastic source of information. I have been following it for several years but it is the first time that I post a comment.

18. **John Baez**
June 11, 2015

    Justin wrote:

    > If you're a young student about to enter graduate school with interests in mathematics and physics, and you're having a tough time picking between the two, do you have any advice on how to choose?

    You didn't ask me, but people often ask me this, so my page of advice to the young scientist includes a section "Math or Physics?"

    This is not about the job situation: it's about the big differences in research in these two fields, which may not be apparent to students who like courses in both subjects.

19. **Chris Oakley**
June 11, 2015

    John,

    I had not read your "advice …" Good stuff. I wonder where "No More Strings"'s "raw naive curiosity" went. Maybe his/her lack of much of this is why he/she decided to get out. What you say about talks is pretty apposite, and the one thing that ought to have persuaded me that I had no future in physics was that I thought 95% of seminars were a waste of time. The most common fault was simply that they assumed that you, too, had been working on a similar problem for the last 6 months. After the first slide nothing much was comprehensible, but no-one in the audience, including me would dare admit that for fear of being thought ignorant. God knows how many hours of my life (and other audience members) went down the toilet as a result. Personally, I would rather outrage the audience than bore them. At least they will remember it.

20. **Tim Campion**
June 11, 2015

    For me, one of the more sobering aspects of this reddit story comes in the comments, where reddit user Valeen discusses his move from string theory to the oil and gas industry. I think there's a big problem if the pipeline of talented young string theorists is being diverted into figuring out ways to burn _more_ of the fossil fuels in the earth.

21. **Peter Woit**
June 11, 2015

    condensed matter and John,
    Thanks for the help with advice to Justin. I should have noted that I'm woefully uninformed about the job situation in condensed matter theory, even more when it comes to Europe or other non-US areas.

Tim Campion,
You might want to keep in mind that probably a lot more ex-HEP theorists end up working in the financial industry and for the NSA or other "Homeland Security" businesses than work for energy companies…

22. **gadfly**
June 11, 2015

Doesn't the existence of the math department hinge more on the intro calculus sequence, remedial courses, differential equations and linear algebra though? Their actual research output is generally of little interest to the outside world short of what goes on in the applied math department. The abundance of math positions then would seem to be furnished by the fact that you can teach intro calculus and ponder the Goldbach conjecture without needing to find a grant to fund your lab equipment or personnel.

In other words, mathematics only possesses superior job opportunities if you are comfortable with being irrelevant; otherwise you're an applied mathematician competing for supercomputing grants like everyone else.

23. **Peter Woit**
June 11, 2015

gadfly,
Sure, the job situation in math is reasonable because of the needed teaching (if you despise the idea of teaching students math at that level, then you should try another field). Not being dependent on grant money has definite advantages. Even on the applied side of math though, while grants are important, there's nowhere near the same imbalance between the number of talented people and the number of jobs as in areas like string theory/HEP theory.

I had in mind contrasting HEP theory vs. mathematics, and was commenting on the job situation. If you instead want to debate who is more irrelevant and unconnected to the real world, it's not at all clear to me that these days mathematics can win that one…

24. **gadfly**
June 11, 2015

Haha fair enough, HEP and much of pure mathematics seem to have considerable trouble relating to the mundane.

I wonder if part of the problem with the modern HEP research paradigm is that it attracts individuals with an attachment to exotic physics/mathematics. Not that such things may not be necessary, thus far no one has formulated GR or QFT without the exotic physics/mathematics, but rather that one seems to get a lot of individuals with an emotional attachment to such things, and if there is a better way to interfere with a scientist's good judgment than to let him/her develop an emotional attachment to an idea I cannot think of it.

25. **CWJ**
June 11, 2015

Most of the students at my not-really-prestigious university who want to be string theorists are swayed by the perceived glamour of the field. It's quite clear talking to them that they are not interested in actually doing physics–they want to come up with that Next Big Idea. Not coincidentally, these are usually not very talented students either. The good students (in our population–the situation is probably different at "better" universities) are more generally interested in challenging problems no matter the subfield. They usually go on to get some sort of good job, if not in academia than at a national lab. (My latest student, who is defending today, has competitive offers from 4 labs.) My own field, nuclear physics, is one that many string theorist may sneer at, but I have steady funding, I work on problems I find interesting and satisfying, I have fun and interesting colleagues from around the world, I get to go to conferences around the world. And the Department of Energy actively encourages universities to hire in my field, as support for their experimental facilities. The competition for jobs is still tough, of course–the grass is no more greener here than elsewhere. True, it's not as glamorous as string theory or particle physics in general–but if and when we actually detect non-baryonic dark matter, or lepton nonconservation in neutrinoless double-beta decay, or many other experimental tests for beyond the standard model, you're going to need nuclear physics, and good, reliable nuclear physics, to make sense of those experiments. Maybe that's "laundry" physics, but it is still fun and satisfying.

26. **gadfly**
June 11, 2015

CWJ:
Sadly I must admit that I used to be just such a student and was quite caught up in the massive hype surrounding HEP. I think part of the problem is the publicity campaign; I was interested originally excited about more "mundane topics", especially polymer physics and biology, but when I heard individuals like Brian Greene wax lyrical about the grandeur of theoretical HEP I had a hard time justifying an interest in something as comparatively "unimportant" as protein folding or percolation. Luckily for me I accidentally stumbled back into my interests and never looked back; a pity, I think, that others are not so fortunate.

27. **Djehha**
June 11, 2015

Dear Commentators,
The picture I get from your comments is not really encouraging for someone who wishes to contribute to theoretical physics.
If theoretical physics seems to cost a lot of money and yet produce very little these days, why not just stop paying people to do research and pay them only for teaching, just as it was done in the past centuries. Good ideas will then certainly come form here and there every now and then. But, since students are supposed to write something before being awarded a degree, why not just let them investigate those ideas: if they don't find anything useful about them, they just report it and they get there degree. If they find something useful, they describe it, they get their degree, and they go on teaching with their diploma and continue working on the idea on their own without getting payed for it. This way, nobody will get payed for doing research.
Is this way of thinking too naive?
I also wonder if the same grey picture is seen elsewhere in some sub-field of other sciences.
Thank you.

28. **CWJ**
June 11, 2015

Djehha,

Why do you say theoretical physics produces very little? There is tremendous vibrancy in theoretical physics, especially if you don't make the mistake of thinking theoretical physics = HEP (or worse yet, = string theory only*). But there is wonderful work being done in nuclear physics, astrophysics, cosmology, biophysics and polymer physics, condensed matter, complex systems…and in HEP, just not only HEP. The job market is tight, but it has been tight since the 1970s or before.

*PS — I am not against string theory, I am against "string theory and nothing else."

29. **Djehha**
June 11, 2015

CWJ,

Sorry, by theoretical physics I meant fundamental physics.

30. **CWJ**
June 11, 2015

Djehha,

So, in other words, you make the mistaken equality. Okay, very well. I don't agree, but let's go with it. Are you suggesting that because "fundamental theoretical physics" is in a bit of lull, that all students of theoretical physics, including "non-fundamental" subfields of theoretical physics that are in fact quite productive shouldn't be paid either?

Also, when you say that the endeavor in "fundamental physics" (I refuse to accept the equality with theoretical physics) costs a lot of money, are you talking about just theory or experiment? As far as theory, only a tiny amount is spent on it. A few years ago the NSF budget for high-energy theory was about $1 million / year, at least for ordinary grants, with about half going to string theory. Maybe about the same from the Department of Energy. But a lot more money goes into experimental physics, and certainly a lot more goes into even other fields of theory such as condensed matter theory. So, relatively few students get supported to pursue theoretical "fundamental physics," and many more get supported to pursue other subfields of theory and even more to do experiment.* So, I think your scenario _is_ naive, or at least not really reflective of how physics is pursued and funded in the US.

*For what it's worth, even in these fields money is very tight and very competitive and I'm not arguing there are just buckets of money lying around. But anyone who thinks string theory is sucking up all the money in the room and failing to produce a final theory for that, is mistaken.

31. **Vlad**
June 11, 2015

"Are you suggesting that because "fundamental theoretical physics" is in a bit of lull, that all students of theoretical physics, including "non-fundamental" subfields of theoretical physics that are in fact quite productive shouldn't be paid either?"

No, he means fundamental theoretical physics only. I thought that was clear from his most recent comment. He's making no statements about non-fundamental theoretical physics.

32. **Peter Woit**
June 12, 2015

Djeha/CWJ,
Theory is relatively cheap compared to experimental physics (although I think the HEP theory NSF budget is more like $10-15 million/year, DOE maybe $50 million/year, compare to HEP experiment of maybe $800 million/year). Much of what this pays for is postdocs, the real problem is the small number of permanent jobs compared to the number of people going into the field. Most permanent jobs are funded not so much by grants, but by university budgets, so funded now out of tuition revenue.

Given university budgets, there's no way you're going to see a big expansion in full-time reasonably paid permanent teaching positions. In principle physics department could decide to hire more in HEP theory, less in other fields, but the trend is the opposite.

33. **CWJ**
June 12, 2015

I agree budgets have been static for a long while so no chance of big expansions. DOE likes to fund theory relevant to their experiments, which nowadays means RHIC, J-lab, and the under-construction FRIB and others. They even offer carrots in the form of "bridge funding" to encourage universities to hire faculty in a certain area. But even that amount is relatively small, and it corresponds only to a mild swelling distributed over many universities, and the competition for these few additional spots–one, maybe two new ones in a very good year–is very tough.

34. **Mesmar Djehha**
June 12, 2015

Dear CWJ, Vlad, and Peter,

I thank you very much for all your comments. Vlad had exactly my point.
Indeed, all your comments give me a more accurate picture of how physics is pursued and funded in the US.

35. **bw**
June 12, 2015

I don't think today's physics job market environment is that different from when I was a undergraduate physics major in the early 1970's with dreams of eventually making a big discovery in theoretical particle physics. (I was at MIT during the charm discovery of the J/Psi – November 1974 Revolution no less!). Fortunately or unfortunately, my travails in the required MIT undergraduate quantum mechanics course convinced me to move out of physics into electrical engineering, and then on to finance.
Over the last 40 years, I have always heard and read about the employment problems of newly graduating PhD physicists, even as I thought about what could have been, as my physics interests continued from afar.

36. **Bernd**
June 19, 2015

Djehha,

there's also a lot of fundamental physics to be explored outside of high energy physics. All sorts of collective quantum phenomena that emerge within interacting many-body systems are no less fundamental than, say, quantum gravity. Or quantum information, which is even more fundamental than physics itself! The techniques people use in these fields are often quite similar to those used in HEP, with the main difference being that there are actual experiments that you can compare your results to.

CMB@50

June 14, 2015
Categories: Multiverse Mania

Last week Princeton hosted what seems to have been a fascinating conference, celebrating the 50th anniversary of studies of the CMB. Hopefully videos and slides will be posted, but one can get some idea of the highlights of the talks from live tweeting that was going on, that is gathered together here. The third day of the conference featured a panel where sparks flew on the topics of inflation and the multiverse, including the following:

> Neil Turok: "even from the beginning, inflation looked like a kluge to me… I rapidly formed the opinion that these guys were just making it up as they went along… Today inflation is the junk food of theoretical physics… Inflation isn't radical enough – it's too much a patchwork. It all rests on rare initial conditions… Akin to solving electron stability with springs… all we have is proof of expansion, not that the driving force is inflation… "because the alternatives are bad you must believe it" isn't an option that I ascribe to, and one that is prevalent now… inflation is pretty but we should encourage young to think about its problems & be creative (not just do designer inflation)
>
> David Spergel: papers on anthropics don't teach us anything – which is why it isn't useful.. sometimes we need to surrender (to anthropics) but that time is not yet now.
>
> Slava Mukhanov: inflation is defined as exponential expansion (physics) + non-necessary metaphysics (Boltzmann brains etc)… we should separate inflation from the landscape… exponential inflation is very useful, the rest is not for scientific discussion… In most papers on initial conditions on inflation, people dig a hole, jump in, and then don't succeed in getting out… unfortunately now we have three new indistinguishable inflation models a day – who cares?
>
> Paul Steinhardt: inflation is a compelling story, it's just not clear it is right… I'd appreciate that astronomers presented results as what they are (scale invariant etc) rather than 'inflationary'… Everyone on this panel thinks multiverse is a disaster.
>
> Roger Penrose: inflation isn't falsifiable, it's falsified… BICEP did a wonderful service by bringing all the Inflation-ists out of their shell, and giving them a black eye.
>
> Marc Davis: astronomers don't care about what you guys are speculating about at all (mulitiverses, pre-big bang, etc).

I was encouraged by Steinhardt's claim that "Everyone on this panel thinks multiverse is a disaster." (although I think he wasn't including moderator Brian Greene). Perhaps as time goes on the fact that "the multiverse did it" is empty as science is becoming more and more obvious to everyone.

Comments

1. **Geoff**
   June 14, 2015

   Although I'm not particularly a fan of inflation and certainly not the multiverse, I can't help but wonder if any theory of the early universe runs into the inevitable problem of initial and/or boundary conditions. It seems that the best one can do in physics is write down a physical law, but there really doesn't seem to be a way to derive the initial / boundary conditions from first principles. Is there any consensus that they are somehow outside the purview of physics?

2. **Mesmar Djehha**
   June 15, 2015

   Geoff,

   From what I understand about the Ekpyrotic scenario, it just claims to do so: eliminate the need for initial/boundary conditions by removing any beginning for the Universe and replacing it with a cyclic history.

3. **Peter Woit**
   June 15, 2015

   Geoff,
   I think Steinhardt's argument is against claims that inflation solves fine-tuning problems (why is the universe so flat?), that all inflation models with a scalar field do is move the fine-tuning problem from one place to another.

4. **Tim Howells**
   June 15, 2015

   As a naive outsider those quotes really surprised me. It looks like something radical has happened since Leonard Susskind was claiming victory in a cafeteria food-fight over the multiverse. That was in 2005, so ten years ago. Was there a turning point, or is this the turning point? I was particularly suprised that they questioned inflation so strongly. Any pointers would be appreciated. Genuinely curious – not flame-bait!

5. **Anonymous**
   June 15, 2015

   This panel is full of (in)famous critics with various agendas. Not very representative of the field, in contrast to the observational talks which looked amazing.

6. **Peter Woit**
   June 15, 2015

   Tim Howells/Anonymous,
   The panel did over-represent critics of inflation, but I think the reason for multiverse skepticism is that string theorists were not on the panel, just cosmologists (except for the moderator, who seems to have been the only one defending the multiverse). Susskind is not a cosmologist…

7. **Douglas Natelson**
   June 15, 2015

   I'm trying to parse Penrose's remarks. Does Penrose think that the BICEP2 results have somehow falsified inflationary cosmology? I don't see how a lack of a statistically significant signal above the dust background is a strong statement one way or the other. Is there some context here that I'm missing?

8. **Student**
June 15, 2015

Peter or anyone,

Where can we watch the videos?

Are they available online?

Thanks!

9. **Peter Woit**
June 15, 2015

Student,
As far as I know, the talks were livestreamed, so in principle there is video. However, it does not seem to be available now, don't know if there are plans to make it available in the future.

Doug Natelson,
I have no idea what Penrose had in mind, perhaps someone else does.

10. **Student**
June 15, 2015

Ed Witten defends inflation:

Ed Witten: the criticisms of inflation are too a priori. Inflation is an incredibly simple theory. The beauty: it's weakly coupled. #CMBat50

Ed Witten: the same (simple, weakly coupled) cannot be said about the competing theories (to inflation) #CMBat50

Why no mention of this Peter? Perhaps you missed it?

11. **Peter Woit**
June 15, 2015

Student,
The extracts I gave were only a small fraction of the discussion, the "sparks flew" ones where people were saying something controversial. There were many other interesting comments, including Witten's, anyone interested should read the whole thing. I don't think it's surprising that Witten (who is not a cosmologist, by the way…) and many others would defend inflation, I'm much more curious whether he'd be willing to defend the multiverse…

12. **Cormac**
June 15, 2015

I think Mukhanov has a point. The word 'inflation' is used in several different ways, and much of the criticism isn't really aimed at the basic notion of an exponential-expansion in the early moments of the cosmos (a hypothesis that gives a very 'natural' and hard-to-rule-out explanation for several features of the observable universe). Most criticisms of inflation are leveled at the apparent consequences of various models of inflation, from the problem of fine-tuned initial conditions to the notion of the multiverse – but if a successful model of inflation ever emerges, these predictions may not part of it. In the meantime, there are few theories that can model current observations the way the hypothesis of an exponential expansion can…

13. **milkshaken**
June 15, 2015

As a naive outsider, I believe Penrose comments (about bringing out all hidden inflation partisans and giving them black eye) was about the premature celebrations of B-mode polarization result that soon turned out to be analysis error…

14. **chris**
June 16, 2015

"The beauty: it's weakly coupled." … speaks volumes. translation: the beauty is that we can use perturbation theory.

this is an unfortunate "search by the lamppost" bias that has influenced physics for far too long now.

15. **Andrew Tho as**
June 16, 2015

Very true, Chris.

"Ed Witten: the same (simple, weakly coupled) cannot be said about the competing theories (to inflation)"

That's no argument in favour of the existence of inflation!

Ordered from the more to less serious…

- On the geometric Langlands front, there's video posted today of this talk by Dennis Gaitsgory. Michael Harris has already commented here about the local geometric Langlands conjecture in terms of 2-categories that Gaitsgory discusses. Today's arXiv listings have a new paper on geometric Langlands by Witten, which begins with his version of a formulation relating the categorical point of view and quantum field theory.
  I wrote recently here about a talk by Jacob Lurie that alluded to an explanation of this categorical equivalence for the simplest case of G invertible complex numbers (rather than the case of G a general semi-simple Lie group that Gaitsgory and Witten are discussing). I'm still far from being enlightened concerning that simplest case, but have learned a lot from Alexander Polishchuk's Abelian varieties, theta functions and the Fourier transform which I take as treating the global versions of this equivalence.
- Witten has been busy, with yesterday's arXiv listings including a 429 page paper with Gaiotto and Moore (does anyone know of a longer hep-th paper that's not a review article?). There's also a companion shorter summary paper. The motivation here is again a categorical picture expressed in terms of quantum field theory models, but for more insight you'll need to find someone more expert than me on this topic.
- Strings 2015 will be held in Bangalore in a couple weeks. Talks titles are now available, so you can see what the hot topics in the "string theory" community are. Of Gaiotto, Moore and Witten, only Witten will be speaking. Perhaps his talk on An Overview of Worldsheet and Brane Anomalies will shed some light on the 429 page paper.
- On the Mochizuki/abc front, hopes rest on a planned workshop at Oxford this December. Fesenko has circulated a letter about the workshop, which gives suggestions about how to approach the subject.
- Via Chandan Dalawat's Google+ page I found out about this autobiographical piece by Misha Gromov. One thing it made clear to me is why I couldn't get anything out of the couple times I've heard him lecture.

  > Being trivial is our most dreaded pitfall: you say stupid things, not original things, outrageously wrong things – all will be forgotten when the dust settles down. But if you pompously call a+b=c "Theorem" in your paper, you will be forever remembered as "this a+b guy", no matter you prove bloody good theorems afterwords…
  > I was introduced to the idea on September 1st 1960 at the then Leningrad University when our analysis professor Boris Mikhailovich Makarov said to me after our first calculus class – he expressed this in somewhat metaphorical terms – that I should've kept my mouth shut unless I had something non-trivial to say.
  > Further encouraged by my teachers and fellow students, I tried to follow his advice and, apparently, have succeeded – I hear nothing disrespectful about my mouth for the last 10-20 years. Strangely, this does not make me feel a lot happier.
  > "Trivial" is relative. Anything grasped as long as two minutes ago seems trivial to a working mathematician.

  Another thought this raises is that I've just spent the last 3 years of my life writing something trivial…

- I really like Jordan Ellenberg's suggestion of Cold Topics Workshops.
- Mathematics makes it into the Guardian with an article about mathematical modeling.
- With the LHC inactive, some LHC physicists have had to spend their time studying plots (trigger warning, and NSFW).

Update: One more, far more serious than anything above. Sabine Hossenfelder brings up an important and rarely discussed topic here.

Comments

1. **M**
   June 16, 2015

   I guess that most readers live in d=4, N=0 and will stop reading at the first line "This paper is devoted to the study of massive two-dimensional theories with (2,2) supersymmetry" unless somebody explains what is the physical relevance of the next 429 pages

2. **Drew Day**
   June 16, 2015

   I understand your long-standing opposition to string theory. I genuinely appreciate your many elucidations on the validity of the subject — especially as an outsider who has no skin in the game (apart from a large part of my physics education coming from Leonard Susskind, who obviously has his now-somewhat baggy skin in).

   However: Not withstanding this sentence, it is grammatically improper to put phrase "string theory" in quotes. It's clear that you (and everyone involved) agree that string theory actually exists, that people label themselves string theorists, and that those opposed to the topic know a string theorist when they see one. So it's unnecessarily derisive to act like the phrase itself is in dispute. Even if all of these fulfilled criteria weren't true, it is **still** incorrect to put jargon in quotes.

   You seem to have plenty of ammunition to attack the content of string theory and those who practice it. So concentrate your fire where it is best applied: the content of your opponents' beliefs and not the name of their community.

3. **Peter Woit**
   June 16, 2015

   Drew Day,
   The use of quotes wasn't in any way intended as an attack on string theory or the string theory community, it was just a quick way of referring to the widely acknowledged fact (see the recent posting "A view from an ex-string theorist") that the name "string theory" is now misleading since most "string theorists" aren't working on strings (and avoiding making the tedious point that most talks at Strings 2XXX aren't about strings). The name really is extremely misleading at this point, but of course I'll keep using it until a better convention comes along. But I don't see a good argument against sometimes adding the quotes in a context where noting that it's no longer an accurate name is appropriate.

   Note added: please, interesting comments about any of the different topics of the posting are encouraged, string theory wasn't actually one of them.

4. **CU Phil**
   June 16, 2015

   Hi Peter,

On the (very serious) topic of Bee's posting, I strongly encourage everybody to read the linked lecture below. It's by a distinguished philosopher, Peter Railton, and was delivered at a meeting of the American Philosophical Association. It's a very personal recounting of many things, but most relevant here is his discussion of his personal battles with depression and the continuing stigma attached to it in academia (and outside academia). He discusses depression starting on p.12 — the section titled "A fourth transition" — but the whole lecture is worth reading.

http://leiterreports.typepad.com/files/dewey-lecture-drs-rev1.pdf

5. **Peter Woit**
June 16, 2015

CUPhil,
Thanks, but I'd rather not encourage a discussion here of the difficult topic of depression, outside of the context of the postdoc system that Sabine puts it in. And, in any case, better that people discuss the topic at her blog, since she has done an excellent job of raising the topic and addressing it.

6. **SeekingSanity**
June 17, 2015

> Being trivial is our most dreaded pitfall: you say stupid things, not original things, outrageously wrong things – all will be forgotten when the dust settles down. But if you pompously call a+b=c "Theorem" in your paper, you will be forever remembered as "this a+b guy", no matter you prove bloody good theorems afterwords…

What a disgusting attitude. I hope he was joking.

7. **Bernhard**
June 17, 2015

I have noticed that Witten has sort of a habit of writing really long "papers" that are actually books. Does anyone read them? I mean, if he wasn't Witten and would bet nobody would. However, being the most influential leader of his field, perhaps there are crazy people who take the challenge? And who judges the usefulness of this kind of paper for the field? Or maybe I'm just being completely naive, so would really like to read an informed opinion to correct my ignorance…

8. **SRV**
June 17, 2015

I agree entirely with M. Peter, is there a way you could tell us what Witten is up to in graduate terms or Susskind lecture level stuff? What is the advance? What did he accomplish this time? Thanks.

9. **jon**
June 18, 2015

Dr Woit linked the summary paper, which is beautifully written and 45 pages long. They state applications on page 2. Treat yourself, don't cheat yourself.

10. **Peter Woit**
June 18, 2015

Bernhard,
The length of the papers isn't really problematic. These are very complex topics, and if you're going to work out details, papers become very long. A shorter paper might be much worse, making it much harder for anyone interested to follow what is going on. There are a relatively small number of people I would guess following the details of many of these things. The time is long gone when just the fact that Witten was working on something brought huge numbers of people into a subject.

Another question is whether the motivation for such technical work is getting enough attention. In the case of geometric Langlands, Witten and others have over the years written up quite a bit of expository material. For this latest 429 page paper, the motivation to me is still somewhat obscure, maybe just because I haven't had time to look more carefully at the summary paper. If there is good motivation for this work, I'm sure in the future we'll see more papers explaining this motivation.

11. **jon**
June 18, 2015

Perhaps 2d N=2 LG models and knot homology as motivations somehow leave the reader cold. The 2d/4d correspondence should not.

12. **Eduardo Lira**
June 19, 2015

One of the most reputed scientists of our time writes a paper but all you have to say about it is that it's too long? Now that's as much trivial as one can get.

13. **MathPhys**
June 19, 2015

I knew that F Dolan died at a young age a number of years ago. I did not know that it was this way. The Hell with the post-doctoral system and the rest of it. It's just not worth it. The abuse that's described in commentaries on the same page is all too real. This is madness.

14. **Peter Woit**
June 19, 2015

Eduardo Lira,
You don't seem to have read the little I did say about it. I'm not of the opinion it's too long, actually wish it were slightly longer, with a bit more explanation of the motivation of the work. If I understood that better I might have more to say (or maybe not, this was a posting intentionally of short items and links).

15. **M**
June 20, 2015

Dear jon, when Einstein started avoiding quantum mechanics, when de Broglie and Heisenberg started avoided quantum field theory, when Dirac started avoided renormalization, physicists thought that they were misguided and moved on ignoring them.

Now, page 2 of the short paper starts: «Let X be a Kahler manifold, and W : X → C a holomorphic Morse function. To this data physicists associate a "Landau-Ginzburg model." It is closely related to the Fukaya-Seidel (FS) category» and concludes «Two of the motivations for the detailed construction of interfaces are the nonabelianization map of Hitchin systems that arises in theories of class S, and the application of supersymmetric gauge theory to knot homology».

Seriously: I don’t know what to think about this. Do such two-dimensional SUSY systems have relevance for physics? If yes, how? Or are they a way of avoiding physics?

16. **Bernhard**
June 20, 2015

Hi Peter,

Thanks, I got it.

Multiversal Journeys

June 17, 2015
Categories: Multiverse Mania

One of the many efforts to promote the Multiverse to the public way back when (2005-2007, some of their advertisements are here) was an organization called Multiversal Journeys. Back in 2006 they got $77,000 in funding from the Templeton Foundation (via FQXi). Since 2007 they seemed to have disappeared, with no more scheduled public events as far as I could tell.

Now they're back though, with an upcoming event defensively called Clarifying theoretical physics and cosmology misconceptions for SF Bay Area journalists. It's unclear exactly what they think the misconceptions are that such journalists need to have clarified. One of the three announced speakers (John Terning) might actually be able to do some clarification, but the other two seem more devoted to the spreading of misconceptions.

Yasunori Nomura likes to promote the idea that the landscape and the many-worlds interpretation of quantum mechanics are one and the same thing (see here and here), a claim I believe few serious physicists have ever been able to make sense of. He also claims that the multiverse can be used to make predictions about physics, and back in 2009 used the multiverse to predict that the Higgs mass would be 141 +/- 2 GeV (see here). This prediction played a central role in the film Particle Fever, which featured David Kaplan and Nima Arkani-Hamed during the period leading up to the Higgs discovery explaining how a 140 GeV Higgs would mean the multiverse was right. Will Nomura clarify for the journalists any misconceptions they might have about what scientists are supposed to do when their theory's well-publicized prediction is tested and shown to be wrong?

The other speaker is Texas Tech chemist William Poirier, who has some sort of "Many Interacting Worlds" theory, which supposedly shows that the observed behavior of particles indicates the existence of parallel universes (see here). Again, I'm curious what misconceptions about physics he plans to clarify to journalists.

Update: I see that this event will be funded by at $5750 grant from FQXi to Multiversal Journeys (Fall 2014 Mini-grant).

Comments

1. **Filux**
   June 17, 2015

   Ah, so the multiverse does make predictions and the prediction was wrong. So, the multiverse is falsifiable. Therefore, you were wrong, Peter.

2. **KJ**
   June 17, 2015

   Filux,
   You misunderstand the nature of the multiverse theory. All Nomura's failed "prediction" means is that the particular flavor of multiverse theory he was espousing in 2009 is false. It does not mean that multiverse theory itself is false. In some other version of multiverse theory, the Higgs mass takes precisely the value that was found at the LHC. In fact, since he is still promoting multiverse theory, he clearly still believes in it despite his failed prediction. And that is precisely Peter's point: Every possible outcome can be "predicted" by some flavor of multiverse theory, thus it is not falsifiable.

3. **Martin Kochanski**
   June 17, 2015

   I have been meaning to ask for some time whether your observations of multiverse mania have got you anywhere near an answer to the question "What is the multiverse for?". To offer meaningful criticism of *any* project it is first necessary to know what the project is trying to do. In this case the doers of the project often don't seem to know, or even to want to know, so it seems to be up to you.

   I dont't even find it easy to discern whether the multiverse is meant to encompass universes with all possible values for the constants of nature, or only of some of them. Or, for that matter, whether we are talking about one common set of laws of nature into which the constants are plugged (raising the question "Why?" all over again but about laws this time rather than constants), or whether there are universes for every possible set of laws as well.

   Does the multiverse contain a Newtonian universe? If not, why not?

4. **Peter Woit**
   June 18, 2015

   All,
   Just deleted a long thread of arguments about math/physics/AdS/CFT, which really had nothing to do with this.

   Martin,
   The goal is to justify failure. The multiverse did it, so the fact that string theory/susy/your favorite theory hasn't worked out despite 40 years of effort is not the fault of your favorite theory and you can keep on working on it, despite the failure of the idea.

5. **Patrick Dennis**
   June 18, 2015

   Peter, have you done a column elaborating your own take on many -worlds?

6. **Peter Woit**
   June 18, 2015

   Patrick Dennis,
   I've probably commented on this somewhere, should someday write more. I don't want to start a discussion here (it's a complex topic). In brief though, my point of view is that you can consistently talk about decohered states as different "worlds" in some contexts if you feel like it, but these are just empty words, and the people using them often do so to evade the interesting questions about QM (how does classical behavior emerge? Why certain observables? why the Born rule? etc.).

   Adding this empty "interpretation" to an empty claim of a multiverse with different laws of physics in each universe seems to me to be emptiness^2, and as far as I can tell that's what Nomura is trying to sell.

7. **Cormac**

June 19, 2015

Hi Peter, I have a different answer to the question "what is the multiverse for?".
Excuse the armchair philosophy, but my understanding is that the hypothesis of a multiverse was not originally proposed "for " anything, i.e., was not proposed as an answer to any particular puzzle. Instead, it emerged uninvited as an unattractive consequence of most models of inflation. While the hypothesis of inflation gives predictions that are nicely consistent with observation, the downside is that it has proved impossible (so far) to rule out the prospect of inflation happening at different rates in different regions of the infant universe…so the multiverse is what you might call a 'bastard' theory.
The fact that some have jumped on the idea to fit various other proposals should not cause us to lose sight of how the idea initially arose..

8. **vmarko**
June 19, 2015

Cormac,

As far as I could tell, what came from inflation was the most benign form of the multiverse — a bunch of bubbles in the ever-expanding spacetime, all of which have identical coupling constants. Such a thing doesn't even really deserve the name "multiverse", as it is a single spacetime continuum with a single set of laws of physics (and with a somewhat complicated structure), i.e. a "universe".

The first real problem started when string theory got mixed with this scenario, with its 10^500 vacuua, so that low-energy physics could in principle be different (and random) for each bubble. Although this is arguably also still just a single spacetime continuum, one could justify the name "multiverse" in some way.

The second real problem started when people started making identifications of different bubbles with different wavefunction branches in the many-worlds interpretation of QM. This is where things really got messy and the "multiverse" idea got promoted to cargo-cult levels… 🙂

9. **Paul Benoit**
June 20, 2015

By the strength of your conviction, I assume you have a solid rebuttal to the Many Interacting Worlds approach? Seems to me that if he can get the same precise predictions with a vast degree less 'work' then he's on to something. You appear to be opposed to his view but have proven yet to provide anything at odds. I don't want to believe in any form of parallel universe, it's messy, unknowable, and puts an insurmountable barrier far to close in the future for comfort.

I'm disappointed in your lack of informed reposte to any of it thus far.

10. **Peter Woit**
June 20, 2015

Paul Benoit,

Look, there are literally thousands of people out there who are convinced that they have some revolutionary new way of replacing the fundamental ideas of quantum mechanics by something they find more appealing. If one paid close attention to even a small fraction of these (such as the ones who get a press release issued and get in the media) and tried to carefully explain what was misguided about what they are claiming, that would be a full-time job. I've got better ways to spend my time, already waste far too much of it trying to argue against bad ideas being pushed by very prominent theorists, so don't feel the need to branch out into arguing against bad ideas that virtually no one takes seriously.

In this case I see no evidence at all that getting rid of wave-functions and the Schrodinger equation in favor of "Many Interacting Worlds" is any sort of improvement of the conventional theory. The claims about "same predictions with less work" are about certain specific approximations to very complex quantum systems and maybe are useful there. As far as I can tell, this idea makes simple quantum systems far more complicated and hard to analyze, so at a fundamental level, it's an idea for "(maybe) same predictions with a lot more work".

11. **Neil**
June 20, 2015

It is not any of the multiple multiverses that I object to. It is the idea that coupled with the anthropic principle, the multiverse has explanatory power.

12. **marten**
June 21, 2015

It should make no difference whether the multiverse concept is coupled with the anthropic principle or with the dinosauric principle.

13. **Andrew Thomas**
June 21, 2015

The MWI doesn't attempt to "get rid of wave-functions and the Shrodinger equation" – it is merely an interpretation. Which means it takes the results you already have, and the equations you already have, and then says "Oh, this appears to indicate the existence of an infinity of parallel universes". But, apart from that it brings nothing new, or changes any of the equations you already have, or else it would be testable.

14. **Andrew Thomas**
June 21, 2015

Paul Benoit says: "Seems to me that if he can get the same precise predictions with a vast degree less 'work' then he's on to something."

Yeah, it would be, but he can't.

15. **Andrew Thomas**
June 21, 2015

Can I point out that absolutely ANY interpretation of quantum mechanics you might want to dream up – no matter how insanely crazy – would be 100% equally valid as the MWI (as long as it fitted the results). Which is why we have so many interpretations of quantum mechanics – all on exactly the same level of validity.

16. **Nobody**
June 21, 2015

The beloved many worlds interpretation is supposed to be simpler because "infinity is simpler than 1" (no symmetry breaking). But is it? Which transfinite cardinal number are we talking about? If the 1st, why is that simpler than 1? Anyone with an IQ over 80 can learn to count starting with '1'. Can you teach him to understand transfinite cardinals?

If we have a continuous distribution of probability, the countable infinity will not do anyway. How does the continuum hypothesis fit into this "infinity is simpler than 1" justification for calling many-worlds simple.

17. **Magnema**
June 21, 2015

@Nobody: Saying "all" is far easier than saying "choose this one" – and I'm pretty sure that holds up from an information-theoretic standpoint, although I don't know too much about that myself. It's not the "1" that's the problem; it's the "that one" that is the problem.

Of course, it's not quite "all" (unless we're talking Lewis' modal realism), it's "all with XYZ properties," but it still stands that "all with XYZ properties" is simpler than "this one with XYZ properties"…

@Peter Woit: So your problem with MWI (setting aside the many people who pretend to understand quantum mechanics but don't) is not so much that it's a bad theory, or even that it shouldn't be preferred fundamentally, but rather that it'll end up being a lot more work for (at best) the same results? So, seeing as we should use collapse mechanics for all practical computations anyway, it's simply not worth studying, so to speak?

18. **Andrew Thomas**
June 21, 2015

Magnema: " It's not the "1" that's the problem; it's the "that one" that is the problem."

Essentially, this is the age-old battle against indeterminism which goes all the way back to Einstein and Bohr: "God does not play dice". Why should it be "that one?"

I suspect people will always try to fit quantum mechanics into a deterministic, classical framework. But that's purely through human bias – not through cold analysis of data. The MWI is merely another step in an attempt to remove indeterminism. I'm sure it won't be the last.

19. **Peter Woit**
June 21, 2015

Enough about MWI. I think there's now plenty of evidence for my point of view that discussion of this topic is just a complete waste of time.

20. **paddy**
June 21, 2015

At the risk of being trivial and other things, I want to note that sometime in the last week or so Jeopardy had a category/question to which I (on my couch) and the ringing-in contestant answered "multiverse". He was told he was wrong and the "right answer" was "parallel worlds". Well..some time later Alex awarded the contestant his lost points saying that the referees judged his answer to have been equally correct. Not sure if this is a good or a bad thing….tho it did amuse me 🙂

21. **tt**
June 21, 2015

just want to point out 'MWI' = many worlds interpretation,
is not exactly the same as 'MIW' = many interacting worlds

22. **Peter Woit**
June 21, 2015

tt,
Thanks, my last comment should have read "MWI or MIW".

23. **Gus Bici**
June 23, 2015

Sean Carroll compares Multiverse to Australia:
https://mobile.twitter.com/seanmcarroll/status/613043720795992066
Crikey.

Strings 2015

June 21, 2015
Categories: Strings 2XXX

Strings 2015 gets underway in Bangalore tomorrow, and so far the press coverage I've seen consists just of two articles that aren't what I'd guess string theorists would like to see:

- In The theory that may have been stringing scientists along for years Robert Matthews starts with

  > Over the next few days, the southern Indian city of Bangalore will be playing host to an exclusive group of people.
  >
  > No amount of money can buy you membership and it doesn't matter how well connected you are. But rumour has it that it helps if you have a brain the size of a planet.

  but soon moves on to

  > There's just one problem: there's not a shred of evidence to support it. And that is now leading to awkward questions about just what all these very smart people have been doing with their time and funding.

  He then goes on to discuss the recent New York Times Op-Ed, as well as a Physics Today piece

  > The American Institute of Physics has now gone further, with an editorial in Physics Today asking if the insouciance of string theorists over the issue of testability may harm public faith in science.

  Finally, there's an accurate discussion of the relation of string theory to the search for superpartners in Run 2 at the LHC

  > The real fun and games will start if the particles are not found. That is because, even after all these years, string theory is not tied down very tightly.
  >
  > As a result, theorists can tweak their equations to explain away the failure.
  >
  > Such flexibility is a classic symptom of pseudo-science, and it is what particularly irks physicists about string theory – along with the arrogance of some of its practitioners, who insist it is the only way to complete Einstein's quest.
  >
  > But there is another source of resentment, and one with which we can all sympathise: that an entire generation of brilliant minds may have been lost to an esoteric mind-game.

- The other string theory news story is at The Telegraph, a Calcutta paper, which has Physicists too can have fun. The article is about Ashoke Sen's bizarre hep-th article Riding Away from Doomsday, which was the topic of an April 1 posting here. Since then, Sen has shot down any idea that this was a hoax, and has turned it into a major research program, with a technical hep-th article and a talk scheduled for the opening session of the conference tomorrow. The article argues for the importance of computing the decay rate of the universe since it

  > is important for planning our future course of action if we are to adapt this strategy for increasing the life expectancy of the human race.

  String theory is supposed to provide this calculation, but Sen characterizes the status of that calculation with

  > it is probably fair to say that we do not yet have a definite result based on which we can plan our future course of action.

  which shows that, despite what some people say, he definitely has a sense of humor.

Given press coverage debating whether string landscape research is pseudo-science or a joke, I wonder what prominent string theorists gathered in Bangalore now think of the string theory community's decision over the last ten years to mostly go along with the idea of the string landscape as an excuse for why string theory predicts nothing. This all started about ten years ago, and it's interesting to take a look again at the panel discussion at Strings 2005, where the panelists were in favor of the landscape, but the audience not so much. The last ten years have shown conclusively that any hopes for predictive science coming out of the landscape were misguided, but will that or bad press cause anyone to re-evaluate their stand on this?

Update: Slides of the talks are appearing here. One of them is so interesting I'll devote a posting to it…

   It's just not true that "There's just one problem: there's not a shred of evidence to support it." It is a consistent unification of quantum mechanics and gravity. That in itself is evidence that it is on the right track.

3. **Dave Miller in Sacramento**
   June 21, 2015

   SPib wrote:

   > It is a consistent unification of quantum mechanics and gravity. That in itself is evidence that it is on the right track.

   But does the theory actually exist? Can you actually write down any non-trivial solutions?

You know the widely accepted claims that phi-to-the-fourth theory does not actually exist in 4D (i.e., except as the trivial free theory)? Do you have any evidence that something of the sort is not true for superstring theory?

For that matter, can you even write down the equations for the mysterious M-the0ry that supposedly is the reality behind strings?

These are not rhetorical questions: I am not as critical of string theory as Peter is. If nothing else, solely as a matter of mathematical curiosity, I would like to know the answers to these questions.

Can you answer any of them?

Dave Miller in Sacramento

4. **Peter Woit**
June 21, 2015

All,
Please resist trying to have the same tired arguments about string theory. At this point, anyone who argues that "string theory is a consistent theory" has long ago heard that the problem "what is string theory?" has not yet been solved, but decided that there's no contradiction between something not being well-defined and its being consistent.
20 years ago, this kind of thing was the problem with arguments for string theory. Things are different and much worse now, with the move to the string landscape pseudoscience/joke.

5. **Jonas**
June 22, 2015

It is an experience of life that whenever persons start talking or writing about the end of the world/universe/civilisation – like Sen is doing – it is because they are feeling their own end approaching. One should be kind and understanding to the person, and at the same time ignore the topic and arguments.

After all, previous experience can be seen to imply that the world/universe/civilisation survives the death of single humans.

But who knows; maybe the person is right this time?

6. **Visitor**
June 22, 2015

"The American Institute of Physics has now gone further, [. . .] asking if the insouciance of string theorists over the issue of testability may harm public faith in science."

Speaking strictly for myself, as a non-scientist, I can say that their concern in misplaced – slightly. My attitude towards science has not changed. My faith in scientists, however, is greatly diminished. (Although this is not solely because of string theory and multiverse mania; the last decade and a half has seen accelerated trends that, along with the growth of "science of a new type", compel me to realize that scientists are as venal and corrupt as the rest of modern society.)

7. **Dave Miller in Sacramento**
June 22, 2015

Although, Peter, maybe someday someone actually will come up with a non-trivial solution to string theory, or a set of definite equations for M-theory or whatever! And, I (and I suspect you yourself) would find that event quite interesting.

Dave

8. **Giotis**
June 22, 2015

Special attention to Gaberdiel talk.

There is a modest revolution going on for some time now regarding the underlying symmetries of String theory.

This revolution encompasses AdS/CFT and Higher Spin HS/CFT dualities.
Roughly the picture is like this:

As it is well known String theory besides its massless sector has an infinity number of massive higher spin fields. These fields are distributed in various trajectories (so called Regge trajectories) based on the relation between the mass and the spin of each field. The leading Regge trajectory is the one with the lowest mass for a given Spin. At its tensionless limits these massive fields become massless and it is generally expected that at this limit String theory will possess a huge underlying symmetry.

Now Higher Spin theories on AdS spaces pioneered by Vasiliev have an infinity number of massless Higher Spin fields too and thus posses a Higher Spin gauge Symmetry. This higher Spin gauge theory includes the spin 2 graviton and generalizes pure gravity in AdS. This basically means that the underlying space possesses a higher space time symmetry which by gauging it gives rise to the higher spin gauge theory much like gauging Poincare symmetry gives rise to pure gravity.
The general expectation is that this higher spin symmetry is a closed subsector of the bigger underlying symmetry of String theory at its Tensionless limit. The higher spin fields of Vasiliev's HS gravity theory should correspond to the higher spin fields of the leading Regge trajectory of String theory.

Now via a Higgs like phenomenon this huge symmetry of String theory is broken and Tension is introduced, as a consequence the higher spin string fields become massive.

The goal is to verify these general expectations and analyze the higher underlying symmetry of string theory using these facts.

For this you can use AdS/CFT by embedding HS/CFT dualities to Stringy AdS/CFT dualities.

Generally speaking an interacting Vasiliev's HS theory is dual to a free CFT on the boundary where the 't Hooft coupling is zero but N is large.

The conserved HS currents of the free CFT correspond to higher spin gauge fields in the bulk.

For example in AdS_4/CFT_3 Klebanov-Polyakov famously conjectured (and later verified by others) that there is a duality between a vector like CFT (and not a Matrix like in Yang Mills theories) and Vasiliev's HS theory in the AdS_4 bulk. Then you can try embedding this HS duality in String theory dualities.

The famous ABJ triality paper for AdS4/CFT3 and Gopakumar Gaberdiel work on AdS3/CFT2 are very important in that respect.

June 22, 2015

The title of Witten's talk is really something "What Every Physicist Should Know About String Theory". So we learn that every physicist should actually know string theory. That's really funny!

10. **Peter Donnelly**
June 22, 2015

I had to look up "insouciance". It means "casual indifference".

Very apt.

11. **paddy**
June 22, 2015

Sorry but todays featured article on Wikipedia is…(drum roll) …M-theory. Thus it must be defined….nicht wahr? 🙂

12. **Peter Woit**
June 22, 2015

paddy,
I notice in that very long article, no space at all is found to discuss what the problems with the idea of M-theory as the TOE are. All I see is one sentence saying that "some" criticize the idea. At least the single source given in the footnote is one I can't argue with…

13. **Jan Reimers**
June 23, 2015

Nima's slides appear to be full of SUSY optimism: here

– LHC run #2:
1 SUSY even per minute,
100 times the particle production of run 1 (because E^4 in cross section),
100 fb^-1 by 2017, which is enough to discover a <=1.8TeV gluiono ot <=1TeV stop.
– Q: Should we be worried/depressed about prospects for low-E susy after run #1?
A: Not much more worried that we should have been (were!) after LEP II.
– There is a "Why no SUSY @ LEP" slide that I cannot understand.
– Naturalness: Not problems – Opportunities (Thankfully no mention of multiverse!)
– He mentions something called "Compulsory Natural SUSY" which apparently gives better unification of the (3) coupling constants than does "Natrual SUSY".
– He is pushing for a 100TeV ring and a Higgs Factory. We need these to map out the Higgs potential.

Of course no mention of strings.

14. **Steamy Ray Vaughn**
June 23, 2015

Peter, just some information that may be of interest:

At Strings 2015 Nima Arkani-Hamed gave a talk 'Collider Physics at the LHC and Beyond' and said, about finding supersymmetry: "we should always be looking for it" 59:28, and "we could just be unlucky and miss it" [at the LHC] 59:49.

https://strings2015.icts.res.in/talkTitles.php

I take this to mean he believes there is >50% chance we'll find something at the LHC.

If I understood correctly, not finding supersymmetry at the LHC would only mean adjusting parameters by 1%.

15. **Peter Woit**
June 23, 2015

SRV
(moved your comment to more appropriate posting).

I took a look at the Arkani-Hamed talk, didn't see anywhere he said he believes better than 50% chance of SUSY at the LHC. He says the multiverse is still the best explanation around, and has nothing new about SUSY: according to "naturalness" arguments you were supposed to see it at the Tevatron or LEP. By the same arguments you could say there was still one chance in 10 that it was at higher energy, so would show up at the LHC. All he's saying is that if you don't see it at the LHC, you can keep playing the same game as for the last 20 years and say there's one chance in 100 (1% tuning) that it is at higher energy. He's spent much of his life on SUSY models, so thinks looking for SUSY is a good argument for a 100 TeV accelerator. I don't think so, instead the LHC will have provided extremely strong (99 to 1) proof that a not very good idea that didn't explain much really doesn't do what you wanted it to.

The more interesting things about the talk I thought were:
1. Despite being at a string theory conference, no mention of strings. For a 100 TeV machine he's not going to even try the "maybe we'll see strings and extra dimensions" argument that many used for the LHC.
2. The serious question for a next generation machine is about what it would tell us about the Higgs, and that was much of his talk.

16. **nicola**
June 29, 2015

Is there any way to see Witten's 2nd talk. It's not here
https://strings2015.icts.res.in/speakerProfile.php?sId=70

I didn't know that every physicist should know anything about ST so I'm curious what he meant.

Convergence

June 22, 2015
Categories: Uncategorized

Another conference that starts today is the Convergence conference at the Perimeter Institute. The concept is explained by Neil Turok here. His point of view is one I'm very much in sympathy with:

> Turok explains that the "large bandwagon" of the last 30 years has not found experimental support. The bandwagon in question is the Standard Model of particle physics established in the 1970s, which, he says, people have been elaborating ever since. "Grand unified theories, supersymmetry, string theory, M-theory, multiverse theory," he lists. "Each is not particularly radical, but is becoming ever more complex and arbitrary."
>
> To illustrate the lack of experimental support for these ideas, Turok describes how many people were hoping string theory would represent a radical development; but since string theory – as currently interpreted – leads to the multiverse, Turok describes it as the "least predictive theory ever".
>
> Indeed, experimental support has not been found for other extensions of the Standard Model either. "We have discovered the Higgs and nothing else," says Turok, "yet the vast majority of theorists had been confidently predicting WIMPS (weakly interacting massive particles) and supersymmetric particles…Theorists are walking around in a bit of a stunned silence." He adds that it could turn out to be right that all sorts of other particles are needed along with the Higgs – but that thought seems to be misguided.
>
> "My view is that this has been a kind of catastrophe – we've lost our way," he says. "What we need are ideas as simple and radical as in the start of the 20th century with quantum mechanics."
>
> So what might these ideas look like? Turok explains how observations have shown that the universe is simpler than we ever expected – in contrast to our theories, which are becoming ever more complex.

It's great to see this, very encouraging to think that a more reality-based point of view on fundamental physical theory may finally be emerging. My only criticism is that the program doesn't seem to include any mathematics or mathematicians (except perhaps in the context of history and Emmy Noether). If you have a structure you don't understand, which is unusually simple, with surprising explanatory power, you might want to ask mathematicians about it…

The schedule is here, there's a blog here.

Update: You can follow a lot of what is going on at this conference on Twitter, here. For example, I was glad to hear about this comment from Dimopoulos

> There is no difference that we know right now … between the story of divine intervention and the multiverse.

It's great to see a conference on fundamental physics where the multiverse is coming in for some appropriate skepticism.

Update: One thing to say about the multiverse, it does provide an excuse for an endless number of popular articles mulling it over. Just today, there's Caleb Scharf and George Johnson.

Comments

1. **Mesmar Djehha**
   June 22, 2015

   Dear Peter,
   I would like to know please what structure do you have in mind when you say "If you have a structure you don't understand, which is unusually simple, with surprising explanatory power, you might want to ask mathematicians about it…"
   Isn't risky to ask mathematicians about the subject because all they will want to do is first put your question into context by inventing all sorts of axioms and, hence, complicate the subject further and drive it farther away from reality without any deeper insight on the physics?
   Thank you.

2. **Andrew Thomas**
   June 22, 2015

   I am most impressed with Neil Turok. I like the fact he is in charge of such an influential institution but he doesn't "play it safe" by going along with the mainstream – which must be the temptation. He is prepared to go against the flow and take some risks.

   I also suspect he is correct – which always helps.

3. **Peter Woit**
   June 22, 2015

   Mesmar Djeha,
   You haven't talked to many mathematicians… They come in all kinds, with all kinds of interest and expertise. Some might behave as you suggest, all you have to do then is ignore them, you haven't risked much.

   I was of course oversimplifying the situation. There is already a very active area of interaction between mathematicians and physicists both interested in fundamental physics. My suggestion was just that Turok and Perimeter might want to encourage that by bringing some of it into this sort of event. You can take the attitude that you don't think mathematicians know anything that could be of use, but given how stuck physicists are, I don't think they should be so quick to convince themselves this isn't a potential route to progress.

   If you want an example of a mathematician who might play a useful role at a conference like this, one would be Graeme Segal. Recently on this blog, see
   http://www.math.columbia.edu/~woit/wordpress/?p=7773
   there was some discussion of a talk by him on Wick rotation. He's a mathematician who has thought very deeply about this, and it's not at all impossible that this could give an insight into the nature of time that physicists would not otherwise come up with. He knows a great deal about quantum field theory, and is not at all someone who is going to make things more complicated rather than less.

4. **AcademicLurker**

June 22, 2015

Peter,

If reconsidering our basic ideas is going to be necessary to move forward, to what extent do you think this will include some of the fundamentals of quantum field theory itself, as opposed to just the standard model?

5. **Radioactive**
June 22, 2015

Peter, I never understand this frequent wish you make for mathematicians to come in and sort out physics. One of the most damning criticisms of string theory (and other "Standard BSM" approaches) is the lack of experimental support and the movement towards anthropics, landscapes, multiverses and the like.

Do you think mathematicians, not well known for their solid grounding in reality, are likely to bring physics back to earth?

6. **Peter Woit**
June 22, 2015

Academic Lurker,
Yes, I think new ideas not just specifically about the Standard Model, but about the kind of quantum field theory (gauge +spinor fields) used in the SM may be needed. More specifically, ways to think about this kind of quantum field theory as constructing representations of certain infinite dim symmetry groups (or whatever the right generalization of a representation is…). In physicists language: new ways of exploiting symmetries in QFT.

Radioactive,
Anthropics, landscapes, the multiverse etc. are the kind of thing physicists come up with, not mathematicians. What mathematicians are very good at is knowing the difference between what they understand and what they don't, and not fooling themselves about it. In addition, there undeniably are some very sophisticated mathematical ideas being used in the Standard Model. While physicists are to some extent trained to know something about these, there are people who are actual experts on them, and they tend to work in math departments.

7. **Radioactive**
June 22, 2015

The historical parallels aren't exact of course (and never are) but it seems like you are waiting for the 21st century equivalents of Jacobi, Poisson and Hamilton to come and formalise existing physical theories and link them to existing mathematical structures. I would prefer the 21st century Plancks, Bohrs and Heisenbergs to bring new physical theories, rooted in experiment, to explain old and new inconsistencies. Perhaps you think the current experimental state of the art isn't leaving enough clues for prospective Planks but, in my opinion, the list of known unknowns now is at least as rich as it was in 1900.

Eventually of course the 19th century formalism turned out to be useful for the 20th century revolution and I certainly wouldn't want to claim mathematicians interested in physics are useless, but I don't think it's debatable that the real progress came from physicists and would have happened with or without the previous century's mathematical developments. Mathematicians are likely to have good ideas about the mathematics of Quantum Field Theory but progress in physics (and that is what we care about right?) is more likely to come from people who understand error bars and know the values of some fundamental constants.

8. **Peter Woit**
June 22, 2015

Radioactive,
Yes, I think the lack of clues in available data is the main reason conventional paths to progress are not working in physics. In particular I disagree that there are now known unknowns anything like what was available in 1900. At that time there was already a huge amount of spectroscopic data about the energy levels of atomic systems, and it was this data that made possible Bohr and Heisenberg's advances.

9. **Radioactive**
June 22, 2015

The combination of cosmological data (CMB, dark matter, dark energy), particle data (neutrino oscillations, old and forthcoming LHC data), theoretical questions (colour confinement, strong CP, black hole information) and null results (proton decay, horizon problem) seems as strong a list as was available at the beginning of the 20th century. I am sure at the time it looked equally impossible to discover anything useful from a hodgepodge of spectra. Perhaps I am just more optimistic than you.

10. **Tammie Lee Haynes**
June 22, 2015

Dear Dr Woit

I was astonished that you were pleased by the absurd statement made by Dr Dimopoulos. "There is no difference that we know right now … between the story of divine intervention and the multiverse."

I appreciate you wish to avoid theological discussion, but my point is more about evidence than anything else. Thus I remind you that a large number of independent witnesses have reported occurrences of Divine Intervention, in the New Testament, at Fatima in 1917, and elsewhere.

Of course, you may find the accounts of these, (or any other witnesses) to be non-credible, But of course, the accounts have been found to be credible by billions of people. And more importantly, the accounts of witnesses is direct empirical evidence, which is a lot more than your Multiverse promoting colleagues can offer.

Sincerely
Tammie Lee Haynes

11. **Peter Woit**
June 22, 2015

Tammie,
I think Dimopoulos was referring to questions of the origins of the universe or of the laws of physics, not of human experience. Sure, in terms of the latter, there's more evidence of divine intervention than of other universes with different physics.

That said, any further theological discussion is strongly discouraged…

12. **David Nataf**

June 22, 2015

"We have discovered the Higgs and nothing else," – Turok
That's incorrect, I don't know why people say that.

Dark energy has also been discovered in the past thirty years. Dark matter and massive neutrinos may have as well, depending on where you set the discovery date.

13. **Peter Woit**
June 22, 2015

David,
Turok doesn't say "We have discovered the Higgs and nothing else in the past 30 years", you're putting together two things a couple paragraphs apart, taking them out of the context of what he is saying. The "30 years" is a reference to the history of speculation about GUTs, SUSY, string theory, M-theory (40 years is actually more like it at this point). The "and nothing else" comment about the Higgs isn't associated with a date, and refers to those speculative ideas. Put differently, I don't see him saying that dark matter and dark energy are not discoveries, but that they are not ones of the sort that were predicted by GUTs, SUSY, string theory, M-theory, the multiverse (unlike nonexistent LHC SUSY WIMPs).

14. **M**
June 23, 2015

dear Radioactive, the situation is different from ≈100 years ago. Then, matter was not understood and a lot of data was accumulating. Today, only Dark Matter remains not understood, and so far we see Dark Matter only trough its gravity.
Then, mathematical physicists had grasped some aspects of classical mechanics later relevant for quantum mechanics, but Heisenberg and Schrodinger invented quantum mechanics from data, without knowing these mathematical instruments.
One similarity is maybe that 100 years ago most physicists believed in aether and tried to insist on it despite negative experimental results…

15. **Thomas Larsson**
June 23, 2015

Apart from the absense of BSM physics, one striking fact has been learnt in recent years: the Higgs mass appears to sit exactly at the border of stability. 1 GeV less and the SM vacuum would be unstable, 2 GeV more and the SM would be boringly safe in the stable region. The authors of http://arxiv.org/abs/1307.3536 calls this the principle of living dangerously. I think this may be an important hint, and in any case it is pretty much the only hint that experiments has provided.

16. **Radioactive**
June 23, 2015

M, I strongly disagree. Kelvin's famous statement "There is nothing new to be discovered in physics now. All that remains is more and more precise measurement." was made in 1900. They had a pretty good grasp of nature and the spectacular successes of Maxwell's electromagnetism, thermodynamics and the kinetic theory gave them good grounds for confidence.

I would draw parallels between the discovery of the Higgs and Einstein's Brownian motion papers. That is, difficult to detect particles, already used with great predictive success, whose existence was believed by most physicists and awaiting experimental confirmation. Or perhaps between blackbody radiation/cosmic expansion – experimental anomalies which fit awkwardly with our current theories (EM+thermodynamics/GR+QFT), whose resolution seems like a bit of a kludge Planck quantization/inflation.

Of course the analogy is not exact in every sense. The problems nowadays are certainly harder because we know more, so there are more constraints and we have picked most of the low hanging fruit already. But my point is that Kelvin had a pretty deep mathematical understanding of classical mechanics which turned out to be completely useless for making progress in clearing up the one or two 'loose ends' of 19th century physics. Moreover these loose ends (dark matter, dark energy, strong CP and the others I listed above) turned out the unravel the whole of physics.

17. **Peter Woit**
June 23, 2015

Radioactive/Andrew Thomas,
I agree with M that the situation then was the atomic scale was a huge unexplored territory, with physicists having a lot of tools at hand to learn more about it. One can have a different point of view about this, but in any case I think maybe physicists should just get over the idea that huge revolutionary progress like that of the period 1900-1925 is just around the corner. This is a stock claim at every conference like the Perimeter one, has been my entire career. One should be an optimist that progress is possible, but maybe it's a naive idea that all that is needed is a new bright young Einstein/Bohr/Heisenberg to take a fresh look at the data and get some insight from that that will change everything and throw our current theories in the trash bin.

18. **Radioactive**
June 23, 2015

Peter, huge revolutionary progress would be nice, or any progress at all. Though what we think of as progress is probably very different. I would prefer a 'Bohr atom' to an elaborate and beautiful theory linking QFT, geometric Langlands and the Monster group but which doesn't explain any of the currently known experimental anomalies. Fortunately these things often come hand in hand.

19. **Jeff M**
June 23, 2015

It's always fascinated me why anyone thinks the Fermi paradox is a paradox. Fermi especially. I mean he clearly knew that the speed of light is a barrier to civilizations finding each other? There could be 100 advanced civilizations within a 100 light year ball around us, and we would never know. It's a pity Mars wasn't just a little bigger, we might have had obvious life right next to us.

20. **Douglas J. Keenan**
June 23, 2015

@ Radioactive, 3:48 am

Regarding the quote attributed to Lord Kelvin, the attribution is disputed, and the earliest known claim for the quote is dated 1988, at least according to Wikipedia:
https://en.wikiquote.org/wiki/William_Thomson#Disputed

21. **Mol**
June 23, 2015

Radioactive, besides Kelvin's famous remark about the future of physics, many theoretical physicists were well aware that something was not quite right about classical physics. Lorentz and Poincaré, for example, were hard at work trying to reconcile the dynamics of the then recently discovered electron to the microscopic Maxwell-Lorentz electrodynamics, long before Einstein's 1905 paper on special relativity. (Give a read on Poincaré's "Sur la Dynamique du Electron" on the Internet that you will see how close he came to discover relativity.) Or the Balmer formula, known since 1885 but that would have to wait for 28 years to be derived by Bohr! J. J. Thomson tried to invent a lot of classical models in order to describe the Hydrogen atom using only classical physics and his beloved electron.

By the way, Einstein's hypothesis of the light quanta and his relativistic energy-momentum relations would be established experimentally only in 1923 with the Compton effect. Even Bohr expressed doubts about the reality of photons before that. So if something like photons or E=mc^2 took almost a decade in order to be proved experimentally, it seems reasonable that SUSY and related ideas should take even a longer period.

About the usefulness of pure mathematicians in guessing new laws, I am inclined to agree with Peter. Remember that pure mathematicians like Gauss, Riemann, Ricci and Levi-Civita created the mathematical structures that Einstein would use later to realize his ideas on gravitation and discover GR. Indeed, I read somewhere that both Einstein and Marcel Grossman studied Levi-Civita's "Absolute Calculus" carefully around 1910.

22. **Don**
June 24, 2015

"What we need are ideas as simple and radical as in the start of the 20th century with quantum mechanics."

I wonder if this is a fair statement. There were completely unexpected empirical discoveries that preceded the "simple and radical" ideas, no? Discreetness was forced on Planck by the data and by the complete lack of fit with classical theory. It's well known he didn't like this "radical" revision of physics, and even resisted when Einstein took his 's ideas further.

Then, when the next steps were taken, again based on new data coming from atomic spectroscopy and the very early particle physics, the people that came up with the "simple and radical ideas", Heisenberg et al suffered much resistance from the determinists like Einstein and Schrödinger, that continues today with all the debates about "interpretations" of quantum mechanics.

What really new radical discoveries have their been? The expansion of the Universe and the accelerated expansion come to mind. But most things after the 1920s generally fit the frameworks that emerged by that point.

Maybe if physics turned to other phenomenon it doesn't currently include in its scope, similar progress could be made. For example: how is living matter different from nonliving matter? What the heck is mind and consciousness? In spite of the tons of smoke and obscurity surrounding these topics, they are "low hanging fruit" for a radical revision of our understanding of the universe. These phenomenon are part of our experience of the physical universe, but right now they are completely outside the bounds of physics.

Thanks for allowing me to express my views.

Best wishes,

Don

23. **Aleksandar Mikovic**
June 24, 2015

It is clear that we need a more predictive theory than string theory. As far as the quantization of gravity is concerned, there are already simpler theories which achieve this, for example, spin-foam and spin-cube models, and these models do not need supersymmetry in order to construct a finite quantum gravity theory. As far as the explanation of the elementary particle spectrum, I believe that one must find a generalization of the concept of symmetry, which means to generalize groups and supergroups. Such generalizations already exist, for example, quantum groups and categorical generalization of groups, called 2-groups, and the goal is to see whether these structures suffice or we need something new. This will also require to make an appropriate generalization of the space-time structure (i.e. to generalize a smooth-manifold).

24. **gadfly**
June 24, 2015

I definitely agree with Don, although as a biophysics student I'm a bit biased.

The fact of the matter is that many regimes of nature stubbornly resist an organized theoretical description. The magnitude of the problem is highlighted by how little we need to move away from typical physics to find systems where textbook physics becomes surprisingly impotent; just look at the semi-classical mess that is a membrane protein to find something which, while technically a physics problem, demands numerous novel methods to study.

More importantly information theory is slowly becoming a more generally accepted framework for thinking about and tackling hard problems. In many regards the problems with protein dynamics are problems of dimensionality reduction; what is the most minimalistic way to describe the entire problem? Working on a variety of problems could spur developments in information theory which could have kickbacks for more traditional challenges (although I'm an outsider so I don't know how deeply related information theory is to fundamental physics, although the observer/reality relationship and cutting edge concepts like the black hole information paradox suggest that it could be).

June 25, 2015

I came across this talk of Feynman (argument from authority!) with his ideas about exactly these issues – mathematics in physics and how to make discoveries.

https://www.youtube.com/watch?v=obCjODeoLVw

26. **gadfly**
June 25, 2015

He makes some interesting points; in particular, I think that the most optimistic take on the relationship between mathematicians and physicists is that mathematicians are typically useful after the fact. I can think of only one major exception and it's an outlier: general relativity. Otherwise the process of pioneering physics is only encumbered by attentiveness to axioms and extreme rigor. Once you've figured out the rules organizing and packaging them as the mathematicians like to do becomes more imperative.

27. **Peter Woit**
June 25, 2015

gadfly/Radioactive,
Actually I thought it was kind of embarrassing to watch Feynman pontificate about something he clearly knows nothing about. The idea that what mathematicians do all day is engage in extremely rigorous discussion of axioms, in very general cases, with no interest in special cases, no idea of the "meaning" of what they are doing, is about the same as the idea that physicists all spend their time wearing white lab coats and standing in front of a bench with a piece of experimental apparatus on it.

28. **gadfly**
June 25, 2015

I wonder if you are reacting to some of the idiosyncrasies of Feynman's communication. For instance I don't think he was saying that something like a ring has no meaning, but was actually referring to levels of abstraction.

To him I would guess the equation x + 5 = 7 has no "meaning" until it is specified that x represents the number of dollars one must add to 5 to get 7, even though the equation still means something in the abstract sense.

It's probably not too productive to argue about what Feynman thought but I suspect it is unlikely he was unaware of the fact that mathematicians work on specific cases considering he worked with people like Kac on occasion as well as more mathematically oriented physicists. At any rate Peter is it not true that a substantial amount of modern mathematics research remains interested in theory building from axioms and high levels of rigor? If we take it for granted that he conflated these individuals with all mathematicians, we can still discuss whether or not this mathematical subculture is relevant to physics I think.

29. **Peter Woit**
June 25, 2015

gadfly,
Like physics, mathematics is a huge activity with a wide range of people doing a wide range of things, with many of those things having various relations to physics. I don't see the point of debating stupid caricatures of what mathematics is, what mathematicians do, and what the relations to physics are, even if they're coming out of the mouth of Feynman.

30. **Radioactive**
June 26, 2015

One of the reasons I posted the video was Feynman's assertion that physicists have to care about 'blocks of copper and glass'. One of my problems with SUSY, strings or multiverses is the failure of the community to abandon or drastically modify these theories in the face of failed predictions or failure to make predictions. Peter, your desire for more mathematicians in physics seems to run opposite to this. There are a great deal of different types of mathematicians but they are as a group, it's fair to say, not concerned with blocks of copper and glass and not likely to care very much if something beautiful, like string theory, has no connection to reality. And this has been your lament about physics for the last 10 years.

31. **Peter Woit**
June 26, 2015

Radioactive,
Unlike a lot of people, my criticism of string theory has never been that too much attention is paid to mathematical beauty and not enough to experimental results, and I think the physics community is making a big mistake if they decide that is the lesson of the string theory fiasco. The current explanation for how string theory works, the landscape, is something of unparalleled ugliness, which only a physicist, not a mathematician, would find appealing.

The underlying problem is the fact that there are very few hints from experiment about how to do better than the Standard Model. It just is not true that there are lots of such hints and they are not being paid attention to. It has been clear now for a long time, long before the LHC results, that string theory unification predicts nothing. The problem is a failure to acknowledge that the internal problems of the theory are deadly, instead creating a bogus pseudo-scientific connection to experiment (the landscape).

What mathematicians are expert at is understanding exactly what the properties of a mathematical framework are, what works and what doesn't. They have a strong culture of abandoning ideas that don't work. Working in a situation where you don't have experimental clues, but have to rely on the coherence of the ideas and models you're studying is exactly what they are experts at, and I think this could be helpful. I don't see the argument that they're going to do worse than the "physical" path that has brought us to the multiverse.

32. **Anonyrat**
June 26, 2015

Contra @Mol, I thought that Einstein's hypothesis of the light quanta was established by Robert Millikan's 1914 experiment on the photoelectric effect.

33. **David Derbes**
June 27, 2015

@Douglas J. Keenan,

I have before me Robert L. Weber's delightful anthology *A Random Walk in Science*, copyright 1973. On page 191, is a selection entitled "Clouds, 1900" from Lord Kelvin: "The beauty and clearness of the dynamical theory, which asserts heat and light to be modes of motion, is at present obscured by two clouds.
I. The first involves the question, How could the earth move through an elastic solid, such as essentially is the luminiferous ether?
II. The second is the Maxwell-Boltzmann doctrine regarding the equipartition of energy."
The citation is "Slightly condensed from *Philosophical Magazine* (6) **2** 1 (1901)." The editor adds: "Kelvin could certainly recognize the important clouds. One needed relativity, the other quantum theory, to blow it away."

Anomalies Revisited

June 22, 2015
Categories: Uncategorized

Some of the talks at Strings 2015 have now appeared online, and one of them I found quite fascinating, Witten's Anomalies Revisited. Some of his motivation comes from string perturbation theory and M-theory, but the questions he addresses are fundamental, deep questions about quantum field theory (and not just any quantum field theory, but exactly the sort of qft that appears in the SM, spinors chirally-coupled to gauge-fields/metrics).

The fundamental issue is that these are theories where the path integral does not determine the phase of the partition function. Part of story here is the well-known story of anomalies, perturbative and global. One interesting point Witten makes is that vanishing of these anomalies is not sufficient to be able to consistently choose the phase of the partition function, and he gives a conjecture for a necessary condition that is stronger than anomaly cancellation.

The standard story of QFT textbooks is that once a Lagrangian is chosen, the corresponding QFT is well-defined. But quantization really is a lot more subtle than that, and the anomaly phenomenon is just one indication of the problem. In earlier parts of my career I spent a lot of time thinking about anomalies; the connections to some of the deepest mathematics around (K-theory, index theory and much more) are truly remarkable. In recent years I've been thinking about other things, but Witten's talk is a strong encouragement to go back and revisit the anomaly story (some of his best work has "revisited" in the title…)

In particular, Witten emphasizes a particular case I'd never paid much attention to: the 3d massless Majorana fermion. One would think that this is among the simplest quantum field theories around, but Witten explains how this is an example of a theory with a potential inconsistency (no way to consistently choose the sign of the partition function), even when the anomaly vanishes. This theory also appears in a hot topic in condensed matter physics, the theory of topological superconductors. One reference Witten gives to related work is to this recent paper (there's a typo in his reference, should be 1406.7329 not 1407.7329).

Witten ends with:

> I hope I have at least succeeded today in giving an overview of the tools that are needed to study the subtle fermion integrals that frequently arise in string/M-theory. A detailed analysis of a specific problem would really require a different lecture. Write-ups of some of the problems I've mentioned – and some similar ones – will appear soon.

I look forward to those write-ups, with the theories he's talking about of a lot more interest than just their role in string/M-theory calculations.

Comments

1. **Dave Miller in Sacramento**
   June 23, 2015

   Peter,

   From time to time, I have seen claims that the anomaly problem amounts to nothing more than the breaking of conformal invariance by renormalization. Can you tell me if this is true, false, part of the story, or not even wrong?

   And, what is the simplest (but correct) exposition of the issues that you can recommend (i.e., for someone who took QFT a *long* time ago)?

   Thanks.

   Dave

2. **Peter Woit**
   June 23, 2015

   Dave,
   That's just a small part of the story. More generally, the anomaly refers to a subtlety in quantization: a symmetry of the classical theory does not work in the expected way in the quantum theory. You already see this in the phenomenon of the one-half energy of the ground state in the harmonic oscillator. You can get rid of this by redefining the Hamiltonian, but that changes how the symmetries of the classical system are implemented in the quantum system. For a finite number of degrees of freedom, you can work with either Hamiltonian, but in QFT, with an infinite number of degrees of freedom, you don't have a finite shift and this causes the anomaly.

   Put differently, the anomaly is due to the fact that normal-ordering is needed in QFT, and this sometimes changes how classical symmetries appear after quantization. Maybe the simplest example is the U(1) global chiral symmetry in the theory of 1+1 d fermions. I wrote something about the general phenomenon in the book I'm writing which is online, would like to add a section working out the 1+1 d fermion story, but that may end up on the list of things I have to drop for lack of time/space.

3. **Chris Austin**
   June 23, 2015

   Witten argues that a partition function or functional integral can sometimes have an undefined phase factor exp(i \alpha), where \alpha is a constant. But in quantum field theory, we always in practice calculate a ratio such as Z[J]/Z[0], where J are some sources or background fields. This is necessary in order to cancel the vacuum bubble diagrams, (or equivalently, if the interactions are turned on and off adiabatically, as in the Gell-Mann – Low derivation of the Feynman diagram expansion, it is necessary in order to get a stable limit as the adiabatic switching is removed).

   Witten's constant phase factor will always cancel between the numerator and denominator of Z[J]/Z[0] if the manifolds and gauge fields in the numerator and denominator are topologically equivalent, so does it really matter? From pages 83 and 84, he is concerned about consistency of his phase factor between different manifolds. Does this mean it is now possible to have topologically distinct manifolds or gauge fields in the numerator and denominator?

   This seems to raise the issue of when one should or should not sum over some topologies in Z[0], which Witten doesn't address. We have to sum over Yang-Mills instantons, so do we also have to sum over all compactification topologies in the M-theory Z[0]?

   Witten must presumably know that the condition he proposes on page 89 is satisfied for D = 11 Majorana gravitinos, gravitons, and 3-forms on all 12-manifolds Y, (so that the condition doesn't say that M-theory is inconsistent), but I can't find anywhere in the talk where he says so. (Nor in Freed and Moore, which Witten cites on page 124.)

   Since spinors are involved, should it be all *spin* D + 1-manifolds, at least in the sense that w_2 vanishes? Page 101 seems to suggest yes. On page 144, Witten invokes RP^4, which is Pin^+ in the sense that w_2 vanishes although w_1 doesn't, (according to pages 45 to 46 of Milnor and Stasheff). What about D + 1-manifolds that are

Pin^-, in the sense that w_2 + w_1^2 vanishes, although w_2 doesn't, for example RP^2, RP^6, RP^10? What about D + 1-manifolds for which w_1 vanishes but w_2 doesn't, for example RP^5, RP^9?

4. **Tim Nguyen**
   June 24, 2015

   Peter,

   "You can get rid of this by redefining the Hamiltonian, but that changes how the symmetries of the classical system are implemented in the quantum system."

   I don't immediately understand what this means. Could you please elaborate? My impression is that you meant something involving Poisson brackets (classical) or commutators (quantum), both of which annihilate constants.

5. **Peter Woit**
   June 24, 2015

   Tim,
   It"s an intricate story, but here's quite a lot of detail about this in
   http://www.math.columbia.edu/~woit/QM/qmbook.pdf

   One basic point is that, even classically, if you have a symplectic action of a Lie group G on a phases space, there's an ambiguity of a constant in how you define the moment map, and that's an origin of the problem. In some sense what you have is a central extension of G that is acting, and it may be non-trivial.

6. **Anon**
   June 24, 2015

   Chris,

   The phase doesn't cancel for all physically relevant operators in the QFT. The typical example is the energy-momentum tensor in classically conformally invariant theories. In this case the overall phase factor comes from the definition of the path integral measure, which no matter how you cut it introduces an unavoidable extra dependence on the metric (besides the explicit occurrence of the metric in the Lagrangian), which may then cause the trace of the EM-tensor (which is the generator of conformal transformations) to be nonzero in the quantum theory.

7. **Alex**
   June 24, 2015

   Anon,
   I'm confused by your comment. The example you gave seems to indicate that the phase factor depends on the metric, hence is not a constant. In the example in Witten's lecture the partition function can be determined up to an undetermined phase factor exp(i\alpha) where \alpha is a constant. Please explain.

8. **Anon**
   June 25, 2015

   Alex,

   In the case I'm most familiar with (two-dimensional conformal theories) the coefficient alpha is a real number that can be expressed as an integral over the manifold of a density depending on the metric (something like alpha = ∫sqrt(g) R, where R is the curvature and the integral is over the whole manifold). This is a constant for fixed background, but can vary if you vary the background metric (which is what you do to determine the EM-tensor, and contributes something nontrivial even to the EM-tensor on a fixed flat background).

9. **Sakura-chan**
   June 28, 2015

   Off-topic to this thread but not to the blog…

   http://www.nist.gov/itl/csd/random-number-generation.cfm

   Looks like NIST has formally removed the Dual_EC_DRBG from its recommended methods for generating pseudorandom numbers.

Summer Break

June 29, 2015
Categories: Uncategorized

Heading out soon for summer vacation travels, this time to Ireland and France, back in about two weeks. While away comments will be shut off.

My vacation will spare readers commentary on the rest of the Strings 2015 talks, which at some point will appear here. It seems that the conference included the usual publicity campaign for string theory, with Ashoke Sen continuing to demonstrate a sense of humor by telling the press that

> In string theory, we are essentially following in the same steps

as the 50 year story of the Higgs mechanism, the Standard Model and the discovery of the Higgs particle. It does put modern HEP research in perspective once one realizes that its greatest success (the Standard Model) and greatest failure (string theory unification) are essentially the same…

Comments

1. **Mesmar Djehha**
   June 29, 2015

   This is a nice but incomplete future prediction for the field.
   50 years will then also be the lapse of time before string theory predictions could be tested, but what would be the lapse of time before the appearance of those predictions?

   Happy vacations Peter.

2. **Peter Woit**
   June 29, 2015

   Mesmar Djeha,
   I think part of Sen's joke is that since the Higgs mechanism was 1964 and the vindicating discovery was 48 years later (2012), taking the birth of string theory as the Veneziano model in 1968, we're on track for experimental vindication of string theory next year…

My Summer Vacation

July 15, 2015
Categories: Uncategorized

When I was young, I recall that a standard assignment when restarting school was an essay on "what I did on my summer vacation". Now that I'm back in the office after a vacation, here's a version of that, covering the physics/math aspects:

- In Paris I visited the Palais de la Découverte, the science museum in the heart of the city. This was the site of some of my earliest memories of getting interested in science, back in the late 1960s. I started out by visiting the physics section, some of which looked like it hadn't changed much since those days. One addition was a video screen with some seating nearby. It was running Particle Fever, and surely someone trying to annoy me had timed things so that I got there just as the part promoting SUSY finished, and the part featuring Nima Arkani-Hamed promoting the multiverse got underway.

  Besides revisiting my youth, this made me wonder what the effect of trying to impress the young with glitzy pseudo-science will turn out to be. Will it turn off youngsters looking for something intellectually serious? What would my 12 year old self have made of this?

  I soon made my way though to a big LHC exhibit, which cheered me up immediately. This was quite well-done, giving a good idea of what a machine like the LHC really is and what the scientists working there are doing. I quite enjoyed the last part of the exhibit, a recreation of typical grimy offices at CERN that people work in. I'd like to think that I'd have appreciated that, with its unspoken message that these are people who care not about appearances but just about the fascinating work they are doing.

- Now that scientific bookstores are gone in New York, checking out the ones in Paris is a high-priority when visiting there. This time I bought a few books in French, one of which was a new biography of Grothendieck, by Georges Bringuier. I've read widely among the many sources emphasizing Grothendieck's mathematics, this is one that instead focuses on his life, including quite a bit about the years after he left the IHES in 1969. This is an amazing story, and there's much in the book that I didn't know, especially about Grothendieck's mystical views.

  The last years of his life he was a hermit, just about completely isolated and perhaps paranoid, but still supposedly writing (the biography explains his view that one shouldn't read mathematics, but write it). Perhaps someday we'll find out what he was writing about, for some information about this, see here. While in the earlier part of his career Grothendieck wanted nothing to do with physics, associating it with the Bomb, evidently at the end he had physics books in his home rather than mathematics ones.

  One person Grothendieck was in communication with in the early 1990s was Robert Thomason, see a letter available here. Thomason died in Paris in 1995, his notebooks have just become available at this site.

- Another book I found in Paris was from a few years back, about the "unification of mathematics" by Parrochia, Micali and Anglès. The topics are Clifford algebras, abstract algebraic geometry (a la Grothendieck), and the Langlands program, wrapped up in an argument that these provide a unified framework for mathematics. The point of view is the very French one emphasizing the "philosophy" of a subject, and much of the argument is that philosophers of science should be paying close attention to the "Langlands philosophy" and its significance as a unifying set of ideas. They also argue that physics should fit naturally into this sort of unification, an idea I'm very fond of, but they don't seem to be very aware of the actual connections between physics and the Langlands story (they refer only to the classification of branes by twisted K-theory).

Comments

1. **RandomPaddy**
   July 15, 2015

   Oi! What did you do in Ireland?

2. **Peter Woit**
   July 15, 2015

   RandomPaddy,
   Nothing math/physics related. Seven days driving around the country, first to a place in East Cork, then two nights in Kerry, three up in Connemara, finally back to Dublin for two nights. Weather was very pleasant, greatly enjoyed getting to know a bit about the country (before this I had just spent a couple days in Dublin).

3. **nc**
   July 15, 2015

   A miracle. Pleasant weather in Eire!

4. **Sudip Paul**
   July 15, 2015

   http://arxiv.org/abs/1507.03414
   Thoughts?

5. **Reader**
   July 16, 2015

   I was reading AG's autobio online soon after he died. The key idea I thought was most interesting was his following paraphrased comment.

   To really understand a subject you have to mentally live outside its room.

   That is, every subject has bounds of thinking in language and concepts. To live outside it, you have to step into the unknown and invent your own language and concepts.

6. **Peter Woit**
   July 16, 2015

   Sudip Paul,
   I don't know much about pentaquarks. It seems quite plausible that QCD allows such states, but as far as I know there isn't a reliable calculational method available.

7. **sdf**
July 16, 2015

“This was the site of some of my earliest memories of getting interested in science, back in the late 1960s”

Somewhat similarly, my own earliest memories of same, were also from Paris but instead from the Cité des Sciences et de l’Industrie in the 19th arr. from the late 1990s. I think I can even remember most of the exhibits…

8. **Richard**
July 16, 2015

Reader,

Understanding presupposes alienation — and profound understanding presupposes profound alienation.

9. **Michael Hutchings**
July 16, 2015

Where do you find scientific books in Paris? (French OK)

10. **Peter Woit**
July 16, 2015

Michael,
Best places I’ve found are Eyrolles on Bld. St. Germain (downstairs) and Gibert Joseph on Bld. St. Michel (top floor). Maybe there are others I’m not aware of…

11. **Thomas**
July 16, 2015

@Michael: There is a small but interesting scientific library which often has hard-to-find second-hand books, rue Dante, between the Collège de France and Notre-Dame. I’ve seen books both in English and French there (although apparently you read both).

@Peter: Wonderful that you are mentioning the Palais de la Découverte, for anyone who hasn’t been yet it is indeed worth a visit. Both for the building and what is inside. Very family friendly; I don’t know what the 12 yo Peter would have thought about Physics, but I can report that my 4 yo loved every moment of it (especially the biology section).

It is not well known that the Palais was on the brink of disappearing a few years ago, threatened as it was by the much bigger and more modern Cité des Sciences. A petition circulated in the french scientific community to save this institution, and was successful. As a compromise now the Palais is semi-private, not entirely state-owned anymore, probably not a bad deal.

12. **Michael Hutchings**
July 16, 2015

OK, thanks for the tips. I’m one of those weird tourists who likes bookstores and not just museums. I previously managed to find Gibert Joseph (impressive place!) but didn’t know about the others.

13. **paddy**
July 16, 2015

Quite a bit off topic: To nc, The weather in Ireland is always fair and “soft”. Depends on ones perspective.

14. **James MC**
July 17, 2015

Hope you had a nice holiday Peter especially the Cork part that’s where I live 🙂

15. **Low Math, Meekly Interacting**
July 17, 2015

OT, but Yoichiro Nambu passed away. It struck me that perhaps the last couple generations of particle physicists to see their fundamental predictions verified is rapidly dying off.

16. **Tommaso Dorigo**
July 20, 2015

We followed a similar trajectory – the museum in Paris is the place where my father first described a synchrotron to me. But it was well into the seventies for me.

Cheers,
T.

GenCyber

July 18, 2015
Categories: Uncategorized

Over the years the NSF has financed various summer camps for high school students, designed to get them interested in mathematics or other areas of science. This summer they've teamed up with the NSA to deal with the problem of bad press due to the Snowden revelations by organizing a massive new program of quite different summer camps. The program is called GenCyber, and the New York Times today has an article about it here. This year the NSA/NSF is funding 43 camps (for a list, see here), with 1400 youngsters attending them, the plan is to expand to 200 camps over the next few years.

The NSA official in charge, Steven LaFountain explains how the PR aspect works:

> Mr. LaFountain said the agency would not make sales pitches to campers, but hoped that the work of the agency would be enough to lure them into the field.
>
> "We're not trying to make these camps something to make people pro-N.S.A. or to try to make ourselves look good," he said. "I think we'll look good naturally just because we're doing something that I think will benefit a lot of students and eventually the country as a whole."

According to the New York Times, one sort of thing being taught is how to crack password files:

> "We basically tried a dictionary attack," Ben Winiger, 16, of Johnson City, Tenn., said as he typed a new command into John The Ripper, a software tool that helps test and break passwords. "Now we're trying a brute-force attack."
>
> Others in the room stumbled through the exercise more slowly, getting help from faculty instructors who had prepped them with a lecture on the ethics of hacking. In other words, they were effectively told, do not try this at home.
>
> "Now, I don't want anybody getting in trouble now that you know how to use this puppy," Darrell Andrews, one of the camp's instructors, warned loudly. "Right? Right?" he added with emphasis.

Teaching thousands of kids how to crack password files? What could go wrong with that?

The program at Marymount features indoctrination visits to the NSA together with the hacking instruction, and one of the instructors seems to realize part of the problem:

> And here at Marymount University, where campers are staying in dorms for their two-week program, visits to the N.S.A. and a security operations center break up classroom time.
>
> The idea — and the challenge — of the camp, according to its head, Diana Murphy, a professor of information technology at Marymount, is to first teach students how to hack, so they can understand and defend against attackers they might encounter in cyberspace.
>
> "It's a fine balance for me as a teacher, because you have to teach them some of the hacking techniques, and layer that in with an ethical discussion," Ms. Murphy said in an interview before camp began.
>
> "They are most interested in the attacking things."

Update: CNN has an article up today about this here.

Comments

1. **telemurk**
   July 18, 2015

   Thank you for posting this. It's the first I've seen about it.

   What an insane waste of resources with a high potential to create all sorts of disastrous blowback down the road.
   I can't imagine what possible legitimate role the NSF can play here. Are they now so corrupted by NSA money and pressure that all common sense and all moral standards have been erased by excuses and equivocation?

   A slight suggestion would be to instead spend government money on math camps, run by the "old" NSF. That might lead to just as many future NSA recruits eventually, but also to engineers, climate scientists, and, yes, physicists and mathematicians-but with no potential downside and no compromising of the ideals
   of academe and of science. And, not incidentally, with the result of providing a much better background for the students.

   As for the NSA itself, instead of wasting money on this, they might still pull Thomas Drake's Thin Thread approach out of the dustbin and thereby have a chance at catching real threats like the Tennessee
   shooter, before it happens. To avoid offending the corporate lobbyists, that could even be run in parallel to the currently in vogue and 1000 times more expensive "create an infinite haystack" approach.

2. **Peter Woit**
   July 18, 2015

   telemurk,
   It seems to me that the NSA tactic of making grants through the NSF here is much the same as the way they use the AMS to make grants. Involving these two organizations allows them to take advantage of their high credibility and reputation. I know of no evidence that both organizations aren't willing sellers.

3. **Chris W.**
   July 18, 2015

   Concerning the reference in telemurk's comment, Wikipedia has an informative article on the NSA's ThinThread project (active during the 90s), for those who aren't familiar with it.

4. **Michael Weiss**
   July 18, 2015

Readers interested in the original generation of post-Sputnik NSF-supported summer science camps should check out "The Summer Science Program," now in its 57th year and supported by its alumni. Designed for rising high-school seniors with a passion for physics and mathematics, SSP has focused on celestial mechanics (from foundations to observational astronomy) and was originally supported by Caltech faculty, including Richard Feynman and Maarten Schmidt in the 1960s and 1970s. SSP currently has two campuses (Boulder, CO and Socorro, NM), with a third campus planned in the life sciences. See link: http://www.summerscience.org and Wiki page. SSP is international in its outreach and remarkable for its mentorship of young women. The extraordinary alumni of SSP exemplify the wisdom of inspiring the next generation.

5. **wereatheist**
July 18, 2015

> Teaching thousands of kids how to crack password files? What could go wrong with that?

They teachthem cracking *password files*. But the interesting thing is to get these password files 🙂

6. **Peter Woit**
July 18, 2015

wereatheist,
Presumably breaking into systems to get the password file was in one of the earlier lesson plans…

7. **Jeff M**
July 18, 2015

It's really upsetting that the NSF and the AMS get involved with the NSA, but it certainly goes way back, at least with the AMS. The NSA always has a big booth at the yearly AMS meetings, talking about how they hire more mathematicians than anyone else. Used to give me a good laugh in graduate school, since there is no way in hell I could ever have gotten security clearance, not that I ever wanted to work for the NSA 🙂

8. **Richard Séguin**
July 19, 2015

Is this displacing other types of summer math and science programs? I hope not. In the 1960s I attended two 6-7 week NSF sponsored math programs for high school students at universities, although at that time we did not call them "camps." They were fabulous experiences, and they were not polluted by politics, dubious ethics, and indoctrination, which impressionable kids should not be exposed to.

I'm sure that the NSA could have directly sponsored these things by themselves, but using the NSF as a front softens and confuses apparent intentions.

9. **Peter Shor**
July 19, 2015

The NSA is the by far largest employer of mathematicians in the country. Clearly, the AMS needs to have *some* relationship with them. (Just like the American Physical Society needs to have some relationship with the Department of Energy, one of whose objectives is the building of bigger and better atomic bombs.) But maybe they need to think about this relationship more carefully than they have in the past.

10. **Peter Woit**
July 19, 2015

Peter Shor,
The problem is that, unlike the DOE weapons labs, the NSA deceives the public about what it is doing, to the extent for instance of having the National Intelligence Director lie to Congress under oath about this. Without Snowden, none of this would be known. What most bothers me about the AMS is the way they allowed themselves to be used by the NSA to mislead the math community in this way (about the back-doored elliptic curves). These summer camps seem to me to have a goal again of misleading the public, in this case kids and their parents, by whitewashing the story of what the NSA actually does.

Besides this, there's the other issue of whether training kids in running tools to break into computer systems is a good idea. The DOE analog would be summer camps for kids on how to design nuclear weapons….

11. **KenW**
July 19, 2015

We ought to be careful about getting all morally indignant. The nation needs its next generation of code-breakers and it starts with puzzle-solving, which is much enjoyed by kids with the right temperament They should be encouraged and, eventually, recruited as one would recruit talent for any government job.

Recruiting them at this young age makes me nervous, however. Mathematical talent surfaces at an early age, and they can handle that. But the ethical issues require a more mature mind. The schools should certainly do a better job of teaching math, including tricky stuff like puzzle-solving

But I'm uncomfortable about this NSA program.

12. **Richard Séguin**
July 19, 2015

"Teaching thousands of kids how to crack password files? What could go wrong with that?"

Of course this could backfire! Once these young kids learn from the government that hacking is a cool problem from all angles, how long will it be before many of these curious, internet savvy, kids discover and connect with the underground hacker bandits and all their cool tools.

13. **Peter Woit**
July 19, 2015

KenW,
The NSF and the NSA have for a long time been sponsoring activities for schoolchildren and undergrads promoting problem solving, and hoping to get students interested in this, partly to provide a workforce for the NSA for the future. This program is however something new and different. Looking at the various websites for the different camps, there's a heavy emphasis on:
1. scaring children about the supposed cyberthreats to the US homeland.
2. promising them a well-paid career working for the NSA or someone else defending against such threats.

14. **telemurk**
July 19, 2015

This is just getting worse and worse:
” This program is however something new and different. Looking at the various websites for the different camps, there’s a heavy emphasis on:
1. scaring children about the supposed cyberthreats to the US homeland.
2. promising them a well-paid career working for the NSA or someone else defending against such threats.”

As the father of a young child, I think (1.) is not only ill-considered but is borderline criminal. Just because China and Russia and North Korea might employ such tactics doesn’t mean we should necessarily rush to emulate them. A background in trust and idealism like that I picked up in part from Boy Scouts, inspiring and admirable math and history and English teachers in public school in a University town (ok I was lucky), would arguably serve not only the children, the world but also the nation much better than this. They will have their whole later lives to learn cynicism and fear of the other.

The reason the whistleblowers’ revelations (Snowden, Binney, Drake and so on) are so disturbing is not only because of the
facts revealed, but because of the subtext: the people involved, at least at the higher levels, are willing to lie to Congress under oath, to intentionally manipulate public opinion to get what they want, all the while making dubious but self-serving policy decisions like this. That is, the programs not only have the potential for being abused but that is already happening, on multiple fronts. If the foxes are in charge of the hen house, what should we expect- and revelations like these can only increase our suspicion that the very wrong people are in charge. A wrong-headed program will select for bad leadership as those who are more reflective and perceptive are shunted aside or worse. “Trust us”, they say? And why, exactly, if you keep on proving the opposite?

15. **Ben R**
July 20, 2015

I don’t think you should be upset about kids learning to use password crackers in summer camp. The idea that this would make them more likely to hack websites is like the idea that playing violent video games predisposes kids to real-world violence. I think there’s no evidence that that’s true, and some evidence that it actually has the opposite effect, maybe by removing some of the forbidden-fruit aspect of it, or by providing a safe outlet for their curiosity. Anyone who protects any data with a password, which is anyone at all these days, needs a basic understanding of how dictionary attacks work so that they pick passwords that aren’t vulnerable to dictionary attacks. We also need kids who are interested in computer security and study it in college so that they can build more secure systems and keep everyone safe. You could just as well discourage kids from learning about any other subject that they might turn to evil. Like chemistry. Sure, let’s teach teenagers how to synthesize chemical compounds—what could possibly go wrong? And don’t get me started about physics.

16. **Axl**
July 20, 2015

I totally agree with Ben R. Plus, I think these teenagers know about the events of the past couple of years with regards to Snowden and that the NSA might be trying to pull a PR stunt and “groom” the next generation (though I don’t think it’s true). These kids aren’t stupid. They’re there because they’re interested and they know full well what the NSA has done and what they are capable of.

17. **Peter Woit**
July 20, 2015

Axl,
I’m glad to hear that US 13 year old children are a lot more sophisticated about the NSA than many of the research mathematicians I’ve talked to, not to mention the general adult population. Impressive…

18. **Fred P**
July 20, 2015

They are learning password cracking. Note that password cracking software tools and instructions on how to use it are both freely available on the internet, and I’d expect any high-schooler interested in the subject to be able to access (and use) it easily on their own.

If your passwords aren’t secure against dictionary and/or brute-force attacks, they aren’t secure (which is, I’d assume, the point of the exercise). When possible, my passwords are 128 random characters; as I use PasswordSafe, I never see them. This doesn’t mean that my passwords are secure; just that they are as resistant as I can make them against several classes of attacks. Password length/complexity is, of course, not a defense against rainbow tables.

19. **Axl**
July 20, 2015

Peter,

You never watched or read the news when you were 13? When you were 13, did you think that everybody was good and nobody had ulterior motives and everyone was being genuine? Impressive…

20. **zzz**
July 20, 2015

“they know full well what the NSA has done”

Really ?? because I don’t and I am 40 something years old.

21. **Axl**
July 20, 2015

zzz,

I meant that they know they deceived the public and that they have spied on American citizens and collect their data. Of course, nobody (except for the NSA) knows full well what the NSA has done. I’m sure these tech savvy teenagers know about Snowden, etc.

Anyway, the camp actually looks interesting and fun, regardless of what the NSA hopes to gain from this. These kids have heard of the Snowden revelations, and that we can’t really trust the NSA. And the NSA isn’t putting a gun to their heads to work for them after they graduate. So I’m not sure what people are so upset about. I would participate in this camp if I was a teenager and had the time.

22. **Low Math, Meekly Interacting**
July 20, 2015

I'm not about to sing the praises of the NSA. But I look at what happened to the OPM recently, and it becomes harder to argue against those with the attittude that, yeah, they're mendacious, amoral spooks, but they're OUR mendacious, amoral spooks. To posess superior cybersecurity is to have the ability to circumvent someone else's inferior security, generally. I'm not sure whether I'd be more disturbed that the NSA deliberately strong-armed NIST into breaking Dual_EC_DRGB if I found out Chinese hackers were so much more clever that they wouldn't have to to gain an edge. We should aspire to promote higher ethical standards in our government, obviously, but I wouldn't want enlightened democracies to find themselves highly vulnerable to cyberattack because we couldn't tolerate our youth learning how to hack. At least it's somewhat out in the open, and if we are to be secure, then we need young people to learn these skills and be passionate about them.

I'm quite sympathetic to your stance, Peter, and it's admirably high-minded and scrupulous. But it's not a high-minded, scrupulous world we inhabit. If this approach is inappropriate (and I'm not saying it isn't), how better to stimulate interest among young people in cybersecurity expertise, which is an incredibly valuable asset we simply must promote?

23. **Peter Woit**
July 20, 2015

LMMI,
Computer and network security is not a new problem, and there's a huge ($100 billion/year order of magnitude) industry already in place devoted to dealing with it. Any problems with recruiting good people to enter the cybersecurity industry can be dealt with in the usual capitalist manner (pay them well and provide good working conditions and training).

I just don't see the argument that the solution to failures of the security setup at a government agency is to have the NSA setting up summer camps for children. It does though look a lot like a solution for the NSA to the PR problem created for them by Snowden…

24. **G.S.**
July 20, 2015

Peter,

By that logic, we shouldn't ever try to engage a teenager's interest or teach him/her a skill. If it's important enough, just pay them well as an adult and the good ones will be motivated purely by money to learn what's necessary on the job. I'd like to see academic departments try that strategy to lure grad students.

25. **Peter Woit**
July 20, 2015

G.S.,
I just don't see any evidence that an insufficient number of people are interested in hacking or computer security. No matter what the skill, companies always complain that it's hard to hire good people, and by that they always mean that it's hard to get good people to work for what they would prefer to pay.

The only problem with hiring in this field that I've heard of is that, post-Snowden, the NSA itself has found it harder to get good people to work for them (for obvious reasons). I don't think these summer camps are motivated by solving any actual problem except the NSA's PR one, and their attempt to do this by going after children is pretty problematic.

26. **G.S.**
July 20, 2015

It's not your main point, but I've been working at software companies for several years now. Some of my responsibilities have included recruiting at job fairs, reading resumes, and conducting interviews for a number of positions, ranging from software/algorithm engineer to IT and computer security. What I mean when I complain that it's hard to find good people is that it really is hard to find good people. There are a lot of applicants who think they can write professional code or work IT but who are woefully inadequate for the jobs. There are some who are qualified technically, but are completely inept at dealing with people in a professional environment — I think everyone has experienced at least one IT guy like that. The true talents are needles in a haystack.

27. **Igor Khavkine**
July 20, 2015

They are literally creating script kiddies.

28. **Low Math, Meekly Interacting**
July 20, 2015

Well, the private sector is good at competition, but it wants to sell to everyone, friend or foe of liberty and democracy. If loyalty to something other than shareholder interests is desired, I'd hope for a trustworthy national agency. Not that the NSA has demonstrated much ability to provide that, of course, but the kids in that article were getting some ethics classes along with learning how to crack bad passwords. The irony isn't lost on me, but maybe it's a start.

29. **Anonymous**
July 21, 2015

It's clear that the NSA realizes it has an image problem and is actively working to change that impression. They have been actively recruiting undergraduates at the University of Utah for their summer program going so far as to invite a recent Utah alumnus / NSA hire to do the recruiting. Although NSA representatives claim analysts must work out of Ft. Meade many expect the situation to change fairly soon due to a recent addition here in the state:

http://www.wired.com/2012/03/ff_nsadatacenter/

There is also rampant speculation that part of the motivation for the Utah location is to not only draw from computer science programs, but also to tap into an extraordinary source for future linguists needed in critical languages (e.g. Mandarin, Russian, etc.)

http://www.npr.org/2014/06/07/319805068/lessons-from-the-language-boot-camp-for-mormon-missionaries

"The approach has also gained traction in the U.S. military. In fact, the ties between the U.S. military and the MTC run pretty deep. The Army's Intelligence Brigade, made up of linguists, is based in Utah and draws on former missionaries to fill its ranks."

30. **Michael Hutchings**
July 21, 2015

I keep hearing that the NSA is the largest US employer of mathematicians, but does anyone have any actual numbers or estimates? (I was rather surprised by the large scale of this summer camp program.)

31. **David J. Littleboy**
July 21, 2015

In addition to the "what could possibly go wrong" problem, the intellectual vacuity of the program is horrific. Couldn't they think of something of intellectual value to teach? Sheesh. There is a bit of math (theory of computation, cryptography) and engineering (programming languages, operating systems) in the computer area that has some intellectual content. But this is so stupid it sounds like a parody…

32. **Fred P**
July 21, 2015

@Peter Woit –
Here's some evidence that there aren't enough people in one sub-area of computer security:

CISOs are "almost impossible to find these days," she said. "It's a bit like musical chairs; there's a finite number of CISOs and they tend to go from job to job in similar industries."

"It's extremely hard to find good people right now," says Tim Eades, CEO of vArmour, a security firm.

Myself, I think the camps are probably both advertisement for the field and advertisement for the NSA. Both help the NSA in the long term.

@Michael Hutchings-

I found a dated (2001) article claiming "The NSA hires about 50 mathematicians a year, about two-thirds of them PhDs. "This is a very significant percentage of US citizen maths PhDs, and we are incredibly worried about the shrinking pool," says Schatz."

I found a less-dated article (2013) claiming: "The agency declares that it is the United States' largest maths employer, and Samuel Rankin, director of the Washington DC office of the American Mathematical Society, estimates that the agency hires 30–40 mathematicians every year."

33. **Peter Woit**
July 21, 2015

Fred P.,
That supposed "shortage" is of top cybersecurity executives, sounds to me like just the usual "shortage" of "stars" in every field (although as G.S. points out, really good people are a minority, but I think this is true in most fields).

Pretty much everything about the NSA is highly classified including their budget, number of employees, and presumably also the number of mathematicians working there (although maybe they told the kids being given tours of the place as part of their summer camp experience). I'd be a little bit suspicious about that "30-40" 2013 number, since I would have guessed that the NSA expanded quite a bit post-9/11/2001, so would have thought the recent numbers would be higher than the 2001 number. Maybe one issue is how you count who is a "mathematician", since a lot of the work they do is applied work on the borders with other fields.

34. **RandomPaddy**
July 21, 2015

The profession of "cyptologist" needs to be terminologically separated from "mathematician" in much the same way as "theoretical physicist" and "computer scientist" were seperated in the post war/Manhatten Project era. It's fine for cryptologists to wander in and out of math conferences and vice versa, but this effective domination of the profession — certainly in terms of youth recruitment programmes at least — is not healthy or desireable in the long term. It's leading to politicisation and increasing ructions. My own fear is that it will lead to nationalist/ideological splits in mathematics, a feat even the cold war did not achieve.

These NSF camps should be "cryptography" camps, designed not to generate interest in "mathematics and science" generally, but codebreaking specifically. De-Facto this is the case, but their de-jure designation as "science" camps is leading to somewhat justified worries about an effective nationalisation of the mathematical profession by its now largest employer. This could be avoided completely, and turned in a win-win for everyone, if the distinction was clearly made between "cryprography" and "mathematics".

The NSA, its policies, and uses of mathematics lies very much in the temporal realm of politics. A profession of "cryptolgy" could exist alongside this realm; Mathematics cannot. It's a subtle, indeed soft redefinition, but it should start happenning sooner rather than later before the NSA embarks on any more such gaucheries.

35. **telemurk**
July 22, 2015

It's an interesting discussion. But I think the idea that the NSA is actually "protecting" us is questionable given the many revelations of Binney, Drake, Kiriakou, Snowden and so on. Listening to some of the interviews on YouTube with these very intelligent, certainly courageous and (at least to their own way of thinking) very patriotic folks is an enlightening experience.

Two small further points:
-an IT security guy I met on an airplane told me that the speculation is that it was actually the Russians and not the Chinese who stole the personnel data; he said that was much more their style, and that perhaps for US political reasons it was more interesting to pressure the Chinese;
-No doubt the kids who do go to these camps – especially the good ones-will forever be on the radar of the NSA, whether or not they end up working there, perhaps diminishing the odds they will use any hacking skills for (non-government-sanctioned) nefarious purposes.

36. **Joshua Rubin**
July 29, 2015

I am writing in defense of teaching about password cracking, and about understanding the tools bad guys are using.

Passwords are one way of establishing the rights that should be granted by a computer system. Others exist too — something you know, something you have, or a physical characteristic. Sometimes two of those are used. Sometimes two people must cooperate. Designers must understand the tradeoffs.

A good system must protect against realistic threats. It is important to be able to spell out those threats. The bad guys might make an educated guess about one person's password . The bad guys might have a complete copy of everything on the computer system, but not have any password. The bad guys might want the password of any account, not a specific one. The bad guys might be monitoring everything the computer does, in real time. The bad guys might have resources that far exceed your own. The bad guys might know far more than you know. The bad guy might pretend to be a user who forgot their password. The bad guy might be the system administrator. The bad guy might be your love interest.

Just as physics students need to play with air tables, future security folks need to play with cracking tools. Doing uses a different part of the brain than reading or listening.

37. **Tom Leinster**
July 31, 2015

Michael Hutchings asked “I keep hearing that the NSA is the largest US employer of mathematicians, but does anyone have any actual numbers or estimates?”

In testimony to the Senate Judiciary Committee on 2 October 2013, Keith Alexander (then director of the NSA) stated that the NSA employed 1013 mathematicians and that they were the largest employer of mathematicians in the USA. He didn’t elaborate on what he meant by “mathematician”. Link here.

Random Notes

July 21, 2015
Categories: Uncategorized

- The LHC has now finished the first part of its physics run at 13 TeV, with intensity ramping up more slowly than hoped. Total luminosity/experiment so far is about .1 inverse fb (see here), about a tenth of some earlier projections (see here), not enough for any likely new physics results this summer (see here).

  According to the latest schedule physics will begin again the second week of August, with beam intensity increasing during the month. Most data-taking is planned for September and October, with a target of 10 inverse fb.

- Yoichiro Nambu died recently, at the age of 94. He was one of the most influential figures in theoretical physics, for his work on many topics, but especially on spontaneous symmetry breaking in quantum field theory. Unfortunately I never got to meet him, it sounds like he was one of the nicest people in the field. There are lots of stories now out about him and his work, I especially liked this one from one of his students.
- Massimo Pigliucci's Scientia Salon project now has a book of essays out, with the title Scientistic Chronicles.
- There's a wonderful article out by Rick Jardine on Grothendieck's great work on homological algebra, known to mathematicians as "the Tohoku paper". It was written while Grothendieck was in Kansas, and immediately had a huge influence on the subject. Jardine explains not only the background of the article and what's in it, but some of the later developments that have come out of it.

Update: Via David Goss, news that the FBI file for Paul Erdos is now available.

   I would like to express my sincere condolence for the death of Professor Y. Nambu, who had been my most respectable acquaintance since 1961.

2. **fg**
   July 22, 2015

   Another recent loss is that of Raymond Stora, the S of BRST, who died recently at the age of 85.

3. **gevtev**
   July 22, 2015

   GeV –> TeV?

4. **Peter Woit**
   July 22, 2015

   fg,
   Thanks for letting us know, I'm sorry to hear that.

   gevtev,
   Thanks, I seem to make that mistake regularly, someday I'll get used to this TeV scale business…

5. **Noboru Nakanishi**
   July 22, 2015

   fg
   Thank you for your information. Professor R. Stora was also my old friend.

   I have also heard that Professor S. Okubo of Rochester University died at the age of 83 on July 20. He is known by Gell-Mann-Okubo mass formula, etc.

6. **Pt**
   July 23, 2015

   The inference magazine that Jardine's article is published in seems to have been created to promote anti-evolution views. It's too bad because their other articles are interesting!

7. **anonymous**
   July 23, 2015

   Don't know if you've seen this, Peter.

   How likely is it that they're seeing a genuinely new resonance ? A super-partner ?

   http://www.symmetrymagazine.org/article/july-2015/something-goes-bump-in-the-data

   "If this bump matures into a sharp peak during the second run of the LHC, it could indicate the existence of a new heavy particle with 2000 times the mass of a proton."

   "Even though this bump is far too small to signify a discovery and presents no predictable pattern, its presence across multiple different analyses from both CMS and ATLAS is intriguing and suspicious. "

8. **Peter Woit**
   July 23, 2015

   anonymous,
   There are good postings about this from Tommaso Dorigo

http://www.science20.com/a_quantum_diaries_survivor/those_three_higgs_events_piling_up_at_18_tev-156030
and Jester
http://resonaances.blogspot.com/2015/06/on-lhc-diboson-excess.html

I think Jester has it right ("there's little reason to get excited yet.") There have recently been lots and lots of papers "explaining" the diboson excess (there's a string theory explanation for this, just as there's a string theory explanation for anything…).
There may be enough data collected in Sept-Oct. to know by the winter conferences in early 2016 whether there's anything there. So, just wait a bit, but I don't think the odds are great that this is something real.

9. **vkrishna**
July 23, 2015

I found the personal remembrance of Prof. Nambu that you linked to, to be very nice. He seems to have been a really decent man in addition to being a great physicist. I have
Thanks.

A Beautiful Question

July 24, 2015
Categories: Book Reviews

Frank Wilczek's new book, A Beautiful Question, is now out and if you're at all interested in issues about beauty and the deep structure of reality, you should find a copy and spend some time with it. As he explains at the very beginning:

> This book is a long meditation on a single question:
>
> **Does the world embody beautiful ideas?**

To me (and I think to Wilczek), the answer to the question has always been an unambiguous "Yes". The more difficult question is "what does such a claim about beauty and the world mean?" and that's the central concern of the book.

Early chapters are of an historical nature, searching out the roots of such ideas, going back to the Pythagoreans and their beliefs about number and harmony, and then on to Plato and Platonism. The discussion of physics begins seriously with Kepler and Newton, and emphasizes very much the nature of light and color, topics about which Wilczek is currently actively pursuing new ideas. Maxwell then appears as the foundation of our modern understanding of light and electromagnetism.

Notions of symmetry (gauge symmetry) then begin to appear, as well as the surprising notion of quantization of wave motion. The basic ideas behind the Standard Model are extensively developed, emphasizing the connections to symmetry and beauty. Wilczek tries to make some changes in the conventional terminology, calling the Standard Model the Core Model, fields "fluids", etc., in an attempt to bring the subject closer to a conventional language that might give the average person some feel for what is going on. He also brings in some of his personal experience: he is of course most well-known as one of those responsible for the final stage of the development of the Core Model.

Wilczek has been traveling a lot lecturing about this recently. You can for instance watch or hear him speak here, here and here, read extracts from the book here or here, find reviews here and here. The Wall Street Journal has "a week in the life" here. I very much like Wilczek's comments in an essay here which explain how the book came about and who it was written for. His conclusion that he had written it to speak to himself as a child or adolescent very much resonates with my own experience writing a popular book.

The later parts of the book deal with more speculative questions about particle physics, and here I find that truly difficult issues appear: can we hope to agree on what beauty is in this context? Wilczek has never been a fan of string theory, and the various problematic claims about its "beauty" really don't come up. He is however a fan of supersymmetric GUTs, and there issues of beauty become problematic. Yes, the fact that a family of SM fermions can be organized into a spinor representation of SO(10) is a beautiful fact, and likely indication of something deep about the world. But there's a serious problem with getting unification by putting things into larger symmetry groups, without at the same time having a compelling idea for what breaks the larger symmetry to the smaller one we see. Just postulating a new set of GUT Higgs is not so pretty.

Similarly, the general idea of supersymmetry has beautiful aspects, but its implementation as a specific extension of the Poincaré group starts to become seriously unbeautiful once one introduces structures needed to break the supersymmetry to correspond to observation. I think one reason for Wilczek's fondness for this idea is his involvement in the first calculation of coupling constant unification in such theories. A parent always thinks their child is unusually beautiful, but may not always be a very good judge of the matter…

Wilczek has made some bets that SUSY will appear at the LHC, but I think he's going to be losing them. Garrett Lisi has an account here of one such bet, which had a problematic time limit. By next summer I think there will be enough data to start making a judgment about whether SUSY is there at LHC accessible energies. I'm quite curious to see how Wilczek and others of his generation that had so long invested their hope in this will react to a negative result. Will SUSY start looking a lot less beautiful?

Bonus item: In today's Wall Street Journal there's another profile of a particle physicist, of George Zweig, a co-discoverer of the quark theory which ultimately was vindicated by the later discovery of asymptotic freedom by Wilczek and others. Zweig is now starting a hedge fund, I hadn't realized that he worked for quite a while at Renaissance, the Jim Simons hedge fund.

Update: This does seem to be the week for profiles of mathematicians and physicists in the media. There's a wonderful one about Terry Tao in the Sunday New York Times magazine.

Comments

1. **Bernhard**
   July 24, 2015

   I haven't read the book, but I suppose Wilczek discuss at the beginning of the book (or somewhere) what he means by "beauty". I remember many years ago reading Weinberg's "Dreams of a Final Theory" that the analogy for him of beauty was with a "beautiful horse" and that "a beautiful horse wins races". So this was a subjective idea that had an objective way to be tested. The same would hold for physics theories (beautiful theories are the ones like QED that are also objectively successful).

   This is interesting as beauty has been one of the big arguments for SUSY (I recall John Ellis' "why I love SUSY" in 2011) but SUSY has been very unsuccessful in the way Weinberg discussed. I don't get how at this point SUSY can still be beautiful but I suppose I need to read the book.

2. **Noboru Nakanishi**
   July 24, 2015

   Peter,
   I agree with your opinion on SUSY. But I would like to claim more definitely: Spontaneously broken SUSY is totally ugly; it can never been a truth.

3. **Walter**
   July 24, 2015

   Just because the result of a broken symmetry is very ugly, doesn't mean the underlying symmetry is less likely to be true. I'm talking about SUSY here. If SUSY is so beautiful, does it matter if breaking SUSY leads to an ugly-looking theory? I thought the general trend was that as you go higher in energy, things look more beautiful. So if you go at high enough energies, SUSY is restored, and everything is nice and beautiful again. So why is the ugliness of broken SUSY a reason for thinking SUSY isn't true?

4. **Sebastian Thaler**
   July 24, 2015

   There is a fascinating profile of Terry Tao in this Sunday's NY Times Magazine:

http://www.nytimes.com/2015/07/26/magazine/the-singular-mind-of-terry-tao.html?hpw

5. **Yatima**
July 25, 2015

Does Frank Wilzeck mention "low Kolmogorov complexity" as one of the driving criteria of "beauty" as mentioned for example here? The postulate being that:

Among several patterns classified as "comparable" by some subjective observer, the subjectively most beautiful is the one with the simplest (shortest) description, given the observer's particular method for encoding and memorizing it.

This sounds very correct. Theories with a low-complexity "core description" and no extraneous "ifs", "thens" and "buts" and randomly tucked-on stuff, all of which would increase the KC (however given) by a factor of 2 at least are indeed what one likes to see.

6. **Peter Woit**
July 25, 2015

Walter,
The argument that "my beautiful idea only applies at high energies where it can't be tested; at energies where we can do experiments it doesn't apply and doesn't say anything " has some obvious problems…

7. **unification**
July 25, 2015

in your opinion are GUT theories of unification like SO(10) promising? is there any GUT you find promising? what do you think is a promising avenue for unification? are there any well motivated theories of GUT, unification, as well as no unification of strong and electroweak forces? thanks

8. **Peter Woit**
July 25, 2015

Unification,
There's a chapter in my book about GUTs, it's a complicated story, but I don't think anything much has changed since I was writing that chapter a dozen years ago.

What isn't really discussed in the book is the construction that Wilczek describes in detail in his, how to make a generation of fermions out of the spinor representation for SO(10). This is "beautiful", there's something important going on there, but I think we're missing some important ideas about what this means.

You can think of the SO(10) spinor representation as what you get from a collection of 5 fermionic oscillators, this is described in detail in my notes at
http://www.math.columbia.edu/~woit/QM/qmbook.pdf
For a good discussion of the relation to GUTs, see the article by Baez and Huerta
http://arxiv.org/abs/0904.1556

9. **Bill**
July 25, 2015

That NYT article was great – not because it was about Tao but because it contained some lovely thoughts about mathematics in general. The article would be more appropriate if Tao actually solved the twin prime conjecture or Navier-Stokes.

10. **Chris Oakley**
July 25, 2015

A general point here. One problem with using "beauty" as a criterion for scientific theories is the lack of a precise definition. In the case of female beauty, though, there is a well-defined unit called the Helen (H), named after Helen of Troy. As this is a large unit, people prefer to work with the millihelen (mH), which is defined as the beauty required to launch a single ship.

11. **Anonyrat**
July 25, 2015

If Ptolemy's epicycles worked, would we consider them to be beautiful?

12. **Bernd**
July 25, 2015

Isn't SU(5) also very beautiful?

13. **PeterH**
July 25, 2015

Carl Sagan in an episode from the Cosmos series stated that the Universe need not be in harmony with human ambition. The human ambition to find a 'beautiful' theory of the laws of nature is meaningless since 'beauty' is subjective.

14. **Peter Woit**
July 25, 2015

Bernd,
The SU(5) vs. SO(10) question in GUTs is a good example of where relative magnitudes of beauty are clear. To describe one generation of fermions using SU(5) you need two irreducible representations, of dimension 5 and 10. Using SO(1o) (more accurately, Spin(10)), you just need one representation, and it's a special distinguished representation, the 16 dim spinor representation. So, the SO(10) case is more beautiful…

One has 16=10 +5 +1, so SO(10) also includes a singlet, which is just what one expects for a right-handed neutrino.

15. **Noboru Nakanishi**
July 25, 2015

Walter,
Spontaneously broken SUSY implies the existence of Nambu-Goldstone fermion, which was experimentally excluded. If one appeals to super-Higgs mechanism by using

supergravity, it implies that quantum-gravity effect cannot be neglected in the energy region of the Standard Theory. Furthermore, quantum supergravity cannot be global-SUSY invariant, because the anticommutator of supersymmetry generators in quantum supergravity cannot have the spacetime index of the translation generator.

16. **Walter**
July 26, 2015

Peter,

I understand your point, but my question was meant to address your thoughts on SUSY leading to the ugliness of having a lot of extra particles. I understand how that can be viewed as ugly. But if the underlying, fundamental theory, valid at the Planck scale (whatever it is, no assumptions here) is "beautiful", even though it leads to a million fundamental particles from the TeV scale to the Planck scale, why should these million particles negate this? That's all I was asking.

17. **manfred Requardt**
July 26, 2015

I have problems with beauty as a scientific criterion. This would imply that our anthropocentric point of view is the same as the view how nature works in its deep structure. Keplers mysterium cosmographicum was a concept derived from beauty but was totally beside the point . I lectured about SUSY several times but while being perhaps a mathematically beautiful framework I never found it beautiful from a physical point of view. The same holds in my view as to string theory.
It is important to understand the biological and psychological roots of a concept like beauty before one can decide if beauty is a useful scientific concept.

18. **Peter Woit**
July 26, 2015

Walter,
The issue isn't number of fundamental particles, it's whether they're tightly constrained by a symmetry argument. The simplest SUSY extensions of the SM have a new particle for each of the ones we know about, which is twice as many particles, but SUSY tells you their properties. You can argue whether this is more beautiful than the SM (more symmetry, but a symmetry that tells you only about unobserved particles, nothing about the observed SM particles), I happen to think not.

The big problem with SUSY though is that these simplest extensions don't work (since they predict superpartners we don't see). So, you need to make the theory more complicated by adding degrees of freedom that will cause SUSY breaking. This is where it gets completely ugly, and it's at the level of the fundamental theory.

19. **David Bailey**
July 26, 2015

I remember as a kid learning the gas laws PV=nRT. I thought that was incredibly beautiful – so much information packed into one equation – and then I learned that this equation is inexact, and that a more accurate equation devised by van der Waals was more accurate, but it had different coefficients for each type of gas!

That made me rather cautious about appeals to beauty in physics.

Maybe every appeal to beauty implicitly assumes there is no deeper structure to mess things up (the quantum structure of molecules in the above example, which give molecules finite size and intermolecular forces).

20. **manfred Requardt**
July 26, 2015

I agree totally with what David Bailey says. The problem is that most of our theories are only effective theories being approximately correct on a certain level of resolution. In a sense there is no real reason that such theories should be beautiful. On the other hand, in the realm of mathematics there is ample room for beauty. This is the platonic point of view uttered by many great mathematicians (recently by e.g. Allan Connes). Nevertheless even there this philosphy is a little bit vague.

21. **Magnema**
July 26, 2015

@Peter Woit: So the real issues come not from SUSY itself, but from the modifications to the simplest ideas of SUSY in order to have it be compatible with observation?

Would these extra degrees of freedom you refer to be yet another (undetermined by SUSY itself) particle (something like the Higgs, given their role in symmetry breaking)?

22. **Thomas**
July 26, 2015

manfred Requardt:
"It is important to understand the biological and psychological roots of a concept like beauty before one can decide if beauty is a useful scientific concept."

I think this is a very important point. And there is a nascent field about that, neuroaesthetics.
http://old.unipr.it/arpa/mirror/pubs/pdffiles/Gallese/2009/DiDio_COP2009.pdf

Even more on topic, you may want to look at this fMRI study co-authered by Atiyah:
http://journal.frontiersin.org/article/10.3389/fnhum.2014.00068/abstract
I wonder whether Wilczek mentions that in his book.

23. **geometriclanglander**
July 26, 2015

The article on Terence Tao doesn't really say anything new, I'm not sure why you consider it 'wonderful'. Tao certainly deserves all the plaudits and praise bestowed upon him, but I'm not sure that such hagiographies give any particular insight. It might be good for scientific outreach I guess.

In any case, on another Tao related matter, the comments on this post
https://terrytao.wordpress.com/2015/07/20/a-nonstandard-analysis-proof-of-szemeredis-theorem/
make interesting reading from a viewpoint of scientific sociology.

24. **manfred Requardt**
July 27, 2015

Thomas, many thanks for your helpful hints and remarks! By the way, there is a related discussion concerning the conventionalism in science as being introduced by e.g.

Poincare (see the nice biography by Jeremy Gray). This is a purely pragmatic criterion without aesthetic qualities (apart perhaps from simplicity and economy of thinking). But, nevertheless, it is obvious that there is some peculiar structure underlying our universe.

25. **Beauty in Mind**
July 27, 2015

I have recently come across Weber electrodynamics. In my view this is an extremely beautiful theory, but it seems that it just doesn't work. If so, this would be a nice example of beauty being deluding, and probably it is not an exceptional case in the history of physics.

"The great tragedy of science – the slaying of a beautiful hypothesis by an ugly fact." – Thomas Henry Huxley –

26. **Peter Woit**
July 27, 2015

Magnema,
There's an infinite variety of ways to get SUSY breaking and explain away the non-observation of superpartners. But all involve postulating additional, otherwise unmotivated, physics beyond a simple SUSY extension of the SM.

27. **Jim Eshelman**
July 27, 2015

It seems to me that "beauty" is largely being used where simplicity is really meant in much of this discussion. IMHO beauty is way too subjective to enter into any discussion in physics, whereas simplicity is much easier to agree on — PV = nRT is simple, the van der Waals equation is certainly less so. Few would disagree. The Standard Model is far from simple. That's what all the fuss is really about—find the overarching simple set of concepts that unify and simplify that mismash of fields and adhoc "constants". Only the means differ.

28. **perry**
July 27, 2015

SU(5) was beautiful till the protons refused to die

29. **RandomPaddy**
July 27, 2015

A 78 year old is starting a hedge fund. I think we've hit the top.

30. **Chris W.**
July 28, 2015

Speaking of Zweig, the Wikipedia profile of him points to this CERN colloquium talk he gave in November 2013, which is a history of particle physics leading to the development of the concrete quark model. (It starts with a review of the stage-setting prior to World War II. In 1947 Zweig was 10 years old.)

The talk has probably been widely read, but I had never come across it before. It's extremely readable, with many fascinating anecdotes about the wrangling that led to the concrete quark model. (It also indicates that Zweig turned to neurobiology by the end of the 60s—earlier than I had thought.)

31. **manfred Requardt**
July 29, 2015

As Jim Eshelman says, simplicity is certainly an important aspect in this field. The concept of symmetry in all of modern physics is an example. On the other hand, even this quality is not entirely clear. Einsteins field equation are looking simple but threy are in fact very complicated if one tries to solve them (non-linar partial diff.-equations). Sometimes only the mathematical representation of an actually complex situation may appear simple.

32. **Jim Beyer**
July 30, 2015

I tend not to like the terms 'beauty' (or especially 'elegance') when describing scientific endeavors. In my opinion, these phrasings seem to be an effort to persuade one towards the author's belief system absent grounded technical evidence.

33. **GoletaBeach**
August 2, 2015

Ground Loops. Fadeev-Popov ghosts. Eventually, there is messiness underpinning beautiful experiments and theories.

34. **Peter Woit**
August 3, 2015

GoletaBeach,
"Fadeev-Popov ghosts"
Exactly. This is one part of the Standard Model that isn't beautiful, and isn't completely satisfactory non-perturbatively. I think that's a strong argument that it should be getting a lot of attention as an aspect of the SM that we don't properly understand, for which there is a more beautiful, more compelling explanation, one that would teach us something about the fundamental theory.

35. **anon**
August 3, 2015

Faddeev-Popov ghosts and BRST are not a fundamental part of the Standard Model, are they? Since there are other ways of fixing the gauge that don't involve ghosts, aren't they mostly a calculational device? But, for what it is worth, I personally find Faddeev-Popov ghosts and BRST to be a technically quite beautiful and elegant calculational device, since they magically automate a lot of the gauge fixing while allowing you to largely do calculations in a gauge-invariant set of variables, as opposed to an awkward and arbitrary choice of reduced variables. I use "magically" on purpose, since the idea of "negative" degrees of freedom embodies in ghosts still seem magical to me to this day.

36. **Peter Woit**
August 3, 2015

anon,
Faddeev-Popov/BRST is the only covariant gauge-fixing procedure I know of (for the non-abelian case). Non-covariant gauge-fixing introduces a different set of technical problems and uglinesses. The only way of dealing with gauge symmetry that I know of no technical problems with (perhaps just because of ignorance…) is what the lattice people do: don't fix the gauge, integrate over all gauge choices. But you can't get the perturbation series this way.

I agree that the introduction of anti-commuting variables to deal with gauge symmetry is not ugly, but a quite beautiful idea. It's closely related to very deep mathematics: homological methods in representation theory. The fact that the same "trick" (introducing anti-commuting variables, a complex, and looking at the cohomology of the complex) occurs throughout modern mathematics is a good reason to believe that it's the right way to handle the problem, and well deserves to be thought of as beautiful.

37. **GoletaBeach**
August 3, 2015

Thanks Peter, I hope a beautiful solution to the ghosts emerges.

As the old joke goes, when Fermi asked God how to solve Ground Loops, God simply replied `Never could solve that problem.'

This Week's Hype

July 28, 2015
Categories: Multiverse Mania, This Week's Hype

Symmetry, the FNAL/SLAC run online magazine funded by the DOE, today is running a piece of multiverse mania entitled [Is this the only universe?](). It's a rather standard example of the pseudo-scientific hype that has flooded the popular scientific media for the last 10-15 years.

Besides the usual anthropic argument for the size of the CC, the evidence for the multiverse is string theory:

> For further evidence of a multiverse, just look to string theory, which posits that the fundamental laws of physics have their own phases, just like matter can exist as a solid, liquid or gas. If that's correct, there should be other universes where the laws are in different phases from our own—which would affect seemingly fundamental values that we observe here in our universe, like the cosmological constant. "In that situation you'll have a patchwork of regions, some in this phase, some in others," says Matthew Kleban, a theoretical physicist at New York University.

No mention is made of the fact that there is no evidence for string theory, with the multiverse given as the usual argument for why this is so.

Kleban also claims the theory is testable in this way:

> it may be possible to experimentally induce a phase change—an ultra-high-energy version of coaxing water into vapor by boiling it on the stove. You could effectively prove our universe is not the only one if you could produce phase-transitioned energy, though you would run the risk of it expanding out of control and destroying the Earth. "If those phases do exist—if they can be brought into being by some kind of experiment—then they certainly exist somewhere in the universe," Kleban says.

No word on how to do that.

Nomura says the way to test the idea is by looking at the universe's spatial curvature (which, according to Planck is zero within the experimental uncertainties). According to Nomura, the implications for the multiverse of possible more accurate measurements of the spatial curvature are

- If it remains zero, that's consistent with the multiverse.
- If it is negative, that's "strong evidence of a multiverse".
- If it is positive, that's a problem for some multiverse models, but not evidence against the multiverse, because you can't have evidence against the multiverse:

  > a positively curved universe would show that there's something wrong with our current theory of the multiverse, while not necessarily proving there's only one. (Proving that is a next-to-impossible task. If there are other universes out there that don't interact with ours in any sense, we can't prove whether they exist.)

Kleban and Nomura are quite excited by this, because the multiverse has the wonderful implication that we can all give up on trying to find a better fundamental theory and do something more useful with our lives:

> If there were different universes with different phases of laws, we might not need to seek fundamental explanations for some of the properties our universe exhibits.

Comments

1. **Scott Church**
   July 28, 2015

   Peter, I find it interesting that Kleban says, "a positively curved universe would show that there's something wrong with our current theory of the multiverse, while not necessarily proving there's only one…" His *own* research has shown that positive curvature at the 10^-4 level would rule out slow roll and false vacuum eternal inflation, and negative curvature on the same scale would rule out slow roll eternal inflation (http://arxiv.org/abs/1202.5037). Guth and Nomura reported similar findings (http://journals.aps.org/prd/abstract/10.1103/PhysRevD.86.023534). Current Planck results give a flat universe to a confidence interval of only +/- 10^-3 so more refined observational data could verify either possibility.

   It seems to me that eternal inflation is… forgive the expression… "the only game in town" for generating a multiverse, and the vacua of string/M-theory are needed if it's to have the widely varying physical constants required by anthropic constraints. The only alternatives I see are Tegmark's Level-4 multiverse or Many Worlds QM (both of which to me seem downright bizarre), or purely speculative new physics of some sort for which there isn't a shred of evidence. So in the absence of this sort of wishful thinking/special pleading, if future refinements in observed curvature do rule out eternal inflation this way, how exactly have we failed to prove that there's only one universe? Am I missing something here?

2. **Peter Woit**
   July 28, 2015

   Scott Church,
   The thing you quote I think comes from Nomura, not Kleban. I've seen the Guth/Nomura paper you mention, but I've never been convinced that you can't get positive curvature out of this kind of scenario. In particular, look at the conclusion of this paper
   http://arxiv.org/pdf/hep-th/0610231v2.pdf
   which I've never seen refuted.

   It seemed to me that all that Nomura was doing was stating the obvious: multiverse proponents will claim victory if the curvature is negative, come up with a different model if it is positive. You'd have to ask him though about this, it's quite possible the writer mangled some subtlety of what he was trying to say.

3. **Scott Church**
   July 28, 2015

   Thanks Peter! I've downloaded a copy of that paper and will give it a read asap. Have you seen the Kleban & Schillo paper as well (the first link)? It was published the same year as Guth and Nomura's, and appears to have taken a somewhat different path to the same results. In any event I imagine you're right… whether eternal inflation is ever falsified or not, multiverse proponents will find ways to keep it alive. They have 10^500 vacua to play with… and who couldn't get what they want out of that? 🙂

4. **Peter Woit**
   July 28, 2015

Scott Church,
I've seen it, but haven't looked at it carefully, beyond noticing that they don't even refer to the earlier paper I mentioned that reaches opposite conclusions. I just don't see how the sort of arguments they're making can possibly be strong enough to rule out all mechanisms for making extra universes.

5. **Peter Woit**
July 28, 2015

Maybe another comment I should have made in the posting is that, as anyone who watched "Particle Fever" knows, Nomura was saying that the multiverse predicts a 140 GeV Higgs. When that was falsified, there seems to have been no impact on his promotion of the multiverse (rather the opposite…), so I see no reason to believe that falsification by discovery of a positive spatial curvature would cause him to abandon the idea. It was interesting in this article that he seems to be explicitly acknowledging that what he is arguing for cannot be falsified.

6. **Scott Church**
July 28, 2015

Yeah… so I saw from some of your previous posts about LHC's failures to date to turn up a gluino. Now that LHC Run 2 is under way it'll be interesting to see how he (and others) respond if no superpartners are discovered by next summer.

Btw, on another note, I just finished your book yesterday, and I cannot tell you how much I enjoyed it! Sadly, I'm in a bit of withdrawal now… what to read next that could be as enjoyable and informative…? 🙂

7. **verruckte**
July 28, 2015

Well, I'm disappointed in Symmetry for running that piece. Their stuff is usually better than that.

8. **Low Math, Meekly Interacting**
July 28, 2015

It's not all bad. Quanta has an interesting recent piece on Navier-Stokes that might help with pop-sci-induced depression.

9. **nicola**
July 29, 2015

Peter,

that 140GeV Higgs was obviously meant for some other Universe, not ours ;).

10. **Chris Kennedy**
July 29, 2015

The magnitude of multiverse nonsense that continues to be perpetuated is really unfortunate. I saw part 1 of the Uranium documentary on PBS last night. Sure it was very basic for a general audience but when you look at what real scientific discoveries and accomplishments were decades ago it shows by comparison just how tragically hollow the community's current goals and purpose have become.

11. **Anonyrat**
July 29, 2015

"…we might not need to seek fundamental explanations for some of the properties our universe exhibits."

IMO, given planetary orbit sizes, orbital periods, masses, planetary diameters, rotational periods, etc., theory eventually tells us that the sizes of orbits and orbital periods can be related easily and follow as a consequence of a fundamental law, the other things do not. To be useful, multiverse theory has to tell us what features of the Standard Model follow readily as a consequence of some fundamental theory, and which do not.

12. **Chris W.**
July 29, 2015

> "…we might not need to seek fundamental explanations for some of the properties our universe exhibits."

Too bad nobody suggested the idea of a multiverse to Isaac Newton. It might have saved him and his successors a lot of work. Never mind that the work actually bore fruit… 🙂

13. **Giotis**
July 30, 2015

Well on theoretical level and since String theory is currently the only reliable theory of everything and Quantum gravity to work with someone must answer first the following question:

What is the correct vacuum of String theory?

To answer this question you must have a background independent, non perturbative definition of the theory and (besides AdS/CFT) we are still lacking of such definition. String Field Theory for example if further developed has the potential to answer such deep questions in a background independent manner (Ashoke Sen's conjectures in OSFT is a clear indication that it can do so).

What we have so far in the String landscape are the low energy effective vacua derived from the perturbative/semiclassical String theory but combining these with eternal inflation and the seemingly (so far at least) unnaturalness of the SM and of the Cosmological Constant the case of the multiverse becomes quite appealing.

But again these are mostly bottom up considerations, if we don't have a complete Cosmology provided by String theory via its background independent, non perturbative definition I don't think we can give a definitive answer. I know for example that David Gross strongly advocates this PoV.

The point to take away is that String theory has not given yet the final OK for the Multiverse picture.

14. **al**

July 30, 2015

Hypothetically true = Real
This is the philosophical equation of strings-cum-multiverse theories.
The hassle is who should bear the burden of proof when rejecting the substitution
noncontradictoriness= evidence.

15. **Peter Woit**
July 30, 2015

Giotis,
"the case of the multiverse becomes quite appealing"

As far as I can tell, the only thing "appealing" about it is that it allows string theorists to explain away the failure of the idea of string theory unification.

16. **Richard Noth**
July 31, 2015

re. Giotis,

I'm sure I'm not the only reader here who is having trouble wrapping their head around something being 'the only reliable theory of everything' whilst simultaneously sufficiently lacking in definition to be able to make any concrete statements about any of the 'everything' around us!

Math and Physics Summer Camps

August 1, 2015
Categories: Uncategorized

With the kids shipped off to NSA summer camp, now is the time for mathematicians and physicists to head off to their own summer camp experiences. Some of these have websites where the rest of us can participate a bit virtually. These include:

- Out at Stony Brook, in mathematical physics there's the Simons Center Workshop going on now. This features lectures at the nearby Smith Point beach.
- Down in Princeton, the summer PiTP program for this year has just ended, with the topic New Insights Into Quantum Matter. In recent years many HEP theorists have given up on applying duality arguments to string theory unification and have gotten interested in condensed matter physics. Links on this schedule will take you to lectures that include three by Witten on Fermions and Topological Phases.
- Utah has been the center of the algebraic geometry world for the past few weeks, with the AMS Summer Institute in Algebraic Geometry held in Salt Lake City ending today. This is one in a series of big events held every ten years and as usual was preceded by a bootcamp for graduate students. Also as usual, the NSA is helping out with the funding.

  Overlapping with this, some algebraic geometers were at camp up in the mountains nearby, at the Zermatt Resort, for the PCMI Summer Session, this year the topic was Geometry of moduli spaces and representation theory.

- Later this month, SLAC will host the 43rd SLAC Summer Institute, with topic this year The Universe of Neutrinos.
- For Spanish-speaking mathematicians, around the same time the place to be will be Cusco for AGRA 2015. Michael Harris has notes for his lectures and has started blogging in the appropriate language.

Comments

1. **RandomPaddy**
   August 2, 2015

   What happens at academic workshops anyway? Are they more for graduate students or do professors learn a few tricks as well? Or are they really just another hazily defined part of the workshop/colloquim/seminar/symposium/conference spectrum?

2. **Peter Woit**
   August 3, 2015

   RandomPaddy,
   Typically these things have some mix of graduate students, postdocs and senior people, as well as some mix of non-professional activities to keep them entertained. A few of them have separate components aimed at graduate students, or even undergrads (PCMI). One reason for linking to them is that there are a lot of good expository lectures, and some of the materials from them are available online.

Multiverses: Science or Science Fiction?

August 3, 2015
Categories: Multiverse Mania

The September issue of Astronomy magazine is now out, with a cover story on Multiverses: Science or Science Fiction? The author Bob Berman does a good job of explaining both the arguments for various Multiverses, as well as the reasons for skepticism about some of these arguments. After quoting Max Tegmark as defending multiverse theory as science since it is a prediction of an "arguably testable" theory (inflation), Berman ends the piece in a way I have to agree with:

> Given the current multiverse infatuation, it may be fairest to give the last word to a prominent skeptic. Columbia University mathematical physicist Peter Woit, who maintains the popular multiverse-critical blog Not Even Wrong, pulls no punches.
>
> "Physicists had huge success in coming up with powerful compelling fundamental theories during the 20th century," he explains, "but the last 40 years or so have been difficult, with little progress. Unfortunately, some prominent theorists have now basically given up and decided to take an easy way out. The multiverse is invoked as an all-purpose, untestable excuse. They allow theoretical ideas like string theory that have turned out to be empty and consistent with anything to be kept alive instead of abandoned. It's a depressing possibility that this is where physics ends up. But I still hope this is a fad that will soon die out. Finding a better, deeper understanding of the laws of physics is incredibly challenging, but it's within our capability as humans, as long as the effort is not overwhelmed by those selling a non-answer to the problem."
>
> Whoa, intense. We've got to toss the multiverse if we care about physics!
>
> Of course, if an infinite multiverse does exist, some other Woit is out there saying the exact opposite.

The same issue of Astronomy has a "Web Extra" entitled What happens if string theory is wrong? It mentions the 2013 poll of theorists discussed here, which had a large majority (73%) answering the question "Do you think that String Theory will eventually be the ultimate unified theory?" with a "No", then goes on to link to a 2007 article by Sten Odenwald. Some of that article includes quotes from an interview with Lenny Susskind, which Odenwald recently included here. It will be interesting to have an update on that material in a year or so once 13 TeV LHC results on supersymmetry are in.

Bonus material: Quanta magazine has a great interactive map of "Theories of everything".

Comments

1. **Bernhard**
   August 3, 2015

   Does Tegmark mention why inflation predicts a multiverse? I suppose the argument is that some models of inflation predict a multiverse (I'm not even sure what that really means, but anyway) ? In the case of string theory is clear what happens, the theory predicts nothing, so the multiverse is used as an excuse for this failure and it also become the main prediction of the theory. But inflation is supposed to make a few predictions (right?). I'm sure one can have inflation without a multiverse, so the whole connection is rather unclear to me. As I'm ignorant in this whole thing I just looked at Wikipedia, where I read "All models of eternal inflation produce an infinite multiverse, typically a fractal." Whatever that means.

2. **Peter Woit**
   August 3, 2015

   Bernhard,
   I'm no expert, but from what I've seen of work on inflationary models, Steinhardt is right that you can get pretty much whatever you want from them, and I assume that means a multiverse or no multiverse. One expert is Katie Freese, and here
   https://www.quantamagazine.org/20140722-in-search-of-dark-stars/
   she comments on the BICEP2 data (which turned out to be wrong)
   "If you take the BICEP data literally, which I'm not saying you should, you never have eternal inflation. So you don't have to have eternal inflation, if you ask me. I was very happy about that."
   See her paper with Will Kinney about this
   http://xxx.lanl.gov/pdf/1404.4614.pdf
   where the abstract says
   "even tiny running of the scalar spectral index is suffcient to prevent eternal inflation from occurring…"
   I have seen multiverse enthusiasts claiming "inflation implies multiverse", but since many of their other arguments are full of holes, I see no reason to believe this one isn't too.

3. **Curious Mayhem**
   August 3, 2015

   It's still hard to understand why people try to connect "multiverses" (in the string sense) with inflation. The two logically have nothing to do with each other. Inflation can give rise to different parts of spacetime having different elementary physics or "eternal" inflation, but they're all part of one meta-universe, or whatever you want to call it. And neither has anything to do with the many-worlds interpretation of QM, which is not a theory, but a particular spin on quantum mechanics, if you'll pardon the pun. (Arguably, it's an obsolete interpretation, superseded by a better approach, decoherence, which is actually testable.)

   Inflation could be proved tomorrow and have no direct bearing at all on string theory. There is an indirect bearing: string theory has a very hard time accommodating inflation, except for some special models with a peculiar symmetry.

   (Interesting lookback: I just saw the old "East/West Coast metric" post. The history of the West Coast metric is simple: Bjorken & Drell's 1964 textbook, before Feynman ever arrived at SLAC. The convenience for particle physicists is straightforward. Time-like and causal spacetime intervals have a positive square-interval, and most importantly, the momentum 4-vector has positive norm = +m^2. In a particle's rest frame, this convention fits naturally with just a time-like component being non-zero. And the phase of a positive wave starts with +omega*t (or E*t in natural units), again matching nicely with the rest frame.

   (The East Coast metric does have advantages if you're working with special or general relativity and need to make contact with the non-relativistic limit. But particle physicists mainly live in momentum space, not real space. Which might explain something about them ….)

4. **Peter Woit**
   August 3, 2015

Curious Mayhem,
I learned QFT from Bjorken and Drell, my invocation of Feynman was just a guess as to where they got their choice of metric from (they were writing in the early sixties, at a time there were already quite a few QFT books around). After I later checked a lot more QFT books I realized that many of the 1950s-era ones, for instance Schweber, or Bogoliubov and Shirkov, were already using the West Coast metric long before Bjorken and Drell. I'm still curious about the history, never managed to find out who first started using the West Coast convention. Interestingly, the earliest sources I looked at treated special relativity by using imaginary time (and thus the East Coast metric), which is very natural from the point of view of modern Euclidean methods.

I don't want to start up that discussion again, but would be interested if someone knew the 30s-50s history of this.

5. **Robert Delbourgo**
   August 3, 2015

   We were brought up on the West Coast metric at Imperial College in the late fifties/early sixties but that may have been the influence of Schweber's book. Bogoliubov and Shirkov was also out then. Again that may also be due to the fact that we were being instructed in particle physics; general relativity took more of a back seat.

6. **Low Math, Meekly Interacting**
   August 3, 2015

   I'll never get over my bafflement at the attraction to the anthropic multiverse. It's not so much wrong as a decision to commit suicide, from a scientific perspective. What's the point of a prediction that can never be tested? Even if one believed in the multiverse utterly, it's still a trust fall into the abyss. Is it really worth redefining science to keep? Isn't human dishonesty enough of a problem for science without having to dispense with the means to combat it?

7. **unification**
   August 4, 2015

   Inflation could be proved tomorrow and have no direct bearing at all on string theory. There is an indirect bearing: string theory has a very hard time accommodating inflation, except for some special models with a peculiar symmetry.
   –
   " string theory has a very hard time accommodating inflation" why is this so? there is a field string cosmology

8. **Bee**
   August 4, 2015

   Did you mean 13 TeV?

9. **Peter Woit**
   August 4, 2015

   Bee,
   Thanks, fixed. I need to figure out some way to stop always making that mistake..

10. **MB**
    August 4, 2015

    "Of course, if an infinite multiverse does exist, some other Woit is out there saying the exact opposite."

    Well that's an entertaining notion at least.

11. **anon**
    August 4, 2015

    Curious Mayhem, I am similarly puzzled by the seeming widespread confusion of multiverses (or phase regions in a single inflationary space-time) and many-worlds, which are completely unrelated concepts. I am also puzzled by the oft-repeated claim among otherwise serious people that every phase and every history that is possible in an infinite (possibly eternally inflationary or not) space-time is therefore *mandatory*. Maybe I am missing some ergodicity assumptions that they never state, but to me that sounds like like saying that because infinity is a lot, therefore any infinite sequence of integers includes every integer (obviously false).

    As for decoherence, though, since most people who study decoherence for good reason don't claim that it is an *interpretation* of Quantum Mechanics, I disagree that it can supersede any candidate interpretation of QM, including many-worlds (which I personally disbelieve, by the way) but this may be veering off-topic.

12. **Wayne**
    August 4, 2015

    Peter,

    I've always wondered why multiverse proponents always say that the laws of physics and the values of fundamental constants vary in each universe. If there is a multiverse (or if eternal inflation is correct), why must this be so? Why can't each instance of inflation somewhere just produce the same laws and constants?

    Also, I don't understand why string theorists say that string theory predicts a multiverse. Do they know how string theory describes the making of these different universes? As far as I know, they just have different solutions, but no mechanism by which these universes can get made. Or perhaps I'm completely wrong.

13. **Peter Woit**
    August 4, 2015

    anon,
    Likewise, I've never understood the "anything that can happen will happen" argument, it seems to be based on an assumption that the underlying theory is mostly vacuous (other than providing some constraints on what can't happen). In particular, in any sensible theory, no Peter Woit would be defending the multiverse…

    Wayne,

As usual in this kind of "string theory", you can come up with "string vacua" that give what ever you want. I'm sure you can come up with a string inflation model that leads to a multiverse with each universe having the same physics, as well as models with each universe having different physics. The appeal of the second is that you can use it as an excuse for not being able to predict anything, the first has the defect of being predictive.

14. **Scott Church**
August 4, 2015

Bernhard/Curious Mayhem/anon,

I'm no expert either, but I believe the confusion over the term "multiverse" is that it's used in different ways. Eternal inflation leads to one in that each of the "bubbles" that have reheated from the larger inflating "fractal" space-time (or "metaverse") are being called "universes." This is what Tegmark referred to as a "Level I" multiverse (Many Worlds "parallel" universes he calls "Level II"). Eternal inflation, if real, would lead to a Level I multiverse.

These days I see a lot of folks doing two things: First, they treat inflation as synonymous with *eternal* inflation, which it isn't (it is true that most inflationary models are likely to be eternal, but not all are, and those that aren't seem to get summarily dismissed). Second, they treat any inflationary multiverse as one based on the string landscape even though, as you said Curious Mayhem, the two logically have nothing to do with each other.

It seems to me this is happening mostly because in the absence of a truly workable theory, the eternal inflation/string landscape show is the only way to generate the widely varying physical parameters/laws one needs to anthropically sidestep fine-tuning issues. Without the string landscape, inflation (eternal or otherwise) only gives us a universe/s with the same physical laws as our own, and that doesn't do much to keep the fine-tuning demons at bay. A lot of people these days are terrified of fine-tuning… and whether they'll admit it or not, for reasons that seem to be more metaphysical than scientific (hence, the ease with which they accept post-empirical "beauty" as more scientific than direct observational verification). Over the last 30 years or so this is the best they've been able to come up with and they're sticking to it… because admitting defeat and facing the alternatives is just too damn scary. 🙂

15. **Magnema**
August 4, 2015

@ Scott: You're off-by-one on your numbers there, with respect to Tegmark.

Level 3 is QM MWI. A note on this: anon is correct in stating that decoherence is a phenomenon, not an interpretation. It's when a thermal system interacts with a quantum one, which effectively wipes away the quantum one – but this occurs in both MWI and Copenhagen-style work.

Level 4, known in the philosophical community as David Lewis' Modal Realism, is "everything possible exists" (up to some possible limitations). This has the strength of working from more-or-less no axioms (and therefore is supremely "simple"), but has the weakness that it's virtually impossible to get anything out of it. I think this is the epitome of "simple theories over understandable predictions," and is much more grounded in aesthetic metaphysics (and plausibly epistemology) than anything physicists (with the exception, as usual, of Tegmark) want to deal with.

Finally, there's the issue of the multiverse as it's most often discussed on this blog and similar sources, which Tegmark splits in half. You start out by realizing that if we have a really big universe, then there's a lot of parts that we haven't seen to date, and – given dark energy – we might never see, and therefore we can never observe. Inflation, in itself, gives you nothing more than what a really big universe gives you (and I believe this is true for both eternal and non-eternal theories). There's the issue of how seriously to take these other possible universes, but if they're all virtually identical then there isn't much of an issue here. (This is the kind of multiverse which, in the most straightforward sense, a positive curvature would rule out.)

The distinction here between "inflationary universe" and "infinitely large ordinary universe" only occurs if you add some theory – any theory – which has multiple low-energy limits, such as string theory. Then, you can get the anthropics on parameters, which is the whole point of people talking about the multiverse in the first place. This is where your numbering mismatch with Tegmark comes from – he calls the former, a really big universe, the level 1, and the latter, where you can get anthropics in physical laws, the level 2.

@Wayne: The (simplified) idea is that different parts of our universe would have no causal contact, and therefore, while they could be the same, there's no reason to be – and if there's infinitely many causally-independent regions, then with probability 1 they will have a representative from every non-probability-zero subset.

16. **Magnema**
August 4, 2015

Insofar as predictions and testability are concerned: I think it would be fair to say that a single-universe perspective makes the prediction that life should be a reasonably generic property of possible universes, given that the one that exists has life (barring both incredible luck and any deific-style selector on life existence). Any multiverse makes no such prediction, although the absence is a prediction itself relative to a single-universe perspective.

These predictions are highly unconventional in that, unlike typical science, these start with the experimental result (life being observed) and make conjectures about the theory, because they make guesses about the space of possible worlds based on our observed one. It's analogous to a physicist making a mathematical conjecture based on a particular model of an observed physical phenomenon, and then (when mathematicians prove the physicist's conjecture) taking it to be evidence that his model of the phenomenon is correct.

It's odd, to be certain, and brings to bear a question in the philosophy of science, namely: what are predictions allowed to be about? Are you allowed to conjecture something based on your theory which is logically either true or false before you conjecture it, then treat that as a prediction? In other words, should you count predicting math with physics as a testable prediction? Personally, I think it would be fair to say yes, but I'm willing to grant that it's not clear…

A mostly-related remark: I started following this blog because I thought it would be a good thing for me to have both pro-multiverse and anti-multiverse resources on my reading list. I'm glad I did that, because my positions have shifted significantly by the exposure to more perspectives… while I maintain a MWI-view of QM (with some QB sympathies), and maintain an acceptance of the multiverse, it's led me to question my views a bit more, as I've seen some legitimate criticism (as opposed to the flawed counterarguments I've heard most often).

In particular, whereas before I took the above test to be "single universe predicts no fine tuning" (which I still do) and "fine tuning exists" (which logically leads to the conclusion "single-universe has been falsified"), this blog has convinced me that we don't understand how to apply anthropics (either in "what life is" or in the prior probability of worlds) well enough to conclude the latter point. I'm still inclined to sympathize, but every time people try to use anthropics and make wrong predictions, I become significantly less certain that they can get the logic correct when they already know the answers they should get…

(Sorry for the longwinded double-comment, but I figured since I was talking about two different things I should split it.)

17. **Peter Woit**
August 4, 2015

Magnema,

I don't see any argument at all from "causally-independent" to "with probability 1 they will have a representative from every non-probability-zero subset" (and I think this is the point anon was raising). Just because you know nothing at all about causally disconnected universes doesn't mean there are an infinite number of them out there uniformly filling out some probability space.

To actually say anything about these other universes you need a theory of where they came from (and no, I'm not convinced such a theory will only produce negative curvature). The problem with all discussions of the multiverse is that they're empty of actual substance: no one has a viable parametrization of the space of possibilities or of the dynamics leading to these possibilities. What people do then is just make an empty statement about things not understood being equally likely, and their "multiverse theory" is indistinguishable from my "I have no idea what is going on" theory.

18. **Scott Church**
August 4, 2015

Magnema, thanks for the sanity check! I actually meant to preface that statement with *"If memory serves me…"* but inadvertently dropped it in my edits. Apparently, memory didn't serve me all that well. 🙂 Anyway, thanks for all your other comments too… very informative and thought-provoking.

19. **adrian**
August 5, 2015

Dear Peter,
I am not fan of taking a quote and deconstruct it, as it may loose the intended meaning, but what you wrote above caught my attention. Indeed, the quote in your article (did I misunderstand? is it you saying this?)

"They allow theoretical ideas like string theory that have turned out to be empty and consistent with anything to be kept alive instead of abandoned. "

Seems to suggest that you believe that

–Sting Theory is an empty idea.
–that String Theory is consistent with anything.

Is it the case that you believe on these two statements above?
Could you please qualify them? what do you mean by 'anything'?
what do you mean by 'empty'?
Are you suggesting that all the work done in String Theory since 1969 is empty of content? Could you please explain? I can think of some counter-examples to you two statements above.

20. **Magnema**
August 5, 2015

@ Peter Woit: Statistically, I believe it is fair to say that, for some distribution, in an infinite number of trials, you will, with probability 1, get at least one point (even infinitely many points) every non-zero measure subset, correct? If the subset has total probability p, then the probability of missing it N times is (1-p)^N, which goes to zero as N goes to infinity, meaning you will almost certainly hit it eventually.

Now, you can question three things that I can see. Firstly is whether or not they are randomly selected at all, which I take to be anon's point. I think the most plausible counterargument would be "if not randomly, then what?" In general, I don't see a way this is distinguished from any other statistical mechanical problem, where you have probabilities arising from a deterministic problem based on one's own ignorance. Of course, there's foundational questions in statistical mechanics, too, but at the very least I don't think this is a different question.

Secondly, there's the more technical issue of where the probability measure comes from. I accept this as an issue, both theoretically and (as evidenced by the repeated failures of anthropics) practically. In fact, to take it a step further, this even assumes a probability measure at all, which would be tricky to derive from first principles. I think this is more your protest, and it's certainly well-grounded as a concern.

However, in order to make assertions in general, we don't really need to know the exact probability measure so long as we know the measure-zero sets, which one can at least make some reasonable-sounding assumptions about. You don't need a particular distribution for anthropic explanation of some sort of finite fine-tuning to come out if the universe were infinite. Of course, you do need a measure to effectively apply anthropics as a predictive tool more generally, which I think is where the greater issue comes in, but I think that's a slightly different problem.

Thirdly, of course, is the issue of whether the universe is infinitely large at all, which would be the point where curvature would come in, as well as some other assumptions (e.g., cosmological principle) which may or may not be justified…

21. **Peter Woit**
August 5, 2015

adrian,
The discussion is about string theory as a TOE, and my claim is that, as such it is empty, predicting nothing.

Magnema,
I just don't see that "pick randomly, I can't tell you why" has any more content than "I have no idea what's going on here, pick randomly if you feel like it".

22. **Neil**
August 5, 2015

"Of course, if an infinite multiverse does exist, some other Woit is out there saying the exact opposite."

Ah, so there is one invariant in the multiverse. All Woits are contrarians.

23. **Peter Woit**
August 5, 2015

Neil,
I don't think skepticism about whether the multiverse is science is contrarian, but rather pretty boringly mainstream and conventional…

24. **John**
August 5, 2015

Scott Church mentions that one possible reason for people supporting the multiverse is to defend against fine-tuning. Peter and others are clearly against the idea of the multiverse. So does that mean Peter is not afraid of fine-tuning, supports it or has another explanation?

25. **Peter Woit**
August 5, 2015

John,
It bears repeating that I'm not "against the idea of the multiverse". Maybe there is a multiverse, I have no idea. My claim is rather that current multiverse theories have no significant scientific content.

As for "fine-tuning", I just don't think there's a real problem there. I have no idea what is responsible for the CC, so no idea how to calculate it. People who think they have a unified TOE, in which the CC is calculable, may have a problem with it generically being determined by the Planck scale and thus way too large. They have a fine-tuning problem.

In practice though, such people don't actually have a viable TOE with a calculable CC, so what they do is say "my TOE has a huge landscape, so I can't actually calculate the CC, instead I'm just going to assume it's equally likely to be anything". When they do that, if they assume things are calculable in terms of the Planck scale, they then have a fine-tuning problem (which they claim to solve with a multiverse/anthropic argument).

26. **Scott Church**
August 5, 2015

John,

When I said that many folks embrace string landscape/eternal inflation (SL/EI) out of a fear of fine-tuning, I didn't mean to imply the opposite–that those who are skeptical of it don't consider fine-tuning to be an issue. My only point was that many people have latched onto it unquestioningly for reasons that are ultimately less than scientific. Few physicists dispute the seriousness of fine-tuning issues, but many think that attempts to account for them via SL/EI have been at best unproductive, and at worst disingenuous. Too many people today just default to them because they're fluid enough to explain *away* what we see rather than explain it, and inappropriately blur the distinction between physics and metaphysics in the process. What's needed are models that are specific and robust enough to make predictions we can verify, and our search for them must be philosophically as well as scientifically honest. In this Brave New Post-Empirical world we're in grave danger of losing sight of that.

Magnema,

Regarding multiverse probability measures, one of the best treatments of the technical issues I've seen was given by [Ellis, Stoeger, and Kirchner (2008)](). But regardless of how we handle these issues we still have at least two fundamental problems. First, there are serious issues with an infinite universe, philosophical and observational, and even if there weren't I don't see how one could ever be verified (even in the case of negative curvature we'd only have infinite spacio-temporal extent if the universe/multiverse was simply connected topologically–an untestable premise). Second, the entire question of multiverse probabilities is moot until there's a demonstrable physical method for actually *producing* one. To that end, the only game in town is eternal inflation, which brings us right back to the whole too-fluid-to-be-useful problem. It seems to me that until there's a way around these conundrums SL/EI is more metaphysical belief than genuine science… turtles all the way down. There's nothing wrong with that per se, but if that is one's view then one should be honest about it, and many today aren't. 🙂

27. **Hank Schraeder**
August 6, 2015

Peter,

All this stuff is horseshit and I wish you'd stop reporting on this nonsense. You're preaching to the choir, so find something else to write about. I wish these so-called researchers stopped doing this garbage. They're trying too hard to justify their overly big paychecks. What nonsense.

28. **Layman 2000**
August 6, 2015

@Hank Schraeder:

You are wrong. Woit is not preaching to the choir. As a layman interested in physics I hear a lot about multiverse these days and even bought and read a book about it which turned out to be totally unsatisfactory. So I went out to look for arguments and counterarguments, and this site is an important source of information and informed opinion.

29. **Simeon Every**
August 6, 2015

The question of whether multiverse theories are scientific depends on what 'science' is taken to mean.
I always assumed that science meant 'that which can be known using scientific methodology', but I sense that some subscribe to a canonical interpretation of science, whereby a theory that invokes entities consistent with established entities that have been accepted as scientific is by default a scientific theory.
I have no good philosophical argument against the canonical interpretation but can see that it is of no obvious practical value.

30. **Peter Woit**
August 6, 2015

Simeon Every,
I don't think "invoking entities consistent with established entities" gets you into the "canonical interpretation of science". For example, few agree that my favorite theory of pre-big bang physics (a big green turtle did it) is science even though it satisfies your consistency criterion.

A more common "canonical interpretation of science" is that it's whatever scientists do. Susskind in particular argues for this. It's also why it's important that scientists speak up and challenge those in their ranks who are on a campaign to get acceptance for pseudo-science. I agree there's a good argument that there's too much on this blog about this, but an equally good argument that someone needs to be doing this, and at the moment far too few physicists are stepping up.

31. **AcademicLurker**
August 6, 2015

"Of course, if an infinite multiverse does exist, some other Woit is out there saying the exact opposite."

This sounds like the motivation for a Woit based research program, in which physicists postulate different string vacua and then try to predict what Peter Woit would think of the multiverse in the resulting universe…

32. **Code Ferret**
August 6, 2015

@AcademicLurker: That gave me a hearty chuckle this morning. Thanks

33. **Anonyrat**
August 6, 2015

In no branch of the multiverse does multiverse theory have significant scientific content, and therefore in all branches, the Peter Woits there will be saying this. That is what is invariant.

34. **Magnema**
August 6, 2015

@Peter Woit: I agree with your issue; however, I think the same question you raise can be applied to classical statistical mechanics – in a purely deterministic system, from whence the statistics? As I recall, that's a serious problem in the philosophy of physics as well – but I'd guess they're one-and-the-same problem, namely, how do you get from ignorance (either of the microstate of a system or the self-locating ignorance in the multiverse) to probabilities? Yet we do like to think we have an idea of what's going on in statistical mechanics.

@Scott Church: For the first question (infinite universe), I admit, I have no response, although I would say that (as a Bayesian) the longer we go without observing topological complications, the higher we may want to raise the probability of a simple topology… but that depends on your priors over topologies, which depends again on a measure over possible universes. I'm also curious about your "problems with an infinite universe" – aside from being untestable and the open question of how to derive probabilities in the infinite case (which I'm not sure is a "real problem" in the same sense as what I said to Peter – it's no different than the usual foundational Stat Mech difficulties).

For the second, I would have two responses. Firstly, "argument without a particular mechanism" can be valid sometimes – after all, it is the entire principle behind (ordinary) inflation. If it works there, one shouldn't necessarily reject the multiverse idea on that ground (although I admit that it weakens the hypothesis, just as it does inflation). Secondly, as I said before, I think anthropic argument may work even when you don't understand the probability measure well enough to make accurate numerical predictions, although the latter would be a key element that would turn you from "a plausible-sounding metaphysical idea, which resolves a particular problem" into "a proper physical theory."

35. **Simeon Every**
August 7, 2015

The most contemporary developments in philosophy of science (that I am aware of) characterise research paradigms in terms of the extent to which theories in given paradigms produce testable predictions. This seems to be favouring methodological issues over canonical issues. Unfortunately there seems to be a prevailing mood amongst theoretical physicists (at least among those with the most public prominence) to declare philosophy irrelevant.

36. **anon**
August 7, 2015

Magnema: "…how do you get from ignorance (either of the microstate of a system or the self-locating ignorance in the multiverse) to probabilities? Yet we do like to think we have an idea of what's going on in statistical mechanics."

I submit that we have less of an idea of what is going on in Statistical Mechanics than we sometimes pretend to. Regarding the "Everything that is Allowed is Mandatory" problem, much of classical Statistical Mechanics take some form of ergodic hypothesis as a postulate, but this is mostly unproved and is often technically false (ergodicity often only holds only modulo a coarse-graining assumption). There are some rather interesting and complicated (even chaotic) classical systems that are not ergodic. See for example the Fermi–Pasta–Ulam problem. These may be the rule rather than the exception.

37. **Low Math, Meekly Interacting**
August 7, 2015

Simeon: I don't have much of an opinion on the relevance of philosophers, except to say a robust research program doesn't need them. I would furthermore posit if your research program could stand to benefit from an infusion of philosophical rigor, that's a sign of deep trouble. History ought to be an adequate guide, and it tells us science disconnected from observation is a dead-end path. There are precisely zero examples of true success in the absence of empirical evidence. There is precisely zero reason to think true success can be found in the absence of empirical evidence in the future. If quantum gravity and/or unification research cannot make contact with experiment, then they have no future as science, or should not, in my opinion. That's why the anthropic multiverse is anathema. It's an attempt at creating a loophole for a line of inquiry that may very well be hopeless. It's an excuse to keep working on it.

To my silly little mind, it really looks about that simple. I'm sure a philosopher could frame the position much better, but is there much added value? It's a question of whether to stop and focus on things one can ever test, or redefine "science" for oneself to avoid that requirement. What more is there to it, in actuality? Very little of true substance, it would appear.

38. **Scott Church**
August 7, 2015

Hi Magnema,

Beyond the untestability issues, the serious problems I was referring to were; 1) The philosophical problems with instantiating *actual* (as opposed to conceptual) infinite universes in the real world (e.g. "Hilbert's hotel", etc.); and 2) Physical difficulties with the formation of spacio-temporally infinite child universes in eternal inflationary scenarios (for instance, see Ellis & Stoeger (2009)). The former in particular is a hotly debated issue and both are off-topic here. My intention was simply to note them in passing.

As for inflation, I'm with you in that I also think its current fluid state, by itself, shouldn't lead us to reject Level I multiverses outright. I must admit, I have something of a love/hate relationship with inflation. On the one hand, it's a beautiful paradigm that solves multiple seemingly disparate fine-tuning issues in one fell swoop (e.g. flatness, CMB isotropy, etc.), and it is testable in the sense that specific characteristics of the CMB and model-specific predictions from tunneling and/or reheating scenarios allow us to rule out many inflationary models. It also seems to be the only viable option for bringing at least some multiverse scenarios into the realm of observational testability… *in principle,* that is. However, in practice it only pushes the fine-tuning problems back a level. And in the absence of any clear inflaton candidates it leaves us free to dream up any scalar field scenario we like (hence the fluidity). Yes, a conceptually valid physical mechanism is involved and those models can be tested, but the end result is little more than whack-a-mole. And to many folks the real appeal of Level I multiverses is that they open the door to possible anthropic solutions to fine-tuning problems. But I don't see how they can do this without the string landscape–all of which is true whether we're able to define valid probability measures on the outcome space or not…

Which sadly, brings us right back to square one… untestability. I must say, I was one of those who eagerly awaited the Planck results hoping for the "smoking gun" of primordial B-mode CMB polarizations. I was also one of those rejoicing when the BICEP2 results were first announced. But once those results started to unravel, it was disconcerting as hell to watch Linde and others furiously backpedal on B-modes as a smoking gun. "Geez," I remember thinking. "Steinhardt is right… they really *can* get whatever they damn well please out of this framework, can't they…?" I'm no expert on these matters, but I suspect that we aren't going to find a viable inflaton candidate or be able to meaningfully evaluate string theories without probing much closer to Planck scale energies. I don't see how this can ever be done without an LHC the diameter of the solar system (that has all the attendant luminosity problems solved as well). Even if it were possible to build and operate such a device, imagine what it would take to get anyone to fund it… especially if Republicans control Congress. (Sorry… I couldn't resist. 🙂)

It may not sound like it so far, but my real complaint isn't with inflation, multiverses, or even string/M-theory per se. It's with all the high priests of "post-empiricism" who expect us to flippantly dismiss all these concerns and line up behind them so they can redefine science as a beautiful, Utopian fairy tale land… with verdant landscapes and lush theoretical gumdrop trees… where gossamer winged math fairies grant every wish… where 72-virgin review committees publish every paper and dry every tear… and nothing as pedestrian as real-world *facts* are allowed to spoil anyone's party. Unfortunately, the trouble with fairy tales is that sooner or later one wakes up from them… and more often than not, with one helluva hangover and someone pressing charges. 😀

Best.

39. **Carlos Looney**
August 7, 2015

Neil: whether there are other universes out there in a multiverse with other "Peter Woits" saying different things depends upon your definition of a "Peter Woit." Do we mean just the DNA structure, what about environmentally induced alterations, mental content, or other variables?

According to some Physicists of the MWI persuasion, each "Peter Woit" is constantly splitting into two Peter Woits in two different worlds everytime a measurement is performed. Should we distinguish between these Peter Woits and what criteria? Are the "Peter Woits" we do not encounter real or unreal? Notice that the Peter Woits in the inflation scenario are real Peter Woits. But with MWI it is an open and probably never resolvable question.

40. **Peter Woit**
August 7, 2015

Actually I think the multiverse is an opportunity for philosophers of science to show that their subject is relevant and useful. There's a lot of material there to apply their best thinking about the demarcation problem to. Unfortunately I haven't seen much of this happening.

41. **Low Math, Meekly Interacting**
August 8, 2015

Peter: I'm probably too dismissive or pat in my thinking, but sometimes professional philosophizing seems like a very convoluted path to the obvious point. Book-length treatises which amount to the substance of clever aphorisms like "beautiful horses win races."

But you're probably right about programs that can keep moving the goalposts of testability due to an abundance of flexibility. It's one thing when a model's predictions are beyond the grasp of mere mortals to test. But what about those that could be, but also could be testable at, say, any energy between what the LHC can probe and the Plank scale? One can call it ugly, but if beautiful horses win races, proponents seem initially to be game for the challenge of science, and I can think of no iron-clad argument for denying their legitimacy at the outset. Of course, if the race is allowed to go on forever, that's a different story.

I.e., there are research programs that start out being arguably scientific, but evolve through repeated failures into something else. My challenge to the philosophers would be to give us a clearer answer to the demarcation problem, one that can tell us the right time to say enough's enough, and have everyone agree.

42. **Magnema**
August 8, 2015

@anon: Agreed on the lack of understanding of Stat Mech – the more I learn, the less I feel like I know about how it emerges. My point was more to make the analogy between established science (with, admittedly, poorly understood foundations) and multiverse-type arguments. I suppose I am assuming something analogous to the ergodicity in the multiverse case as well.

@Scott Church: I agree with everything you just said.

However, I note an issue here on Bayesian vs. Popperian science. In the former, which is usually regarded as the stronger theory, the CMB tests were taken as evidence, rather than a total disproof. It would seem that those individuals place a very high prior probability of inflation/string theory/related hypotheses, which means that, while the test should have been sufficient to bump an "uncertain" person into a "very certain" position, the converse is insufficient to bump a "very certain" position into anything less than a "moderately less certain" position. (E.g., suppose that they think: 100% chance of positive results meaning inflation, 99% negative results do; then, while they should reduce their confidence in their theory from, say, 99.999%, it's not going to be reduced too dramatically.) Now, whether or not their utter confidence in their theory is justified (I tend to think not) is a different concern, but it can still be scientific seeing as the prior probabilities have no scientific way (to my knowledge) of being determined…

43. **Jason**
August 9, 2015

Hey Peter,

I'm a former physicist; I got my PhD working on CMS before the LHC turned on, finishing in 2006. Although my research was focused on rare signature events, specifically Z' searches for indications of Super Symmetry, most of my colleagues and I thought Super Symmetry was probably made up non-sense. We all knew the reasons the theorists wanted it, but from an experimental perspective, it seemed a big stretch that there would be twice the number of particles, and not a single bit of evidence that they impact any Standard Model (SM) measurement. Wouldn't it be difficult to exclude the idea that those extra SM particles would have changed the result of any SM measurement going on already? There are many high precision measurements of the SM, surely something would have shown up by now, not just in the high-energy experiments?

I have been enjoying your blog for a while now. I don't really have a strong opinion one way or another about the multiverse. However, I do think your arguments are a bit more persuasive for me that what I've heard on the other side. I'm just wondering, if it were for the practice of debate, what would be your best defense of the multiverse? Or in other words, what would be your best arguments against yourself?

Thanks Again!

44. **adrian**
August 9, 2015

Dear Peter,
I have followed the discussion about the topic of the landscape in this blog post. Before, I asked you to qualify a statement you were quoted on—see message above, you did it. I probably disagree about the total lack of value of string theory as a theory of Everything, but the topic in itself [I mean TOE] interests me very little.

I wanted to comment something, probably a bit influenced by my daily read of the hep-th arXiv. As you may guess, I do work on string theory, publish regularly and never worked on 'the landscape'. I may be a bit unfair in the comment that follows.

It is my impression that most physicists or most string theorists are actually NOT working on landscape related topics. So, when people refer to the 'multi-verse mania', I find hard to understand what they are talking about. It seems to be something that most goes on the press than on the actual work of physicists/string theorists.

Let me take as an example the work of two physicists I know personally and have discussed at length with them: Matt Kleban and Ben Freivogel. They are both solid and serious physicists. It is a pleasure to discuss any particular problem with them, they will always make an interesting observation–probably also a correct one– and one always leaves enriched after a conversation about Physics with them.

Having written this, we open the spires page for their work. I will take them as representatives of physicists working on landscape related topics. Again, may be there are other representatives, but these two, at least, I know for a fact are serious and will not lie in a paper. As you can see, their work on the topic is not excessively cited by colleagues. It is just cited like any other set of papers of other colleagues. I mean, papers cited order 60 times since 2008 is not reflecting a real rush of activity, many of my more recent papers have more citations than that. Notice, this is NOT an evaluation of the quality of the papers of these two physicists. I -know-the papers are very good. This is just a reflection that there is not a lot of activity. It is not the case that large amounts of money in funding are deviated into that topic.

It is certainly NOT my intention in this comment to offend anyone, much less Kleban or Freivogel. I am just taking them as representative of a line of work [actually as serious physicists working on that line]. I do know that a very cited paper does not mean it is a good paper, but it reflects the level of activity on the topic, sometimes, it also reveals the paper is very good, but is not always the case. I know many papers that are very good and almost not cited.

Could you please let me know if my view of this topic is misguided? Let us also observe that of Susskind or Linde say 'multiverse' many times, this does not mean the topic has wide acceptance among the majority of working physicists. Does not mean either that big amounts of funding are assigned to that area. I may be wrong, could you please correct me? I do not have good data.

Having written this, I believe the criticism you voice on the topic is healthy.
I have the impression that you sometimes get carried away and involve the whole area of String Theory under the same criticism. This is pernicious. But it is your blog and are your opinions.

Thanks

45. **Peter Woit**
August 9, 2015

Jason,
I think your argument about why to not expect SUSY at the LHC (zero evidence, direct or indirect, for a single SUSY state, out of a large expected number) is one a lot of physicists shared. It's too bad that it rarely got made publicly.

I'm not much of a debater… The best argument the multiverse people have is the one for the CC. As for the landscape, you can try and argue that research should continue, absent a successful idea. All in all though, I think arguments for the multiverse are even weaker than arguments for string theory.

46. **Peter Woit**
August 9, 2015

Adrian,
You're right that most string theorists don't work on the multiverse, and pretty much do their best to try and ignore it. Many of them do however invoke it as an excuse when challenged about the failure of string theory TOE ideas to work out. Many of those promoting the multiverse are not string theorists (for example Carroll and Tegmark), but physicists who want to address "big ideas", and end up falling for something empty which seems to do this.

It is a fact though that the string theory landscape and the multiverse get a huge amount of public attention. Good string theorists may not take them seriously, but they're also not willing to go on record saying anything critical about the subject (there's a strong ethos of "string theory is under attack, so thou shall not criticize anything about string theory or the arguments being used to justify it"). By letting this go on and doing nothing, they are allowing some serious damage to be done to their field. There are a lot of people out there that the press and the public rightly turn to, and they're not stepping up to the job (put differently, why aren't there more like David Gross?). I confess to a certain level of annoyance about this, that I'm doing something unpleasant because the people whose job it is to deal with it don't want to.

47. **adrian**
August 10, 2015

Dear Peter,
I would like to briefly comment on your answer above. You stated
'Good string theorists may not take them seriously, but they're also not willing to go on record saying anything critical about the subject (there's a strong ethos of "string theory is under attack, so thou shall not criticize anything about string theory or the arguments being used to justify it") '

I have two observations:

1–that many string theorist do not go 'on record' with their opinion about the landscape and anthropic arguments because they have not worked on the area actively. It is difficult to have an opinion and record it somewhere if one have not contributed or deeply thought about the thing. Do you agree? In my case, I see anthropic arguments with some fascination-rejection (for example, I find the book by Barrow and Tipler beautiful to read). I see the landscape as a VERY interesting geometrical problem. But since I wrote no paper on any of those areas, all I can contribute are 'feelings'. Why should I go on record or on the press to say my 'feelings'?

2–The area of String Theory is, indeed and unfortunately, under attack. The attack that people who are NOT working in the area are expressing is sometimes short sighted, sometimes ill-intentioned and sometimes based on misconceptions. Sometimes it is fair criticism. This is a type of 'high-profile' attack that other areas of Physics [QCD, Collider Physics, Condensed Matter] do not suffer from–I mean press articles, books, blogs. Believe me that the most interesting criticism of the topic, I have heard from physicists working in the area. Indeed, I find that the fairest criticism is made by those who are actively working on the topic, in seminars and papers. Of course, some other people write press-articles "in favour" of String Theory that are pathetic to read.
But as I wrote some months ago in your blog's comments—that time about Amanda Peet's talk at Perimeter: the science is made in papers, seminars and conferences, not in blogs, not in press articles nor in popular talks.

thanks for the attention

48. **Lucy M**
August 10, 2015

Adrian "It is difficult to have an opinion and record it somewhere if one have not contributed or deeply thought about the thing. Do you agree?"

Yes…it's a fact of life that the people immersed in a theory understand by far the most. Would you agree that this is the same for every theory that has ever existed?

A serious problem of this, is that while people on the inside of a theory may be totally impartial, sometimes they are not. This is a serious problem that bedevilled knowledge before and outside the scientific revolution. Knowledge inevitably gave power to those who preached it.
Prediction is there among other reasons to prevent scientific incumbent knowledge from having to adopt new theories on the word of its insiders, and they from becoming philosopher-kings in the event their theory is adopted.

Can I just say that it is very clear that String theorists have had 'group shared experiences' that leave them with a shared sense of sureness Strings are the right way forward.
The problem with group experiences like this, is that the sense of sureness has no skeptic on the inside, at all. This means there is nothing to check excesses. The attempt to re-define Science without predictions, and with a set of traits exactly matching what string theorists think they can demonstrate, is an astonishing example of what can happen.
But also the quality of argument from string theorists….without internal criticism for standards, these arguments have become really superficial and liced with fallacious debating devices. Your most senior theorists – founders even – have come out with the most specious and frankly dishonest arguments.
I believe this is a direct consequence of a group of people succumbing to group shared experiences instead of treating such things as par for the course. Because they are. Everyone has them in the realm of their own theory.

49. **Lucy M**
August 10, 2015

Adrian "It is my impression that most physicists or most string theorists are actually NOT working on landscape related topics."

Yes but the REASON is that there literally are zero research directions, the multiverse is perfectly sterile.
What it doesn't mean is that most string theorists BELIEVE or SUPPORT the multiverse.
If they won't come out and make a firm break with their colleagues that do support the multiverse, then – again – we're being asked to trust the word of insiders bonded to each other by nebulas group shared 'experiences'.
Why aren't you giving your full details? Can you post a link to a website set up by dissenting string theory insiders?
I notice you use the subtly modified general vocabularly that is the hallmark of the 'shared group experiences'. For example the word 'beautiful' gets used rather a lot.
Another hallmark is more than a whiff of ego involving ideation not unlike those who have had religious experience.
Another hallmark is avoidance of fundamental criticism, and of the tactics of own side.
Apart from that you seem a very sweet person :O)

50. **Lucy M**
August 10, 2015

Peter Woit "Actually I think the multiverse is an opportunity for philosophers of science to show that their subject is relevant and useful. There's a lot of material there to apply their best thinking about the demarcation problem to. Unfortunately I haven't seen much of this happening."

the problem with deploying philosophy is that the very enactment of that effectively answers the central question that has been there from the start and still remains unanswered to this day. Is science unique, or is it a continuation of pre-scientific philosophy.

If science were unique philosophy would not be able to see that uniqueness. All it would see would be the elements in which science is like philosophy.

This happens to always be the conclusion of philosophy. The productivity gets played down, as well as every other unique feature. The special meaning of a whole range of words within science, are rejected out of hand by philosophers because they don't understand the word in the first place. Words become like they are outside science; just instances of more general effects. Nothing can be a special case because nothing ever was before science. Prediction is just a special case of criticism. Or one of many ways to determine the truth value of a theory. Consensus is about dogmatic authority. And so on. Just exactly what those words and the effects they describe intractably always were before science.
p.s. Popper on science that it had to be 'falsifiable' is a widespread misconception of the thrust of his work. In fact Popper thought science was an unprivileged domain of philosophy and Conjecture&Refutation would suffice there as everywhere else. In other words rational criticism replacing prediction.

51. **Peter Woit**
August 10, 2015

adrian,
I don't think the problems with the landscape require being an active researcher in the field to understand. The more general issue of what the problems are with string theory as a TOE and whether it is accurate to describe the situation there as "failure" are much more complex. I've wasted a lot of my life following that story since its beginnings when I was a graduate student, others quite sensibly may want to just ignore it.

If you make that decision though, I think you forfeit both the right to complain about people criticizing this failure, as well as the right to justify your research as related to a promising path to a TOE. I do see a lot of string theorists these days claiming the TOE problems have nothing to do with what they do, but then their grant proposals start with a reference to string theory as a TOE. They're also often unhappy about people criticizing string theory's failures, while at the same time unconcerned about dubious TOE claims being made by their colleagues.

52. **student**
August 11, 2015

One of the general "landscape" goals is to find "top-down" constraints on effective field theories (EFTs). These give constraints on the landscape. Quite remarkably string theory predicts constraints on EFTs that aren't immediately apparent from a purely EFT perspective. One example where string theory has provided insight into the structure of effective actions is dissipative relativistic fluid mechanics.

Another example where "top-down" constraints were found first from string theory is the classification of 6d (1,0) SCFTs. Recently the "landscape" of 6d (1,0) SCFTs has been nearly tamed into a complete classification. Of course this is a far ways away from the landscape problem being discussed here, but it seems quite plausible that many of the general lessons will apply.

The work on the landscape might be interesting or not, but without serious effort it would be difficult to say anything intelligent about a narrow sub-field. It is perfectly fine if this blog doesn't care to maintain such a standard, but it is completely unfair to criticize others for not going "on record" about papers they haven't studied in depth.

Hopefully the media will eventually follow the example of Quanta Magazine and there will be a much richer and diverse discussion of contemporary research.

53. **Peter Woit**
August 11, 2015

student,
I've no idea whether, as you claim, string theory provides insight into fluid mechanics. I do know though that the classification of 6d (1,0) models provides nothing at all in terms of the basic problem of getting a prediction about observable physics out of string theory.

This is a very good example of the problem: the question of what is known about supposed "string vacua" is an infinitely complex one, so people can attack anyone who points out the disastrous nature of the landscape problem as just insufficiently expert on the technicalities of "string vacua" research. By invoking irrelevant calculations you're just misleading people, claiming "progress" that isn't there, and doing your best to obfuscate the failure of the whole research program.

I agree that many of the writers at Quanta are doing a great job of covering diverse topics of current research, in particular by avoiding what the science media has done far too much of for 30 years, which is promoting misleading claims about string theory as a TOE (like the one you're trying to make…).

54. **student**
August 11, 2015

Peter,
The only claim that I made is that without serious effort, one can't say anything intelligent about a research program. I think your post illustrates this nicely. The classification of 6d (1,0) SCFTs might pave the way for classifying 4d N=1 SCFTs and eventually give constraints on the possible 4d SUSY quantum field theories (or their SUSY-breaking cousins) or it might not. Without hard work, it is hard to say if this approach will succeed or fail. Independently if this is interesting for the landscape or string theory as a TOE (which I am agnostic about contrary to claims otherwise) it is certainly interesting as a vast generalization of the geometric Langlands program.

55. **Peter Woit**
August 11, 2015

student,
I have no idea who you are or if you actually are a student, but if you are I'll just point out that you probably lack the experience to know what "serious effort" is relevant to understanding the issues behind getting the SM out of string theory. This is a problem that a huge number of smart people have worked on for over thirty years, and almost all of those people have decided to work on something else. Back in 1985 there were specific proposals of how to compactify string theory and get the SM. After much effort, there are now well-understood reasons why those proposals don't work. The history of the subject is that of continually finding new possible ways to construct "string vacua", getting farther and farther away from the goal of a predictive framework. The fundamental problem with "string phenomenology" is not just the current state of the subject (which is dismal), but the derivative: things just get worse and worse every year and this has been going on now for three decades. This is both at the theory and experimental level (no SUSY, no evidence for GUTs). If you had been following the subject since 1984 and paying attention to the results being claimed (as opposed to the technicalities of how they were achieved), I think you would understand a lot better the current situation, as well as how ridiculous are the claims you are making about classifying possible string vacua using 6d superconformal field theories. Far more promising ideas than that have foundered long ago on basic problems that such superconformal theories have nothing to say about. You can do anything you want and claim that "maybe a miracle will happen and those problems will go away", but that's wishful thinking, not science.

56. **student**
August 11, 2015

Peter,
Your reply has almost nothing to do with what I wrote. The only relevant statement you make

> how ridiculous are the claims you are making about classifying possible string vacua > using 6d superconformal field theories.

is manifestly false. The statement is that the classification of specific string vacua also classifies ALL 6d superconformal field theories. Again, I'm not saying anything about "string phenomenology" besides the fact that not having studied it, I can't say anything meaningful about it.

Do you still do research anymore? In thinking about prospective research topics, it seems that there are many fascinating areas of string theory that you completely ignore. However, despite your criticisms, you don't really offer any program or vision that a student could work on besides some notes summarizing some basic mathematical results from the 70's.

57. **Peter Woit**
August 11, 2015

student,
"I'm not saying anything about "string phenomenology" besides the fact that not having studied it, I can't say anything meaningful about it."
OK, this makes things clear. Obviously I was discussing string vacua possibly relevant to the real world, and you have no interest in that.
"some basic mathematical results from the 70s"
You're changing the subject, but that too makes some other things clear.

58. **Curious Mayhem**
August 14, 2015

It's scary to think about an infinite number of universes, each with a copy of Peter Woit saying something slightly different.

It's comforting to realize that this universe seems to instantiate at least a local maximum of verificationism in our incarnation of Peter.

Short Items

August 12, 2015
Categories: Multiverse Mania

A few short items:

- The New Yorker has its own coverage here of the NSA GenCyber summer camp program for children that was discussed here.
- The LHC is about to start doing physics again at 13 TeV, with beam intensity slowly ramping up in coming days and weeks. You can follow what's happening here.
- Some filmmakers are planning an IMAX film about the LHC, more information available here.
- Online media stories with skepticism about the multiverse continue to appear. The latest one is by Shannon Hall at Nautilus, with the title Is it Time to Embrace Unverified Theories? (I think it's a general rule that the answer to all questions in titles is No). I like one of the comments on the piece, arguing that some speculative physics is best thought of not as science or religion, but as a game.
- It's behind a paywall and I haven't seen the full story, but this week's New Scientist has a piece entitled What if .. Most of reality is hidden? A large amount of theoretical activity in recent decades has gone towards ways of figuring out how to hide new physics from any possible interaction with experiment. It seems this is another way of characterizing the problem discussed in the Nautilus article of unfalsifiable theories. Again, since it's the title of an article, the answer should be No.

Comments

1. **Stephen Olsen**
   August 12, 2015

   "(I think it's a general rule that the answer to all questions in titles is No.)"

2. **Ben R**
   August 12, 2015

   The existence of that paper ("Is Hinchliffe's rule true?" by Boris Peon) does mean that Hinchliffe's rule (as defined in the abstract) can't be true, but the abstract is wrong to say "Hinchliffe's assertion is false […] only if it is true". It's false whether or not it's true.

3. **unification**
   August 13, 2015

   what about theories that could be verified in principal but the technology to verify them do not exist or are too expensive or too difficult ? i.e GUT scale physics

4. **Peter Woit**
   August 13, 2015

   unification,
   For the multiverse and string theory, the problem is not being falsifiable even in principle. For things like GUTs which are much more well-defined, there may be legitimate predictions, in principle testable (SUSY GUTs typically make proton decay predictions that could be feasibly testable).

   There is an obvious problem though with theories that claim some new physics at untestably high energy scales, when such theories don't explain anything about observable physics. My theory that the universe is made up of very small green turtles, turtles which appear to be pointlike at distance scales below the Planck scale, is in principle testable. That doesn't mean you should take it seriously as science…

5. **Michael**
   August 13, 2015

   In media, the principle is known as Betteridge's law:

   https://en.wikipedia.org/wiki/Betteridge%27s_law_of_headlines

   and a few amusing Twitter accounts apply it to the day's news:

   https://twitter.com/yourtitlesucks
   https://twitter.com/betteridgeslaw

6. **Jesper**
   August 13, 2015

   Perhaps I don't get it, but is it not a problem to assign a color to your turtles, when they are that small?

7. **Low Math, Meekly Interacting**
   August 13, 2015

   It's a metaphor for a new force, quantum chromophorodynamics.

8. **bb**
   August 13, 2015

   I was under the impression that GR received experimental validation well before the 60s (Mercury's perihelion, Eddington's measurement of the bending of light, …).

9. **Carl**
   August 13, 2015

   The New Scientist piece is a mix of stuff. The reference to string theory is around extra dimensions wrapped too tightly to be probed with foreseeable technologies, rather than any "landscape" stuff.

There's also some talk about bubble universes beyond our horizon, and the usual quantum Many Worlds stuff. It's all very muddled (as, in fact, is most of the larger article that this is a part of.)

10. **CU Phil**
August 13, 2015

Jasper,

The color is confined at longer distances for "in-shell" final states.

11. **Peter Woit**
August 13, 2015

Jesper,
The physical laws at the turtle scale are quite different, and if you create a macroscopic state of many turtles, it should interact with visible light such as to have a greenish appearance. Note that this theory is quite falsifiable: if you get a lot of these turtles together, shine light on them, and it looks blue, the theory is falsified.

Your comment does make clear that there remains lots of research to be done on turtle-TOE theory, it's a wide-open field…

12. **Nobody**
August 13, 2015

"turtle-TOE theory"

Call the media!

13. **Jon Lennox**
August 13, 2015

If a headline asks a question that isn't yes-or-no, the answer is ¯_(ツ)_/¯.

14. **Scott Church**
August 13, 2015

This and other threads of late have gotten me to thinking… It's no secret that we cannot test string/multiverse theory and will not be able to anytime soon. It's doubtful we'll be able to in our lifetimes. But… *what if we could?* Would anything be different? Suppose we actually *did* have a working solar system-sized collider or similar device that allowed us to probe Planck-scale distances and energies. This is all speculative of course, but it's reasonable to assume we'd find new particles and/or symmetries, a viable inflaton candidate perhaps, and more. What would we do with these discoveries? It seems to me that even if all this comes to pass we'll still be faced with a fundamental problem.

Historically, successful theories have been able to make predictions because they offered fundamental paradigm shifts that led to them via their formalism. General relativity predicted things like gravitational lensing and the perihelion shift of Mercury's orbit because it postulated a fundamentally different sort of space-time than classical mechanics did, and new field dynamics to go with it. The SM proposed actual underlying symmetries in the universe unlike those of its predecessors, and it was those that led to predictions of otherwise unexpected new particles, including the Higgs. All viable theories come in two parts: 1) A paradigm that proposes some new physical entity, state, or behavior; and 2) A mathematical framework that describes it. Successful theories are validated not by their ability to mathematically describe observation, but by *their ability to verify their underlying paradigms* within the frameworks they propose.

So here we are… our amazing super-duper-Planck-collider has scraped the universe right up to Planck scale energies and filled our databases with new particles, fields, etc. I suspect that *regardless of what we find,* all of that data will fit quite nicely with at least one possible string vacuum state. We will only have discovered which of the the 10^500 theoretically possible string vacua describes our universe. This raises a dilemma. For string/M-theory, the new paradigm is string/brane objects embedded in extra compactified dimensions. The mathematical framework that formalizes it has proven to be powerful but as we've seen, fluid enough to describe anything, including virtually anything our super-duper-Planck-collider manages to find. So the question is… *how does the paradigm get verified here?* How do we know that our "theory" of reality is an *explanation* of new physics in our universe and not simply an arcane but beautiful mathematical description of it?

The only way around this dilemma I can imagine would be to verify a multiverse… that is, to somehow directly observe other regions with different string vacuum states. But that *is* impossible, in principle as well as in practice. Unless I'm missing something, it seems to me that regardless of how elegant or workable the string/M-theory formalism is or how well it describes our observations, *if it does not provide a way to verify its underlying paradigm it is nothing more than an arcane but lovely mathematical framework*. It describes everything, but explains nothing… even if we do have Planck-scale observations.

Thoughts?

15. **David Metzler**
August 13, 2015

Peter, regarding the LHC, do you know of an easily accessible primer and/or glossary for the bewildering variety of acronyms and specialized accelerator physics notions that are tossed around, say at the morning meetings? I've become a bit of an LHC junky but there's a lot that goes on that's still over my head.

16. **Peter Woit**
August 13, 2015

David Metzler,
Sorry, maybe someone else can help. Some of this one can figure out with a bit of googling, but for some of it you probably need an expert to explain the significance of what they're doing. At least the bottom line is clear: they're back in business as of last night, now doing physics with 86 bunches in the beam. They will be increasing the number of bunches in the beam, trying to get up to something like 2800 bunches.

17. **Bill K**
August 13, 2015

"Peter, regarding the LHC, do you know of an easily accessible primer and/or glossary for the bewildering variety of acronyms and specialized accelerator physics notions that are tossed around, say at the morning meetings?"

Try http://lhccwg.web.cern.ch/lhccwg/Bibliography/UsefulAcronyms.htm

18. **Chris W.**

August 13, 2015

Scott Church,

That sounds like a very clear characterization of what Peter has always considered the problem to be—at least, leaving aside the practical computational difficulties of matching one or more vacuum states with the data.

The vacuum states become surrogates or “fall guys” for the underlying theory. This or that vacuum state may fail to match the data, but another will eventually work. The theory is never threatened, i.e., *by construction*, no data can contradict it.

Some people may thoughtlessly consider that to be a virtue—the ultimate hope for any theory…

19. **srp**
August 13, 2015

Now for a thought experiment: A string theorist, before the Ultra-Hyper-Mega accelerator goes online, comes up with a particular vacuum configuration (call it Turtle Conformal Theory) that produces the SM and also makes predictions for the Planck-scale phenomena. So long as that configuration were a) provably unique in producing the SM and b) made unique predictions at the Planck scale, then the UHM would provide a real test and would tend to confirm belief in TCT if its new particles and fields matched what the theory predicted. But if either a) or b) were not true, then the theory would probably still have lots of doubters.

20. **Chris W.**
August 14, 2015

srp,
The UHM would provide a real test of TCT, i.e., the *particular* vacuum configuration. It wouldn’t provide anything close to a test of the underlying theory, unless that theory implied that TCT was the only configuration that might work, i.e., that wasn’t already ruled out by established tests of the Standard Model.

If the latter was the case one could view the TCT as string theory combined with a correspondence principle, which eliminates the other (10^500?) conceivable vacuum configurations. On that basis one could consider the TCT as *the physical theory* being proposed, with string theory relegated to the status of a mathematical framework used in identifying this viable candidate. Of course, given the uniqueness of the TCT, if it fails the mathematical framework fails as the basis for as a fundamental theory. (It may still have many other uses in mathematical physics.)

Of course we’re nowhere close to arriving at this milestone. Also note that the idea of multiverse becomes basically irrelevant—just so much untestable metaphysical window dressing.

Aside from this, note that the initial arbitrariness of the vacuum configuration—before applying the correspondence principle—sounds a lot like the empirically determined and otherwise freely adjustable elements of the Standard Model we were hoping to eliminate. Achieving the milestone and passing the subsequent tests could be taken as evidence that the given arbitrariness is unavoidable, and reflects the choice of vacuum configuration.

That would be very interesting, but again, we’re nowhere close to that point, and we don’t really have a good idea how to get there.

Genius at Play

August 15, 2015
Categories: Book Reviews

A month or two ago I read the new biography of John Conway, Genius at Play, by Siobhan Roberts (whose book about Coxeter I reviewed here). Since then, writing about it has been on my to-do list, but I wasn't at all sure what to say. In today's Wall Street Journal Jordan Ellenberg has done a better job of this than I ever could, so I have a place to start: read Jordan's review.

Probably the first thing to say about the book is that it's an excellent portrayal of its subject, who is an unusual and well-known figure in the math community. Roberts spent a great deal of time with Conway, traveling with him and getting to know him rather well personally, then very ably turning that experience into a quite readable and enjoyable book. It's hard to imagine that a better biography of Conway would be possible.

In his review, Jordan crystallized precisely for me why I was having trouble writing about Conway and the book:

> Will you like this book? Here's a simple test. What's the rule that produces the sequence 1, 11, 21, 1211, 111221, 312211 . . . ?
>
> This is Mr. Conway's "look-and-say" sequence, so called because each number (after the first) is what you get when you look at the previous number and say it aloud: "one one; two ones; one two, one one; one one, one two, two ones . . ."
>
> If that makes you laugh with surprise, as it did me, you'll like Mr. Conway, and you'll like "Genius at Play." If not, you might want to quit here and go read something improving about the Greek debt crisis.

I'm afraid this didn't make me laugh with surprise; it seems that I'm immune to the charm of this sort of thing. While there was a lot of Conway's story I found interesting and which kept me avidly reading, his mathematical interests are very different than mine. Mathematical games make up a big part of his life and career, but the only aspect of this I've at any time found appealing was back in high school, when I remember writing a computer program to run the game of Life. I learned from the book that this is Conway's most famous creation, a fact he's not entirely happy with.

I also learned that my one personal experience with Conway is widely shared: at lunch with a group here at Columbia he mostly spent the time explaining how to calculate in one's head what day of the week any date is. Unfortunately I just didn't enjoy the idea of spending time on this then, and still don't.

Conway is one of the main figures responsible for an important piece of mathematics, discovering and working out the properties of some of the sporadic finite groups. This isn't something I've ever known much about, and I was quite interested to learn from the book some more about the subject and the history of how it came about.

I can't think of any other biography that I've read that gives such a vivid impression of its subject. In Conway's case this is somewhat of a mixed bag. He can be a very entertaining character, but his personal flaws are also apparent, with a suicide attempt and several failed marriages testifying to some real problems. Whenever books like this appear, I think one reaction of some mathematicians (not me…) is "is this good for the public portrayal of mathematics and mathematicians?". Conway's mixture of genius, highly accessible mathematical discoveries often related to games, and serious issues dealing with the outside world fit rather well with a certain caricature of what mathematicians are like. In my experience with great mathematicians, very few of them other than Conway fit the caricature. While any book about him would likely reinforce the caricature, at least this one gives a very well-written and comprehensive view of its subject.

Comments

1. **JSE**
   August 15, 2015

   It totally makes me laugh with surprise! I often teach that sequence to undergrads in discrete math; it really emphasizes the point that a sequence is an arbitrary list of numbers, generated however you please, not "a button on your calculator." On the other hand, I find the idea of computing days of week totally boring.

   Anyway, thanks for kind words. One thing I'm sad about is that I addressed the point you make: "Conway in many ways fits a public stereotype about mathematicians, but many of the qualities that match the stereotype actually make him highly ATYPICAL among real mathematicians" more explicitly, but some of it got cut for length, so I hope the point is still somewhat clear.

2. **KJ**
   August 15, 2015

   I wouldn't worry too much about this book propagating stereotypes. The set of people who 1) are not already interested in math 2) are the sort that is influenced by stereotypes and 3) decide to read this book has to be vanishingly small.

3. **Puffin**
   August 15, 2015

   Peter,
   What is your opinion of Conway & Kochen's Free Will Theorem (which I believe he was alternately referring to as his "Free Whim Theorem" a while back.) This seemed to me to be saying something surprisingly deep about the relationship of observers with the principles of QM and relativity. It's almost like having a theoretical bound on Bells inequalities if you believe observers can change their minds. I was surprised it didn't receive more attention.

4. **Richard Séguin**
   August 16, 2015

   Damn, JSE's review is behind a pay wall. It would have been nice to settle now with just that since I'm already off on a (ultra-)marathon read of something else and probably won't get to the book for quite some time. I, for one, found the answer to the sequence problem amusing.

5. **Chris Lott**
   August 16, 2015

   Richard, google "wsj a fellow of infinite jest" and click on the first link.

6. **Ben R**
   August 16, 2015

Puffin, I'm not PW but the "free will theorem" seems to be just a rebranded variant of Bell's theorem. Bell's setup was pretty awkward and I think Conway & Kochen's is better, but I don't think it says anything about free will that Bell didn't understand in 1964. Scott Aaronson seems to feel similarly (http://www.scottaaronson.com/democritus/lec18.html).

7. **Jeff M**
   August 16, 2015

   See and say is wonderful, even more so since Conway proved things about the sequence despite the fact that it has no "mathematical" definition. When I was in grad school Conway came and gave a talk about surreal numbers, which included his doing rope tricks to demonstrate the relation with knots. He's much more than games. As for Free Will, it's related to Bell's, but they are different as best I understand. One can explain Bell in various ways, some of which have nothing to do with free will. The free will theorem, as best I remember, says that if you want to throw out free will, you have to throw out lots of other stuff too.

8. **KenW**
   August 16, 2015

   That sequence reminds me of sudoku. Although I realize that you could play sudoku with mahjong tiles.

9. **Richard Gaylord**
   August 16, 2015

   i read the book, was not amused by the opening test and felt that while it might be an accurate portayal of Conway, it in no way, represents the way serious mathematicians work. I personally came away with the feeling that "it's too bad that an obviously brilliant person would fritter away his professional life working on amusing but trivial problems". i thought his own explanation of the history of the game of life which is referred to in the book (http://blog.tanyakhovanova.com/2010/07/the-sexual-side-of-life/) was fascinating. i can understand his conflicted attitude to GoL since he would prefer to be known for his mathematical work rather than for GoL, the profound implications of which in regards to emergent phenomena, he apparently missed, but according to his biographer, Conway would prefer to be known for anything than for nothing at all so he's come to terms with this notoriety . As for his free will theorem, it is vacuous and shows a basic lack of understanding of the philosophical nature of the issue (much as Wolfram's free will argument does). physicists and mathematicians trying to do philosophy are always amusing (we see this in the work of Tegmark, Deutsh, Dawid and others you have mentioned in your blog postings).

10. **John Baez**
    August 16, 2015

    What made me "laugh with surprise" is not that Conway *invented* the look-and-say sequence, it's that he showed the ratios of successive terms approach a constant 1.303577269034… which is the unique positive root of a polynomial of degree 71, and that he proved even deeper results about this idea.

    Anyone who thinks Conway has frittered away his time on trivial problems must not know the *Atlas of Finite Groups*, the book *Sphere Packings, Lattices and Groups*, and Conway's profound analysis of the Leech lattice and its symmetry groups. I think anyone who did those things has done enough hard work – and if they want to goof off and have some fun, that's fine with me.

11. **John Rennie**
    August 16, 2015

    If you're interested in a mildly technical history of the finite group work then I recommend Mark Ronan's book Symmetry and the Monster. This is a popular book not a maths book, but Ronan frequently slips and injects enough real maths to whet the appetite.

    Actually I have an idea I heard about the book on this site, though searching your site doesn't find anything. My apologies if I'm telling you something you already know.

12. **Richard Séguin**
    August 16, 2015

    Chris Lott: It doesn't depend on how you get to that page. If you're not a subscriber, WSJ throws up a paywall. At this point, it might already be too late to find this issue on a newstand somewhere.

13. **JSE**
    August 16, 2015

    Richard, I promise, it depends how you get to the page. I'm not a subscriber and when I get there through a Google search, I can see the whole thing. Otherwise, just the intro.

14. **Montague**
    August 16, 2015

    Man, Ellenberg really missed the mark with his account of the Look-and-say sequence. The definition of the sequence is a trifle–I mean it can be amusing that a young child might be able to guess how it works where a Fields medalist would be stuck, but that is not the beauty of the thing. The beauty of the thing is how Conway takes this trivial-seeming property which does not promise any mathematics at all, and spins from it a whole theory of "audioactive decay" involving a startling analogy with the periodic table. The mind that is moved to construct such things from a child's toything, alongside his deeper contributions to mathematics (see the Atlas of Finite Groups and the Sphere-packing book with Sloane) is a mind that I want to know more about!

15. **Anonyrat**
    August 16, 2015

    @John Baez, per Wiki, if L_n is the number of digits in the nth item in Conway's sequence, then Limit n -> infinity of L_n+1 / L_n = 1.303577269034….

    Also, was his proof lost?
    Proof of Conway's lost cosmological theorem
    Authors: Shalosh B. Ekhad and Doron Zeilberger
    Abstract: John Horton Conway's Cosmological Theorem about sequences like 1, 11, 21, 1211, 111221, 312211,…, for which no extant proof existed, is given a new proof, this time hopefully for good. – See more at: http://www.ams.org/journals/era/1997-03-11/S1079-6762-97-00026-7/home.html#sthash.txtWMezQ.dpuf

16. **Peter Lund**
    August 16, 2015

    Séguin: yes it does. Following the link gave me the paywall, going via google gave me the review with no paywall. This is my standard experience with WSJ.

17. **Richard Séguin**
August 16, 2015

Chris and Peter: Thanks! I originally did the search with DuckDuckGo, and I got the paywall. I switched to Google and got through. I'll remember this trick in the future.

18. **Cosmonut**
August 16, 2015

Must agree with the comment about caricature mathematician.

I've often found that while theoretical physicists are seen as "Brilliant minds unlocking the secrets of the Universe", the perception of mathematicians is "Borderline nutcases obsessing over arcane stuff".

19. **John Baez**
August 16, 2015

Anonyrat wrote: "if L_n is the number of digits in the nth item in Conway's sequence, then Limit n -> infinity of L_n+1 / L_n = 1.303577269034…."

Right, sorry: I said "ratios of successive terms", but it's "ratios of successive numbers of digits".

"Also, was his proof lost?"

Not of this fact, but of a stronger fact of which this is a corollary: the Cosmological Theorem. The paper you mention is quite fun, and it adds to the reputation of mathematicians as borderline nutcases obsessing over arcane stuff. First, one of the authors, Shalosh B. Ekhad, is actually a computer. Second, the abstract says:

Abstract: John Horton Conway's Cosmological Theorem about sequences like 1, 11, 21, 1211, 111221, 312211,…, for which no extant proof existed, is given a new proof, this time hopefully for good.

Third, it ends with a rant on the four-color theorem, titled "On *a posteriori* trivial theorems: The ultimate proof of the Four-Color Theorem should emulate our proof".

It explains the lost-and-found story:

> **The Cosmological Theorem.** There exists an integer N such that every string decays in at most N days to a compound of common and transuranic elements.
>
> Conway stated that two independent proofs *used* to exist, one by himself and Richard Parker (that only proved that N existed), and another one by Mike Guy (that actually proved that one may take N = 24, and that it was best possible). Unfortunately both proofs were lost. Here we announce a new proof (which establishes that one may take N = 29; with more computations one should be able to rederive (or else refute) Guy's sharp N = 24).

20. **David Roberts**
August 17, 2015

@John

DZ goes on to write:

"eventually one should be able to type Prove4CT();, and the truth of the theorem should be implied by the halting of the program. In order to check the validity, the checker would not need to see any specific configuration. Everything should be done internally and silently by the computer. All that the checker would have to do is check the program."

and this is now the case! Gonthier and Werner have of course completely formalised the proof. (for those who may not know: http://www.ams.org/notices/200811/tx081101382p.pdf)

21. **Peter Woit**
August 17, 2015

It does seem that the WSJ prefers Google to my blog: if you access the same URL via Google as the one in the link in the posting you get the full review.

Puffin,
I confess to have pretty much paid no attention to the "free-will theorem". It starts from assumptions that ignore anything interesting about the measurement problem, and claims to reach conclusions about something that to me is a question about consciousness and how brains work. As far as I can tell, Conway knows little about either physics or neurobiology. Maybe there's something interesting going on in this "theorem", but I'm happy to let others be the ones to spend their time on it.

22. **Martin S.**
August 17, 2015

Can anyone hint on the experimental setup of the spin-component-square measurements of the Free will theorem? I am into the basic physics they use, not the overall theorem herein.
Regarding their spin axiom (on measuring squares of spin components), they cite several possibilities for such measurements at their article, endnote 1, page 27.
I have looked at the Kochen/Specker work that is one of those cited possibilities. It seems that it is based on spectra measurements (of systems where Hamiltonian contains spin-based parts that alter the base Hamiltonian); see part 4 there, pages 13-16 (71-74 in journal page numbering).
If I get it correctly, the Free will theorem takes entangled systems and looks at corresponding measurements. Does it mean that measurements of spectra on one of those entangled components can affect whether the other (entangled) component has (or does not have) its base Hamiltonian altered by the spin-based interactions?
May be it is different for molecular beams that they cite as another possibility for the measurements. Yet when I looked at work of Erwin Wrede (that is cited by them), I have not seen anything on Hamiltonians or spin there; not being surprised, since that work of Wrede is from 1927.
They mention interferometry with crafted coherent beams (see the endnote 1 at their article) too, but they do not go into details there.

23. **Douglas Natelson**
August 17, 2015

About "lost" proofs: This is the second "lost" proof story I've heard about Conway. Manjul Bhargava told a story at a talk I'd attended that Conway had also lost his original proof of the 15 Theorem. . Are "lost" proofs common among practicing mathematicians? Is Conway particularly disorganized?

24. **Peter O.**
August 18, 2015

Yes, common. If a proof reduces to checking six hundred trivial cases, one can sit down and check them. At the end one has proved to oneself that a certain statement is true, and can tell it everybody else. The proof is an unpublishable pile of waste paper, but others will find nicer proofs, or program a computer to check these cases.

25. **Shantanu**
August 18, 2015

Peter, OT to this, but some sad news, in case you were unaware.
Jacob Bekenstein passed away yesterday.

26. **Chris W.**
August 18, 2015

Concerning Jacob Bekenstein, Jennifer Ouellette posted [this scientific obituary] on her SciAm blog yesterday, and Scott Aaronson [posted a personal tribute] today.

27. **Jeff M**
August 18, 2015

Douglas

Yes, Conway is particularly disorganized. And I don't believe his lost proofs were the "check 600 cases" types, though those proofs certainly exist. Mathematicians prove all sorts of things, and sometimes it isn't even that the proofs are lost, it's just that the result is not interesting. BTW, I know Conway is disorganized since when he was giving the talk on surreal numbers I mentioned before, someone had to drive to Princeton from NYC to make sure he would show up, and he had in fact completely forgotten he was supposed to give a talk 🙂

28. **Erraticon**
August 19, 2015

Interesting how people easily forgive a famous person his/her unpleasant excesses clearly caused by a personality disorder (most likely bordeline in this case).

29. **Neil**
August 19, 2015

Well, that did make me smile, if not laugh. I plugged it into the online encyclopedia of integer sequences (https://oeis.org) and sure enough it came up, along with a few interesting tidbits (no integer larger than 3 appears, and 333 or longer does not appear, although 222 does). But the cosmological thing–I don't know.

30. **Joseph O'Rourke**
August 21, 2015

One minor correction that may be implied by John Baez's post ("…Conway invented the look-and-say sequence…"): Conway did not invent the sequence. The biography says it originated in a Math Olympiad in Belgrade.

Lepton Photon Interactions at High Energies and the Multiverse

August 22, 2015
Categories: Experimental HEP News, Multiverse Mania

This past week the large biennial "Lepton-Photon" (International Symposium on Lepton Photon Interactions at High Energies) conference has been taking place in Ljubljana. These have been going on since 1965, now alternating years with the ICHEP ("Rochester") conference. It's been quite a while since the main topic of the conference was lepton-photon interactions, these days it covers the entire field of HEP, with a format of plenary survey talks. Taking a look at the slides will give you an excellent survey of what is going on in HEP, both in experiment and theory.

One newsworthy talk was Mike Lamont's on the current state of the LHC Run 2. The new LHC run is at 13 TeV collision energy, with 25ns bunch spacing (as opposed to 8 TeV, 50ns in Run 1). No showstopper problems so far, but increasing the luminosity (by increasing the number of bunches) has been a slow process. As a result, Lamont expects only about 3.4 inverse fb luminosity this year, down from early hopes for a number more like 10 inverse fb. The plan is for 30 inverse fb next year.

The summary talk by John Ellis featured undimmed enthusiasm for SUSY. What will be very interesting to see will be the treatment of this subject at the next Lepton-Photon conference.

One subject that was not mentioned at all in Ellis's talk, and, as far as I could tell, not in any of the other ones either, was the multiverse. The organizers and speakers seem to all realize that there's no scientific content to this idea worth discussing, so best to ignore it. I'm completely mystified though by the decision to have as public outreach a promotional talk about the multiverse by Alan Guth. Why anybody in HEP thinks it's a good idea to make pseudo-science the public face of the subject just baffles me. If you want to see one reason why this kind of thing is really a bad idea and doing great damage to the public perception and understanding of the subject, take a look at this.

Away from serious scientific conferences, the multiverse continues to dominate the media's coverage of fundamental physics. The usually sober publication The Economist features both an article and a video this week promoting multiverse pseudo-science. As usual in such pieces, no skeptical voices are to be heard. Susskind deals straightforwardly with the lack of scientific evidence problem by simply saying things that aren't true:

> This idea of a multiverse is not gratuitous speculation. No, it really comes out of both experiment or observational physics about the universe and the current theories as best we understand them.

He doesn't explain what the experimental evidence for the multiverse is. The BICEP2 observation of primordial gravitational waves perhaps?

Comments

1. **andrew**
   August 22, 2015

   Useful links. I still believe in SUSY and that naturalness is important. I concede though that an alternative narrative – that naturalness and SUSY were follies, followed by a generation of physicists but scorned by nature in experiments for years – is gaining traction.

   Does that make you hopeful regarding the perception of ST? Could the dominant narrative – the world's geniuses following in the footsteps of legendary physicists, uncovering bizarre secrets of the multiverse at elite institutions – come under pressure? Is it plausible that, like SUSY and naturalness, we'll come to see ST as smart people getting it wrong?

   The thing with narratives is that isn't events per se but our perception of events that matter. Although LHC says nothing about ST, one perception is that theoretical speculation was wrong and that we need new ideas. Ultimately that might shift our feelings about theoretical physics including ST in the last 30 years or so. Do you think we're any closer to that point?

   I'm aware that this a contentious view on the development of scientific ideas, but I'm not looking for a discussion on that.

2. **Ilya**
   August 23, 2015

   I don't think it's fair to say that Susskind lies, just from that quote. He doesn't claim that evidences exists, he just writes "comes out of", which is more like "is hinted by". He doesn't write that it's not speculation (it is), he says that it's not *gratuitous* speculation – that's debatable but not plainly false.

3. **Peter Woit**
   August 23, 2015

   Ilya,
   I don't think that
   "This idea of a multiverse … really comes out of … experiment or observational physics."
   can be characterized otherwise than as a statement that is not true. The weasel-word reformulation you suggest (a "hint" can mean any degree of evidence, no matter how negligible) is different.

   Note that I was careful to say that Susskind was saying something untrue, but did not say that he was lying, which would imply that he was intentionally saying something he knew to be untrue. Quite likely he believes what he said. I don't think multiverse-maniacs are liars. I think that they have for various reasons convinced themselves of bad arguments, which they unfortunately are very actively trying to promote to their colleagues and the public.

4. **Cosmonut**
   August 23, 2015

   Peter,
   I've read your criticisms of multiverse mania for a while now and I agree with you.

   But is there any push back within the scientific community against this rubbish ?

   Or is the pro-multiverse camp winning by virtue of constant repetition ?

   It seems every time I read a popular article about fundamental physics in the media, its the same old bilge about string theory, inflation and multiverse – or even worse, the "Tegmarkian hierarchy of multiverses".

No genuine new understanding of fundamental physics and cosmology over the last 10 years or so, as far as I can tell.

5. **phil fogle**
August 24, 2015

I agree that Susskind is (probably) sincere but (likely) delusional. It's not at all uncommon for good scientists to 'believe' in some of their speculations – subjectively confusing 'sufficient' for 'necessary'.

The Spectator review is in another category (parallel universe?) all together, and is an utter disgrace. But it's the entertainment industry, on the level of mesmerism and radium therapies, and will always be there as a background pollutant.

6. **verruckte**
August 24, 2015

The reason that the multiverse narrative keeps getting pushed is that it's what the public wants to hear. Media picks up on it, because it sounds mystical and exciting. Saying "no, nothing new here yet, we are still just stuck with the standard model" is NOT mystical and exciting. It sells no books, attracts no eyeballs to advertising, and is basically just boring.
The intoxication of popular interest and the financial opportunities thereof are tempting. The fact that the subject matter is not able to be tested is *not* a disadvantage, it is a huge advantage, for the simple reason that no one can ever actually show you are wrong. This plus the mantle of authority given by being an ACTUAL SCIENTIST are the perfect recipe to sell books and headlines and expensive talks. I believe, as Peter seems to, that most proponents have probably convinced themselves first of all. The capacity of humans to adjust reality to match desires can not be overestimated.

7. **Shantanu**
August 24, 2015

Peter, I think the problem lies with the organizers and also the audience.
Hope at least some brave member asked some provocative question.

Peter: an OT question prompted by the recent passing away of Bekenstein. When you were an undergrad student at Harvard, were you impressed by Hawking's (and related work by others) 1974 work on the black holes have a temperature and radiate? Was this extensively discussed in the hallways at Harvard?

Or is it that in Harvard at that time, no one cared about GR and you don't recall any discussions of this

8. **Peter Woit**
August 24, 2015

Shantanu,
I've never met Bekenstein. When I was at Harvard (1975-79), the focus was on the SM, few people were thinking about quantum gravity. At Princeton (1979-84) there was a lot of interest in quantum gravity, especially in Hawking's semiclassical Euclidean methods, which were closely related to the semiclassical gauge theory methods a lot of people there had been working on. Malcolm Perry, Hawking's student, was a young faculty member and Hawking visited and gave lectures.

9. **Dave Miller in Sacramento**
August 24, 2015

Peter,

Alan Guth is, of course, one of the inventors of inflation: I knew Alan, very slightly, when he did his initial work on inflation at SLAC back around 1980. So, doesn't the inflationary multiverse predate the "landscape scenario" by a couple decades or so? Is there any reason for the two to be connected?

I know there is an ongoing confusion among the "many-worlds" interpretation of quantum mechanics, the landscape scenario, and the inflationary multiverse. Is there any "accepted" connection among these, or is it just a free-for-all open to anyone's speculation?

By the way, I would interpret Lenny's "comes out of" as just meaning that Lenny thinks the ideas are suggested or motivated by observation or experiment, not that there is any firm connection.

All the best,

Dave

10. **Dave Miller in Sacramento**
August 24, 2015

Shantanu,

To elaborate on your question to Peter: I was an undergrad at Caltech when Hawking gave a talk on his recent work on black-hole evaporation — I think it was in '74: I had enough sense to keep my copy of the typewritten paper that was handed out to the audience (although I looked at the paper a few months ago and still cannot understand his notation). I do recall that we all understood enough to grasp that Hawking was saying that black holes evaporate and therefore do not last forever; however, even when I took Kip Thorne's class on GR a year or so later, I do not recall any discussion of Hawking evaporation in class (Kip was obsessed with accretion disks around black holes at the time — we students were not so obsessed).

At SLAC around 1980, I remember a casual discussion with a post-doc, Subhash Gupta, about the issue: we were specifically interested in the point that, prima facie, Hawking evaporation means the event horizon never actually forms. Nothing came of that discussion and no one else at SLAC seemed interested. (If Subhash and I had only known, we could have ignited the discussion about the "firewall" thirty years earlier!)

Hope this gives you a bit more info as to how it was viewed back then.

Dave

11. **Peter Woit**
August 24, 2015

Dave,
I think claiming that the multiverse is "suggested or motivated by observation or experiment" is also an untrue statement.

A small number of people (Susskind among them) have been known to speculate about a connection between MWI and the inflationary multiverse. I've yet to see a comprehensible explanation of how that is supposed to work. Popular press articles often conflate the two, as far as I can tell purely because the writer doesn't understand what they're writing about.

Multiverse fans often claim that "typical" inflationary models imply eternal inflation and thus a multiverse (while not mentioning that in such models physics will be the same in all universes). Others claim that there are plenty of inflationary models that don't imply eternal inflation. The big problem with inflation right now (and I think this is a point Steinhardt emphasizes) is that you can get pretty much whatever you want out some model in the framework, making it of dubious testability.

12. **Dave Miller in Sacramento**
    August 25, 2015

    Peter,

    You wrote:
    >Multiverse fans often claim that "typical" inflationary models imply eternal inflation and thus a multiverse (while not mentioning that in such models physics will be the same in all universes).

    I recall that Alan claimed he had a proof that inflation that was eternal in the past direction was not possible, though I myself could never understood the details: I think I ran across a reference to it in Alan's book.

    In fact, this paper (http://arxiv.org/pdf/hep-th/0702178.pdf) seems to make that point (from the abstract: "Although inflation is generically eternal into the future, it is not eternal into the past: it can be proven under reasonable assumptions that the inflating region must be incomplete in past directions, so some physics other than inflation is needed to describe the past boundary of the inflating region"), though I do not believe this is where I first saw it.

    The paper also does have a brief discussion of the landscape (p.9-11), but it is frustratingly vague: Alan indicates a bit of skepticism, but, while he suggests that you can get different physics in different universes (at least different cosmological constants), no details are given of how that could work.

    Anyone know where anyone has actually talked about that in any detail? I fear I am still confused.

    It will be interesting to hear what Alan has to say in his talk.

    Dave

13. **Shantanu**
    August 25, 2015

    Thanks, Dave. However Caltech had a strong GR group then (in fact still does).
    and 70s was the golden age of GR. As Peter mentioned, very few people in Harvard were interested in quantum gravity.

14. **Chris W.**
    August 25, 2015

    Speaking of Hawking and black hole evaporation, he is in the news again with another (?) take on the problem:

    > The [Wall Street Journal] notes that Gerard 't Hooft of Utrecht University, winner of the 1999 Nobel Prize in physics who was present at the conference, had presented a similar idea in 1996.
    >
    > He said the problem was that his math did not add up.
    >
    > "I claim he is now where I was 20 years ago," he told the Journal. "If he announces this as a new idea, I won't be thrilled."

15. **Peter Woit**
    August 25, 2015

    Chris W.,
    I'm not convinced that what the world needs is more unclear speculative claims about the black hole information paradox, even if they're coming from Hawking. I have no idea what's going on here, urge those interested to try Sabine Hossenfelder, who wrote about the talk here:
    http://backreaction.blogspot.com/2015/08/hawking-proposes-new-idea-for-how.html

    Personally I'll wait for the paper with Perry promised for next month and see if I can make any sense of that. Maybe before then the experts on this will have come to some consensus on whether it's worth paying attention to.

16. **Chris W.**
    August 26, 2015

    I'm not convinced of that either, which is partly why I excerpted the comment from 't Hooft. Pushing out preliminary conclusions and arguments to make a conference deadline doesn't help.

17. **Curious Mayhem**
    August 27, 2015

    Even if primordial gravitational waves are detected (which I think will happen soon), it's no evidence for the multiverse. The multiverse theory is constructed in such a way as to not require such evidence, or any evidence for that matter.

    >(:-P

A Singularly Unfeminine Profession

August 23, 2015
Categories: Book Reviews

Phenomenologist Mary K. Gaillard has recently published an autobiographical memoir, with the title A Singularly Unfeminine Profession, and last week's Nature has a detailed review.

Gaillard is a very distinguished HEP phenomenologist, with a career that began in the 1960s, taking her in 1981 to a professorship at Berkeley, from which she is now retired. She has been married to two other physicists, Jean-Marc Gaillard and Bruno Zumino.

One highlight of her career is her work on charmed particles, which included an accurate prediction of the charmed quark mass (1.5 GeV, in this paper with Ben Lee, see page 905). The prediction came in a paper published in mid-1974, months before the discovery of the J/Psi in November. Unfortunately she and Lee didn't have the courage to put the prediction in the abstract, which just said "the average mass of charmed pseudoscalar states lies below 10 GeV".

Wikipedia also credits her (with Chanowitz and Ellis) with a prediction of the b-quark mass. Maybe I'm missing something here, but this appears to be much less justifiable, since the paper was based on an SU(5) model which is known not to work. It's also a much vaguer prediction, and appears in the abstract in a mistaken form. In the book, Gaillard tells the story:

> We were correcting the proofs for the published version of the paper in July, at around the same time I went to pick up Leon Lederman at the Geneva airport, and, through a screen near the baggage claim gate, he handed me a beautiful histogram showing clear evidence for a b-bbar spin-one bound state – named Upsilon by its discoverers – with a mass of about 10 billion electron volts, in other words, evidence for a bottom quark with a mass of about five billion electron volts. John quickly penciled in a correction to the abstract with our more precise prediction, but his handwriting was so bad the "to" was read as "60", and our prediction came out in print as
>
> $m_b/m_\tau=2605$
>
> implying a b-quark mass of over 5000 billion electron volts.

The upsilon discovery was announced publicly at a press conference only later, in August. I can't help noticing that it seems that back in 1977 discussing results of an HEP experiment before the press conference wasn't unusual. It is only more recently that one hears that to do this is to subvert the scientific process.

Among the many other things I learned from the book was the origin of John Hagelin and the Maharishi's posters explaining that N=8 supergravity was the TOE fitting together with the Maharishi's ideas. Hagelin was dating Gaillard's cousin and learned about the N=8 story from Gaillard.

The latter part of her career focused first on supergravity, then in 1985 on superstring phenomenology. Thirty years later she's sill working on much the same idea as in 1985 (see here). The book explains the idea of string theory unification using a compactification, but doesn't reflect on the question of when or whether it might be a good idea to finally give up on this.

A major theme of the book is that of how her gender has affected her career, including more discussion of the details of her employment and job offers than would be usual in a book of this kind. It's a complex story, with the details of it well worth paying attention to for anyone interested in the problems women encounter in science. Gaillard started out her career facing serious obstacles as a woman, but later on achieved a large degree of professional success. She has a lot to say about the attitudes and remarks she ran into from men along the way, often from ones who were close friends.

She is most critical of the CERN theory group, which she left in 1981 after being turned down for a senior staff position (at a time she had job offers from Berkeley and Femilab). To this day, as far as I can tell, CERN-TH has no women as permanent scientific staff, and only one (out of 19) female staff members. Perhaps things will change with the incoming CERN director…

Comments

1. **David Nataf**
   August 24, 2015

   I'm just posting to second the comment made by Peter: the book review at Nature.com is very good, very informative and well-written.

2. **Shantanu**
   August 24, 2015

   Peter, who is the new CERN director?
   (sorry I don't know)

3. **Peter Woit**
   August 24, 2015

   Shantanu,
   Fabiola Gianotti will become CERN DG on Jan. 1.

4. **Jr**
   August 25, 2015

   There seems to be a word or two missing in the following sentence.

   "The upsilon discovery was announced publicly at a press conference in August, and I can't help noticing that it seems that back in 1977 the LHC-era idea that saying anything about results to those outside the experiment pre-press conference hadn't yet taken hold."

5. **Peter Woit**
   August 25, 2015

   Jr.,
   I think the sentence is correct, if not very well worded, I'll do some editing.

One problem with it is that I was implicitly referring to something many people might not be aware of, the criticism of this blog for discussing the Higgs discovery results before the press conference (I was "subverting the scientific process"), see
http://profmattstrassler.com/2012/06/18/new-higgs-rumors-have-arrived/

6. **sm**
August 25, 2015

jr,

Perhaps also missing a comma to help with the parsing.

Peter,

Who did get senior staff Cern positions in and around 1981? This might help clarify whether or not the innuendo is justified.

7. **Peter Woit**
August 25, 2015

sm,
I personally know very little about the people involved, or what was going on at CERN-TH around that time. Sergio Ferrara's online bio says "In 1981, he joined as a staff member the Theory Division at CERN." Maybe he was chosen over Gaillard. (*Note added: this is not the case. Ferrara was hired in 1981 to a junior position that had nothing to do with the Gaillard story*). In any case, I think only those actually involved in the decision likely know what considerations were behind it and why they did not choose Gaillard.

One interesting thing is that, looking at the CERN-TH archive page here
http://library.web.cern.ch/archives/CERN_archive/guide/theory/isath
it seems that this was so long ago (more than 30 years) that all the records can be consulted. If anyone at CERN wants to go take a look, perhaps they can report back…

What is clear is that Gaillard is still pretty unhappy about this. She had been there for quite a while, was professionally very successful, and had job offers from Berkeley and Fermilab. Turning someone down in such a situation is pretty much tantamount to telling them you'd be happy if they left. I find it hard to believe that losing both her and Zumino is not something they came to regret.

There's always far more in such decisions than the gender issue, but to me Gaillard's discussion of how it affected her professional life seems like a reasonable one, well worth reading. She doesn't seem like someone quick to take offense at the inconsequential.

8. **sm**
August 25, 2015

Peter,
What a remarkable data source you cite. Thank you. Have you thought of sharing your insights into data mining with that community?

You're surely right that when it comes to job offers at places like Cern there is more to the decision than gender (or spousal relations for that matter – poor Zumino, Cern forcing him to choose between his wife and a deep collaborator!). This is evidenced by the Cornell job offer to the non-publishing Wilson, which could have seemed outrageous at the time, even though he presumably conformed to the gender stereotype of those days.

9. **Piscator**
August 25, 2015

Could it be as simple as the fact that Mary K is not European? It has certainly been said that CERN has, at least informally, nationality quotas for the staff positions in the theory group, based on the nations that fund it. I don't know anything definite about the politics as far back as 1981, but I wouldn't be at all surprised to learn that there was a political expectation that the permanent staff be from the CERN member states.

10. **Peter Woit**
August 25, 2015

Piscator,
I doubt that was it. Gaillard got her degree from Orsay, and by 1981 had been in France, married to a Frenchman, for nearly 20 years. I don't see how that could have been the problem, and I don't think she mentions it as an issue in the book.

11. **Radioactive**
August 26, 2015

It's a bit tedious to wade through all this 35 year old gossip, and I'm sure there was and still is sexism at CERN, but it sounds just as likely that whoever was in charge didn't want to have to employ this woman as well as her ex- and new husband, which would be quite disruptive.

12. **Peter Woit**
September 3, 2015

It turns out that Ferrara was hired as a junior staff member in 1981, which had nothing to do with the issue of a senior appointment that year that Gaillard discusses in her book. I've thus deleted several comments that discuss him in this context.

This Week's Hype

August 28, 2015
Categories: This Week's Hype

Bogus media stories about how "physicists finally find a way to test string theory" have now been with us for decades, with a large number of them documented here. Recently this phenomenon seemed to finally be dying down, with such stories the province of more obscure media outlets and the press offices of not very well-known institutions. Yesterday though saw a new example of the genre, coming to us from IAS faculty and the Fermilab/SLAC publication *Symmetry*, which announces that Theorists from the Institute for Advanced Study have proposed a way forward in the quest to test string theory.

The source of all this is the Arkani-Hamed/Maldacena paper Cosmological Collider Physics from earlier this year. As usual with a lot of these bogus stories about "testing string theory", the work in question actually has nothing to do with string theory. It's about possible ways to look for particle physics effects in subtle effects in non-Gaussianities in the CMB. This is a theoretically interesting topic, but suffers from the obvious problem that, experimentally, there are no non-Gaussianities in the CMB. The limits on non-Gaussianity from Planck and other CMB experiments are quite strong.

The connection to string theory is given in the article as:

> But scientists are working out ways that experiments could at least begin to test parts of string theory. One prediction that string theory makes is the existence of particles with a unique property: a spin of greater than two.

This is of course complete nonsense, since there are plenty of known particles of spin greater than two. String theory arose as an attempt to explain some of these, but it turned out that it didn't work, the actual explanation was QCD, a quantum field theory. The author seems to have gotten this argument from the following statement in the Arkani-Hamed/Maldacena paper:

> Of course, if we were to detect the contribution of a spin 4 state in the non-gaussianity, it would be a strong indication of string theory during inflation, since we suspect that a structure like string theory follows when we have weakly interacting particles with spin s greater than 2.

Knowing that there is a spin 4 state up at the inflation or Planck scale would of course be quite interesting, but I don't see any reason to believe that effective field theory would apply to it or that this would "of course" "be a strong indication of string theory". This argument would actually make better sense at lower energy. I suppose you could claim that lots of work being done at the LHC is "a way forward in the quest to test string theory", since any day it could lead to evidence for a new weakly interacting spin 4 state. That would of course be pretty silly, but less silly than this article.

Combined with the bogus "test", the article includes a large helping of the usual promotional material, ending with a section on "The value of strings". We're told that

> Witten and others believe that such successes in other fields indicate that string theory actually underlies all other theories at some deeper level.

"All other theories"???

Update: I should make clear that my comment about the strength of the limits on non-Gaussianities was about the quality of the experimental results, and my impression that there are not near-term prospects for doing much better. Depending on what models one is talking about, such results are often not strong constraints. A correspondent suggest this source for more information about all of this.

Comments

1. **M**
   August 28, 2015

   I discovered a spin 4 particle:
   http://pdg.lbl.gov/2014/listings/rpp2014-list-a4-2040.pdf

2. **Nathalie**
   August 28, 2015

   We are indeed living in the golden age of bogus speculations presented as facts.
   Here is another example from a recent talk by Hawking, taken from

   https://www.kth.se/blogs/stockholmtech/2015/08/hawking-proposes-way-for-information-to-escape-destruction-in-black-hole/

   "The existence of alternative histories with black holes suggests this might be possible," Hawking said. "The hole would need to be large and if it was rotating it might have a passage to another universe. But you couldn't come back to our universe."

3. **Shantanu**
   August 28, 2015

   Peter nice article. I sincerely hope the author of this article reads your critique
   and wish journalists for such magazines are more responsible.

4. **KJ**
   August 28, 2015

   Note that the author's comment that string theory "underlies all other theories" does not qualify that he is talking about correct, or even approximately correct, theories. Thus, string theory underlies even all false theories. If there are really 10^500 versions of string theory, this may very well be true!

5. **Avattoir**
   August 28, 2015

   KJ, then that's even more exciting, given there's no limits at all, not even theoretically, on the number of false theories.

6. **George Ellis**
   August 29, 2015

"There are plenty of known particles of spin greater than two." – Theoretically proposed, or experimentally verified? What are they?

7. **TS**
August 29, 2015

The particle data group lists 17 states of spin 4 or above. Now the PDG is partly a political entity and one should be a bit careful about these listings (something LHCb's now-famous pentaquark analysis wasn't), but e.g. the a_4(2040) is a spin-4 resonance established beyond all doubt. Actually, the next edition of the PDG listings will include my measurement of its properties — and I can assure you that the data are unambiguous about its spin being 4.

8. **vmarko**
August 29, 2015

Folks,

I think that Arkani-Hamed and Maldacena are talking about spin-4 fundamental (i.e. elementary) particles, as opposed to composite particles which can be of any spin (some atomic nuclei can have spin 9/2 or such). The fundamental particles with spin higher than 2 are sort-of forbidden in QFT due to a no-go theorem (Coleman-Mandula, Weinberg, Weinberg-Witten — see for example 1007.0435 for a review). But apparently they are not forbidden in string theory, so if (say) a spin-4 elementary particle has some signature in the CMB, string theory would be able to describe it while ordinary QFT wouldn't. Or something along those lines.

Of course, observation of spin-4 fields is not a *prediction* of string theory (AFAIK). IOW, the existence of such particles is *allowed* by ST, but not *required* by it.

HTH, 🙂
Marko

9. **Peter Woit**
August 29, 2015

vmarko,
The problem is that how do you tell if a spin 4 state up at that scale is "elementary"? Composite particles look elementary unless you can probe them at some higher scale. This is why they specify "weakly interacting" instead. It's extremely unlikely that you can see evidence at all that such a state exists, much more so that you can study its interactions. And all of this is going to be taking place up near the Planck scale, where all bets based on effective field theory arguments are off.

10. **vmarko**
August 29, 2015

Peter,

I fully agree with you. It's just that I saw some confusion in the comments regarding the question whether spin-4 particles have already been detected in nature or not. So I wanted to clarify that the existence of composite spin-4 particles is not controversial, while the existence of elementary spin-4 particles is. Of course, establishing (experimentally) that a given particle is indeed elementary is a very hard task even at the LHC scales, let alone near the Planck scale.

🙂
Marko

SUSY 2015

August 29, 2015
Categories: Multiverse Mania, Uncategorized

SUSY 2015, this year's version of the big annual conference on supersymmetry, has been going on for the past week at Lake Tahoe. Joe Lykken began his summary talk by explaining how as a kid he was a big fan of the Bonanza TV show, about a ranch along the shores of Lake Tahoe. He always wanted to travel to Lake Tahoe and visit the Ponderosa ranch, was bitterly disappointed when he finally got to Lake Tahoe and found that the Ponderosa did not exist. The relevance of the story to his talk is "left as an exercise for the audience", with a hint in the next slide, which gives the executive summary of the search for SUSY at the LHC: "We haven't found it." He ends the summary talk with this now well-known prediction for the SUSY 2215 conference.

In his discussion of "naturalness" (see slide 25), he makes what to me has always been an obvious point, but I haven't seen it made ever at a conference like this:

> **Is the Standard Model (almost) all there is?**
>
> Maybe the naturalness argument applied to the Higgs is just wrong (well, it was apparently wrong for the vacuum energy too)
>
> The Standard Model plus some TeV scale renormalizable additions (like dark matter) might be all there is
>
> The Standard Model itself, or with such modest additions, is completely natural (EW scale is not a prediction)
>
> Usual counterargument involves the putative Planck scale and unification thresholds, but this is speculative
>
> An unsatisfying scenario, leaving many questions unanswered, but has a certain minimalist appeal

Some of the other talks included:

- Nima Arkani-Hamed's slides and title aren't available, but the Twitter coverage of the conference included a picture of one of his slides. This tweet reports that he announced that he was "rather annoyed" and "sick of thinking" about naturalness. I guess if you've spent most of your career arguing that the LHC would "resolve the naturalness problem" (because it would move fine-tuning from the Tevatron 10% to 1% if it saw nothing), gearing up now for an argument that a 100 TeV collider is needed to "resolve the naturalness problem" (by going from 1% to .1%) would be kind of annoying… In the slide he makes the same argument as in Particle Fever: no SUSY means particle theory should commit suicide and embrace the multiverse.
- In Gordon Kane's talk he gave his latest string theory-based predictions for the masses of superpartners. For the last twenty years or so, his gluino mass prediction has always been the same: just a little bit higher than the current bounds. These bounds however keep moving up, so his prediction has moved from 250 GeV in 1997 to 1.5 TeV today ("Detectable soon"!). I think one very solid prediction that one could make is that Kane's SUSY 2016 gluino mass prediction will be 2 TeV.
- Joe Polchinski's talk defended moduli stabilization schemes such as the KKLT one that came out of his original work with Bousso, ending with the claim that

  > The KKLT construction has been thoroughly vetted, and it seems to me has survived robustly.
  >
  > The de Sitter vacua are still there, as is the landscape.

  Besides his pre-KKLT role in moduli stabilization, Polchinski is one of the most prominent exponents of the idea that particle theorists should just give up, using the KKLT moduli-stabilized string vacua as a reason for why string theory can never be tested, but we should believe it anyway. He's been promoting this heavily since 2004, when he got Scientific American to publish this article with Raphael Bousso. My take on that article seems to have upset him greatly, and had a lot to do with the arXiv policy of not allowing trackbacks to this blog (which continues to this day).

  This blog does seem to have played an odd role in the topic of Polchinski's talk. Back in early 2014 someone wrote to me to suggest that I might want to discuss a series of papers by Bena, Grana et al. which pointed out problems with KKLT. I responded that I didn't think this was a good idea: while I was no expert, it seemed to me that the KKLT construction was an absurdly complex one involving poorly controlled approximations (thus hard to conclusively decide if it was "right" or "wrong"), and it had entered the realm of ideology, as a bedrock for explaining why string theory could never predict anything. What I didn't say was that I'm a fan of arguments showing string theory can never predict anything, so why should I publicize work challenging them?

  Later in 2014, the same person wrote to me again to suggest that I change my mind, that there was a new preprint about this. I weakened and mentioned it here. A couple months later Polchinski published this, which mounts a defense of KKLT against criticisms like those of Bena, Grana, et al. I didn't know about this, but did write a long posting about another arXiv preprint he had posted the same day, which was about "dualities" in general, and which I found quite interesting. Only after he and Bousso appeared in the comment section to criticize me about KKLT did I realize that they saw me as responsible for promoting anti-KKLT views, not realizing that I'm actually a KKLT fan. Some strange things have happened over the years at this blog, that Christmas Eve discussion was right up there.

  In any case, just to make my views clear: I'm a big fan of KKLT, glad to hear that it now has been "thoroughly vetted". Back when I first heard about it in 2003, I thought "this is great! now that string theorists have proved to themselves that their theory isn't predictive, they'll move on to something else". I've been surprised though about how long that is taking to happen…

Comments

1. **CIP**
   August 29, 2015

   Very droll!

2. **Thomas Larsson**
   August 30, 2015

   Ah, Bonanza. Or the Cartwright brothers, as the show was called on Swedish television. The intro music was very catchy.

   It is nice to see that Lykken mentions what I see as the single most striking result from LHC Run I – that the SM seems to be sitting precisely at the edge of stability. If we elevate this observation to a principle – the principle of living dangerously – we can immediately make a prediction, both for LHC Run II and future accelerators: there will be no new physics which moves the SM away from the stability boundary. New physics which stays on the stability boundary is not affected, of course.

3. **Gianleo**
   August 30, 2015

Peter,

one reason that people have difficulties to believe that the standard model is final might be the following. When the electromagnetic and the weak interaction were made consistent by Salam, Weinberg and Glashow, physicists did not call it electroweak mixing, but called it electroweak unification. Voices of dissent (Feynman above all, in a fit of desperation, shouted that the standard model is made up of "three independent theories!") were ignored.

This misuse of the term `unification' put almost everybody on the wrong track for several decades. Everybody started looking for similar kinds of `unification'. And of course, they had no success, because GSW did not unify anything in the first place.

Even today, this is a minority view, but maybe it can explain part of the story.

4. **Peter Woit**
August 30, 2015

CIP,
Thanks. I think the comic aspects of some of what is going on here are greatly underappreciated…

Gianleo,
"unification" is just a word, one that I think can justifiably be used for the electroweak theory. I don't think though the SM is a "final theory", it leaves unanswered questions that should have an answer, including that of the relation of the three different gauge theories in it. One reason I've always been skeptical about SUSY extensions of the SM is that they don't answer such questions, just introduce more.

5. **Gianleo**
August 30, 2015

Peter,

you are right, `final' is not correct for the standard model ( I meant `almost all there is'). But electroweak `unification' did not reduce the number of parameters. So in what sense is it a unification? In what sense is it correct to speak of electroweak interaction as just a single interaction? The weak interaction remains separate from electromagnetism, or doesn't it?

6. **bw**
August 30, 2015

Peggy Lee had a good song for this https://www.youtube.com/watch?v=LCRZZC-DH7M

7. **Peter Woit**
August 30, 2015

Gianleo,
I think that "unification" is an appropriate word because the theory describes weak and EM forces in terms of the same sort of QFT (gauge theory), so a "unification" of framework. Then there's the Weinberg angle: this is not just a simple product of two gauge theories. But "unification" is just a word and there can be more and less of it. The question of why the two different couplings, why the different charges, why the Higgs, are still awaiting a good idea about further unification.

8. **Curious Mayhem**
August 31, 2015

Takes a Lykken. He has a dry sense of humor, as befits his Scandinavian ancestors. I was a fan of Bonanza when I was a kid as well, and I too was disappointed when I finally made it to Lake Tahoe and saw no Cartwright brothers.

Particle physics will commit suicide *by* embracing the landscape. The Planck scale isn't speculative, but the unification scale of the other three forces is. There are surely alternative "naturalness" problems that arise from other unification schemes, and alternative ways to solve those "naturalness" problems. The landscape is surely and thoroughly unnatural — illegal in 38 states, or it should be.

There's likely to be something to SUSY, but she's probably not dressed in a convenient, easy-to-spot, quasi-perturbative outfit. Particle physicists have wanted to believe in this implementation because it looks like, and lies close to, the Standard Model they know already.

Someone needs more imagination. Too much particle theory of the last 25 years has been virtuoso performances on a few, already established, strings whose tunes might have already been exhausted in, say, 1990. Young folks have had to dance to these worn-out tunes if they wanted to get jobs. The field has been dominated by a small number of established senior people pushing strings for too long.

9. **Shantanu**
August 31, 2015

Gianleo, do you have a reference to the Feynmann quote about standard model?
First time, I am hearing something like this.

10. **Low Math, Meekly Interacting**
August 31, 2015

"Genius: The Life and Science of Richard Feynman" – by James Gleick

https://books.google.com/books?id=LYEFPnMxXQUC&lpg=PA433&ots=UOox-G1Qw3&dq=%22the%20standard%20model%20feynman%20repeated%20dubiously%22&pg=PA433#v=onepage&q=%22the%20standard%20model%20feynman%20rep

11. **Matt Grayson**
August 31, 2015

Interesting. The same interview is described in The Second Creation by Crease and Mann. I guess they were the recipients of Feynman's ire.

12. **Anon**
September 1, 2015

I think Feynman was being precise….. that nature may not have unification like in grand unified theories, where the SU(3), SU(2), U(1) of standard model are unified into one force such as SU(5) or SU(10).

13. **Low Math, Meekly Interacting**
September 1, 2015

I hope this isn't too OT, but I myself have wondered for a long time what Feynman really meant by that. My limited understanding aside, it seems to me quite legitimate to say there is an electroweak force with a broken symmetry, with some fairly compelling experimental evidence even by the time of that interview. Certainly the case for a Grand Unified Force is much more tenuous to this day, experimentally. Feynman seems to be rejecting even the case for there being even a convincing unification of the electromagnetic and weak forces, which makes him sound more like a contrarian than a skeptic on that particular subject. Am I in error?

That said, I've admired the unfashionable integrity of this view overall. Like his many comments on a host of other subjects, he was often remarkably prescient.

14. **Art Brown**
September 1, 2015

Matt Grayson: Nice! Only connect!

LMMI: I once heard Feynman comment after a colloquium: "You have to explain why the weak force is so much weaker than EM", with emphasis on "why". Or words to that effect. Or so my memory insists…

15. **Low Math, Meekly Interacting**
September 1, 2015

I'm probably confused, but I never had the impression that electroweak unification aspired to answer the "why" kinds of questions that people find so unsatisfactory about the Standard Model. But is this limitation a good reason to suspect that unification may somehow be illusory? I just can't tell if Feynman is being overly scrupulous here, because I can't figure out exactly what he's being scrupulous about.

16. **Anon**
September 1, 2015

If we drop the U(1)_Y group from the Standard model, there will only be the weak and strong interactions and no photon. The photon owes its existence entirely to the U(1)_Y group. In std model there are 3 forces and 3 gauge groups. There is electro-weak physics, but the words "electroweak unification" are probably just to say it is the unified framework of QFT rather than unification of forces like in grand unified or even Pati-Salam (partially unified) models.

And of course there is no evidence so far for GUTs or Pati-Salam and a lot of parameter space is being ruled out. If there is no such unification of forces in nature (which appears to be more and more the way experiments are pointing) then we will have just have several forces and several gauge groups.

17. **Gianleo**
September 2, 2015

Yes, the story is from "Genius" by Gleick. Search for "three theories".

(I was wrong to add "different", but if you read the text, you will see that Feynman meant it.)

18. **sm**
September 2, 2015

Anon: Your ideas are very close to those of Veltman, who expresses them in a colourful and forthright way in his 1999 Nobel prize interview. Veltman stresses that nature could just as well be non-unified, so discussions in the popular literature of unification are a form of (annoying and possibly stupid) propaganda for that area of research. I recommend the whole 30 min interview for those who have not already seen it – it is informative as well as entertaining. In the interview he also gives a 'Veltman centric', (and on the face of it correct) explanation for why the LHC was built but the SCC was not!

19. **Anonyrat**
September 2, 2015

^^^ 6:39 of Veltman's interview here: http://www.nobelprize.org/nobel_prizes/physics/laureates/1999/veltman-interview.html

20. **Anonyrat**
September 2, 2015

Veltman's Nobel lecture also makes the point, http://www.nobelprize.org/nobel_prizes/physics/laureates/1999/veltman-lecture.pdf (PDF file)

> "To what extent are weak and electromagnetic interactions unified? The symmetry used to describe both is SU2 x U1, and that already shows that there is really no unificaton at all.
>
> True unification, as in Maxwell's theory, leads to a reduction of parameters; for example, in Maxwell's theory the propagation velocities of magnetic and electric fields are the same, equal also to the speed of light.
>
> In the electroweak theory there is no such reduction of parameters: the mixing angle can be whatever, and that makes the electric coupling constant e = g sin(θ) a free parameter. If the Higgs sector is not specified, then the Zo mass and the photon mass are also free parametrs. There is really no unification (apart from the fact that the isovector part of the photon is i the same multiplet as the vector bosons).
>
> However, if one specifies the simplest possible Higgs system then the number of free parameters diminishes. The Zo mass is fixed if the weak mixing angle and the charged vector-boson mass are fixed, and the photon mass is necessarily zero. So here there is some unification going on. It seems to me, however, utterly ridiculous to speak of "electroweak unification" when choosing the simplest possible Higgs system.

21. **anti**
September 2, 2015

"Usual counterargument involves the putative Planck scale and unification thresholds, but this is speculative"

is there a hierarchy problem if there is no planck scale or unification threshold?

22. **Peter Woit**

September 2, 2015

anti,
No. The hierarchy problem is that of why the electroweak mass scale is so much smaller (and thus "fine-tuned") than the GUT or Planck scale. If you give up the assumption that the SM is just some effective theory for some other theory with those mass scales, than the "fine-tuning" problem disappears.

23. **anti**
September 2, 2015

peter

what are the physical consequences and predictions if you give up the assumption that the SM is just some effective theory for some other theory with those mass scales?

24. **Peter Woit**
September 2, 2015

anti,
Giving up such assumptions about unification leaves you with just the SM, it doesn't make the SM itself more predictive, and the origin of the electroweak scale remains a mystery. It does get rid of certain "problems" that appear generically when you make those unification assumptions (e.g. the hierarchy problem).

25. **anti**
September 2, 2015

is that a serious proposal among particle physicists? what is your own personal view?

26. **Peter Woit**
September 2, 2015

anti,
It's not a "serious proposal", it's just a reminder that the "hierarchy problem" is based on certain assumptions that we do not know are correct. I've often made this point here, and I think it's understood by most people in the field. I was just interested to see that Lykken was making the same reminder in his survey talk, since it is not often brought up explicitly in such talks.

27. **Anon**
September 2, 2015

sm, Anonyrat — thanks for the pointer to Veltman – that is interesting.

If we do not have unification of course we can still have new physics such as due to a higher theory based on parity (P) symmetry, or another way to proceed could be horizontal gauge symmetry between generations, and see what regions of their parameter space can be tested. Non-unification would motivate more work in such directions, I think.

Peter — Normally I agree with you on most things you write and am a regular visitor to your blog. However on Hierarchy problem, I think it does not matter whether there is or there isnt new physics at an intermediate scale such as GUT scale — we have the hierarchy problem even if it is standard model all the way up to the Planck scale — or if we argue that is a non-problem in this case, then I think an argument can also be made that it is a non-problem even if there are intermediate GUT scales.

This is because the Planck scale still exists even if there are intermediate scales — and the divergence due to Planck scale can be fine tuned to give any mass just as if it were the divergence in pure standard model from Planck scale.

Anyway there are more direct ways to see that not having intermediate scales is not a solution to the hierarchy problem.

I do think that experiments are showing that hierarchy problem is not solved in nature and I feel it maybe that its a non-problem — whether or not there are intermediate scales.

28. **Peter Woit**
September 2, 2015

Anon,
The point is the same for the Planck scale. You're making an assumption that there is some different physics that acts as a cutoff for the SM, and that this different physics takes place at the Planck scale. But we actually know nothing at all about what is happening at the Planck scale (this is why Lykken refers to it as the "putative Planck scale").

The standard argument for quantum gravity coming into play at the Planck scale is dimensional analysis. We know Newton's constant, it's a dimensional number, and if we assume it can be calculated as some number of order one times the scales in the problem, we get the Planck scale. But (whatever string theorists might tell you), we don't have a viable theory in which to do such a calculation. How do you know that if we could do this calculation, we won't get some exponentially small number, not a number of order one (for example, some "induced gravity" theory, where the Einstein-Hilbert action is an effective action, caused by some exponentially small effect)? Of course I don't have a viable quantum gravity theory of this kind. But I think it's important to be reminded of what assumptions one is making, and to remember that we don't have any evidence for assumptions about what is happening at the Planck scale. All we do know is that the cut-off SM is quadratically sensitive to what is happening at the cut-off. This is undoubtedly a clue, but only a "problem for the theory" if you make some assumptions such as a high quantum gravitational scale acting as a cutoff.

29. **vmarko**
September 3, 2015

Regarding the electroweak unification — I often like to present it as "half-unification". Namely, the only thing that makes it more unified than taking the simple product of weak and electromagnetic forces is the fact that SU(2)xU(1) is broken down to the electromagnetic U(1) subgroup which is *not* the second factor in the product (i.e. charge and hypercharge are not the same thing). Other than that, there is really nothing that unifies electromagnetic and weak forces in the way that doesn't also unify the strong interactions in SU(3)xSU(2)xU(1). Crucially, the number of free parameters is not reduced, which should be the main feature of any proper unification. So while there is something nontrivial in the electroweak unification, it is still not the proper real thing. Therefore half-unification. 🙂

Regarding the hierarchy problem — in the appropriate classical limit, we observe three scales in nature: the Planck scale (i.e. the Newton's gravitational constant), the electroweak scale (i.e. the Higgs mass) and the cosmological scale (i.e. the cosmological constant). The huge discrepancies between these three scales are called the hierarchy problem (ratio of Higgs to Planck scale is around 10^{-34}) and the cosmological constant problem (ratio of the CC to Planck scale is around 10^{-122}).

At the fundamental quantum level, it may happen that the ratios of these scales are of order one (case A). If that is the case, the hierarchy and CC problems become the problems of explaining the differences in the scales when taking the semiclassical limit of the theory. This has to be quite nontrivial, since we need to obtain some extremely small numbers by solving equations which feature only numbers of order one. It is likely a nonperturbative effect, and given some putative theory of everything, it is ultimately a mathematical problem.

OTOH, it may also happen that at the fundamental quantum level the ratios of the three scales remain basically the same as in the classical regime (with only small quantum corrections). In that case (B), the hierarchy and CC problems become the unanswered "why" questions for the fundamental theory. Then it is a matter of taste whether or not they are considered problems (a failure in our understanding of nature) or just facts of the real world (either by God-did-it design or by multiverse-did-it randomness). While the design/randomness resolutions are metaphysical, I prefer to think of the hierarchy and CC problems as our failure to understand something, which maintains them as physical problems, and means that our putative theory of everything is still not fundamental enough.

To sum up, case (A) requires a proper fundamental theory and a proper mathematical resolution of both problems. Case (B) either reduces to case (A), or denies the hierarchy and CC problems at the metaphysical level.

HTH, 🙂
Marko

30. **Low Math, Meekly Interacting**
September 3, 2015

Very interesting. Thanks all, learned a lot (with awareness, of course, that deeper understanding of most of the relevant facts are beyond me). There just isn't much discussion in popsci literature about what nature might look like in the absence of a "unified" TOE of the sort you are all familiar with. These subtleties are glossed over to the point it becomes difficult for the interested layperson to even imagine how or why it might not be so, or what HEP might focus on profitably in place of the putative new broken symmetry at the TeV scale…or any scale.

31. **Anon**
September 3, 2015

Peter and Marko,

Thanks for your comments. What I feel is that there is a procedure of doing calculations that gives finite and meaningful answers — regularization and renormalization — that works both for Standard model as well as for GUTs and non-GUT extensions of the standard model (that have more mass scales than the standard model).

I think therefore if hierarchy problem is a non-problem in Standard model, it is also a non-problem in any renormalizable extension of the standard model that may have additional mass scales.

With neutrino masses and mixing we are already going beyond the standard model. Any theory that takes them into account will be consistent and will only lead to a different set of "why" questions.

— if we just add 3 neutrinos and give them small Dirac masses so as not to introduce any new scale, then the why questions would be: why are the Dirac Yukawa couplings so small ~10^-12 (esplly nagging for the third generation)? Why is there an ungauged global B-L symmetry? Why is electric charge quantized if there are no Majorana mass terms? Why is the Majorana mass term absent?

— if we add 3 neutrinos to Std Model and add a Majorana mass term this will lead to a new mass scale (lets say much greater then SM scale, example 10^14 GeV), and all the above why questions disappear. A new why question would be: why is the seesaw scale 10^14 GeV. The hierarchy problem (/ hierarchy non-problem) which was anyway there in SM remains as a hierarchy problem (/hierarchy non-problem) in this case.

In both the above cases we can do QFT, renormalization and get finite answers for measurable quantities.

32. **Peter Woit**
September 3, 2015

Anon,
This has now wandered far away from the topic of the posting. Questions such as the ones you bring up about neutrino masses are important, but a very different topic, and I have to remind everyone that I'm not able/willing to run this blog as a general discussion forum.

33. **Oliver**
September 4, 2015

Hi Peter,

I don't understand what you mean by "the assumption that the SM is just some effective theory". The U(1) and scalar sectors of the standard model are renormalizable only within perturbation theory; non-perturbatively they suffer from the triviality problem. As such, the standard model as it stands strictly only makes sense if defined with a cutoff.

34. **Peter Woit**
September 4, 2015

Oliver,
Yes, all indications are that the SM is not a complete theory, and that something new has to come into play at shorter distance scales. My comment was very over-simplified. One point it intended to refer to is that we know that appropriate gauge field + fermion theories are asymptotically free and make perfectly good sense at all distance scales, not just as an effective theory. This doesn't work for the U(1) factor in the SM, but one can assume for instance some GUT scenario where at short distances there is no U(1) factor (it is part of a larger gauge symmetry)

The real problem are the scalars, with that part of the theory only seeming to make sense with a cutoff. One should keep in mind though that at this point we have limited experimental information about the scalar sector of the theory. While we know much more since the observation of the Higgs and many of its decays, still nothing is known experimentally about scalar field self-interactions. It is the scalar sector and its Yukawas that is responsible for most of the parameters in the SM that we don't know how to calculate. It also has the odd property that to a good approximation the self-coupling is running to zero.

So, my argument is more that most of the ingredients of the SM make sense at arbitrarily short distances, with the main exception the scalar sector, which is the least understood and most problematic. One can imagine a deeper insight into the scalar sector which would change its high-energy behavior to make the triviality problem disappear (not that I have the vaguest idea how to do that).

35. **Louise Riofrio**
September 5, 2015

The Ponderosa Ranch location was near Lake Tahoe. It was open as a tourist attraction until 2004. Those of us too young for the show (Lorne Greene was on a TV show before Battlestar Galactica? Who's Lorne Greene?) still enjoyed visiting the ranch.

36. **GoletaBeach**
September 6, 2015

LM,MI …. thanks so much for the link to the story of Feynman and SU(3)xSU(2)xU(1). Made my day. But there is something to the concept of the Conserved Vector Current. Perhaps Veltman nailed it. Seems to me once there was a mini-industry of testing from the ground up whether the electroweak Lagrangian was really right, but everything was so consistent that eventually everyone caved. Well, there are still some STUck on similar concepts. Good.

This Week and Next Week’s Hype

September 3, 2015
Categories: Multiverse Mania, This Week's Hype

This week’s hype comes to us from Discover Magazine, which has Is Our Universe One of Many? Here’s How We Can Find Out. Needless to say, the author doesn’t actually tell us how we can find out, just repeats the usual “maybe we’ll see bubble collisions” argument often discussed here. We’re also told that

> It is important to keep in mind that the multiverse view is not actually a theory, it is rather a consequence of our current understanding of theoretical physics.

It seems that our “current understanding of theoretical physics” is the string theory landscape. If you ask what the evidence is for string theory, you’ll be given the usual circular reasoning that we don’t have evidence because of the multiverse.

For next week’s hype, there will be a promotional public talk in Paris next Tuesday entitled String Theory: results, challenges and magic. Presumably this will be much the same as the speaker’s String theory: results, magic and doubts from two years ago. The argument for string theory seems to be that it is “magic”, and somehow in the past two years the “doubts” have turned into “challenges”. The abstract describes string theory poetically as having

> soured and captured the imagination of a generation of high energy physicists.

which I would say is a deep truth, if probably not one the speaker intended.

Comments

1. **5371**
   September 4, 2015

   The word “soured” is rather hard to emend. I incline toward “spurred” rather than “soared”, but neither is really satisfactory.

2. **jjg**
   September 4, 2015

   Perhaps from “faire tourner” which can mean rotate, revolve, churn or sour.

3. **DrDave**
   September 4, 2015

   Soured…how very odd…soared, perhaps, with a split clause.

4. **Chris W.**
   September 4, 2015

   The author of the Discover Magazine piece (Crux blog post) also flirts yet again with conflating the multiverse with the Many Worlds interpretation of quantum mechanics, although he seems to back away from that in the last section (“Testing the Theory”).

5. **a l**
   September 4, 2015

   Carlo Rovelli posted recently a refreshing essay which demolishes most of ‘our mathematical universe’ and its incarnation in the multiverse.

   “…science can be said to be nothing else than the denotation of a subset of David Lewis’s possible worlds: those respecting certain laws we have found. But Lewis’s totality of all possible world is not science, because the value of science is in the restriction, not in the totality.”

   Rovelli C., Michelangelo’s Stone: arXiv:1508.00001 [math.HO]

6. **Patrick Dennis**
   September 4, 2015

   My layman’s understanding of the concept of multiverse as “… a consequence of our current understanding of theoretical physics,” is that it would be a consequence of inflation, not string theory (and that one does not depend upon the other.) Wrong?

7. **David**
   September 4, 2015

   perhaps (in a French-speaking context referring to imagination)
   ‘soured’ = ‘piqued’ ?

8. **Peter Woit**
   September 4, 2015

   Patrick Dennis,
   The “inflation implies multiverse” claim is a common one, and I’ve often written about the problems with it. This particular author though is not talking about inflation, but writes
   “Instead the idea that the universe is perhaps one of infinitely many is derived from current theories like quantum mechanics and string theory.”
   putting string theory and QM on a par.

9. **Yatima**
   September 5, 2015

   Thanks, “a l”, for the link to Carlo Rovelli’s Michelangelo’s Stone: an Argument against Platonism in Mathematics. It’s an interesting read (and I will read it again), but it’s not very convincingly written.

Not a believer in hard-core Platonism myself. I like to consider Mathematical Structures as computers (syntactic machines) with no limits imposed by computational complexity, whose actual (entirely imagined) behaviour one wants to unravel. Very much linked to the real world.

However, Carlo Rovelli's examples seem rather ill-chosen and trying too hard. In particular, they are free of constraints that the real world would impose. Alien intelligences that don't develop counting? Nice for Asimov's Magazine of Science Fiction but I can only say good look in the real-world predation game with THAT. Marvin Minsky handled this rather better in 1985 in [Communication with Alien Intelligence](). Develop Riemannian geometry before Euclidean one? Possible, but general ideas (highly compressed and with book-length contextual baggage) do not spring fully-formed out of someone's real-world brain machinery, it's a building-up process from simple ideas. Always. Linear algebra not so universal? I really don't think so, and the fact that it was formulated rather recently is not an argument against its universality. We don't program a computer to slowly unravel the platonic world's theorems because we want to find the interesting ones only? Of course not! It's because no-one is mad enough to use computers on problems clearly far, far, far outside of the polynomial complexity problem set (itself a platonic concept, actually), Gödel's completeness theorems notwithstanding. I suspect Carlo Rovelli might profit from a course in the Theory of Computation.

It made me think of Hilary Putnam's, The Logic of Quantum Mechanics (Originally, "Is Logic Empirical", Boston Studies in the Philosophy of Science Vol. V, 1969), wherein the (entirely unsurprising) claim is made that classical logic is actually not universal and that this can be illustrated by the necessity of having other logics to describe QM for example (no mention is made of Linear Logic for this, still in the future). It's like "Dude! No need to crash in. That door was open. Take a seat, I'll buy you a drink."

But this is getting rather off-topic.

10. **Peter Woit**
September 5, 2015

a1/Yatima,
"But this is getting rather off-topic."
Yes, I left the link to Rovelli because people might be interested, but it has little to do with the topic of the posting, and this is not a great place to discuss it.

11. **a l**
September 5, 2015

Reading Rovelli's piece might give you a somewhat different perspective on the multiverse topic. Otherwise it's once again "not testable, blah blah". If our knowledge of mathematics is contingent, it looks less convincing that something is real just because there is a theory for it.

12. **Neil**
September 5, 2015

Rabinovici is not the first to invoke magic. Did not Witten himself suggest that the M in M-theory could stand for "magic"?

13. **Vincent**
September 6, 2015

What struck me (a mathematician with very limited knowledge of physics) in the Discover article is the claim that 'The universes predicted by string theory and inflation live in the same physical space (unlike the many universes of quantum mechanics which live in a mathematical space), meaning they can overlap or collide.'

This seems a huge improvement over multiverses where the universes are truly disjoint and cannot be detected from within one another. But it also left me with a very basic question: what is the definition of a universe? This 'same physical space' sounds pretty much like what I would naively call the universe. What do I miss?

14. **Peter Woit**
September 6, 2015

Vincent,
The cosmological multiverse and the QM many-worlds multiverse are two completely different things. In both cases the "universes" are part of a larger structure. In the many-worlds case there is one overall state space, with different subsectors that "decohere", so can effectively be treated as independent. In the cosmological case, there is one space-time manifold, with different "bubble universes" which are causally independent. The "bubble collision" business is about the possibility in some multiverse models of a violation of causal independence, an interaction of the bubbles. However there is no evidence this is happening in our "bubble", and no reason at all to expect it to.

15. **Ronan**
September 6, 2015

BBC's popular science documentary series "Horizon" aired an episode about the multiverse last week – featuring Max Tegmark, Seth Lloyd …..

Available to watch here (I think only in UK)

http://www.bbc.co.uk/programmes/b0695t56

16. **Peter Woit**
September 6, 2015

Ronan,
Here in the US we got to enjoy that last fall:
http://www.math.columbia.edu/~woit/wordpress/?p=7352

17. **Narad**
September 7, 2015

> perhaps (in a French-speaking context referring to imagination)
> 'soured' = 'piqued' ?

I was thinking that Hebrew would be a better angle to approach this one from than French, but that wasn't particularly promising, either, without acrobatics (m.m. *Sauerstoff*).

I'm inclined toward a typo in an odd construction using "sourced"; it doesn't quite seem to be at the mystery level of "homologous recombinaltion *tiniker*."

18. **Neil**

September 8, 2015

I vote for roused. Somehow the r and s got exchanged.

19. **Anon**
September 9, 2015

"Soared" would be consistent with Discovery writing style, so I suspect a typo, maybe Freudian. I have to say, though, that despite the occasional exaggerations, Discovery magazine has become better that Scientific Amercian, in my opinion, but maybe only because SciAm has become so awful.

20. **marten**
September 10, 2015

If it is a typo, "sourced" seems more likely to me..

21. **Lindsay Berge**
September 11, 2015

I would guess 'soured' should be 'stirred' as in the collocation 'stirred the imagination'. So the phrase would be 'stirred and captured the imagination of a generation of high energy physicists.'

22. **Low Math, Meekly Interacting**
September 11, 2015

"The universes predicted by string theory and inflation..can overlap or collide. Indeed, they INEVITABLY MUST COLLIDE…" (caps mine)

Oh really? Am I wrong, or is there no consensus on this, even among Lanscapers and Eternal Inflators?

23. **Scott Church**
September 11, 2015

Peter or anyone, I have a quick question which hopefully isn't off-topic here… In eternal inflation, SM, Landscape or otherwise, bubble universes will nucleate amidst larger inflating regions and reheat in the usual manner. Presumably this means that each nucleating bubble "neighborhood" is surrounded by isotropic inflating regions out of which other bubble universes are nucleating. So… how can bubble universe collisions occur between bubbles that are all inflating away from each other in full afterburner? Am I missing something…?

24. **Marty Tysanner**
September 12, 2015

Scott,

I don't know your background so I'll give some detail. You're getting somewhat more than you asked for!

To do its job, inflation must smooth out and/or dilute preexisting inhomogeneities of the pre-cosmological space by rapidly expanding the space, and then it must stop. General relativity offers a way: a space that contains a constant, positive energy density will expand exponentially as *exp(Ht)* in all directions. The energy density determines the rate *H* ("Hubble parameter"); *t* is the time.

In the simplest models, the vacuum is presumed to be filled with a *scalar field* whose associated potential energy curve has special characteristics; more complicated models may employ more than one field. The curve generally has a (nearly) flat part or/and a metastable "bowl," both at a high energy where inflation does most of its job; this is followed by a steep drop to a stable (or at least metastable) minimum where reheating and subsequent cosmological evolution occur. The scalar field and its potential energy curve exist to cause inflation: they are imposed by *fiat*, not by anything in the Standard Model. Beyond general characteristics, the particular assumed shape of the potential depends on the model. Since there is no *a priori* choice that is dictated by a fundamental theory there is substantial freedom to choose the potential to give you what you want in terms of consistency with observational evidence.

The scalar field must somehow get into the state of high energy density for inflation to begin; an actual inflation *theory* would explain this, ideally. Once it starts, inflation will continue as long as the scalar field state remains there, e.g. while the "inflaton" "rolls" down the gently sloping part of the potential (the Hubble parameter decreases slowly as the inflaton rolls down). It ends when the inflaton rolls down the steeply falling region and reaches the stable/metastable lower energy state.

(You can think of inflaton motion at some point "x" in the space as the time-dependent change of energy density of the scalar field at x. Note that we're talking about energy *density* — the energy density can have different values at different points, and different values correspond to different places on the potential energy curve.)

In some models the potential curve has a metastable high energy "bowl" where the inflaton remains trapped for a time. Since the energy density remains stuck there with a constant value, the Hubble parameter *H* is constant so that the exponential expansion *exp(Ht)* produces a de Sitter (hyperbolic) space. This is probably the kind of scenario you are referring to. Being a quantum mechanical entity, the inflaton can probabilistically tunnel through the "bowl wall" onto a gently sloping/ steeply sloping/ stable minimum region of the assumed potential, depending on the model. Spatially, in the bubble universe scenario the tunneling event corresponds to formation of a spherical region of finite radius; this region has the energy density given by the tunneled-to part of the potential curve, and subsequent evolution inside continues from there down the curve to the minimum energy.

In this scenario, the newly formed spherical region has a lower energy density than the ambient de Sitter vacuum (maybe even zero), and thus a domain wall forms to separate the "inside" region from the ambient vacuum. This is the bubble wall, initially stationary with respect to the bubble center. Being of lower energy than the ambient vacuum, the wall continually "eats" energy of the surrounding high-energy vacuum and thereby adds to its kinetic energy, causing the wall to rapidly accelerate outward into the de Sitter space. If the tunneled-to region of the assumed potential is gently sloping, the bubble interior will meanwhile undergo a secondary but less rapid inflationary period until it drops into the stable "true vacuum" state.

Of course, the de Sitter vacuum outside the bubble continues its exponential expansion all the while: the de Sitter space expands faster than the space inside the bubble, so compared to the exponentially increasing volume of a "box" that contains the bubble, the exponentially increasing bubble volume occupies a rapidly decreasing fraction of the (expanding) box volume over time. Inflation is eternal in this scenario (as in nearly all inflation models) because, even though inflation will eventually end "almost surely" at every point in the de Sitter space via tunneling, the expansion of space occurs faster than tunneling can stop that expansion.

(Some people get confused by exponential expansion, since it implies that an object far enough away will be moving away faster than the speed of light. The bubble wall speed increases exponentially from the center, but "speed of light" in an expanding space is only meaningful if measured locally: at any given moment the wall speed is with respect to a *fixed* point infinitesimally distant from the wall at that moment, whereas the wall can move faster than the speed of light relative to a point a *finite* distance from the wall.)

Having a quantum mechanical origin, bubble nucleation is a probabilistic event. Nucleation events are independent, so two bubbles will sometimes form nearby. Both bubbles expand and their walls accelerate toward each other. Now to answer your specific question (finally!): If two bubbles form *sufficiently closely*, the acceleration of their respective walls toward each other can "outrun" the accelerated expansion of the ambient de Sitter vacuum between them, and they will collide.

This is all hypothetical of course… In principle, the aftermath of a bubble collision could be detected today if it had occurred under very optimistic/ideal (and probably very unlikely) conditions. Such an event would presumably have a marked effect on the energy density in the collision region which would ultimately manifest as a strong, circularly symmetric inhomogeneity of the cosmic microwave background. But no such inhomogeneity has convincingly shown up, yet at least. Importantly, only collisions that occurred very soon after nucleation would cover a significantly large region of the sky to be observable; later collisions, if their effect could reach us at all, would subtend too small an angle to be statistically discernible.

Sorry Scott (and Peter!) for such a long comment!

25. **Marty Tysanner**
September 12, 2015

As a side comment to my previous one, the kind of eternal inflation that arises from single field inflation models should lead to all bubbles having essentially the same particle content and laws of physics. A scalar field has no obvious properties that should affect what kinds of particles appear during the reheating phase that immediately follows the inflationary phase, nor do they indicate why fundamental constants should be bubble-dependent (to me, anyway). That seems to make the kind of multiverse indicated by most inflation models less than WOW!-worthy, but that's just my opinion…

26. **Peter Woit**
September 12, 2015

Marty,
I think the question that always comes up is whether inflation implies endless new bubble universes, which must "inevitably" collide. Some experts seem to say no (e.g. Katie Freese), Lim and others say yes, although often in the context of popular articles like this one that are chock-full of other misinformation, so hard to take seriously. I'm not expert enough on the details of all inflationary models to judge who is right here, and, honestly, there seem to be much better ways to spend ones time than trying to sort this one out. If anyone knows of a reliable source with a definitive answer, please do tell.

27. **Low Math, Meekly Interacting**
September 12, 2015

Marty,

That was magnificent. Thank you.

28. **Scott Church**
September 14, 2015

Marty, sorry for the delayed response… I just got back from a week in Alaska and am finally settled in again. Thanks so much for your thoughtful and informative response! I do have a physics background (MS level) and was aware of much of that already. But the key piece I was missing–which you so graciously provided–was that domain walls will acquire kinetic energy from their immediate inflating deSitter neighborhoods at a rate that can allow bubbles that are suitably near each other to grow faster than the underlying inflation can separate them, thus leading to collisions. Now it makes sense.

Of course, as Peter points out this still leaves us not only with the question of whether there is evidence of such collisions occurring (the answer to date being a resounding No), but also whether they're inevitable within the extant chaotic inflationary framework, with or without M-theory. The question is important, I think, if for no other reason because should it turn out that such collisions *are* inevitable within those frameworks, the fact that they aren't observed raises some serious issues with chaotic inflation. I too would be interested in finding reliable sources with a definitive answer.

Best.

Various and Sundry

Categories: Multiverse Mania, Uncategorized

The semester here is finally underway, and I'm getting back to work on my quantum mechanics and mathematics book (latest version available here). Current plan is to have a final version by next spring, with publication by Springer late next year. This semester I'm teaching Calculus II, a subject where there's only one thing I really dislike about pretty much all textbooks, their refusal to use Euler's formula. Since I couldn't find an online source I was completely happy with, I spent some of the last couple days writing up some notes for the students on Euler's Formula and Trigonometry, which maybe someone else will find useful. In other news:

- Nima Arkani-Hamed was here today, giving a talk on a new model he calls "NNaturalness". The basic idea is to consider something like N copies of the Standard Model, with N a large number. Large N fixes the technical naturalness problem, with something like $N=10^4$ fixing the MSSM's current naturalness problem, and $N=10^{16}$ fixing the non-supersymmetric problem. He makes clear that he's well aware that this is a pretty contrived thing to do, but argues that it's interesting one can do this while evading dramatic disagreement with experiment, and coming up with potential CMB signatures soon observable (e.g. the effective number of relativistic degrees of freedom).

  He has a nice description of the naturalness problem as "in any theory where we can compute the mass of the Higgs it has a fine-tuning problem". Probably there are people out there who think they have a way to compute the Higgs mass who would disagree with him. To me the problem is that the theories he's talking about (GUTs, string landscape) don't actually explain anything about the underlying physics of electroweak symmetry breaking (where does the Higgs field come from and why does it have those couplings?). Given this, it's unclear why one should worry about the fine-tuning.

  He describes the landscape and the multiverse as "like democracy, the worst idea except for everything else", and gives a defensive argument for why one should study alternatives like "NNaturalness", even if they're not as good as the multiverse (which he finds "simple and deep"). To him it's worth thinking about alternatives to the multiverse (as a "foil") not because the multiverse is untestable pseudo-science, but because maybe one shouldn't just give up. So, it seems that at this point he's not quite signing up with the intellectual suicide of multiverse mania, although he sees it as the most attractive path available.

  In other Arkani-Hamed news, the IAS has an article about his activities promoting a next generation collider here.

- The KITP has a newsletter here, including a description by Graham Farmelo of his visit there. Oddly, no matter what he writes about, Farmelo almost always includes an unconvincing defense of string theory and/or the current activities of string theorists (for examples, see here, here, here and here). In this case he assures us that the KITP theorists are not given to "mathematical adventurism". I think he's right, but that's the problem…
- Someone pointed me recently to Olivia Caramello's web-page on Unifying theory and her arguments with fellow category theorists. I had a youthful infatuation with category theory, but ultimately came to the conclusion that there's a real danger in that kind of "unification" of going too far in the direction of saying less and less about more and more. Many of the ideas involved are powerful and attractive, but the remarkable thing about mathematics is that, even for the lover of grand ideas, less generality is sometimes even more so.

Update: One more. If you're in the Bay Area next week, you might want to head up to MSRI for a series of elementary talks on the Langlands program by Edward Frenkel.

Comments

1. **Unemployed**
   September 14, 2015

   Surprised to hear Euler's formula is absent from introductory texts. After discovering it as a youth, I used it just like this, and found it a wonderful alternative to the pain that my classmates were suffering without it. But I always assumed its absence from our curriculum was merely one more manifestation of our crap teachers and textbooks. Kudos for re-introducing it to the world.

2. **mitch**
   September 15, 2015

   Peter,

   You have a typo in your exponential notes on page 9.

   Where you are evaluating the integral of cos(ax)cos(bx), on the second line, the second term in the integrand should be exp[i(b-a)x].

   See, I'm looking out for you.

3. **Veríssimo**
   September 15, 2015

   What's up, Peter. Nice post, but I was expecting something about the latest hype as well:
   http://www.theguardian.com/science/life-and-physics/2015/sep/14/straws-in-the-lhc-wind-lepton-universality-and-an-update-on-that-bump

   September 15, 2015

   As far as the category theory is concerned, the way to obtain some interesting results is to avoid generalizing too much. For example, the Turaeev-Viro 3-manifold invariants were obtained by using special tensor categories (associated to representations of quantum groups at roots of unity) while the invariants of 4-manifolds can be associated
   with 2-categories. Moreover, the 2-categories also appear as 2-groups or crossed modules, which generalize our notion of symmetry (which is based on the notion of a group). This is useful for constructing new TQFT's and quantum gravity theories.

5. **Ru**
   September 15, 2015

   Isn't Euler's Formula and Trigonometry taught at grade 12?

6. **Peter**
   September 15, 2015

"An engineer / scientist … starts out knowing a great deal about very few things but over time learns more and more about less and less until eventually s/he knows everything about almost nothing".

"A philosopher / architect … starts out knowing a little about a large number of things but over time learns less and less about more and more until eventually s/he knows almost nothing about everything"

September 15, 2015

Can you give a few more details about N-Naturalness? I cant find any of Arkani-Hamed's slides are on the web, but I've heard about his idea anecdotally from a few sources.

8. **Olivia Caramello**
September 15, 2015

Thank you for your pointer to my website. I should clarify that the kind of unification that I pursue in my work is not through (Lawvere-style) category-theoretic generalization/axiomatization, but rather through transfer of suitable invariants. While category theory can be regarded as a unifying language since its concepts are sufficiently general to specialize to many important 'concrete' notions in specific fields of Mathematics, Grothendieck toposes provide a substantially different way for relating different mathematical theories with each other, which is based on the possibility of transferring invariants across their multiple representations. The kind of insight that these novel topos-theoretic methods can bring is therefore much deeper than the "static unification" through generalization achieved by category theory (the distinction between these two different kinds of unification is explained at this page): they allow, for instance, to translate a difficult-to-check property in the context of one mathematical theory into a completely different-looking one which can be much easier to tackle in another theory, and to generate concrete results in different mathematical areas which might be hard to prove using alternative methods (a list of examples is available on my website).

9. **sm**
September 15, 2015

"By the end of this course, we will see that the exponential function can be represented as a power series"

Peter, why leave them 'dangling in expectation' to the end of the course? The power series follows in two lines – satisfies the stated equation and meets the initial condition, both only requiring calculus 1if I am not mistaken?

You would then have a 100% 'do it all yourself' physicist's exposition!

10. **Peter Woit**
September 15, 2015

Ru,
In the US Euler's formula is not part of the standard secondary school curriculum. Even worse, it's not part of the calculus curriculum at the college level. I hope this is not true in most other countries.

One fundamental problem (besides that of not having a crucial, powerful tool) is that without using Euler's formula, there's no sensible way of understanding why the addition formulas (and thus most trig identities) are true. As a result, students are led to believe that mathematics is about some list of formulas you should memorize without understanding why they are true.

Another way of getting the same thing (cos + isin\theta is a rotation by \theta), while avoiding complex numbers would have been to use two by two rotation matrices, but that requires introducing matrix multiplication.

I don't really understand why the US math curriculum makes this choice not to use Euler's formula. It seems to be that the logic is "to understand Euler's formula you need to understand complex functions of a complex argument, and we can't talk about that until a complex variables course"

sm,
The difference between a math and a physics course is that in the math course you're supposed to pay attention to whether the power series converges, and whether what it converges to is the function you have in mind. Much of the later part of the course is devoted to understanding series and convergence issues, so, yes, I'm leaving them dangling…

11. **Peter Woit**
September 15, 2015

Andrew,
Sorry, it's a slightly complicated picture, and I don't think I'd be doing anything very helpful by explaining badly what I understood of it here. He says a paper is underway, collaborators are Cohen, D'Angelo, Hook, Kim, Pinner, maybe you can find out more from one of them.

12. **Peter Woit**
September 15, 2015

Verissimo,
The Butterworth article isn't hype at all, it does an excellent job of explaining the story.

13. **anon**
September 15, 2015

It is unfortunate to see promising young researchers potentially destroying their own careers by being so clueless with regards to social skills, as Olivia Caramello seems so bent on doing right now. I hope someone would give her better advice, and that she would follow it.

14. **Peter Woit**
September 15, 2015

anon,
I don't know her field and I didn't look that carefully at all the details of her exchanges with other mathematicians. But some of them did seem to be giving her good advice, and I hope she'll make use of it. The issue of "folklore theorems" in mathematics is a very tricky one for a lot of reasons. Her choice to make all this debate quite public is very unusual. To the extent it makes the situation with the mathematics and its history clearer, that may be a good thing. On the other hand, to the extent it gets people worked up and annoyed about priority claims, not a good thing at all.

15. **Peter Woit**
September 15, 2015

mitch,
Thanks. Fixed.

16. **tt**
September 15, 2015

I think Dr. Caramello comes off well in the exchange.
Besides the accusers admitting to writing letter of reference that insulted her, one accuser defends himself with this statement.

"You'll recall that, when you first told me about the `de Morganization' construction (the largest dense de Morgan subtopos of an arbitrary topos) I was very surprised — not so much by the fact that this construction existed, but by the fact that no-one had spotted it before.

However, a little later I discovered that I had found the construction myself,…"

that is just absurd.

17. **Jeff M**
September 15, 2015

Alex Heller, who taught me topology my first year in graduate school, was a student of Eilenberg in the 40s and around while category theory was being developed. Used to drive me crazy in class, every proof was "the diagram commutes." That said, though Alex was a category theorist in some meaningful sense, even he used to call it "general abstract nonsense" which I believe was a quote from Eilenberg. It is possible to get to general. Then again, what Caramello is doing is somewhat different, Grothendieck had a very interesting take on things. Not that I'm an expert on that sort of stuff. I have crossed paths with Grothendieck in his work on dessins des enfants.

18. **Tony Smith**
September 15, 2015

As to "… Calculus II … textbooks … refusal to use Euler's formula …"
years ago when I was at Georgia Tech a physics PhD candidate friend of mine
was teaching a comparable calculus course using a book with no Euler's Formula
and
he took it upon himself to show how Euler's Formula made calculations easy and natural.
The students rebelled (it is not in the book – we don't want to know about complex numbers – complex number theory is not a prerequisite – …. etc …)
and complained to the head of the department.
My friend was admonished and told to apologize to the students
and to avoid all use of the devil's tool of complex numbers in the course.

Maybe that was not the isolated incident that I thought it was
and
maybe that is why publishers even today keep Euler's Formula out of such textbooks.

Tony

19. **Peter Woit**
September 15, 2015

Tony,
Hopefully that won't be the reaction of the students this time. The odd thing is that complex numbers are a topic in high school math, so is trigonometry. But explaining to students the relation between the two subjects is somehow off limits.

20. **Low Math, Meekly Interacting**
September 15, 2015

I was first introduced to Euler's formula in pre-calc in high school. It's about the only thing I remember clearly from that class, actually, because I thought my teacher had found God or something. Very few things that I can recall floored me like that did. It was also the first time my lack of innate skill in mathematics made me a little depressed.

21. **si**
September 15, 2015

I think that for more adventures students, specially if they have a computer software background, an introduction to the Chebyshev polynomials and their relationship to the trigonometry and de Moivre's formula may be interesting (this is actually how computers calculate the trigonometric and many other functions).

22. **cthulhu**
September 15, 2015

My high school (in the late '70s in the rural Midwest) had only trig as the highest math, and we barely got into complex numbers. Then in college (engineering school) I did math through PDEs, but we didn't talk much about complex numbers; I got more about complex numbers in my control systems class (Laplace transforms) than the math classes. But being something of a math and science nerd, some years ago I found Paul Nagin's book "An Imaginary Tale: The Story of sqrt(-1)", from Princeton Science Library Press; it is ostensibly a history of complex numbers, and quite entertaining at that, but it also has a lot of semi-rigorous derivations of things like Euler's formula, de Moivre's formula, and a lot more. Might be worth recommending to your students as a resource.

23. **Douglas J. Keenan**
September 16, 2015

"Euler's Formula and Trigonometry" notes that e^($i\pi$) = −1 and then says that the equation "relates three fundamental constants of mathematics".

I like the discussion in the Wikipedia article [Euler's identity](), which is based on the equation e^($i\pi$) + 1 = 0.

> Three of the basic arithmetic operations occur exactly once each: addition, multiplication, and exponentiation. The identity also links five fundamental mathematical constants: 0, 1, π, e, i. Furthermore, the equation is given in the form of an expression set equal to zero, which is common practice in several

areas of mathematics.

24. **srp**
September 16, 2015

I got the formula from Eric Temple Bell's Men of Mathematics, who rhapsodized over its astonishing combination of all the fundamental constants in math. But I never was exposed to it as something useful.

25. **Jeff M**
September 16, 2015

The question of exposure to the complex numbers is an interesting one, from what I can tell they have been largely disappeared from the curriculum, even for math majors. At my university, there isn't complex variable course, and realistically you could get through a whole major without really seeing them, except peripherally. I just checked, and Stewart's precalc book (a standard) does mention them, about 5 pages pretty early, then a few more when it does polar coordinates. It mentions DeMoivre. So students will probably see them then, for a minute, and might not again until grad school. I saw them first in high school, not because we got taught them, but because all the math nerds did it on their own. And when I took Calc in high school, we did do Euler. I also of course did complex as an undergrad (out of a very interesting book by Polya).

26. **AcademicLurker**
September 16, 2015

Huh. I don't know about Euler's formula, but we certainly learned about complex numbers, basic operations with them, and the idea of the complex plane in high school. Has all of that disappeared from the curriculum?

27. **Peter Woit**
September 16, 2015

Academic Lurker,
Complex numbers are taught in high school, generally in the context of roots of polynomials. Euler's formula is about the exponential function, and essentially says that you can extend it from the real numbers to the complex numbers, preserving the property that exponents add when you multiply. The remarkable, beautiful fact is that when you do this you get trig functions: the exponential of an imaginary number is a complex number with real part the cosine, imaginary part the sine.

28. **Low Math, Meekly Interacting**
September 16, 2015

Where I went to school, i was all about factoring, as I recall, and that was all we were tested on. I found the exercises chugging through complex conjugates, etc., very tedious. Euler's formula was just an aside, alas. We were wrapping up the complex numbers unit, and he pulled it out of his hat, so to speak, during the last lecture. We never had time to learn what it was "good for". I think we were just meant to be amazed at how raising e to the i*pi power gives you -1, of all things, and he walked us through the proof to hammer it home. I was duly amazed.

29. **MB**
September 16, 2015

Nice notes on Euler's formula. There's another typo at bottom of page 9, in the last point where you're deriving the orthogonality of the exponential functions: you need minus signs in various places. Either you want n -> -n in the exponentials or in the conditionals and the text below.

30. **Peter Woit**
September 16, 2015

MB,
Thanks! Fixed.

31. **G.S.**
September 16, 2015

Peter,

You say "One fundamental problem (besides that of not having a crucial, powerful tool) is that without using Euler's formula, there's no sensible way of understanding why the addition formulas (and thus most trig identities) are true."

What's wrong with drawing the picture? You can quickly derive both addition formulas by drawing a couple of right triangles and using the definitions of cosine and sine. https://en.wikipedia.org/wiki/Proofs_of_trigonometric_identities

In my experience teaching college math and physics, the students are already struggling to remember the definitions of basic trig functions (hence SOH-CAH-TOA). Introducing complex numbers, rules for multiplying and conjugating them, and another formula (Euler's) for memorization is probably going to overwhelm them.

Then again, the better students in the class will probably love it. I know I was amazed when I first learned about Euler's formula. It was an episode of the Simpsons. It flew by Homer after he crawled through a portal to the "hypothetical" third dimension.

32. **AcademicLurker**
September 17, 2015

@Peter: I meant that while I remember complex numbers being covered in high school, I can't recall whether Euler's formula specifically was covered. I suspect that, as LMMI mentions, it might have been mentioned as an aside and so didn't stick.

My first clear memory of Euler's formula being presented in a way that made clear how useful and cool it is was in the Vibrations and Waves section of one of my early university physics courses.

33. **Peter Woit**
September 17, 2015

G.S.,
Would any mathematician who needed to derive the addition formula do it using that triangle argument, or would they use Euler's formula (as the page you link to also does)? Why use a non-obvious argument about triangles when there's an obvious one using exponentials?

As Academic Lurker points out, the other reason students should know Euler's formula is that it's crucial for solving ODEs, including the basic ones used in physics to describe wave motion. If it's needed for a second year physics course, it should be taught early on in the math curriculum.

I was wondering how our ODE textbook deals with this and just took a look at the book for our basic math ODE class. They use Euler's formula, don't assume students know it, put the explanation for why it's true in a footnote. The idea that that's the way math students should encounter this subject is kind of appalling.

34. **Dato**
September 17, 2015

So I specifically went to the bookshop to take a look at the book for 12th grade ("première enseignment secondaire classique"):

The formula

It's a bit short, in a "just learn this" kind of way, but it's there. I do remember that our *professeur* ~30 years ago enthusiastically showed us that it was indeed an extension of the exponential over the reals and we went on from there.

35. **Jeff M**
September 17, 2015

Well, really, the best way to teach the various trig identities is to use the Taylor series 🙂
Peter is right, it's depressing that this has been dropped from the math curriculum (in large part), especially since calc books have added so much useless garbage. I learned calculus first out of Sherwood Taylor, my dad's book from City College in the early 50's, it was 5 x 9 and maybe an inch and a half thick, missing most of what's in current calculus books, but somehow they included stuff like Euler, and actual proofs.

36. **vmarko**
September 17, 2015

I'm a little surprised by this whole discussion about Euler's formula. The way I learned math in the first-year calculus course at my University (as a physicist) is more or less the way math students learned it as well — one introduces the exp function in a complex plane via its power series, prove convergence, basic identities etc, and then go on to introduce both trigonometric and hyperbolic functions (also over the full complex plane) by splitting exp into real and imaginary part, and evaluating the corresponding series on the real line, imaginary line, etc. The Euler formula is then actually a part of the definition of sin and cos.

The interesting question then is what do these functions and their power series have to do with triangles and planar geometry. This connection is then being made in a nontrivial manner, by studying the relationship between the complex plane and the real plane, and the map between U(1) and SO(2)…

But I was generally under the impression that everyone learns math in this way in a university course. The "elementary" trigonometry was something one learns in high school, but that any serious calculus course (university level) would introduce all elementary functions more rigorously, as a suitable power series in a complex plane, etc. So I am surprised that this is not the curriculum at every university out there.

Also, the Euler formula, despite its elegance, is not universally powerful in proving identities in trigonometry. For example, the famous identity

A sin x + B cos x = \sqrt(A^2 + B^2) sin (x + arctan B/A),

is a bit more tough nut to crack using Euler formula. 🙂

HTH, 🙂
Marko

37. **sm**
September 17, 2015

vmarko:
Depends what you mean by "using Euler's formula". Simply by considering (Asin(x)+Bcos(x))/sqrt(A^2+B^2) we have (as the mathematicians say) reduced to problem to the case(s) already proved by Euler's formula.

38. **Low Math, Meekly Interacting**
September 17, 2015

I did the same first year calc in college that all the other science majors had to take, including the physics and math majors (if they didn't place out, which was rare, of course). Complex numbers barely came into it. Neither Euler's formula nor the famous Identity were even mentioned, if I recall (and I would have, since the lattered bordered on mystical to me).

Well, to me the argument for including it early is simply that it's amazing. I know, I know, it's also terribly useful. But is it gauche to simply marvel at it? Generate a little more excitement for a subject that many find intimidating without having to resort to gimmicks, like they do in my niece's high school? Sorry, OT probably. I'll shut up.

39. **G.S.**
September 17, 2015

Peter,

Every mathematician before Euler used arguments about triangles to prove those trig identities. While it's true that I use Euler's identity today to quickly derive trig identities and perform integrals involving trig functions, that method is only "obvious" to me because I've spent the last 20 years using complex numbers. I agree that they should learn it, but I question whether introducing it in Calc 2 is wise. I think you'll end up confusing more students that you end up helping.

This whole thing actually reminds me of my own experience TA-ing a lower level physics class in grad school. I was always appalled that physics books simply state the solution to the simple harmonic oscillator differential equation as a linear combination of sine and cosine (or as complex exponentials). You can prove that it works, but there's never an explanation for how that solution was guessed in the first place. It's usually chalked up to "experience" that the students don't have.

The only method they had seen up until then for solving a differential equation was to try a power series. So, away I went. I spent a discussion session showing that the power series solution that you get ends up being a linear combination of the power series for sine and cosine (which they had memorized from a previous class). Then I showed that this can be equivalently written as a linear combination of the power series for complex exponentials with opposite sign (by proving Euler's identity from the power series).

The A students liked it, but most of the B and below students (the ones who could most use the discussion session) stopped attending after that.

September 17, 2015

G.S.,
I've taught Calculus II several times before, and often tried saying something about complex numbers and Euler's formula. Some students get it, some don't. The big problem is not that this is too hard for them, but that it's not in the book, so they don't have a good source outside of class to learn from. This year I tried to do a bit better on that with the notes I wrote, but that can't replace the book.

The problem with saying "don't teach this in Calculus II" is that there's no where else we do teach this (I checked, it's not explained in the ODE book). So, many students either leave here with several years of university mathematics education, but not knowing this, or they have to pick it up in the gutter (their physics class on wave phenomena….)

41. **Miki**
September 17, 2015

Quick application and mastering Euler's formula is taught to every sophmore electrical engineer, as the practical method to represent AC currents, and more generally Narrowband Stochastic processes Every cellular modem works on the "I and Q" representataion of the received Signal + Noise.
It is so common like using a calculator, that probably nobody remembers that Euler invented it more than 300 years ago…..

42. **vmarko**
September 17, 2015

sm,

The standard way to prove the formula I quoted is to use addition formula for the sine on the right-hand side, and then use the identities expressing sin and cos in terms of tan, reaching the left-hand side after a little algebra. That is the standard trigonometric proof.

My point was that there is no simpler way to prove it, say by using Euler formula but without invoking addition formula and sin-to-tan, cos-to-tan identities. So Euler formula is not an all-powerful magic bullet for everything in trigonometry. You can use it to simplify proofs of *some* theorems, but by no means *all* of them. Some things are just equally hard, whether you use Euler formula or not. 🙂

That said, I'm still completely perplexed to hear that it is not the main part of the standard curriculum at universities. I learned it as a central piece of complex analysis — second year undergraduate calculus course (both for math and physics majors). Somehow it seems odd that the University of Belgrade, Serbia, has a stronger undergraduate calculus course than Columbia University, New York. If that's really the case, I'll never suggest to any future student to ever go study at CUNY, since its math curriculum is just sub-par.

Best, 🙂
Marko

September 17, 2015

Math 1a is the basic mathematics course for all Caltech freshmen.
The curriculum is here:
http://www.math.caltech.edu/~2014-15/1term/ma001a/
Lecture 23 is complex numbers (lecture notes PDF: http://math.caltech.edu/~nets/lecture23.pdf)

There was a major revision in undergraduate mathematics requirements in 2012, the detailed outline is here (PDF): http://cue.caltech.edu/documents/22-core_with_tables_appendix.pdf

e.g.,

> Changes for students entering in fall 2013:
> 1.Reduce the requirement in mathematics to 27 units from the current 45 units.

You may want to read through the document, e.g., later on:

> The transition from high school to college presents problems for all students, but for some students it is particularly challenging. At Caltech, many newly admitted students lack the background in mathematics that is necessary to succeed in Ma1a. Unfortunately, few of them are even aware that their background in mathematics is deficient. This is not their fault. The mathematics curriculum in high schools is less rigorous than it was even a few decades ago.
>
> In conversations with Caltech students who have struggled with freshman mathematics, most report that they were star math students in high school, which of course is a major reason why they were offered admission to Caltech in the first place.
> Many of them, however, have never seen mathematics as it is taught at Caltech.

The specific problems have been identified and are made up with a at-home online course: Transition to Mathematical Proof (TMP) course, for incoming students.

The TMP outcome is supposed to be:

> Incoming freshmen who successfully complete TMP will be able to:
>
> * Write simple but logically correct proofs that utilize appropriate terminology and notation.
> * Understand various proof methodologies, including direct proof, proof by contradiction, proof
> by contrapositive, and induction.
> * Manipulate sets using the various set-theoretic operations and theorems.
> * Compute the cardinality of various classes of sets.
> * Prove when a function between sets is injective, surjective, and bijective.
> * Prove or disprove that a real-valued function is continuous.
> * Use the definition of the derivative to prove various differentiation properties.
> * Use various differentiability and continuity theorems in proofs beyond calculus.
> * Prove when a sequence converges or diverges.

44. **Jeff M**
September 17, 2015

Perhaps a good way to get a handle on what has happened as far as student's preparation in high school is to consider Spivak's calculus book. As I understand it (one of my professors in college was good friends with Spivak at Princeton, so I got various stories) he wrote it basically from his teaching notes for honors calc at Brandeis in the mid 60s. You would have trouble using it in a junior level analysis course now. He proves e is transcendental! It's one of the prettiest books ever written, but no one is close to ready for it, certainly not as freshmen. Hell, in Calculus on Manifolds Spivak says all a student needs is one year of calc and one semester of linear algebra. In 22 years I've had one student who could handle that book as an undergraduate, and she's a math professor at Carleton now.

45. **Ru**
September 17, 2015

I learned about Complex number in grade 12.

We used something called cis(x) = cos(x) + isin(x)

you get the idea. We just didn't call it Euler's formula.

It made things much easier.

46. **Thomas**
September 18, 2015

Dear Peter,

The idea of your book seems very similar (although, of course, completely different in style) to this book http://www.springer.com/us/book/9783319192000, also published by Springer. Have you already read it? If yes, would you recommend reading it before or after reading your book (or not at all)?

47. **sm**
September 18, 2015

vmmarko:

"My point was that there is no simpler way to prove it, say by using Euler formula but without invoking addition formula and sin-to-tan, cos-to-tan identities."

And my point was that it is just a rewriting of the addition formula, which has already been elegantly proved by Euler.

Are you complaining that it is cheating to use cos(arctan(B/A))=A/sqrt(A^2+B^2), which follows using scaling to set sqrt(A^2+B^2)=1 and Peter's unit circle – no more really than was already put into Euler (from the geometrical point of view) in the first place?

Long live Euler!

48. **Paul Vetter**
September 18, 2015

Dear Peter,

Longtime lurker —
Thanks for the interesting notes on Euler's formula — I will share with my children, who are in geom/trig and calculus in school. One topic that this always raises for me, though, is WHY e and pi are transcendental. There seems to be little material available for interested laypersons. As I understand it, pi is transcendental because e is, and they are both transcendental because they have something to do with what we mean about having multidimensional space with directions orthogonal and how it is we rotate. Can you suggest good reading about why pi must be transcendental and why it is that it has the value of about 3, (order 1) rather than 0.1 or 1000?

49. **AcademicLurker**
September 18, 2015

they have to pick it up in the gutter (their physics class on wave phenomena….)

It wasn't easy learning Euler's formula on the mean streets, but it toughened me up.

50. **Narad**
September 18, 2015

> Perhaps a good way to get a handle on what has happened as far as student's preparation in high school is to consider Spivak's calculus book.… You would have trouble using it in a junior level analysis course now. He proves e is transcendental! It's one of the prettiest books ever written, but no one is close to ready for it, certainly not as freshmen.

I almost mentioned this earlier, but I don't think it invokes Euler's formula. My copy (second edition) is around here somewhere, but I was lazy and just looked what was online.

And yes, we used it as freshmen ('84). My high school didn't offer calculus, so I took it by correspondence course from the University of Wisconsin Extension. This was enough put me in the honors calc tier and do it all over from scratch. (Nonetheless, I didn't qualify for honors analysis with a certain eyepatch-wearing fellow the next year; the substitute was not pretty. I'm not sure what honors analysis actually used, but I tried working my way through Apostol on my own.)

51. **steve newman**
September 19, 2015

re-"why pi must be transcendental and why it is that it has the value of about 3, (order 1) rather than 0.1 or 1000?"
the value of about 3 comes easily from the definition of pi as the ratio of the circumference to the diameter of a circle. The perimeter of a square circumscribing the circle is 4 x diameter and the perimeter of an inscribed square is 2 x square root of 2
x diameter. The circumference of the circle is greater than 2.83 and less than 4 times
the diameter which puts pi somewhere near 3. (if you look at inscribed and circumscri bed hexagons you get pi between 3 and 3.46).
why pi must be transcendental is not so easy.

September 19, 2015

maybe already said : of the "Euler's Formula and Trigonometry, " pdf : page 5 on top, 6th line (3th line of the expansion) is wrong : you forgot a pair of brackets ;
Nice PDF, thanks for that

53. **Peter Woit**
September 19, 2015

Ru,
Yes, one can define "cis" that way and show that it has all the properties of an extension of the exponential to pure imaginary arguments, and that's a common strategy. Still, once one has done that, I don't see why one shouldn't just drop the "cis" notation and use the exponential notation, which will be much simpler to work with.

Thomas,
Thanks I hadn't seen that book. It does have some similar goals to what I'm writing, and there's a significant amount of overlap. I'd describe my version as going for more mathematical depth, which is why it's about twice as long. Also, that book sticks to the fairly conventional Lagrangian symmetry story of most physics textbooks, while I'm trying to emphasize parts of the story that aren't in such books, including paying much more attention to the Hamiltonian point of view.

herman claus,

Thanks. fixed.

As somebody who was accepted to Caltech as an undergraduate from overseas in the 1980s, this sounds incredible. At the time I could scarcely believe the type of remedial-level mathematics (and physics, and chemistry, for that matter) on which the best and brightest from the finest US high schools wasted a year and more of tertiary education. The Euler Formula that Peter Woit's students are encountering for the first time should surely have been year 9 or 10 high school material for any student destined for a tertiary education in any quantitative field.

That the situation might be even worse today is both hard to understand and dispiriting to consider.

Are things as bad outside the USA? Are "four year" tertiary degrees also becoming two year programs on top of two years (or worse) of remedial secondary school material elsewhere in the industrialized world?

55. **Peter Woit**
September 19, 2015

Richard,
The situation with the level of math and science instruction in US secondary schools is bad, but I don't think any worse now than in the 1980s, and in some ways better. As far as I can tell, the US high school math curriculum right now is more or less identical to what I experienced forty years ago in the early 1970s (and so is the set curriculum for calculus classes, whether offered at the end of high school, or beginning of college). On the positive side, many more US high school students are taking calculus classes in high school.

But, with Euler's formula not even in the calculus textbooks, US students are still highly unlikely to see that in high school.

56. **Doug McDonald**
September 20, 2015

I looked at my own freshman math book, from 1962 "Thomas", which apparently still has nominal successors in print. Euler's formula is there, quite prominently, though near the end. There is an online version of a near-recent successor, and its still there.

I taught for many years junior level quantum mechanics to chemists, and we used that formula a lot; the students were not bothered by it. What they were bothered by was the idea that they had to generate even an obvious three line derivation or proof. We never of course asked for mathematical rigor.

57. **Oiler**
September 21, 2015

It's great that you passed on your Euler notes; that kind of commitment to teaching is too often missing!

I teach at a university somewhere outside the US, and I always work in either Euler's formula (almost exactly as you present it!) or the 2×2 matrix version or both as soon as possible. The matrix version allows me to make the linear transformation/matrix link. This is in Calc 1,2,or 3: because it is guaranteed they haven't seen it either in high school or with any earlier prof.

I use the power series definition for exp, but heuristically (and if they are interested,
I will explain the convergence). I hand out a little resume of the material to them since no book has it. I also draw a graph of the function e^(it): \R\to\C
and explain that looking at this "Slinky" from the side gives you sin and cos.
And to draw sin, I set my arm in "harmonic motion" and walk along with time. And: there is always some mention of music synthesis, as a motivation.

This is just one example of similar missing material. As a student I had many moments of frustration/fury when I realized some obvious explanation had been left out. almost as if the secrets were being kept within the guild.

Somebody mentioned Spivak and old editions of Thomas. Both I have warm memories of for completely different reasons. Spivak is simply beautiful and is a great backup for the prof, but is only good for that rare student who wants to really know what is going on and is ready to learn on their own. Old Thomas has some great word problems as I recall, although it is too dry for self-study.

Back to Euler, when I teach power series (calc level) I use that to treat Fourier series
-proving orthonormality, and writing the formulas, is so much easier than with sin/cos-and then I make the Fourier series- Taylor/Laurent series link. This is done not too rigorously: mainly just to blow their minds- as it did for me when I realized that–in grad school!!!–In other words, it gives them a good advertisement for what is to come, and a taste of why math is at once so cool and so powerful and so simple.

58. **Richard E**
September 21, 2015

Does anyone have links to talks on the Nima's N-naturalness? Am curious to understands its implications for the thermal history of the early universe.

59. **Dave Miller in Sacramento**
September 28, 2015

Peter,

Maor suggests that the idea of the exponential function first arose from the concept of compound interest and the question of what would happen if the compounding became instantaneous.

I was a young kid when the banks started decreasing their compounding periods back in the '60s, and I remember hoping that I would get incredibly rich as they reduced their compounding periods to zero!

Of course, my hopes were dashed because the limit of (1 + x/n) to the nth is just exp (n), which is, alas, a finite limit for any real x.

You can in fact easily derive the power series for exp(x) from this by just taking the binomial expansion of (1 + x/n) to the nth and taking the limit n -> infinity. This easily shows that the limit is finite.

If you then plug in an imaginary number, you get the limit as n goes to infinity of (1 + i x/n). For n very large, it is easy to see that one is taking a small angle close to x/n and "compounding" it n times to get to the angle x. (A bit of thought shows that in the limit n goes to infinity, the radius remains at 1: e.g., look at the binomial expansion for (1 + i x /n) times its complex conjugate all to the nth..) Using the binomial expansion to get the power series of course works in exactly the same way as in the real case.

All this does not meet the mathematician's standards of rigor (although I suspect it can be "cleaned up" as easily as any other approach). However, if Maor is right, it may be close to the historical development. And, multiplying (1 + i x/n) by itself n times,. is a somewhat intuitive way of reaching the angle x (in the limit n goes to infinity of course) on the unit circle.

Dave

September 30, 2015

This is a comment to your notes on Euler's formula.

Do you know the book `Numbers' (multiple authors, edited by J.H. Ewing), Springer GTM 123? Among many other things, it has a very nice treatment of complex numbers, exponential function, trigonometric functions and, of course, pi. One might even find that treatment a bit too comprehensive.

61. **Peter Woit**
September 30, 2015

Michael Mueger,
I know the book, hadn't looked at it recently. It is quite wonderful, and the chapter on "pi" has an excellent treatment of the issues.

62. **Step Maths**
October 10, 2015

I've just taught Euler's theorem and De Moivre's theorem to my A-level Maths class and I wanted one of my brightest students to do some independent study on how to use it to integrate and differentiate products and powers of trigonometric functions (as extra reading) – I'm going to share your document with her. Thanks 🙂 @Olier – do you know of any resources / books which describe how to use Eulers formula for Fourier Series? That might be good extension material too!

Connes on the Riemann Hypothesis

September 21, 2015
Categories: Uncategorized

There's a fascinating new preprint out from Alain Connes, called An essay on the Riemann Hypothesis, written for a volume on "Open Problems in Mathematics". Evidently the late John Nash is an editor, and responsible for commissioning this piece.

Connes is a mathematician of the first rank, and a very original one at that. He has now struggled with the Riemann hypothesis for many years, and his account of various approaches to the problem and the state of efforts to pursue them is a remarkable document of a sort that too rarely gets written.

Much of what he is concerned with is the question of how to find a proof along lines related to those used to prove the analog of the Riemann hypothesis in the case of function fields (this was successfully carried out by Deligne in the early 1970s). James Milne has a wonderful expository piece on the topic of this proof, going into details of the history and the mathematics. It provides a great supplement to the more speculative article by Connes.

For something much more concrete about the Riemann hypothesis, there's a new book by Barry Mazur and William Stein, Prime Numbers and the Riemann Hypothesis. Among a long list of attempts to relate this to physics, there's an interesting relatively recent discussion of one idea from John Baez.

Comments

1. **John Fredsted**
   September 22, 2015

   Thanks for the link to the book by Barry Mazur and William Stein. Browsing the available PDF of the book, it strongly seems to me that this is a book I just have to buy when it arrives in the stores. What I like about it is its, at least apparently, accessibility for non-mathematicians (I am myself a physicist) and people not experts in the field of the Riemann Hypothesis.

2. **a l**
   September 22, 2015

   I can't resist to quote:
   Physics of the Riemann Hypothesis arXiv:1101.3116

3. **Abdelmalek Abdesselam**
   September 22, 2015

   A little less known (e.g. not mentioned in reference by a 1) connection to physics and in particular QFT is that the Riemann Hypothesis is equivalent to the existence of a 1d QFT with specified translation invariant 2-point function. See page 6 of "The explicit formula in simple terms" by Jean-Francois Burnol
   http://arxiv.org/abs/math/9810169
   or the earlier paper http://arxiv.org/abs/math/9809119
   Here it is QFT in the Euclidean formulation and the main requirement is not unitary or Osterwalder-Schrader positivity but rather Nelson-Symanzik positivity which makes the model an honest probability distribution on D'(R) or D'((0,infinity)) if one wants to use the log or not.

Visions of Future Physics

September 22, 2015
Categories: Uncategorized

There's a great profile of Nima Arkani-Hamed by Natalie Wolchover just out at Quanta magazine, under the title Visions of Future Physics. I recently linked to another profile of him from the IAS, which covers some similar ground.

He's often been a topic of postings here, and the profile explains why, with his colleagues describing him as the "messiah", "Pied Piper" and "impresario" of high energy physics.

> "He keeps coming up with the goods, and his persuasiveness is hypnotic," said Raman Sundrum, a theoretical physicist at the University of Maryland in College Park, "so a lot of people follow where he leads."

I've often marveled at his performances, with his talks sometimes a unique mixture of brilliance, insight, and over-the-top outrageous indefensible claims (his talk here last week was uncharacteristically restrained). As an example of the genre, the IAS profile includes:

> "It is extremely interesting to think about getting sophomores up to the speed of a second-year graduate student. I think it is possible," says Arkani- Hamed.

which is simultaneously quite inspirational and, well, nuts.

A couple years ago I was struck by a talk of his in which he showed a lot of self-knowledge, describing himself as an "ideolog" (see here). There's more about this in the Quanta profile:

> "It's important for me while I'm working on something to be very ideological about it. And then, of course, it's also important after you are done to forget the ideology and move on to another one."

The ideologies on display this time include a very speculative picture of a future union of mathematics and theoretical physics:

> Ultimately, he said, anywhere from 10 to 500 years from now, the amplituhedron and these cosmological patterns will merge and become part of a single, spectacular mathematical structure that describes the entire past, present and future of everything "in some timeless, autonomous way."…
>
> There is a mathematical proof, Arkani-Hamed observed, that all algebraic numbers can be derived from configurations of a finite whole number of intersecting points and lines. And with that, he expressed a final conjecture, at the end of a long, cerebral day, before everyone else went home to bed and Arkani-Hamed headed to the airport: Everything — irrational numbers, along with particle interactions and the correlations between stars — ultimately arises from possible combinatorial arrangements of whole numbers: 1, 2, 3 and so on. They exist, he said, and so must everything else.

Personally, I don't think this is going to work out, but he's right that people need a vision to pursue, to drive them forward in finding new things. Unless he gets a lot further with it, I don't think this one is going to get so much interest as to drive out other ideas, especially from mathematicians interested in physics, who have other competing visions.

Where Arkani-Hamed has become a really problematic ideolog, one endangering the health of the subject, is in his insistence on "naturalness" as the central question of HEP theory at the TeV scale, coupled with the ideology that if the LHC doesn't see new "natural" physics at the TeV scale, then the intellectual suicide of the multiverse is all HEP theory has to look forward to. He's been pushing this ideology, hard, for quite a while now, and I think it's long past time for him to take his own advice and "forget the ideology and move on to another one."

Much of the article is about his efforts to push forward a Chinese plan to build a next-generation collider. Perhaps his great enthusiasm will help move this project along (a book about it by Yau and Nadis, From the Great Wall to the Great Collider, will soon come out). It raises all sorts of difficult issues for the future of experimental HEP, including that of the future of CERN, issues that will play out over many years (timelines for things like this are generally wildly over-optimistic, and here people are talking about 2042). Framing the case for a 100 TeV machine as "1% fine-tuning evidence for the multiverse from the LHC wasn't convincing, even though we said it would be, so we need a bigger machine to get .1% fine-tuning evidence" is something that I think isn't going to fly, no matter how enthusiastically presented. In the article Kyle Cranmer makes the point that .1% tuning versus 1% tuning means little:

> "I am very sympathetic to the idea that this is a critical point in the field and that naturalness/fine-tuning is a deep issue," he wrote in an email. "However, I'm not convinced that if we built a 100-TeV collider and saw nothing that it would be conclusive evidence that nature is fine-tuned." There would remain the nagging possibility that a natural completion of the Standard Model exists that a collider simply can't access.

and Jester

> argues that if no new particles are found at 100 TeV, this will leave physicists exactly where they are now in their search for a more complete theory of nature — clueless.

I think David Gross has it right:

> Gross, who considers naturalness a murky concept, simply wants a last-ditch search for new physics. "We need more hints from nature," he said. "She's got to tell us where to go."

The case for mankind to embark on a new project to push forward the boundaries of science is the same as it has always been: even though it's expensive and difficult, we should do it because we'll see how the world works at an even smaller distance scale. Just possibly we'll learn enough to understand how to improve the Standard Model and achieve an even deeper insight into the physical universe.

Update: Gross and Witten have an editorial today in the Wall Street Journal (as usual with the WSJ, try Googling the article to get around their paywall), supporting the idea of a Chinese Great Collider project.

Comments

1. **Magnema**
   September 22, 2015

   I mean, technically, last year I was a sophomore and was taking a class that was typical of a second-year math grad student at my institution (namely, manifolds). It was difficult (although a part of that is because I'm more of a physics person than a math person), and I was an unusual case to boot. However, with more background support structure, I would think it intellectually plausible on behalf of (smart) students, albeit that the investment into education is likely larger than what the general population is willing to commit…

2. **Peter Woit**
   September 22, 2015

   As a sophomore in college I also took a second-year level graduate course (quantum field theory). Then, and even more so now, I'd describe the suggestion that I (or any other similarly ambitious undergraduate) was operating at the level of a typical second year Harvard grad student as, well, nuts.

   To be honest, I have no idea what Arkani-Hamed is actually talking about here. Presumably he has some more specific idea in mind about certain skills needed in a 100 TeV collider project, but I have no idea what they are. I do strongly suspect though that, whatever it is he has in mind, inspirational as well as delusional likely is an accurate way of characterizing it.

3. **Peter Woit**
   September 22, 2015

   And, by the way, I don't think he'd necessarily disagree. "Inspirational and delusional" characterizes what it is to be an ideolog (at least a good one), and he's well aware that's part of his nature.

4. **chris**
   September 23, 2015

   I've had a sophomore in the QFT class I was teaching last year and I can confirm that it is nuts. What I fear Arkani-Hamed is going for is a "physics" education that skips the actual physics and goes right for the stringy multiverse thing. Classical mechanics and wave guide exercises in E+M are for the old generation and totally useless – we start with an arbitrary dimensional supersymmetric membrane…

   Also, I find the political lobbying for the next hadron collider immoral. Come on, we all know that the chances of a factor 5-10 in energy getting us anywhere are slim. That's what a skeptical look at the current situation tells us. Should we sink billions into an almost hopeless endeavor for political reasons or rather pause a moment and use that money for finding other ways of accessing much larger energy scales?

5. **Bee**
   September 23, 2015

   It's like watching a public case study on chronic caffeine overdose 😉

6. **srp**
   September 23, 2015

   There is another moral and practical issue for the collider project. China is an unfree country that is unfortunately becoming less free in recent months as Xi imposes his new security law (that makes science, culture, and journalism emphatically security concerns–basically everything is security) and cracks down on Western ideas (to the extent of trying to get rid of foreign textbooks in universities, etc.). Moreover, there is evidence that the Party is very concerned about long-term stability and its ability to keep control over society. A long-term transfer of the center of gravity of particle physics into such an environment does not seem wise to me. This project isn't like putting on an Olympics, where journalists mostly have to be contained for just a couple of weeks.

   One could, of course, argue that swarming the country with cosmopolitan international physicists would exert a salutary influence on the political/cultural situation. To me the downside risk seems more compelling than the upside opportunity but I'd be happy to be convinced otherwise.

7. **Michael Hutchings**
   September 23, 2015

   As a naive outsider, I would think that a machine with 10 times the energy of previous machines would have a good chance of seeing something new. I don't know why chris writes that the chances are slim. But the enormous resources that this would require are probably better spent on something else.

8. **Frank Quednau**
   September 23, 2015

   "There is a mathematical proof, Arkani-Hamed observed, that all algebraic numbers can be derived from configurations of a finite whole number of intersecting points and lines"

   May I ask what this refers to and how I can find more information about it?

9. **Scott Church**
   September 23, 2015

   It's only a hunch… who can say…? But unless I'm missing something it seems to me that while increasing collider energies of 100 Tev or more may reveal some new physics, as things stand today vis 'a vis the SM and/or M-theory we have no real reason to expect any until we can probe at something on the order of the Planck scale. That will require either radically new detector technology (and I mean *radically* as in unlike anything we can currently conceive)… or a collider roughly the diameter of the solar system (with all the attendant luminosity and detection issues overcome). Anyone care to speculate how we're going to get *that* funded and built? 😉

   And if not… are the billions we're liable to spend trying to bridge the intervening gap really anything more than a Hail Mary? It seems to me we need some new ideas… *New* ideas.

10. **John**
    September 23, 2015

    Isn't being an ideologue about the same as being a true believer? You position is not swayed by facts but instead you search and cherry pick results you like to support your position. To me this is the exact opposite of what a scientist is defined as.

11. **Jan Reimers**
    September 23, 2015

    Can someone comment on calculating backgrounds between 10 and 100TeV. In particular
    1) Is the data useless if we can't calculate the standard model background between 10-100TeV?

2) Can we reasonably expect to calculate the high particle count (i.e. 2 in –> N out diagrams where N>6) cross sections given that the Black Hat team came to rescue with 2->4, 2->5 gluon cross sections at the last minute before the LHC started.
3) Or am I miss-understanding the history?

Thanks
JR

12. **M**
September 23, 2015

«Whatever the answers are, here's one monkey that's going to keep on climbing, and looking around him to see what he can see, as long as the tree holds out». 99.9% of the world annual GDP is a byproduct of scientific progress, and a 100 TeV collider costs only 0.01% of it

13. **Peter Woit**
September 23, 2015

Michael Hutchings,
The 100 TeV collider proposal is different than the LHC in the sense that with the LHC we knew that it had to see the Higgs or something even more interesting. There's no similar argument for the next order of magnitude in energy. So the case for the next jump is harder to make. I think though the case can be made, the fact that the LHC case was a slam-dunk and this one isn't shouldn't matter.

If we do go to 100 TeV, maybe we'll see what the SM predicts, maybe we'll see something new and unexpected. The only way to find out is to look, and I think it would be a shame if humans decided it wasn't worth looking, better to spend the money on some aircraft carriers. You could reasonably argue that we should save the money, and theorists can try and figure it out by pure thought. So far, trying to get beyond the SM by pure thought hasn't worked out well.

The standard arguments about this are usually I think very naive, with those in favor saying "better than weaponry" (like my argument above…), those against saying "cure cancer instead" (or, essentially, "spend the money on me and what I do"). One thing to keep in mind is that while this is a very expensive project, it's also one with a very long time scale, so the budget needed per year may not be out of scale with what is already being spent. We're talking about modest spending shifts on the scale of budgets like the US,EU, China. It's not at all clear what would get crowded out by a Chinese decision to devote part of its economy to a big project like this, instead of what people would otherwise be doing. Fewer aircraft carriers is a real possibility…

John,
I think Arkani-Hamed is making the case that you need to be a true believer to devote your life to this kind of work. There's something to that, but it becomes problematic if you go beyond convincing yourself to keep going on a project that may not be working, and start convincing other people that something is working when it really isn't. The question of when and how you decide to admit that something doesn't work and move on is a huge problem for HEP theory now, and I don't think he's addressing that one, even while he acknowledges that you have to do this at some point.

Jan Reimers,
I assume that those kinds of questions are just what Arkani-Hamed's Chinese institute is supposed to be addressing. As mentioned above, the time scale for such a machine is very long, lots of time for improvements in background calculations. Especially with all those sophomores doing the work of graduate students…

14. **Michael Hutchings**
September 23, 2015

I don't know what the budget is like for the 100 TeV machine; the book should be interesting. Anyway I would hope that we could build it sometime, and probe as far as we can, since it is our nature to do so. My argument against building it for now, call this naive if you will, is that we have some urgent problems to solve in order to ensure the long term survival of human civilization, and the latter seems to be a prerequisite for really big science projects. For example, there is a lot of activity in China to develop "green", "sustainable" technologies (out of acute necessity), and this is something that might get crowded out.

15. **paddy**
September 23, 2015

At the risk of sounding like a Philistine: When does advocating for a 100 Tev collider become also a "spend the money on me and what I do"?

16. **Daniel Tung**
September 24, 2015

"Personally, I don't think this is going to work out…"
May I know why?

17. **Yatima**
September 24, 2015

When does advocating for a 100 TeV collider become also a "spend the money on me and what I do"?

When it becomes a private venture? "Shut up and take my dollars" applies. Of course, one can still apply for subsidies at *L'Etat providence*.

But I would like to see a [muon collider] and the [International Linear Collider] first.

18. **Radioactive**
September 24, 2015

We should build a collider orbiting the earth if it would add a tenth of a percent to the sum of human knowledge. Worrying about budgets is for accountants. I could give a damn what is politically feasible at any given moment as long as it's physically feasible.

19. **chris**
September 24, 2015

Michael Hutchings,

it is essentially as Peter explained: there is no "slam-dunk" case for anything popping up below the GUT or Planck scales, which are at least a further factor 10^10 away. Note that Peter, contrary to all that his string theory enemies say, is a real "optimist" here. A "pessimist", like myself, sees the standard model as a complete theory up to essentially the GUT scale, because all current evidence (GUT scale, right handed neutrino scale, instability scale of the Higgs potential and Planck scale) points at that.

It's a good question what conclusion to draw from this. As Peter pointed out, it is very unlikely that money not spend on a future hadron collider will be used in any more sensible way. And while we might not find new physics, the simple benefit of keeping the technological knowledge alive might very well be worth the effort. What I am worried about though is that hyping this collider for more than it will probably be is very dangerous. Scientists should state clearly that the chances to find new physics are at best unknown and it would not be a surprise if such a machine just pushed limits. In this respect, one could think of lobbying rather for either building another collider (e.g. CLIC or a muon collider) or for investing the money into accellerator technology research or alternative experiments.

20. **JohnB**
September 24, 2015

Given the enormously successful history of particle accelerator discoveries, right up to the LHC, isn't the right approach to experimentation, to just keep on building bigger and bigger accelerators (lets say 10x as powerful as the previous one, if there are no solid predictions for new particles), until a project finally fails and nothing is discovered?

If the available beyond-SM theories are inadequate, all you've got left is experimentation – and once experimentation fails (still doing more than well enough there, to justify a new generation of accelerators…), the primary focus will have to shift back onto applied-physics/material-development, aimed at developing accelerator tech, that is a couple/few orders of magnitude better than the last failed experiment (likely a multi-generational effort – unless theory advances and gives some new solid predictions).

21. **Scott Church**
September 24, 2015

Chris, I agree… those are the points I was trying to make earlier. This isn't a question of what is, and is not worth funding–I think we all agree that the search for new physics up to and including GUT scale, is. The real questions are;

1) Is it possible to get there from here with the technical means available to us today and for the foreseeable future?

2) Are we pursuing said new physics down the right paths, with the right technologies, and on a potentially fruitful theoretical basis?

3) Given 1) and 2), is funding for such endeavors possible, and who will do so?

The answers to 1) and 2) are anything but clear. Indeed, as Chris said, given what we know of the SM today and the lack of fruitfulness the whole M-theory framework has returned to date, render it likely that we *aren't* going to find anything this side of GUT/Planck scales. And that leaves us with 3)… which is a sorry business because we're left with trying to sell funding for ever larger collider projects to governments that are already strapped, and rightly or wrongly, not in a mood to invest in projects for which we can't guarantee big returns.

Radioactive, I feel your pain. I agree that budgets are for accountants, and in my heart I don't give a damn about political feasibility either. Unfortunately, unless our personal checking accounts are larger than the GDP of a middle-sized nation–a claim few of us can make–we don't have the luxury of indulging such a stance. Like it or not, we're going to end up dealing with accountants… Treasury Dept. accountants… who report to world leaders indentured to their electoral base and already up to their necks in failing social security, a collapsing Greek economy, etc. etc. etc. It sucks, I know. But the sad reality is that we aren't going to get donuts delivered to the CERN lobby next week, much less funding for colliders and other projects, unless we convince those folks to agree to signing the checks. How do we deal with that? I have no idea… but we certainly don't have the luxury of pretending that we can continue to move forward without doing so.

While these are important concerns, I think it's just as important for us to continue exploring other ways we might push back the boundaries. For instance, pursuing advances in cosmological observation and detection technologies that might allow us to peer deeper into primordial events where the energies we can't reach today with colliders were the rule; Or exploring other theoretical avenues that might bear more testable fruit than M-theory. Regardless of what we can, or cannot achieve with ever larger and more costly colliders, these are things that *are* within our reach today… and perhaps, more likely to convince those who sign checks.

22. **Dom**
September 24, 2015

On the subject of the output of colliders, Jon Butterworth's latest article in the Guardian is quite nice [Guardian Higgs Article]

23. **Peter Woit**
September 25, 2015

Frank Quednau,
I don't know, but two people who might are Goncharov, who was involved in the "amplituhedron" business, and Deligne, who I hear was talking to him about this stuff, and knows this kind of mathematics.

Daniel Tung,
I just don't see any evidence at all that you can explain anything about the standard model this way. Much of our understanding of the standard model is based on its symmetries and I suspect that a deeper understanding will come from a deeper understanding of these symmetries. Arkani-Hamed's speculation ignores these completely (he's been known to say very unkind things about gauge symmetry…).

24. **srp**
September 25, 2015

It's encouraging to hear a couple of breaths of rationality vis a vis the obvious next step of investing in the exploration of advanced accelerator technologies. These could end up finding paths to ultra-high energies that cost much less, plus they are more likely to create new spin-off benefits than simply scaling up the existing designs. It would be irrational to commit to spending $15 billion on a the Big Dumb Accelerator without first investing a few hundred million bucks to find out if there were a better and cheaper way.

25. **Peter Woit**
September 25, 2015

srp,

Spending a few hundred million dollars to make the problems of why going to higher energies is so expensive go away isn't an idea that's been ignored. As far as I know, there just is no idea around such that throwing money at it is going to solve the problems anytime soon. Such ideas are more the sort of thing that will take many decades to see if they will work at all (and certainly should be investigated and funded). But if you want to start building something ten to twenty years out from now, to have it ready when the LHC has been fully exploited, your choices of plausible technology are limited, and all expensive.

26. **Tony Smith**
September 25, 2015

As to Nima's "… efforts to push forward a Chinese plan to build a next-generation collider …" and "… Gross and Witten have and editorial in the Wall Street Journal … supporting the idea of a Chinese Geat Collider project …"
Gross and Witten say in WSJ:
"… China would leap to a leadership position in an important frontier area of basic science. More practically, to build such a massive collider, China would need to develop frontier technology in many fields, from superconducting magnets to high-speed electronic detectors, attracting many of the world's top scientists and technologists …".

Since the USA cancelled the SSC Collider project it has relied on Europe and the LHC for fundamental collider physics, seeing the center of the physics world shift from the USA to Europe.
Now Nima, Gross and Witten advocate that China, with its increasing wealth and industrial dominance, become the new center of the physics world.

Why can't the new center be the USA itself, so that the USA would be the developer of frontier technology and be the center of attraction of the world's top scientists and technologists?

Some (maybe including Nima, Gross and Witten) might say that the USA cannot afford such an expensive project, and under current USA policies that might be true, but Citigroup has recently released a note entitled "Cold Fusion" advocating a way to transform the currently "ineffective monetary policy" of the USA into "effective fiscal policy … via central bank monetization … essentially monetizing … spending".

The Citigroup plan would allow the USA to undertake many-billion dollar programs (such as the new Great Collider) just as easily as it has undertaken Quantitative Easing to aid its financial sector,
with the USA reaping the benefits of advancing science and technology.

As to why Citigroup entitled its note "Cold Fusion", the note says:
"… Essentially you are combining Paul Krugman fiscal with Republican tax and Bernanke 2002 … monetary.
…
a (very cold) fusion of Krugman macro, Republican tax and Bernanke (2002) monetary policies …".

Tony

27. **Marc**
September 26, 2015

Does going to higher energies really help to understand the standard model?

This is only true if we discover something new. But will we discover something new?

We will discover something new if nature has more degrees of freedom at higher energy than at low energy. But is this the case?

Quantum theory usually does not confirm this. Does nature get more complex at higher energy?

Usually not. After all, higher energy means lower distance. But it seems obvious from quantum theory that nature will get simpler and simpler at low scale.

It might well be that the hope to find new things at smaller and smaller scales is ill-founded. In any case, the unification attempts discussed at present (new dimensions, new particles, new symmetries) do not seem to get simpler at small scales, but more complex. We should look for simpler attempts, not for more complicated ones.

28. **Peter Woit**
September 26, 2015

All,
Attempts to turn this comment thread into a tedious political debate about US monetary and fiscal policy will be ruthlessly suppressed.

29. **Neil**
September 26, 2015

Why do Gross and Witten think there is a question about the Higgs mass?

In any case, the Great Collider would probably cost less than the ISS and produce more science.

30. **Peter Woit**
September 26, 2015

Neil,
I'd guess that's a badly done edit, presumably what they meant is that we have no idea why the Higgs mass is 125 GeV.

One of the main goals of a new collider would be to measure the interactions of the Higgs with itself, something that may be inaccessible at the LHC.

31. **Anon**
September 26, 2015

PW re srp,

Laser-Driven Particle Accelerators?

32. **Peter Woit**
September 26, 2015

Anon,
Exactly what I was thinking of as an example of a technology not ready for use anytime soon.

For a circular machine the fundamental limits are due to the magnets for a proton machine (and there seem to be no prospects of dramatically higher field strengths), or synchrotron radiation for an electron-positron machine (a muon collider would solve this, but the short lifetime of the muon is a huge problem). For a linear machine, to build something much cheaper you need something like such a laser acceleration scheme. Maybe someday this will be doable, but it seems that much more work is needed before one will have a usable technology.

33. **srp**
September 26, 2015

The point is that “much more work” is not being funded. DOE keeps these alternative concepts barely ticking over as theoretical exercises, but there’s not much money or community attention devoted to actually building prototype components, etc., and there is no organized program to figure out the specific roadblocks of the main alternatives, investigate each one to see if there are any showstoppers or to develop solutions, etc. Saying “it’s a lot of work” while systematically preventing the community from doing the work is silly. If you drew out a decision tree for the next-generation accelerator at the energy frontier, there’s no way you would rationally end up spending even a billion dollars on preparatory planning for a scaled-up traditional machine without first spending a fraction of that to try to rule out the practicality of wakefields over the relevant time horizon. I know that Burton Richter has written than some kind of wakefield design is the sensible next step at the energy frontier, but I guess when people reach a certain age in physics its hard to get anyone to listen no matter one’s track record.

34. **Anon**
September 27, 2015

Look, if I had 10-100G dollar I’d like to spend on a scientific project, and you’d manage to somehow convince me that spending on high energy physic is presently more pressing than finding earthlike planets, or quantum computing, or robotic exploration of Titan, or proteomics, or human on mars, or artificial intelligence, or permanent facility on the moon (to name a few project I'm not working on), then you’d still have to convince me it’s not smarter to put my money on laser driven technology first. No one want to build a 100G dollar accelerator, and by the time it’s ready you can use another technology to reach the same target for 1/1000 of the price.

35. **Peter Woit**
September 27, 2015

Anon,
The question of “why not build a laser (or plasma wakefield, or whatever)-driven linear accelerator to get to the 10 TeV energy scale, instead of the proposed Great Collider”? is a legitimate one. But my impression is that at this point the cost of such a thing is not 1/1000 less, but infinitely more, since no one knows how to do it, at any price. srp is likely right that this kind of research deserves more support, but I’d like to see some sort of realistic time frame + cost estimates for a machine using such a technology. If anyone can point to a convincing document about how such a thing can be designed and built in my lifetime (I figure I’ve got maybe another 25 years or so..), at dramatically less cost, I’d like to see it. And, by the way, claims of “1/1000 the cost” are not confidence inspiring…

If it’s not at all clear that this can be done, and the timescale for finding out is many decades, then the problem is that a decision to put all the marbles on such a speculative idea is that it may be tantamount to a decision to shut down energy frontier physics for good. The clock is ticking, twenty years or so from now it will not make sense to keep running the LHC, and if there is no viable next generation project on the horizon the field will have to shut down, with trained people changing fields to something else, and no new people being trained.

I should make clear that I don’t think the case for a 100 TeV machine is at all a slam-dunk one. HEP is facing a very difficult future and some tough decisions. As part of this, I don’t think unfounded claims that a speculative new technology is going to make the problem go away are helpful.

36. **Anon**
September 27, 2015

It’s not confidence inspiring to suggest 1/1000 the cost in the next three decades? Please remember of the human genome project: 3 G dollars in 1990, and 30 years later it would cost not 1/1000, but 1/1000000 the price.

But on retrospect it’s not fair of me to make this argument, because I’d not support the Great Collider for the next two decades even if you could garantee that the price won’t drop. The main reason? Simply because I don’t see any garantee that it’d significantly increase our knowledge.
Actually, from reading your blog one could have expected that you thought the same. How then would you justify priorising high energy physics over the many inspiring projects I mentionned previously? Or you think we could all fund them in the next 20 years?

37. **Dave Miller in Sacramento**
September 28, 2015

Peter,

You wrote:

> a decision to put all the marbles on such a speculative idea is that it may be tantamount to a decision to shut down energy frontier physics for good. The clock is ticking, twenty years or so from now it will not make sense to keep running the LHC, and if there is no viable next generation project on the horizon the field will have to shut down, with trained people changing fields to something else, and no new people being trained.

Well… for better or worse, I suspect that your statement will turn out to be an accurate prediction of the rest of the century in “high-energy” physics.

Things have not worked out the way you and I had hoped when we were doctoral students way back when.

Dave

38. **Radioactive**
September 28, 2015

Anon: “I’d not support the Great Collider for the next two decades … Simply because I don’t see any garantee that it’d significantly increase our knowledge.”

So you’d like to defund all speculative research then?

39. **Peter Woit**
September 28, 2015

Anon,
My view on prioritizing funding is that you have to look at the situation in each field, get a realistic idea of what funds are needed to significantly move forward, decide whether such a level of funding is feasible, then deal with the politics of competing for funding.

Some fields (like quantum computing) are already hot topics and well-financed, I’m suspicious that there aren’t good ideas out there that aren’t already getting funded. Other fields you mention (e.g. manned space exploration) I personally don’t see as worthwhile at the costs it takes to do them. One way to argue against manned space exploration would be to say “let’s wait to do it until the costs come down by a factor of 1/1000”, but that would be effectively the same as saying “it’s not worth it, so shut the field down”. Better to deal with the difficult actual argument, not evade it, for manned space exploration as for high energy frontier experiment.

40. **Jeff M**
September 28, 2015

Well, I've stayed out of this, since I'm a mathematician and we don't have to worry about funding really. But everyone seems to be dancing around the real issue, which is WHY you fund research. You can do it for the sake of advancing knowledge, or else to advance the well being of humanity/the planet via technology. AFAICT HEP funding is solely based on the first, it's not like it has any technological implications. Neither does QFT research that I can tell (correct me if I'm wrong). Basic QM, sure, solid state of course, fusion research and nuclear physics in general of course. If you want to argue someone should fund a collider, be honest, the only reason to do it is abstract. Once you do that, you can argue about whether even then it's worth it, since it's very unclear that you're going to get anything from a much bigger collider. Personally, I don't think you've gotten much from the LHC, I mean did anyone expect them not to find the Higgs eventually? And given that nothing else has shown up (and I'm willing to bet you actual money nothing else will) where are you now?

41. **Peter Woit**
September 28, 2015

Jeff,
Actually, QFT research does have a lot of practical applications. Solid state physics is based on it, since the field effectively deals with an infinite number of degrees of freedom, not the finite number of simple QM.

You need to, when possible, experimentally test an idea like the Higgs mechanism, not just believe it since it seems to be the most plausible idea. Often ideas you think are the most plausible turn out to be wrong (or only part of the story). Besides verifying conjectures about the Higgs mechanism, the LHC has also shot down huge areas of conjecture about TeV scale physics (there's an interesting ongoing question of when many theorists will acknowledge this reality). With no LHC we'd forever hear that SUSY is the most plausible idea about TeV scale physics and should just be believed.

42. **Scott Church**
September 28, 2015

The Oct. issue of Scientific American has an intriguing article called [How Big is Science?] From the opening… "Mammoth instruments such as CERN's Large Hadron Collider are often held up as symbols of the human commitment to decoding the world. But how highly does humanity as a whole actually regard science? How big *is* science? This is not an easy question to answer, but by gathering what credible data exist, we can approximate an answer."

Haven't had a chance to read it yet, but among other things it discusses some of the issues surrounding funding of large physics projects like the LHC, and how public perceptions impact that. The graphic on the first page alone is enlightening.

43. **Jeff M**
September 28, 2015

Peter

Had no clue solid state used QFT's thanks for correcting me 🙂 As for the Higgs, my point wasn't that it wasn't interesting, just that if you were thinking practically it wasn't going to get you anywhere. As far as the LHC chucking supersymmetry etc. out the window, has that really happened? Aren't all the SUSY people just running around saying "wait for the next bigger accelerator?" I'm not holding my breath

44. **Anon**
September 28, 2015

PW,
Your opinion on how to prioritize funding is perhaps unclear (one way to read it is you're happy to offload this on political games, but hopefully this is not what you intended to say). I happen to agree on manned mission (except most children trill, and the more they trill the more will turn scientists…), disagree that quantum computing is funded at an appropriate level (I even suspect that, in the long run, progresses in high energy physic will depend on first making a quantum computer work), disagree that not adding 10G USD to a field is the same as shutting the field down.
Radioactive,
No, I'd glad to support the next collider if the cost was 10-100 millions USD.
Scott Church,
Great link! This kind of graphic is arguably the best support for the GC, e.g. maybe a new collider "just to check there's really nothing to see" would be fine after all, if only expanditures on Science were enough to make the F35 program looks cheap.

45. **abby yorker**
September 28, 2015

The article says 10 billion for 100 Tev. LHC cost 13 billion(Forbes). I recommend that we go for a Planck energy machine, to minimize costs.

46. **Peter Woit**
September 28, 2015

Jeff M,
It's been a long time since HEP people had a good case that what they were learning about fundamental physics would have practical implications. If those who argued that the LHC would see SUSY try to follow the Gordon Kane model, and try to use it as an argument for the Great Collider, I think they will run into serious questions about their credibility.

Anon,
I think it's the job of physicists to come up with the cheapest way of successfully investigating higher energy scales, and if the budget numbers are plausibly affordable, make their best case to the politicians who will have to sign off on budgetary decisions. I understand the US budgetary and political situation, and it's clear that there's no way this kind of project is now doable in the US. I understand nothing about the analogous issues in China, but don't see an argument why physicists shouldn't make their case for this.

abby yorker,
I think 13 billion is a maximalist way of accounting for LHC expenditures, 10 billion a minimalist estimate. I don't understand the economics of this well enough to understand the cost differences between doing this kind of thing in Geneva (one of the most expensive places in the world) vs. China.

47. **srp**
September 28, 2015

As between moving the center of experimental HEP to China v. exploring advanced concepts, I'm not sure which one is the riskier bet of all the marbles. ISTM that the technological and economic facts have eliminated the bet-one-marble actions from the strategy space on the energy frontier. One advantage of the advanced concepts is that one cannot be so definitively sure about the lack of technological spinoffs as one is for the scaled-up conventional machines. Work on dielectric concepts, for example, involves building structures similar to the sort handled by the semiconductor industry.

Moreover, the time lags for such machines (if they turned out to be feasible) would be more concentrated on R&D than on construction because they would be much, much smaller. While a Manhattan Project-style organization chasing down two or three alternative technologies and the relevant engineering would be no joke to manage, the construction, operation, and maintenance of the machine itself ought to be much less of a superhuman feat of coordination than the LHC or the proposed Chinese Gargantuan Collider. In fact, if these time savings were not possible on the back end of the project then that would mean that the entire concept offered no cost savings at all.

48. **Hiro**

Linear 1 PeV Muon Collider, will it become a reality or a delusion?

The Free Particle

September 29, 2015
Categories: Quantum Mechanics

Following on my notes about Euler's formula, I've finally finished some work on another piece of elementary exposition, a discussion of the free quantum particle, which can be found as chapters 10, 11 and 12 of the book I'm working on.

These chapters are a complete rewrite and major expansion of what used to be there, a rather slap-dash single chapter on the subject. The excuse for this in my mind had been that it's a topic treated in detail in every quantum mechanics textbook, so best if I passed over it quickly and moved on to things that weren't so well treated elsewhere. Another reason for this was that my understanding of analysis has never been what it should be, and it seemed best if I not make that too obvious by how I handled the mathematics of this subject.

This summer I started rewriting the book from the beginning, and once I hit the chapter on the free particle it became very clear that it needed improvement, both for its own sake and for how the material was needed in later chapters. I spent some time doing some remedial study in analysis, and after a while got to a point such that I felt capable of writing something that captured more of the relevant mathematics. Finally, today I got to the point where these three chapters are in decent shape, and soon I'll move on to later ones.

One thing that I'd never thought much about before, but that struck me while rewriting these chapters, is the quite peculiar nature of a position eigenstate in quantum mechanics. Normally one only thinks about this in relativistic quantum field theory, where the problems associated with localizing a relativistic particle motivate the move to a quantum field theory. Of course a position eigenstate is just a delta-function, but what is peculiar is the dynamics, what happens if you take that as an initial condition. See the end of chapter 12 for what I'm talking about (be sure you have the latest version, today's date on the front), I won't try and reproduce that here. Part of this story is the tricky nature of the free-particle propagator in real time, as opposed to its much better behavior in imaginary time. The issue of analytic continuation in time continues to fascinate me, including the quite non-trivial nature of what happens even for the supposedly trivial case of a free particle in one spatial dimension.

   Hi,

   a small typo on the pg.146:

   "At any time T >0, no matter now small, this will be a phase factor with
   constant amplitude extending out to infnity in position space"
   in that quote: n->h

   as someone with a physics background, but with interest in more mathematical topics I think I'll start with your book when I try to refresh my memory of the nonrelativistic QM.

   thanks for making the drafts public!

2. **vmarko**
   September 30, 2015

   Peter,

   Page 145, equation for U(T,q_0,q_T). You say "to make sense of such an integral, on can…" [define it using Wick rotation, basically]. This is not really correct, and is a common misconception. The integral is perfectly well-defined as it stands, and can be evaluated with no additional analytic continuation, Wick rotation or otherwise. It's called the Fresnel integral (there is a Wikipedia article about it), and it can be solved by using the solution of the Gauss integral on the real line, the Cauchy residuum theorem, and a creative choice of the integration contour.

   The Wick rotation is not necessary to define that integral. Rather, it has to do with the fact that the Dalambertian operator is hyperbolic, and does not have an inverse. Then one uses the Wick rotation to transform the Dalambertian to a Laplacian (which is elliptic and therefore has an inverse), and then define the inverse of the Dalambertian by analytic continuation of the inverse of the Laplacian.

   HTH, 🙂
   Marko

3. **Peter Woit**
   September 30, 2015

   vmarko,
   "creative choice of integration contour"
   I should look more closely, but I'm still not convinced that's not a definition that uses analytic continuation.

4. **Peter Morgan**
   September 30, 2015

   Agreeing with vmarko about page 145. For another treatment, for example see Bogoliubov&Shirkov, page 147ff.

5. **Peter Woit**
   September 30, 2015

   vskrin,
   Thanks. Fixed.

   Peter Morgan,
   That's the relativistic propagator, which is trickier. As far as I can tell Bogoliubov and Shirkov use the +i\epsilon method to deal with the issue I'm discussing. Doing this

defines the integral as the boundary value of something well-defined in a complex half-plane, away from the boundary. I don't think it's inaccurate to characterize this as analytic continuation definition.

6. **Peter Morgan**
September 30, 2015

Seeing your response to vmarko, perhaps all that's necessary is to replace "To make sense of such an integral …" by something like "To derive an analytic expression for such an integral …".

7. **vmarko**
September 30, 2015

The propagator is more complicated, precisely because of the distinction between hyperbolic and elliptic operators, i.e. Minkowski vs. Euclidean spacetime. For that story you really need the Wick rotation. But for the integral discussed in Peter's book, this is unnecessary, because the integral can be evaluated without any analytic continuation.

The integration contour is drawn in the Wikipedia article on [the evaluation of the Fresnel integral](), and the rough steps of the evaluation are explained briefly. It's a simple exercise in complex analysis. Moreover, the function under the integral is the exponential, and since it doesn't have any poles the calculation does not contain any undefined quantities or such, so no analytic continuation involved.

HTH, 🙂
Marko

8. **Peter Woit**
September 30, 2015

I took a look again at Brian Hall's "Quantum Theory for Mathematicians", and it has an excellent treatment of the free particle (see chapter 4), as well as much more about the subtleties of the Heisenberg uncertainty relation (chapter 12).

In exercise 2 of chapter 4 he derives the integral discussed here in a manner that doesn't initially seem to be the usual boundary of a holomorphic function derivation. I'll have to look more carefully at that…

9. **Peter**
October 1, 2015

Dear Peter,
to show the convergence of the Fresnel integrals (without complex analysis) one can use the Dirichlet test. Evaluation is more painful though, but is in most classical analysis books. For a newer exposition, you can check this book by S.Popescu:

http://civile.utcb.ro/cmat/cursrt/ma2e.pdf

The convergence is in Example 50, p.122 (of the text), the evaluation is Example 60, p. 164.

10. **Dave Miller in Sacramento**
October 1, 2015

Peter,

The "tricky nature of the free-particle propagator in real time" is part of the Feynman path-integral approach as presented in Feynman and Hibbs, if I recall correctly. And, of course, if you convolve the kernel against any reasonable function, it works as it should.

Back in the mid-'70s, I had a conversation with Weinberg about how this is different in the QFT case due to the pesky 1/E factor (1/sqrt(E) in terms of the definition of the quantum field) required by relativistic invariance of the volume element in momentum space. Steve said he had never thought of the fact that that this messed up localizing the particle at a point.

Of course, there is another way of looking at it — you can view the vacuum as having non-trivial correlations at short distances (revealed in the non-zero VEVs), but Steve likes looking at particles as primary and the fields as just a way of describing interactions among the particles.

I'm still bothered as to how this works out in the fermion case — I know the math, but I am not sure how to view it physically, especially if one tries to think in terms of fields rather than the infinite number of particles of the Dirac sea. Alice Rogers has had some things to say relevant to this, but I'm not sure I understand her.

Dave

October 1, 2015

It is not hard to see that he Fresnel integral exists as an improper Riemann integral without any need for analytic continuation or deformation of integration contour away from the real line. As you take the integration limits to infinity, the function oscillates more and more rapidly (cancelling itself out more and more) so the contribution of any interval of given size at larger and larger distances becomes less and less. You can show the limit exists.

This is not true, however, for the moments of the Fresnel integral we often need to calculate, e.g., \int dx x^n e^{- alpha x^2}.

These can be calculated, though, without analytic continuation also. A nice source on how to do this is
Albeverio et al., J. Funct. Anal. 113, 177

Basically they do this by the generalization of the e^{-epsilon x^2} convergence factor we often add in Physics, do the integral, and take the limit epsilon -> 0. They generalize this to a general class of test functions and show that the limit is unique and independent of the test function.

We do something very similar to calculate Fourier transforms of tempered distributions

12. **Bob**
October 1, 2015

Hi Peter,

At the end of chapter 12, you've given the expression for a time-evolved position eigenstate as a Gaussian that broadens over time. What do you mean when you describe it as "a phase factor with constant amplitude extending out to infinity"?

13. **Andrew**
October 1, 2015

Can you tell us more about the process of writing a book? How did it come about? Was it commissioned by a publisher? Or did you begin a draft and later contact a publisher?

14. **Anon**
October 1, 2015

By the way, while the Fresnel integral straightforwardly converges as a improper Riemann integral, I believe it doesn't exist as a Lebesgue integral. To define it in the sense of Lebesgue, you do need the kind of convergence factor trick as in the Albeverio paper I mentioned above. Since you need that trick anyway as soon as you want to calculate moments, that might as well be your starting point. Still, no analytic continuation is ever necessary in either case.

15. **Peter Woit**
October 1, 2015

Many thanks to all who provided references about the question of convergence of this integral. I wasn't aware of ones not using some sort of i\epsilon argument (or equivalently a -\epsilon^2 convergence factor. I still think though the highly singular nature of what you get when you try and localize a non-relativistic particle (as opposed to the good behavior in imaginary time) is remarkable.

Bob,
It's only a Gaussian in imaginary time, in real time it's a phase factor.

Andrew,
The book came about because I started teaching a quantum mechanics course for mathematicians. There was no appropriate book covering a lot of what I wanted to do (e.g. the representation theory point of view, for other topics there are good books, for instance the Brian Hall book is great on the analysis side of the story). So I started writing notes for the class, at some point it became clear these were turning into a book. This project has now though gone on much longer than I wanted, I hope to finish soon.

I heard from several different publishers interested in what I was writing, earlier this year signed a contract with Springer. No, in case you're wondering, there's no money to be made writing this kind of thing, the motivation is purely the feeling that someone should do it, and that one learns a lot by working on something like this.

16. **Bob**
October 1, 2015

Hi Peter

So it is. You're right, it is strange.

If you take a normalisable but very sharply peaked wavefunction at t=0, you can presumably convolute it with that object and get the corresponding wavefunction at t=T. The further you go spatially from the original peak, the more rapidly that phase changes with distance, so beyond some distance the contribution it makes to the wavefunction at time T will be arbitrarily small, provided the original function has a finite gradient everywhere.

I see that it works, but the way that it works is certainly strange.

17. **John Baez**
October 2, 2015

Anonymous wrote:

> By the way, while the Fresnel integral straightforwardly converges as a improper Riemann integral, I believe it doesn't exist as a Lebesgue integral.

That's right, functions like sin(x^2) or cos(x^2) or exp(ix^2) are not Lebesgue integrable, because Lebesgue integration can't handle the "infinite cancellation" required to get a finite answer. But you can use any reasonable way of first imposing a cutoff or forcing the function to decay for large x and then removing this; they all give the same answer. Analytic continuation is essentially one of these methods.

This goes to show that the Lebesgue theory is not the last word on integration, and not nearly good enough to do path integrals in real time.

The Henstock-Kurzweil integral is able to handle this particular integral.

> In general, every Henstock–Kurzweil integrable function is measurable, and f is Lebesgue integrable if and only if both f and |f| are Henstock–Kurzweil integrable. This means that the Henstock–Kurzweil integral can be thought of as a "non-absolutely convergent version of Lebesgue integral"…

18. **Peter Woit**
October 3, 2015

Thanks John,
The lack of Lebesgue integrability makes precise the problem with the definition I was trying to put my finger on.

19. **Anon**
October 6, 2015

Bob, these propagators are certainly strange objects. It may help sometimes to remind oneself that propagators are not generally functions. Rather, they are distributions (generalized functions), which generally don't even need to have any representation as pointwise functions. Even when they do have such a representation on part of their range (as happens to be the case with the t>0 free particle propagator), you can do all kinds of things with them (e.g. Fourier transforms, moments, etc.) involving "integrals" that are divergent in the Riemann or Lebesgue sense. I promise that for the most part all this makes intuitive sense once one familiarizes oneself sufficiently with generalized functions.

The canonical source for generalized functions is the brilliant multi-volume:

I.M Gel'fand and G.E. Shilov, Generalized functions

Oddities

October 2, 2015
Categories: Uncategorized

A few odd things that I've run into recently:

- The IAS has a weekly meeting to discuss current topics in HEP theory. From their events calendar, next week's meeting will be devoted to "The Cosmological Constant and the String Landscape", with suggested readings the 28 year old papers by Weinberg on anthropics and the CC, as well as the KKLT paper (I'm a fan, see here) and its Bousso/Polchinski predecessor from about 15 years ago. I would have thought this was a very well-worn topic. The one recent reference is a defense by Polchinski of KKLT against some technical challenges, but if the intent is to discuss those, it's unclear why they're not in the references (and they have nothing to do with Weinberg/CC/anthropics).
- Mochizuki has two new things on his website. One is a long discussion of the use of the words "anabelioid" and "Frobenioid", the other is an animated video of a diagram explaining a theorem (see near bottom of here).
- A couple years ago there was a controversy over the proof of the so-called "Yau-Tian-Donaldson" conjecture (see here), with Donaldson and his collaborators publicly complaining about Tian's paper claiming credit for proof of this conjecture. The Tian paper was submitted to the Courant journal *Communications on Pure and Applied Mathematics* in February 2013, was published there in the July 2015 issue (a technical corrigendum appeared a couple weeks ago). More expertise than I have would be needed to see if the published version addresses the Donaldson et al. concerns, a quick look doesn't indicate evidence of that.

  At the time I wrote:

  > On a more positive note, perhaps this controversy will not interfere much with future progress in this area, as Donaldson and Tian are jointly organizing a Spring 2016 workshop on this topic at MSRI.

  The MSRI directory for this year though lists Tian as visiting, but not Donaldson.

- Among the many oddities associated with string theory is the decision of a group in Philadelphia to name a group of charter schools there the String Theory Schools. I don't think they teach string theory, just liked the name. The financing of these schools is now attracting controversy. It seems they are running into some financial trouble, involving huge real estate deals and tax-exempt bond financing. For the details of the story, see here. For some analysis, see a Naked Capitalism piece: Private Equity Asset-Stripping Strategy Meets Charter Schools to Produce Even Better Looting.
- Presidential candidate Ben Carson has been widely (and quite appropriately…) criticized for some of his odd and non-sensical views about science. In USA Today's factcheck piece about this, we're told

  > Carson went on to claim that the presence of stars and planets is related to the existence of multiple Big Bangs that eventually might produce an ordered universe:
  >
  > Carson: And then they go to the probability theory, and they say "but if there's enough big bangs over a long enough period of time, one of them will be the perfect big bang and everything will be perfectly organized." And I said, so you're telling me if I blow a hurricane through a junkyard enough times over a long enough period of time after one of them there will be a 747 fully formed and ready to fly?
  >
  > That is not an accurate reflection of the Big Bang theory. Though some theories of the origin of the universe suggest that the Big Bang was only one of many such explosions, these theories do not state that the currently ordered existence is a spontaneous result of one of these repeated Big Bangs.

  He's getting it somewhat wrong, but this does sound a lot like Carson has been reading about the string theory multiverse…

Update: Please do not use the reference to Carson as an excuse to post your thoughts on US politics and the ongoing political campaign. I think everyone would appreciate not having to be subjected to that topic here.

   October 2, 2015

   Let's not be quick to blame string theory for everything. They could have been G-String Theory Schools, and the curriculum may have included (*ahem*) … but the name was shortened to avoid unwanted attention from the Tea Party.

2. **Benny Oid**
   October 3, 2015

   The word is "Frobenioid".

3. **Peter Woit**
   October 3, 2015

   Benny Oid,
   Thanks, fixed.

4. **prize**
   October 3, 2015

   http://www.nytimes.com/2015/10/03/opinion/the-folly-of-big-science-awards.html

   Nobels coming up. NY Times editorial "The folly of big science awards". Many other prizes pay more, and the recipients are indeed in the least need of funding, but the Nobels are the best known and the most prestigious.

5. **Shantanu**
   October 4, 2015

   Peter any rumors of this year's nobel prize?
   Here is my guesses

Either neutrino physics and it goes to Yoichiro Suzuki and Art Mcdonald
Or in astrophysics/GR goes to Vera Rubin and Irwin Shapiro
Shantanu

6. **Peter Woit**
October 4, 2015

The physics Nobel announcement is scheduled for Tuesday morning. I have no idea who it will go to, seems unlikely to go to my choice, which would be to make up for their 2013 mistake of only rewarding theorists, not experimenters, for the Higgs discovery (so, a prize to ATLAS, CMS and CERN).

At $3 million, the big prize now is the Breakthrough Prize, which will be awarded Nov. 8. For that one also, I have no idea.

7. **Bernhard**
October 4, 2015

Shantanu,

I also have no idea, but wouldn't be really fair to give a prize to Rubin and forget W. Kent Ford. The work for which Rubin is most recognized for is co-authored by him and in this particular case the Nobel committee wouldn't be able to use the excuse of just acknowledging the group leader like they did with Powell. But anyway, not much to discuss, maybe the prize this year will in the end go to solid state physics or alike.

8. **Thomas Larsson**
October 6, 2015

Kajita instead of Suzuki, otherwise you were right, Shantanu.

9. **Shantanu**
October 6, 2015

Yes Suzuki was the spokesperson of Super-K from 2002 until recently. Kajita was the co-chair of the atmospheric neutrinos and proton decay group which announced 10 sigma evidence for non-0 neutrino mass.
It should have been awarded to Totsuka who initiated SK, but unfortunately the committee was late as he passed away in 2008.

That said, its still not clear to me what non-0 neutrino mass has told about physics beyond standard model, string theory etc.

10. **Bernhard**
October 6, 2015

The Nobel committee keeps making these kind of mistakes. Why not give the prize to the whole Super-K collaboration? It's a huge disservice to science to create these false myths around one person and give the public a wrong idea about how science works. And that should be the point of these prizes. It's so typical of Swedish mentality this leadership/boss thing (no matter how much they will deny this till death). Peter, sorry for the off-topic comments, last one from me.

11. **AcademicLurker**
October 6, 2015

I was predicting Rubin and Shapiro. Good thing I didn't bet any money. My reasoning was that since they're 87 and 85, respectively, the prize for dark matter should be awarded soon if it's going to be awarded at all.

12. **Regretacles**
October 6, 2015

Sno and super kamiokande had some systematics which actually left the question open. Kamland nailed it. I wish Stuart was still around to help me see how to find this all amusing

13. **David Nataf**
October 7, 2015

It's not clear if dark matter should ever get a prize. What's "proven" is that the gravitational mass of matter in the universe , assuming GR or even Newtonian gravity, is ~5x higher than what one would get from baryons.

The exact meaning of that is debatable until WIMPs are confirmed.

14. **Low Math, Meekly Interacting**
October 7, 2015

I've seen a lot of grudging approval of the latest Physics Nobel. While some show the usual unbridled enthusiasm for the pick, there's a significant amount of chatter on the interwebs expressing the opinion that while the prize is probably deserved, it's also one of the most boring, anticlimactic subjects ever to be so honored. There are no deep concepts here about BSM physics. The math is fairly trivial. We haven't actually learned anything interesting (Dirac or Majorana?) about neutrino mass, and the mere fact that it exists is hardly surprising. And so on.
Me, I'm just glad someone still thinks experimental verification in particle physics is extremely important.

15. **Peter Woit**
October 7, 2015

LMMI,

I think the attitude that it's not interesting to study the neutrino sector is quite wrong-headed. It's not just a copy of the quark mass matrix, mixing-angle story. The possibility of Majorana mass terms, and the fact that a right-handed neutrino state would be something quite different than anything else, neutral under all the SM forces, mean that there is definitely something new to study. Maybe there's a hint lurking there of a new insight into the SM, it would be absurd not to look. And, obviously, the discovery and measurement of neutrino mass terms is a significant advance in our understanding, well deserving of a Nobel prize.

16. **NeapTide**
October 7, 2015

I think Peter Woit is right on target. The theory of neutrino mass/mixing may not be challenging, but the experiments are quite challenging. In the end physics needs experimental/empirical proof. And then the theory of what causes neutrino mass/mixing is a `tail of the dragon' just as CP violation is… the dragon is BSM physics.

17. **Neil**
    October 7, 2015

    Boring and anti-climatic subject? Remember the solar neutrino problem, which was considered so puzzling that there was even a serious (or maybe not so serious) suggestion that the sun's fusion engine had shut down temporarily.

18. **Low Math, Meekly Interacting**
    October 7, 2015

    Hi, Peter & NeapTide,
    Well, yeah! There's obviously been considerable letdown in the wake of the Higgs discovery, and related anxiety about the future of collider physics, given the lack of hints about what energy scale is now necessary to probe to have a good chance of discovering something new. What better prospects are there, experimentally, than in neutrino physics? And besides, the work done on improving these detectors to help explore foundational questions appears to be accelerating progress in the field of neutrino astronomy, with obvious positive side-effects for astro- and nuclear physicists. Seems to me there's tons to love about neutrino physics, and the "meh" the latest Prize has gotten in some quarters is pretty surprising to me.

19. **Low Math, Meekly Interacting**
    October 7, 2015

    Sorry, should have written "fundamental", not "foundational"…

This and That

October 7, 2015
Categories: Uncategorized

- The Perimeter Institute's public lecture series tonight will feature Neil Turok on The Astonishing Simplicity of Everything. I think Turok is one of the few theorists speaking to the general public who has got the story of the current situation right: the LHC and CMB results point to the Standard Model + simple model of cosmology, ruling out many of the complicated models that have enthralled theorists for decades. By all rights, this should change the behavior and attitudes of theorists, I hope talks like his will have an effect. In any case, it should be vastly better than the last one of these, devoted to a misleading sales job for a failed theory.
- Nature magazine has a very good piece by Davide Castelvecchi on Shinichi Mochizuki and his impenetrable proof. It gives an accurate picture of the current situation: still virtually no experts have been able to understand Mochizuki's claims well enough to evaluate whether he has a valid proof. One counter-example is Ivan Fesenko, who is organizing a December workshop that may clarify the situation.
- The big news this week is the physics Nobel for the discovery of neutrino masses. I haven't written about this partly because I'm pretty ignorant about the history of the experiments awarded the prize (or, more accurately should have gotten the prize, not just a single person from the experiment), and the web is full of well-written coverage of this. The issue of the theory of neutrino masses is a fascinating, but quite intricate one, and some day I hope to write a bit about it, but lack the time right now.
- Tommaso Dorigo has a posting here about the great Italian theorist Guido Altarelli, who passed away last week.
- At some point I came across a list of the top donors to US political campaigns and was a little bit surprised to see that Jim Simons was on it, at number 7. I also noticed that someone else at his hedge fund spends even more on politicians than Simons does: Robert Mercer, a computer science Ph.D., is at number 4 (better informed people have pointed out to me that these numbers only include some publicly reported categories of donations). The Washington Post has a profile on Mercer today, which explains that he's one of the people we have to thank for Ted Cruz (Mercer is the top donor in the US to 2016 presidential campaigns, according to this).

  In terms of funding politicians and science, increasingly it's the hedge fund guy's world, we just live in it. I'm a big fan of much of what the Simons Foundation does, less so of Mercer's science funding, which goes to the Oregon Institute of Science and Medicine. The people there seem to be interested in climate denialism, surviving nuclear attack, and getting ahold of your urine.

  Physicists and mathematicians don't always have huge success in the hedge fund business. Robert Stock, a physics Ph.D from Carnegie-Mellon, seems to have gone from trying to blow up missiles with lasers to instead having more success blowing up a hedge fund, Spruce Alpha.

Update: According to today's New York Times, for the 2016 presidential election cycle, Mercer is the number two donor in the US, at 11.3 million. Simons is way, way down the list at 550,000. Their list of donors is heavily dominated by the financial industry (64 individuals or families), with the next largest number from the oil and gas industry (17 individuals or families).

Comments

1. **martibal**
   October 8, 2015

   Well, sentence like "We stand on the threshold of breakthroughs, both theoretical and experimental, which could change our picture of the world and the development of our society" doesn'it sound like pure propaganda ? It does not seem to me as the most honest attitude from a theorist. What in the present situation of physics allows to claim that we are close to a major breakthrough that will change the development of our society ? This permanent claim to the next-to-come major breakthrough is very much in the spirit of PI, but what is the benefit for physics at the end ? Why do physicist have to behave like teenagers so sure that what they are doing is the coolest thing ever ? I know this is how people like Arkani-Ahmed needs to behave, but it seems that mathematician are more modest. Remember years ago Connes about Riemann hypothesis saying that what he just explained was an epsilon in the good direction, but infinity minus epsilon is still infinity.

2. **Peter Woit**
   October 8, 2015

   martibal,
   I'm sympathetic to your point, but I do think that Turok has somewhat more of an excuse for this sort of thing than most people. As director of Perimeter, he has to find funding for the place. Being a salesman making the best pitch he can is part of his job description…

3. **NeapTide**
   October 8, 2015

   On the Nobel this year… just from memory, without a refresh… the neutrino oscillation evident in atmospheric neutrinos was `glimpsed' in a variety of experiments… old ones long forgotten under the Alps, in the IMB, and the original Kamiokande. Seems to me Kajita led the definitive analysis of this effect with the (then) new Super-Kamiokande, and proved it was a new neutrino oscillation beyond all reasonable doubt.

   Most of these experiments started as proton-decay detectors, and found nothing. I still remember them showing their low-energy events (in the early 1980's) and saying they were `boring low energy neutrino physics'. Turns out there was a Nobel discovery in the `boring low energy neutrino physics'. A nice turn of serendipity.

   However, the atmospheric neutrino effect was also noted in Koshiba's 2002 prize citation. If there is an oddity here, it is that Kajita's work overlaps quite a bit with Koshiba's.

   As for SNO, it really showed that the total solar neutrino flux, independent of neutrino flavor, agreed with the solar models of Bahcall. SNO is just a phenomenal experiment, a tour de force. On the other hand, it provided a verification that all the neutrino flux was really present, while the Ray Davis experiment, which measured just electron-flavored neutrinos, found a deficit. So you could say SNO really proved that the Davis deficit truly was oscillation of the nu_e's into other nu_x's.

   Qualitatively, though, the KAMLAND experiment did it a bit more convincingly. KAMLAND was a bit quicker and dirtier than the spectacular experimental care of SNO. But KAMLAND saw the neutrino oscillation independent of all sorts of solar uncertainties. Hardcore experimentalists like the control present in KAMLAND.

   You see where this is heading, I suppose…. MacDonald + (KAMLAND) might have made a bit more sense than MacDonald + Kajita. But Kajita really led the team that nailed atmospheric neutrino oscillations, which were not probe by KAMLAND, but have been verified subsequently by K2K, T2K, and MINOS, so Kajita is definitely deserving. It's just that Koshiba kind of got rewarded for that already.

   Possibly KAMLAND will get worked into yet another prize. Possibly with Daya Bay and/or RENO, for theta_13.

   Also, there are several major experiments underway or planned in the neutrino world: KATRIN (neutrino mass), DUNE (CP violation in neutrino mixing), Majorana, CUORE, NEXO (double beta decay), Project 8 (clever neutrino mass advance in sensitivity), LSST (astrophysical neutrino mass measurement).

And there is kind of a fault line between the LHC experimentalists and the neutrino experimentalists. The natural fault that results from questioning why continue the LHC if nothing seems to be there, and from the LHC the questioning of the more modest discovery potential of the neutrino program…. if you measure all the neutrino stuff, it implicitly points to BSM physics, but doesn't help identify what that physics really is. Passing a threshold at the LHC does do that.

4. **Peter Woit**
October 8, 2015

Surely no one who regularly reads this blog could possibly believe that I'm going to tolerate the usual tedious arguments about climate change. Please just stop.

5. **srp**
October 8, 2015

According to the linked article, Stock had long (several months) departed Spruce when the fund collapse occurred. It's hard to see how the blowup of a strategy using short-term movements in ETFs could be retroactively pinned on him.

6. **Peter Woit**
October 8, 2015

srp,
Yes, the article says Stock left 4 months before the blow-up. It also says that he had been there ten years and designed the strategy they were using of taking money from ETFs by "by identifying daily-resetting, highly-levered ETFs experiencing volatility decay, and shorting them in bull and bear pairs," and that this strategy blew up in August due to the usual sort of "fat tail", a "seven-sigma" event that was not supposed to happen. They attribute the collapse to the strategy they were using, which seems to be the one designed by Stock, with the fault not theirs, but "unprecedented market events that led to similar strategies losing money".

In his defense he says that he doesn't know how the strategy was implemented after he left. Maybe his successor changed things, maybe if he had stayed there he would have seen the seven-sigma tsunami coming and gotten out in time. And, maybe he's just another one of many quants who designed a strategy that makes you money reliably for a while, until the day it wipes you out, after which you whine about "unprecedented market events".

7. **Chris Oakley**
October 9, 2015

To the above I might add that although the financial markets generally had huge respect for people with mathematics or related Ph.D.s, I doubt that majority of the ones I knew made money overall (and personally, not wanting to involve myself in things over which I had no control, I kept clear of trading). One blew up a hedge fund c. 1998. Another one, a loner who combined the roles of quantitative analyst, programmer and trader, had, like Stock, a strategy that made small amounts of money slowly and then lost all of it and more quickly when market conditions no longer suited.

And then of course there was the LTCM debacle. The so-called "smartest guys in the room" simply turned out to be the most reckless. The melt-down they caused was a nice little practise run for the one that occurred ten years later. Shame that no-one seemed to learn anything from it.

8. **Shantanu**
October 9, 2015

NeapTide, nice summary. Just to add that Kajita was the co-analysis coordinator
of the atmospheric neutrinos and proton decay group at Super-K (the other co-chair
was yours truly's thesis supervisor). But Kajita also did the similar analysis in Kamiokande and had given the talk at Neutrino 98. Also Koshiba's nobel prize was for neutrino astrophysics.

However, its still not clear to me as to what exactly we have learnt about BSM physics
from neutrino data (and not just hints).
shantanu

9. **martibal**
October 9, 2015

Peter,
yes you are right, I do not know Turok but being Director of a prestigious private institute can justify a bit of propaganda for fundraising purposes 🙂

10. **Art Brown**
October 9, 2015

From the wallpaper behind Turok it looks like Perimeter favors the West Coast metric.

11. **Yatima**
October 9, 2015

NeapTide says: *Also, there are several major experiments underway or planned in the neutrino world*

I didn't know so many neutrino experiments where in the pipe. Excellent. Still, I suppose the first results will be in a decade or two? I still remember reading in a popular science magazine about Kamiokande II obtaining data from Supernova 1987A, back when Z80-based home computers were a thing.

12. **srp**
October 9, 2015

It is true that there are a number of sucker strategies that involve the risk equivalent of writing out-of-the-money options, allowing you to make "free money" for a while before being ruined by the occasional "fat tail" event. Whether physicists are more arrogant than finance/econ types or more prone to fool themselves that their strategies are foolproof would be an interesting empirical question.

13. **Bane**
October 10, 2015

Srp: I believe there's a saying in finance: Losing money when everyone is losing money is seen as not good but understandable. Not making money when everyone else is making money will get you fired.

In other words, it really doesn't pay (literally) to concentrate too much on strategies which take measures to avoid extreme downsides, since doing so will pretty much have to reduce your "normal" profitability and that's what the employer cares about.

14. **sm**
October 10, 2015

"I have never denied that the most profitable investment for a wealthy person in Russia is an investment in politics" – Boris Berezovsky.

He learnt this from the Americans who 'helped' (themselves to) Russia in the early 1990s.

I would add that that if you have been accused on Capitol Hill of tax avoidance to the tune of six billion dollars, Berezovsky's observation is spot on.

15. **Jeff M**
October 10, 2015

The coverage of Mochizuki's supposed proof of abc is really strange. First, everyone seems to compare him to Perelman, which is silly. Perelman (who proved the Thurston geometrization conjecture, a much bigger deal than just the Poincare conjecture) was working in a well known field, with a well known idea, which went back to Thurston. His student Hamilton had worked on it for a while, but got stuck, and couldn't get unstuck. People in the area, which is pretty close to mine, always thought Hamilton's approach was maybe the way to go, it was just that no one could get past some problems. Perelman did. I was at a conference not long after it was announced, and various big shots were reading his stuff and trying to work out if it was OK. Even then, the feeling was it probably was fine. Mochizuki, no one as far as I can tell, has a clue. Grothendieck wasn't like that either, he made enormous strides, but people in the field knew quickly they were enormous strides. Maybe he's right, or close, but he's going about it very very weirdly. In math, people are usually very very good about sharing their work, and explaining it. Perelman's papers were understandable, they just took some normal refereeing, more or less. Mochizuki no one knows anything, as far as I can tell. And it's not like it's not people who know what they're talking about. Faltings? Really? On top of everything else that's his thesis advisor. When de Branges claimed to have the Riemann hypothesis, I remember talking to Peter Sarnak, who told me in no uncertain terms it couldn't be, other people had tried the same technique, and realized it couldn't work. I have the same feeling about this – could be wrong, but I wouldn't bet on it.

16. **Peter Woit**
October 11, 2015

Jeff M,
I think you're right that this situation is not similar to the Perelman one, but I don't think many people see it as similar, especially now that it has been three years, and experts still don't understand the purported proof. What Perelman did was post basically an outline of a proof, far from something refereeable as a proof. But it was quite comprehensible to experts, who could then do the work to check details and write up a refereeable proof.

Mochizuki's papers purport to contain a refereeable proof, but it seems that almost no experts have been able to understand these papers and their argument well enough to judge whether they contain a valid proof. It's a very unusual situation…

By the way, Hamilton wasn't Thurston's student, he's older, got his degree in the 60s.

17. **captain obvious**
October 11, 2015

Perelman's paper had a key advance at the very beginning of the work that could be checked as a routine (for experts) calculus exercise, i.e., that differentiating his entropy functional along the Ricci flow gave a positive quantity, so it was increasing. And then he gave a quantity whose gradient was Ricci flow!! Incredible stuff that could be checked by direct calculations assignable to a graduate student. No big new terminology getting in the way, and immediate visible easily checked insights that clearly had the potential to do what he claimed.

Wiles also had quick, if not immediate, spinoffs from the main argument such as neat lemmas in commutative algebras.

18. **Jeff M**
October 12, 2015

Peter,

About Hamilton, thanks, I can't remember why I thought he was a student of Thurston, maybe just confusing him with Anderson. And you're right about what Perelman posted, but as captain obvious points out, Perelman's outline was pretty easy to check, and from what I remember it was in fact pretty clear that what he said was right, and very very clever, and fit right in with a bunch of previous work. Filling in the details took some time, but everyone I was talking to was very confident from the get go it would work. Wiles was a bit more interesting, it was clear he was on to something, again he was working with well known ideas, plenty of people had a feeling about Fermat once Taniyama-Shimura hit. The hole in Wile's proof took serious work to plug, but again the experts I talked to always thought it was doable.

19. **Bill Daniels**
October 12, 2015

Didn't Terry Tao solve an Erdos posed problem recently? Didn't see anything on this blog about it. But more interesting than Turok's TED talk. A nice contrast to the ABC situation.

20. **RandomPaddy**
October 13, 2015

A proof means your agument has to convince another person. If you can't do that then you haven't proved anything. The theoreom is either right or wrong to begin with but your proof of it is an entirely seperate thing.

21. **Anon**
October 14, 2015

RandomPaddy, mathematical statements are not necessarily right or wrong to begin with. See, e.g., the Continuum Hypothesis, which is unprovable in our usual foundational systems for Set Theory. We can either assume its truth or its falsity as an axiom and get a consistent theory (assuming ZF set theory is consistent to begin with).

22. **Peter Woit**
October 14, 2015

All, please resist the temptation to use off-hand remarks in comments to start off-topic discussions. I promise to try and find time later today to come up with some new material. Anything to head off a discussion of the foundations of set theory….

23. **Low Math, Meekly Interacting**
October 14, 2015

I liked most of Turok's lecture. He's one of those rare critics whose style is so genteel and sweet he can make a body blow feel like a warm hug. I've worked with a couple people like that. They have the gift of making you feel unburdened when you give up on a stupid idea, rather than just stupid for having pursued it. He left me pretty cold when he started pitching his own highly speculative ideas without adequate disclaimers, though. I find it persuasive that the apparent simplicity of the universe on vastly different scales may be an important clue, and scale invariance of one form or another may be a fruitful avenue of investigation. I'm happy to be shown wrong, but if I understand his and Steinhardt's work correctly, what largely distinguishes their cyclic universe models from inflation, as far as we can currently observe, is the lack of measurable B-modes in the CMB. Maybe inflation's ability to give you any B-mode prediction you want disqualifies it as science, but the fact remains you can't use the absence of a signal to distinguish between the two. I really hope gravity wave detectors advance as much as Turok predicts, but the jury still seems very much out on that one. It's also not clear to me how "cyclic universe" models aren't just multiverse models with a different topology. Lastly, the philosophical point he makes during the Q&A sounds perilously like positivism to me. "More of the same" beyond our cosmic horizon seems the most parsimonious hypothesis. Would some other possibility not simultaneously deviate from the Cosmological Principle and invoke a landscape of some sort? I know we can't say either way with absolute certainty, but the actual evidence seems more supportive of mediocrity, and, with a few caveats, it's a fair stance to have based on current knowledge, isn't it?

I'm not trying to debate these points, just offering my view that Turok's gently devastating critique of stringy anthropism in its current guises, as valuable as it is, may not make up for enthusiastically popularizing ideas that perhaps themselves are open to serious philosophical question.

24. **not ed**
October 14, 2015

Another case of prizes going to those in least need of funding? "Exceptional Achievement in Research" etc

Comment edited, I believe the included link was meant to send people here:
http://www.aps.org/programs/honors/prizes/apsmedal.cfm

25. **Leonardo**
October 15, 2015

Go Yamashita was writing "a proof of abc conjecture after Mochizuki" which would supposedly clear up Shinichi's work and put it on a more familiar ground to other mathematicians. Yamashita is known to this kind of stuff, as evidenced in some of his past papers, such as "a simple proof of convolution identities of Bernoulli numbers", in which he took the work of T. Agoh and K. Dilcher, whose proof was complicated calculations in more than 10 pages, and simplified it to just one formula on a new kind of generating function. It was expected that Go's work would severely lower the barrier for others to understand IUTeich (although I'm not sure he would actually cover all of it).

However, there's been no news on this front for a long time.

Does anybody know if Yamashita is still working on this? Should we expect it to be ready on time for December's workshop? I'm pretty confident this is the refreshing breath IUTeich needs.

26. **Davide Castelvecchi**
October 17, 2015

Thank you very much Peter, I am glad you liked the article!

Jeff: I hope I made it abundantly clear in my profile of Mochizuki that his case is different than Perelman 🙂

Leonardo: My understanding is that Yamashita has now finished writing up his notes in Japanese and that they are currently being translated into English.

27. **Leonardo**
October 17, 2015

Davide, those are great news. Are you aware of the scope of his notes? I hope they are a self-contained proof of the abc conjecture through IUTeich and not just a survey as was Fesenko's. Of course, both are pretty helpful and welcome, but I'm of the opinion that a full double-check, independent, paper would be far more important. Well, let's wait and see. The Oxford Workshop is just around the corner, many news should come from it.

28. **Curious Mayhem**

The page has links to the key original papers.

Prizes and Other Stuff

October 15, 2015
Categories: Uncategorized

- There will be an awards ceremony November 8 for the 2016 Breakthrough Prizes, hosted by Seth MacFarlane, and airing live on the National Geographic Channel, later to run on FOX. The next day at Berkeley there will be a Breakthrough Prize Symposium, featuring talks by the winners and others.

  In physics the prizes to be awarded include the big $3 million prize and up to three $100,000 prizes for young researchers. The symposium physics schedule lists as speakers "2016 Breakthrough Prize Laureates", with the plural perhaps a hint that more than one person will be sharing the $3 million. The first three rounds of these mostly went to string theorists but there seems to have been some sort of policy change last year (the award went to Supernova observations indicating an accelerating cosmology). I have no idea at all who they'll choose this year. The theorist speakers discussing the future of the subject at the symposium are Arkani-Hamed, Hall and Bousso, a clean sweep for multiverse mania.

  On the mathematics side, there's also a $3 million prize and up to three $100,000 prizes. The symposium schedule lists "2016 Breakthrough Prize Laureate", so maybe a hint there's just one in math.

- In other news on the prize front, the APS will now be awarding a Medal for Exceptional Achievement in Research, with the first one going to Edward Witten.
- The Wall Street Journal has published a response to the Gross/Witten piece advocating a Chinese "Great Collider". Physicist Jonathan Katz describes particle physics as a "dying", "moribund" subject. He argues that research funding should go to "tabletop experiments", like for instance the ones he does.
- The new AMS Notices is out, with a piece by Loring Tu on the origin of the theorem due to Atiyah-Bott often known as the Woods Hole Fixed Point Theorem. Tu does a great job of explaining this beautiful mathematics, as well as the details of the controversy over Shimura's role in sparking this by a conjecture. He doesn't much discuss Shimura's memoir, which I wrote about here, which includes the claim that Serre attacked him out of jealousy about Shimura's conjecture. I've never really understood Shimura's point of view on this, since usually mathematicians value theorems over conjectures, and it is clearly Atiyah-Bott who had the theorem here.
- From David Mumford's blog I learned about an experimental neurobiology paper co-authored by Atiyah. It is quite interesting, but even more interesting is the blog entry by Mumford that it inspired. Mumford is one of the greats of algebraic geometry, and he gives a fascinating characterization of the different sorts of ways in which mathematicians pursue research. Mathematics done at the highest level involves strikingly different personalities and research strategies, which Mumford characterizes as four different tribes: "explorers", "alchemists", "wrestlers" and "detectives". If you're at all interested in how mathematics research is done, this is highly recommended reading.
- Also recommended, if you're interested in the overlap of physics and philosophy, is a new piece by Massimo Pigliucci on String Theory vs. the Popperazi.

Comments

1. **si**
   October 15, 2015

   The part of the Atiyah's paper I found interesting is the ranking of a bunch of formulas as beautiful or ugly by mathematicians. Not surprisingly, the Euler formula ranked consistently as the most beautiful. But the one ranked as the "ugliest" was the Hardy-Ramnanujan formula for calculation of pi. I know it has strange, seemingly random constants, but I consider these as the essence of its beauty, not ugliness. I think one cannot talk about mathematical beauty without also considering what is ugly. My guess is that there is a wider range and variation in the ugly side.

2. **zzz**
   October 15, 2015

   Table top experiments, yeah that sounds like a good idea.
   Google 'Jonathon Katz physicist' to see what he is doing.

   yikes

   http://www.riverfronttimes.com/newsblog/2010/05/19/controversial-wash-u-prof-jonathan-katz-cut-loose-from-gulf-oil-spill-relief

3. **Bill**
   October 15, 2015

   It says on the website you linked to: "Each of the Breakthrough Prize laureates receives a $3 million prize, and a total of seven prizes will be awarded."

   First of all this means that the laureates don't share one prize, but also gives more than a hint that there will be multiple winners.

4. **Peter Woit**
   October 15, 2015

   Bill,
   I think that info is for the first round of these awards several years ago. After those awards, now the plan is for a single $3 million award/year (one in physics, one in math).

5. **Bill**
   October 15, 2015

   My guess is that the prize in Mathematics will go to Yitang Zhang.

6. **Davide Castelvecchi**
   October 16, 2015

   The "beauty of math" paper actually came out last year
   http://www.nature.com/news/equations-are-art-inside-a-mathematician-s-brain-1.14825

7. **op ed**
   October 16, 2015

   About WSJ and Katz and the Chinese Great Collider, look up what Phil Anderson had to say about the SSC. For example this http://www.the-scientist.com/?articles.view/articleNo/8688/title/The-Case-Against-the-SSC/

or this
http://www.math.columbia.edu/~woit/wordpress/?p=6419

See also if you can find Rustum Roy's numerous articles/speeches against the SSC.
Ultimately the SSC projected cost ballooned to about $8.4 B and Congress pulled the plug. But that pot of money did not flow into the hands of condensed matter physicists. Instead the consequence of the SSC's termination was a general cut in funding across all of science (or maybe just physics). Essentially, "if the HEP community can absorb an 8B loss of funding, then other areas of physics can also learn to make do with less".

Science funding is not a zero sum game, where if money is cut from one area, it goes to another.

8. **srp**
October 16, 2015

Regarding the Great Collider of China and other science mega-projects, I recommend Freeman Dyson's 1988 essay "Six Cautionary Tales for Scientists" in his collection From Eros to Gaia. He there describes how the internal ecology of a field can be ruined by a too-large unripe Great Leap Forward project. It isn't a question of sending the money from HEP to condensed-matter; it's a question of distorted resource allocation within HEP itself. The essay is also a beautiful and fascinating read.

9. **leap**
October 16, 2015

The key word/concept is "unripe". I suppose one can say the SSC was unripe and too big of a leap forward. Who knows. It was certainly jingoistic, and that rubbed many people the wrong way. But Freeman Dyson was also unhappy about HST, advocating smaller telescopes or whatever. (See if you can find cartoons from the 1980s about the Large Space Binoculars.) Who is to determine what is too big of a leap forward? Usually only hindsight decides that.

Freeman Dyson is a good author (so is his son George). Read "Disturbing the Universe" it's another fascinating read.

10. **Bernd**
October 19, 2015

Op ed,

you're right about science funding not being a zero-sum game*, but then building such a gigaproject with no clear vision other than "umm, maybe nature will unexpectedly throw something at us" is going to result in a backlash against all science funding in the long run.

* Although to a large part, it is. And, of course, a lot of science funding does not go to scientists. How much of the LHC budget went to construction companies?

11. **srp**
October 19, 2015

The HST turned out to be a great thing, but the opportunity cost of it for astronomy was pretty high, especially given all the problems it had leading to extra delay and expense. Once a project like that is up and running, the incremental cost per discovery is quite low–most of the costs are sunk upfront. So it makes good sense to support these projects' continuing operation ex post, as then they are the cheap option. But one should not allow this post-investment optimality to obscure the potential pre-investment suboptimality of a project that crowds out all others in its field.

12. **Low Math, Meekly Interacting**
October 20, 2015

It's probably unfair to characterize much of modern functional neuroimaging as "the new phrenology", but studies on the vanguard of subjective experience and their voxelated correlates need to be viewed with a great deal of skepticism. It's only very recently that we're approaching being able to use more advanced neuroimaging to reliably diagnose devastating neurodegenerative diseases like Alzheimer's. For subtler (but not terribly subtle, really) conditions like major depression, bipolar disorder, and schizophrenia, these techniques have essentially no value as diagnostic tools, and it's only with considerably larger sample sizes and impeccable statistics have reproducible correlations generally survived much beyond the first reported observation.

The paper is remarkable, though. A Fields medalist senior-authoring a neuroscience article in an open-source journal? That's an encouraging development, if nothing else. And the language…I assume Atiyah wrote the stuff that doesn't read at all like a bioscience manuscript. I mean, it's loads of second-hand rhapsody slathered on a base coat of anecdote, but very lovely all the same, and a damn sight more enjoyable to consume than most of what I have to slog through on a regular basis.

13. **Paul D.**
October 27, 2015

The WSJ has also published an essay that is down on basic science in general.

http://www.wsj.com/articles/the-myth-of-basic-science-1445613954

14. **Yuri**
November 3, 2015

"The Breakthrough Prize today announced that ten-time Grammy Award winner Pharrell Williams will perform at its third annual Breakthrough Prize ceremony, held to honor the world's top scientists and mathematicians, on Sunday, November 8 in Silicon Valley.

Williams will be joined at the exclusive ceremony by a star-studded lineup of presenters, including Academy Award winner Russell Crowe, Academy Award winner Hilary Swank, Lily Collins, and Thomas Middleditch and Martin Starr of HBO's Silicon Valley. As previously announced, Emmy-nominated Cosmos executive producer and Family Guy creator Seth MacFarlane will serve as the ceremony's host."

The Latest Information on Information

October 17, 2015
Categories: Uncategorized

The field of hep-th has always been quite faddish, with many of the fads easily recognizable just from looking at the buzzwords appearing in paper titles. In recent years "entanglement" is a buzzword that has been all the rage, and John Preskill has some data here (slide 3) on how many hep-th papers have it in their title. Extrapolating from 62 in 2011, 119 in 2013 and a projected 220 this year, long before we see a new accelerator, all hep-th papers will have "entanglement" in their titles. Another very visible trend is that an increasingly large fraction of these and other papers in hep-th (which used to mean high-energy particle physics) are now about low-energy non-particle physics topics.

I make periodic attempts to listen to talks or read papers explaining the hot topics at issue, but have to confess that I tend to lose interest, not seeing anything relevant to the standard model or unification, or to the kind of deep mathematics that in the past has provided insights into those topics. Suggestions of what to read to follow these latest fads are welcome, when I have more free time I'll look into them. In the meantime, I'm just reporting a trend, will leave it to others to decide what it all means.

This brave new world of hep-th is generating a lot of activity. The week before last saw a big "The Information Universe" conference in the Netherlands, that addressed questions such as

– Is the universe one big information processing machine?
– Is there a deeper layer in quantum mechanics?
– Is the universe a hologram?
– Is there a deeper physical description of the world based on information?

Last week was the kick-off meeting of the It from Qubit collaboration, which is supposed to bring together quantum information theory and fundamental physics. This is an extremely large effort, very well-funded by the Simons Foundation. They just announced that they're planning on hiring a dozen or so postdocs this year. If you get one of those jobs, there's a warning that you'll have a "significant burden" of having to travel to collaboration meetings in places like Bariloche, but at least on long flights you'll be flying business class.

For a detailed explanation of the plans of It from Qubit, see here.

After the Simons-funded meeting a few days ago at Stanford, this weekend there's yet another quantum information/entanglement/HEP meeting at Stanford, this one funded by the Templeton Foundation. The program for the Templeton Program meeting is here.

Update: It seems that this page has been edited this weekend to remove reference to the It from Qubit collaboration travel policy, however you can still find it here.

Update: For popular expositions of these ideas, there's a new article in Science News, and a book coming out by George Musser, reviewed today by Sabine Hossenfelder. I haven't seen the book, but the Science News article doesn't help me understand much: all I get out of it and the papers its links to are some very vague conjectures about understanding quantum gravity via AdS/CFT. Standard facts about quantum mechanics on the CFT side become more exciting sounding conjectures about gravity on the AdS side, but it remains unclear to me exactly how any of this is supposed to really work. For one thing, we don't live in AdS space.

1. **Steamy Ray Vaughn**
   October 17, 2015

   I saw Leonard Susskind give a lecture as long ago as 2013. I vaguely remember, he said something like '… by the way, we're undergoing some kind revolution in entanglement… every day [week?] there's a new paper out…'

2. **Matt W**
   October 17, 2015

   Modelling the fadishness of HEP-TH titles might actually be an interesting little project. Am wondering if each fad (information, firewalls, multiverse, etc) follows the same initial geometric increase followed by a plateau and decay.

3. **Anonyrat**
   October 18, 2015

   The fadishness of technology has been well-captured in the Gartner Hype Cycle.
   http://www.gartner.com/technology/research/methodologies/hype-cycle.jsp
   It is likely that the curve they draw is of validity for scientific topics as well.

4. **anon**
   October 20, 2015

   I like it when they have these conferences at kitp, because then all of the videos are available and promptly posted. Thanks for pointing this meeting out.

5. **Jeff M**
   October 25, 2015

   Well, Peter seems to be being finicky with posts about this, but here's a try. I read the it from qubit writeup pretty carefully, and found it quite scary. Does that really pass for science now? It reads like a press release trying to sell a new piece of software. Conjectures are theorems. Completely open problems are discussed as if there is some sort of established theory about them. Rigor is completely absent. There is no expectation that anyone will have to prove anything, ever, mathematically or via experiment. HEP has jumped the shark.

6. **Peter Woit**
   October 25, 2015

   Jeff M,
   Physicists have never been much interested in rigor or proof, so you can't really criticize this project on those grounds. Some parts of what they are doing though seem to be completely divorced from any contact with experiment, so a real question arises as to how you evaluate work like this if the usual standards of neither mathematics nor physics apply. That their proposal leads off with some pretty extreme hype ("A rapid change is taking place in our thinking about fundamental physics that amounts to a

nascent paradigm shift.") and also makes an argument based on the exponential increase in use of a buzzword, isn't really confidence inspiring.

Personally I'm dubious that quantum information theory is going to revolutionize our understanding of fundamental physics (eg. the SM and gravity), or our understanding of QFT (it seems more likely that our understanding of QFT may revolutionize quantum information theory). I see not a hint here of anything addressing the problems of the SM or unification, and the problem with claims to have a quantum theory of gravity has always been that, in isolation from the rest of physics, quantum gravity theories seem to be untestable. But, that's just me, in a few years we'll see what emerges from this activity, and maybe it will be clear if there's anything to the revolutionary claims. The danger is that the claims will just get a lot more exposure, with the problem of evaluating whether this is a useful paradigm shift never solved.

While I don't think it's going to be a revolution in physics, quite possibly some interesting things will come out of this research. Hopefully part of what the grant will fund will be some readable expository literature, such that one can learn what people have found without having to wade through mountains of hype.

October 25, 2015

Musser has a Cliff's Notes summary of his book in the latest SA. I read it twice and still got nothing out of it. I am a bit reluctant to invest my time reading his book until someone whose opinion I respect, like Peter, tells me it is worth my time.

On it from bit, I don't understand why this is a promising path other than the fact that Shannon's theorem is a transformation of the Second Law.

8. **Jim Akerlund**

Off Topic.

Nautilus magazine has a good article on Sloane's encyclopedia of number sequences.

http://nautil.us/issue/29/scaling/how-to-build-a-search-engine-for-mathematics

9. **Jeff M**
October 27, 2015

Peter

I completely appreciate that physicists don't do proof (it's a running joke among us mathematicians) but I had hopes for rigor. Perhaps I'm misremembering, but when I worked through the field equations of GR or Dirac's equation for the relativistic electron I seem to remember a lot of rigor. Ah well, perhaps it's good you're in the math department 🙂 As for Jim Akerlund and Sloane's Encyclopedia of Integer Sequences, it's an amazing resource. I was working on something and we got this sequence, we plotted it and stared at it, and knew it had to be something, but no one we talked to had ever seen it. Plugged it in to EIS, found out it was Stern's sequence, discovered in the 1840's, used to help make watches, more or less lost by the 20th century (though used to construct the rationals). Lots of fun to reference a paper written in the middle of the 1800's…

October 27, 2015

Neil wrote:
>On it from bit, I don't understand why this is a promising path other than the fact that Shannon's theorem is a transformation of the Second Law.

I think even that is an over-statement: I've done some work involving information theory (I hold some patents on implementations of error-detection-and-correction systems). The way I'd put it is that anything that involves multiplicative counting (you know m choices followed by n choices, etc.) lends itself to taking logarithms, and then it inevitably looks a little bit like entropy. Of course, Shannon chose to use the word "entropy," hence he encouraged this sort of over-statement. But, I don't think Shannon's theorem really is a transformation of the Second Law.

By the way, I am not attacking you personally: I know that your statement is a widely accepted view. I'm just pointing out that, in my experience working in both physics and information theory, that widely accepted view is misleading.

However, like Peter, I am open to being shown to be wrong: I've always been curious about "It from Bit" (I went to a lecture by Wheeler pushing the idea way back in the mid-'70s), even though I'm skeptical.

Dave.

11. **Neil**
October 27, 2015

Dave,

Yes, I misspoke. I meant Shannon's equation is a variant of Boltzmann's entropy equation. But, as you point out, that could just reflect that they both deal with combinatorics.

12. **Chris W.**
October 27, 2015

Dave and Neil,
Wikipedia has [a pretty good discussion](#) of this very topic. By now it has a long history.

13. **Baruch Garcia**
October 27, 2015

If you wish to learn more about ¨It from Bit¨ from Wheeler´s perspective, I suggest reading his autobiography – Geons, Black Holes, and Quantum Foam. His work is also mentioned in Amanda Gefter´s book – Trespassing on Einstein´s Lawn. An archive of his papers can be found at jawarchive.wordpress.com.

14. **Peter Woit**
October 27, 2015

Please, enough about "It from Bit", which, as far as I can tell, has little or nothing to do with "It from Qubit". I would be interested in hearing more about this second topic from someone who understands recent developments. Personally I've never seen anything interesting coming out of the first topic, but replacing bits by qubits does seem more promising.

15. **Dave Miller in Sacramento**
October 28, 2015

Peter,

Most of the "It from Bit" presentations going way back that I remember seeing did in fact invoke quantum mechanics — certainly Wheeler did so, and I remember even old sci-fi novels that did so.

And, the idea of tying in wormholes to quantum entanglement also has a long history, at least going back to Dave Deutsch's famous Phys. Rev. article, which tied his theory of quantum computation into wormholes, time travel paradoxes, and parallel universes: certainly the most interesting case for many-universe theory I've ever seen, even if it was a bit, let us say, speculative (I always wondered how he managed to get the Phys. Rev. editors to approve it for publication!).

Dave

16. **Will Nelson**
October 28, 2015

I feel like the entanglement and more generally "information" angles are sort of under-delivering. It's not clear to me what, if anything, has been gained by focusing on the "information" of a quantum system or a putative analogies with computation (Lloyd: "the universe is a quantum computer, computing itself"…gee thanks for that!) With entanglement the goal is to see spacetime "emerge" from specific forms of entanglement, but we already see this kind of entanglement in the states of a standard QFT, and it doesn't seem to be particularly helpful (so far) to think of this is as creating the spactime.

Well I think it's unwise to ignore the fads or hot topics of hep-th since plenty of smart people obviously think they are promising, but I do think these two may be not as promising as hoped.

17. **Anonyrat**
October 28, 2015

An interview with Abhay Ashtekar of general interest.
http://thewire.in/2015/10/29/good-scientists-solve-problems-but-great-scientists-know-whats-worth-solving-14279/

A little clip about string theory:

There's even been talk of "post-empirical science".

Yes. There was another Strings conference in India at TIFR, in 2001. I happened to be in India at that time – people had just discovered that the universe is going through accelerated expansion, so that the cosmological constant may be positive. And I saw in newspapers that Tom Banks and Edward Witten had said that, no, the cosmological constant cannot be positive because it is incompatible with string theory. It has to be negative, they said. And that these observations are premature. They were completely wrong. The fact is that nobody goes back to these things and says, well, let us be a little more modest about it.

It's like shifting the goal post.

Exactly! There is nothing wrong with making the statement. But then ignoring completely that you made that statement – that is wrong. And then to say that this is the only theory. It has not had hard experimental/observational success, and it has not made that much progress in quantum gravity.

18. **Mitchell Porter**
November 3, 2015

Abhay Ashtekar supposedly said

"And I saw in newspapers that Tom Banks and Edward Witten had said that, no, the cosmological constant cannot be positive because it is incompatible with string theory. It has to be negative, they said. And that these observations are premature. They were completely wrong."

This comment makes no sense. Witten's talk – available at http://arxiv.org/abs/hep-th/0106109 – was about quantum gravity in de Sitter space. He discusses theoretical difficulties but certainly does not conclude that it's impossible. As for Tom Banks, I don't see him in the Strings 2001 program but the claims make even less sense in his case, since he was already writing papers specifically about adapting string theory to do Sitter space.

19. **Anonyrat**
November 3, 2015

Well, Jan 1, 2002, Dennis Overbye wrote in the NYTimes:
http://www.nytimes.com/2002/01/01/science/the-end-of-everything.html

> In 1998 the two teams announced that instead of the expected slowing, the galaxies actually seem to have speeded up over the last five or six billion years, as if some "dark energy" was pushing them outward.
>
> "It's definitely the strangest experimental finding since I've been in physics," Dr. Witten said. "People find it difficult to accept. I've stopped expecting that the finding will be proved wrong, but it's an extremely uncomfortable result."

which means that at sometime, per the newspapers, Witten thought that the result must be wrong, etc.

Anyway, Ashtekar (elsewhere in the interview) remarks on S. Chandrasekhar's powers of memory, and disclaims having any such.

20. **Peter Woit**
November 4, 2015

Mitchell Porter,

Witten had this to say at the time
"This means that there is no classical way to get de Sitter space from string theory or M-theory… In fact, classical or not, I don't know any clear-cut way to get de Sitter space from string theory or M-theory. This last statement is not very surprising given the classical no go theorem. For, in view of the usual problems in stabilizing moduli,

it is hard to get de Sitter space in a reliable fashion at the quantum level given that it does not arise classically".

Ashtekar may not be quite accurate, but do you have any doubt that if the data showed the universe to be AdS, this would now be heavily advertised as evidence for string theory?

21. **Anonymous**
    November 5, 2015

    The It from Qbit hype is certainly over the top, partly due to the personalities involved, some of whom have a habit of declaring their own work revolutionary based on very little that is solid. There have been various fads over the years proclaiming new theories of spacetime, including non-commutative geometry, deconstruction, two dimensional gravity, et cetera. They have each been interesting in some ways, but none really lived up to the claims of proponents.

Russian Math-Physics Film News

October 27, 2015
Categories: Uncategorized

I'm pressed for time, heading out tomorrow for a short vacation in San Francisco, but I did want to write a little bit here before leaving. Last year around now, a theme was Hollywood blockbuster films with physics/math themes, this year there seem to be none of those, instead I'm hearing about some Russian films with such themes.

This evening here at Columbia there was a showing of Ekaterina Eremenko's [Colors of Math](), an exploration of the sensual nature of mathematics, pairing research mathematicians with the five senses. Part of it is [available on Youtube](). Eremenko went to graduate school in mathematics in Moscow, then later on to a career in modeling and TV, and in recent years has been making films (see [here]()). Her current project is called [The Discrete Charm of Geometry](), trailer is [here]().

Somehow I'd missed until today hearing about a truly fantastic Russian film project which has been going on for years, showing no signs yet of reaching an endpoint. The topic is the life of the great Russian theoretical physicist Lev Landau, and the London Review of Books has a column by James Meek about the film [here](). It seems that the director, Ilya Khrzhanovsky, has been working on this for a decade, creating a huge set in Kharkov, where Landau worked during the 1930s, and doing his best to recreate the time as accurately as possible. Meek describes the shooting as follows:

> For more than two years, between 2009 and 2011, hundreds of volunteers, few of them professional actors, were filmed living, sleeping, eating, gossiping, working, loving, betraying each other and being punished in character, in costume, with nothing by way of a script, on the Kharkiv set, their clothes and possessions altered, fake decade by fake decade, to represent the privileged, cloistered life of the Soviet scientific elite between 1938 and 1968.

Among those brought in to participate in all of this were well-known physicists and mathematicians Dmitry Kaledin, Nikita Nekrasov, Andrey Losev, Carlo Rovelli, David Gross, Shing-Tung Yau and Alexander Midgal.

Post-production is now going on in London, in a huge five-story building in Mayfair, financed by someone who doesn't want to be identified. It's unclear what will emerge from the seven hundred hours of film shot in Kharkiv, perhaps "a dozen or more movies, a TV series, and a user-directed internet narrative system." Whatever it is, I'm very curious to see the result.

Comments

1. **SimpleBiologist**
   October 28, 2015

   Eremenko also did short films about Nash and Nirenberg for Abel price foundation.

   http://www.abelprisen.no/artikkel/vis.html?tid=63683

2. **Visitor**
   October 28, 2015

   "For more than two years, hundreds of volunteers, few of them professional actors, were filmed living, sleeping, eating, gossiping, working, loving, betraying each other and being punished in character with nothing by way of a script, on the Kharkiv set…"

   Because if you put enough amateurs together, and leave them to their own devices, the results are bound to be professional. Or maybe not.

   Don't expect too much in the way of a watchable movie.

3. **Boris**
   October 28, 2015

   I don't think the youtube piece mentions the name of Anatoly Fomenko (starting at 5:00), you can find more of his drawings on the internet. Also, it is unfortunate that Perelman wasn't living on that set in Kharkiv.

4. **Peter Woit**
   October 28, 2015

   Visitor,
   I agree there may be a "watchability" problem with whatever emerges, but if you compare to last year's example of a film portrayal by professional actors of mathematicians gathered in a research institute of the period (Bletchley Park), I'd much rather watch real mathematicians dressed up doing who-knows-what than the Hollywood completely bogus version of what supposedly happened.

5. **Chris Oakley**
   October 28, 2015

   Re: Hollywood's interpretation of Bletchley Park, i.e. *The Imitation Game:* it should have been listed under comedy. It seems that having built the enormous and complex bombe – entirely without the help of any technicians, it seems – Turing still does not realise that its purpose was to search for cribs until someone says something in a pub about the possibility. So I suppose that he was building the machine for the sheer fun of it up to that point. He was apparently also a traitor.

   I really do not mind professional actors reciting technical jargon with obviously no understanding, but I do object to needless blackening of peoples' names in the name of "drama".

6. **Chris W.**
   October 28, 2015

   So perhaps the lesson from *The Imitation Game* is that no script might be better than the deliberate hash that a few professional scriptwriters could make of the actual events, especially with producers breathing down their necks. There is nothing stopping those volunteers, especially if many of them are mathematicians, from studying the original history and the personalities involved and improvising a story that bears a decent resemblance to what actually happened. A smart director who cares about the history might help a lot.

   Anyway, we'll see. The Moscow News has [this story]() about the making of *Colors of Math*. (There is an NYU connection.)

7. **Luca Signorelli**
   October 29, 2015

   Hi Peter, on a completely different topic, have you seen this?

   http://thewire.in/2015/10/29/good-scientists-solve-problems-but-great-scientists-know-whats-worth-solving-14279/

8. **Chris W.**
   October 29, 2015

   Luca, thanks for pointing to that wonderful interview. It deserves to be widely read.

9. **Chris W.**
   October 30, 2015

   PS: On that interview, see Anonyrat's comment on the previous post, where it is more directly relevant. (Post responses there, not here.)

10. **theoreticalminimum**
    October 31, 2015

    Regarding Landau, it's probably worth mentioning the excellent 2013 collection, by physicist Mikhail Shifman, of memoirs and reviews on the scientific activities of some the most prominent theoretical physicists belonging to the Landau School, Under the Spell of Landau: When Theoretical Physics was Shaping Destinies (World Scientific).

11. **AcademicLurker**
    November 2, 2015

    Is there a decent biography of Landau in English? I haven't seen one.

    Feynman and Landau are widely agreed to be the 2 greats of the first post-quantum generation; the contrast between the huge amount of Feynmanalia and the relative lack of material on Landau is striking. Blame the cold war, I guess.

    I do recall how at Caltech, the bookstore had one whole shelf filled with copies of the Feynman lectures and another shelf filled with Landau and Lifshitz.

12. **Richard**
    November 2, 2015

    > Is there a decent biography of Landau in English? I haven't seen one.

    Neither have I, and I'd certainly seek out and read such.

    Much simpler than that: "Landau's List" is a nice piece of non-apocryphal folklore, but (aside from the few top Newton, Einstein, Dirac entries) its contents seem to be relatively obscure. Any leads?

The Elephants in the Room – What every physicist should know about string theory

November 3, 2015
Categories: Uncategorized

The string wars seem to still be going on, with the latest salvos coming from Ashtekar and Witten. In a very interesting recent interview, at the end Ashtekar has some comments about string theory and how it is being pursued. About claims that string theory is the only possible way to get quantum gravity he says:

> I don't know why science needs such statements; indeed, scientists should not make such statements. Let the evidence prove that it's the only theory. Let the evidence prove that it is better than other theories or let its predictions be reproduced more than those of others. Science should not become theology. And, somehow such statements have a strong smell of theology, which I don't like.

About AdS/CFT and the current state of its relation to quantum gravity:

> We seem to be using these gravity ideas in other domains of physics rather than solving quantum gravity problems. I don't think that the quantum gravity problems have been solved. And I have said this explicitly in conferences with panels – in which Joe Polchinski, Juan Maldacena and I were panellists – that, in my view, this is very powerful and these are good things. However, the AdS/CFT conjecture is the only definition of non-perturbative string theory one has – and it's a definition, it's not a proof of anything. It talks about duality, but there's no proof of duality. To have a duality, A should be well defined, B should be well defined and then you say that A is dual to B. Since we don't have another definition of string theory, we cannot hope to prove that string theory is dual to its conformal field theory. You can define string theory to be the conformal field theory. You have to construct a dictionary relating string theory in the bulk and conformal field theory on the boundary. That dictionary has not been constructed in complete detail.
> Again, nobody is taking anything away from the successes that the AdS/CFT duality has had; but there is a big gap between the successes and the rhetoric. The rhetoric is at a much higher level than the successes. So, for example, in this conjecture, first of all the space-time is 10 dimensional. The physical space-time is supposed to be asymptotically anti-de Sitter, which has a negative cosmological constant. But we look around us, and we find a positive cosmological constant. Secondly, the internal dimensions in the conjecture, or this definition, are macroscopic. The Kaluza-Klein idea is that there are higher dimensions but because they are all wrapped up and microscopic, say, at Planck scale, we don't see them. That's plausible. But here, in AdS/CFT duality, they need the radius of the internal dimensions to be the same as the cosmological radius. If so, if I try to look up I should see these ten dimensions; I don't. So, it can't have much to do with the real world that we actually live in. These are elephants in the room which are not being addressed.
> … there are these obvious issues and practitioners just pretend that they don't exist. And that to me is unconscionable; I feel that that's not good science. I don't mean to say string theory is not good science, but publicizing it the way it's done is not good science. I think one should say what it has done, rather than this hyperbole.

A good example of the problems Ashtekar is concerned about is provided by an article in the latest Physics Today by Witten with the title What Every Physicist Should Know about String theory. It's devoted to a simple argument that string theory doesn't have the UV problems of quantum field theory, one that I've seen made by Witten and others in talks and expository articles many times over the last 30 years. This latest version takes ignoring the elephants in the room to an extreme, saying absolutely nothing about the problems with the idea of getting physics this way, even going so far as to not mention the first and most obvious problem, that of the necessity of ten dimensions.

The title of the article is the most disturbing thing about it. Why should every physicist know a heuristic argument for a very speculative idea about unification and quantum gravity, without at the same time knowing what the problems with it are and why it hasn't worked out? This seems to me to carry the "strong smell of theology" that Ashtekar notices in the way the subject is being pursued.

Witten is a great physicist and a very lucid expositor, and the technical story he explains in the article is a very interesting one, with the idea that most physicists might want to hear about it a reasonable one. But the problems with the story also need to be acknowledged and explained, otherwise the whole thing is highly misleading.
Besides the obvious problems of the ten dimensions, supersymmetry, compactifications, the string landscape, etc. that afflict attempts to connect this story to actual physics, there are a couple basic problems with the story itself. The first is that what Witten is explaining as a problematic framework to be generalized by string theory is not quantum field theory, but a first-quantized particle theory, with interactions put in by hand. This can be used to produce the perturbation series of a scalar field theory, but this is something very different than the SM quantum field theory, which has as fundamental objects fields, not particles, with interactions largely fixed by gauge symmetry, not put in by hand. For such QFTs, there is no necessary problem in the UV: QCD provides an example of such a theory with no ultraviolet problem at all, due to its property of asymptotic freedom.

Another huge elephant in the room ignored by Witten's story motivating string theory as a natural two-dimensional generalization of one-dimensional theories is that the one-dimensional theories he discusses are known to be a bad starting point, for reasons that go far beyond UV problems. A much better starting point is provided by quantized gauge fields and spinor fields coupled to them, which have a very different fundamental structure than that of the terms of a perturbation series of a scalar field theory. A virtue of Witten's story is that it makes very clear (while not mentioning it) what the problem is with this motivation for string theory. All one gets out of it is an analog of something that is the wrong thing in the simpler one-dimensional case. The fundamental issue since the earliest days of string theory has always been "what is non-perturbative string theory?", meaning "what is the theory that has the same relation to strings that QFT has to Witten's one-dimensional story?" After 30 years of intense effort, there is still no known answer to this question. Given the thirty years of heavily oversold publicity for string theory, it is this and the other elephants in the room that every physicist should know about.

Update: For another take on string theory that I meant to point out, there's an article quoting Michael Turner:

> Turner described string theory as an "empty vessel," and added: "the great thing about an empty vessel is that we can put our hopes and dreams in it."

The problem is that the empty vessel is of a rather specific shape, so only certain people's hopes and dreams will fit…

Update: Many commenters have written in to point out this article, but I don't think it has anything at all to do with the topic of this posting. There are lots of highly speculative ideas about quantum gravity out there, most of which I don't have the time or interest to learn more about and discuss sensibly here.

Update: It is interesting to contrast the current Witten Physics Today article with a very similar one that appeared by him in the same publication nearly 20 years ago, entitled Reflections on the Fate of Spacetime. This makes almost the same argument as the new one, but does also explain one of the elephants in the room (lack of a non-perturbative string theory). It also includes an explanation of the T-duality idea that there is a "minimal length" in string, an explanation I was referring to in the comment section when describing what I don't understand about his current argument.

Comments

   November 4, 2015

   What Abhay Ashtekar is saying about String Theory and ADS/CFT is exactly to the point. I think it is a fair description of its scientific status.

2. **Warren**

November 4, 2015

You are being too positive.
The real problem is that all approaches to high-energy theoretical physics are seriously flawed.
The Standard Model is not asymptotically free.
Even QCD is not saved by asymptotic freedom, which has the problem of renormalons.
Experience with rigorous approaches, as constructive quantum field theory or lattice gauge theory, has shown us that nonperturbative approaches do not solve perturbative problems.
Loop quantum gravity has problems even with the continuum limit, and doesn't solve renormalizability of gravity, only regularizes it.

But string field theory does exist, & people have addressed nonperturbative problems with it.
So rather than denouncing or over-promoting the various alternatives, a more useful attitude would be to just admit that there is no well-defined approach to this problem yet, and recognize the practicality of complementary formulations that are all incomplete.

3. **martibal**
November 4, 2015

Is there a free link to Witten paper ?

4. **Bori**
November 4, 2015

Is this just an American phenomenon because of the culture of self-promotion and exaggeration resulting in a natural counter-reaction? Speaking to physicists in Europe, they seem to be more pragmatic about string theory – a certain proportion of positions goes to string theorists and they do their job, but no hype and no bad feelings.

5. **Tammie Lee Haynes**
November 4, 2015

Dera Dr Woit

String Theory has "a smell of theology"?
As a Christian, I am astonished that you would make such a statement.

Christianity's claims to being true are based on the accounts of witnesses to certain events such as the miracles of Jesus. The account of what a witness saw is the very definition of empirical evidence. (Of course, from time to time all of us find witness accounts to be non-credible, which is why you are not a Christian)
But the point is this. Before String Theory can claim to have "a smell of theology", it will need to have support from empirical evidence.

Very truly yours
Tammie Lee Haynes

November 4, 2015

"motivating string theory as a natural two-dimensional generalization of one-dimensional theories is that the one-dimensional theories he discusses are known to be a bad starting point"

Loop quantum gravity itself has a roughly comparable foundational issue : we are assuming that the 3-metric tensor of gravity – or canonically transformed analogues – can be subject to a "quantization" procedure analogous to those developed for fields on Minkowski space-time treated as assemblies of harmonic oscillators : themselves quantized by techniques developed for non-relativistic finite degrees of freedom.

8. **Peter Woit**
November 4, 2015

Warren,
I think there's a difference between elephants in the room (we don't know how to connect string theory to known 4d physics, with or without going to a string field theory) and something much smaller (mice? cockroaches?), such as the renormalon problems or the Landau pole at exponentially large energies.

Charles,
Thanks for making sure that Witten's article is available.

Tammie Lee Haynes,
Perhaps theology is the wrong word. Maybe a better one for some string theory promotional activities would be "evangelical", dedicated to spreading the good word. But, all, please resist temptation to discuss religion here.

Bori,
I don't think there's that much difference between string theorists in the US and Europe. There is a bigger market here for a small number that want to evangelize. However, one thing to say about both Ashtekar and Witten is that they are the sorts who would usually much prefer to stick to the technical details of the science, and not engage in public battles. I can see why Ashtekar might have had enough of the hype over AdS/CFT, I'm not so sure why Witten feels it necessary to make this well-worn claim at this point.

Anonymous,
Sure, a basic problem of quantum gravity is that we don't know what fundamental variables to work with and/or what the correct quantization procedure is. Ashtekar is responsible ("Ashtekar variables") for what seems to me the most intriguing such choice of variables.

9. **Tom**
November 4, 2015

There's a new book coming out in December, published by CRC press, called "Why String Theory" by a young theoretical physicist named Joseph Conlon (found on Amazon). Though the description seems to indicated it is pro-string theory, does anyone have advance knowledge of its main premise? Just another semi-religious screed, or does it turn on any critical spotlights? (Admittedly, I wasn't interested enough to do a thorough web search.)

10. **garcol euphrates**
    November 4, 2015

    A link from the interview in the Wire references one of Abhay Ashtekar's formative books on cosmology, Gamow's 1 2 3 … Infinity. The link referenced contains a reading list of science books (some of my favorites) compiled by a fellow named Robert Anton Wilson, a writer of some stature, who is quoted as:
    "Wilson also criticized scientific types with overly rigid belief systems, equating them with religious fundamentalists in their fanaticism."

    Full circle!

11. **Peter Woit**
    November 4, 2015

    Tom,
    That book does look like mainly an advertising effort, an expansion of the web-site of the same name:
    http://whystringtheory.com/about/
    I notice there's a chapter on "Direct Experimental Evidence for String Theory". No page numbers, but I'm betting that one's rather short…

12. **martibal**
    November 5, 2015

    Thanks Charles !

13. **Dave Miller in Sacramento**
    November 5, 2015

    Peter,

    You wrote:
    >The first is that what Witten is explaining as a problematic framework to be generalized by string theory is not quantum field theory, but a first-quantized particle theory, with interactions put in by hand.

    This is something that has bothered me for decades, but that I rarely see discussed.

    Isn't it the case that string theory does not even rise to the level of a non-relativistic first-quantized theory? It seems to me that it is the 2-D equivalent of Klein-Gordon, which, of course, does not give an acceptable version of probability (until you second-quantize it).

    Specifically, does free string theory , even in principle, actually give a probability for a string to have a probability (probability density function, of course) to actually be in a specific configuration in spacetime? If so, how you do numerically calculate this?

    Everyone: I am honestly not trying to score rhetorical points here against string theory. These are sincere questions, and if I am ignorant of work that answers these questions, please point to that work.

    Dave

    Warren,

    You wrote:
    >But string field theory does exist, & people have addressed nonperturbative problems with it.

    I have followed enough of your work to know that you have seriously worked on the subject: I truly appreciate that someone seems to take these issues seriously.

    Could you point us to the best source with the most concrete discussion of the existence of string field theory, if possible a source that addresses basic issues such as the state space, actual calculation of probabilities for at least the free string case, etc.?

    Thanks.

    Dave

    Does an empty vessel stop making most noise once filled only with hopes and dreams?

16. **Warren**
    November 5, 2015

    Peter:

    Renormalons are a low energy problem in QCD (strong coupling), not large, because of asymptotic freedom. They make QCD nonperturbatively nonrenormalizable. A related problem is nobody knows how to calculate parton distribution functions. In particular, nobody can do higher-twist corrections, because they require experimental input of more PDF's, ad infinitum — more nonrenormalizability (in the sense of lack of predictability). Of course, you could calculate PDF's if you could calculate confinement, but you can't.

    Dave:

    Free string field theory is the same as string quantum mechanics, by the correspondence principle. Work has been done on nonperturbative vacua (due to the tachyon) for the bosonic string: The basic result is that the bosonic string is crap. So you need supersymmetry, but little has been done in SFT there yet. A similar situation exists in QFT in D=4, where you need supersymmetry to eliminate renormalons, by making the theory finite.

17. **Peter Orland**

Warren,

QCD is far from a finished problem, but claiming renormalons ruin its properties is not an accurate statement.

It is not known what the implications of renormalons are. They are special terms in perturbation theory, which (like instantons) ruin Borel resummability (all of which I'm sure you know). But there is no evidence that they render theories nonrenormalizable. There are models with perturbative renormalons which suffer from no such problem (I have worked on one of these). You may be familiar with the idea of resurgence, which does seem to deal well with Borel singularities in quantum mechanics (though not yet relativistic QFT).

In any case, the lattice gives pretty good evidence that QCD is fine at large distance scales. There is even work under way to find pdf's. The real problem is getting to extremely weak coupling (and string-inspired models do even worse).

I am not disagreeing that there is a lot of work to be done in QFT (confinement, mass gaps, and a lot more), but it is not a failure.

18. **Warren**
November 5, 2015

Peter Orland:

The only models I know of that solve the renormalon problem are quantum mechanical, not QFT. "Nonrenormalizability" comes from arbitrary coefficients of each ambiguity in the inverse Borel transform, corresponding to VeV's of an ∞ # of composite color-singlet operators. This is quite analogous to higher-derivative terms in nonrenormalizable field theory (the higher-twist problem even more so). This problem is seen also in constructive quantum field theory, as well as an analysis by 't Hooft in the complex coupling constant plane. In lattice QCD, this shows up as nonuniversality @ the origin in coupling constant space.

I did not mean to imply QCD was a failure. Only that it has problems, just as string theory does. But Peter Woit was implying that QFT was OK, in contrast to string theory being a complete failure. I would say string theory is the only theory that shows Regge behavior & spectrum of the type corresponding to confinement. Lattice QCD, on the other hand, has managed to calculate only ground state properties, & can't deal with even rotational invariance, so can't calculate cross sections.

" A should be well defined, B should be well defined and then you say that A is dual to B. Since we don't have another definition of string theory, we cannot hope to prove that string theory is dual to its conformal field theory."

I'm pretty sure I read this somewhere before…

20. **Peter Orland**
November 5, 2015

Warren,

Whatever problems of consistency QFT has, there is no comparison to those of string theory. I'm not claiming this makes it better than strings, just that it is a much better-developed field.

As to your first paragraph, one can do better than quantum mechanics. Asymptotically-free models in 1+1 dimensions have renormalon singularities in perturbation theory, yet there is good analytic evidence of sensible non-perturbative solutions. The exact S matrices are known, and there is even information about correlation functions.

Concerning your second paragraph; there is no serious controversy whether lattice QCD (or any lattice QFT) will have rotational invariance, in the continuum limit, assuming that limit exists. Approximate rotation invariance is seen on the lattice, although a weaker coupling would be better. There is also some numerical evidence of Regge behavior (although this may not have been studied much in more than three dimensions). A lot more is known than ground state properties. I do not mean there are theorems or analytic solutions (yet), but the computer is a good guide to what the theory predicts.

You are right to say that QFT has problems (which is why people work on it), but string theory is not as far along.

What are PDF's? Googling the term just gets swamped by the other sort of PDF's. Thanks.

22. **Peter Woit**
November 5, 2015

Warren,
My comments were about UV problems, which is what Witten was writing about, and claiming that string theory solves, unlike QFT. I'm still quite surprised that Witten thought such a claim was what "every physicist should know about string theory". I'd have expected that title to be used these days to make an argument for string theory as a way to handle strong-coupling problems, via its relation to AdS/CFT.

From the talks of his I've seen, Witten likes to claim that in string perturbation theory the only problems are infrared problems, not UV problems. That's never seemed completely convincing, since conformal invariance can swap UV and IR. My attempts to understand exactly what the situation is by asking experts have just left me thinking, "it's complicated".

The problems with QCD are IR problems, and I'm certainly willing to believe they can best be addressed by finding some form of string theory dual to QCD. As far as I know, there's no well-defined candidate for such a theory (i.e. that matches QCD in the UV, behaves like we think QCD should in the IR). QCD has the virtue that it works beautifully in the UV, and has a conjectural definition in the IR (via the lattice), even if it is hard to calculate things. I'm not claiming this is satisfactory, just that it's completely inconsistent with the story Witten is trying to tell about string theory being necessary to solve QFT UV problems.

PDFs = Parton distribution functions

24. **Warren**
November 5, 2015

Orland:

I wasn't disagreeing, only that string theory is by far better than alternatives to its problems. If you want to compare apples to oranges, pQCD is by far worse than QED. S-matrices in 2D massless theories isn't much better, since only backward & forward scattering, so just numbers, not functions (& usually reduces to just 2->2). Proof of rotational invariance & being able to calculate anything with angles are 2 quite different things. Similar remarks apply to Regge behavior & getting an actual Regge trajectory. And properties vs. numbers, which you really get from lattice QCD basically for ground states.

Woit:

I hope you're not confusing conformal invariance on the worldsheet with that in spacetime. As far as solving UV problems, I'm pretty sure Witten means in quantum gravity. String theory seems to solve that. No alternative does (although some people have a conjecture for 4D N=8 supergravity).

"empty vessels make the loudest sound"

26. **Peter Woit**
November 5, 2015

Warren,

The problem with Witten's article is that his story about what goes wrong in QFT that doesn't in string theory is about the small proper-time behavior of loops in perturbation theory, applying equally well to QCD and GR. Given the fact that QCD has no UV problem, it seems to me that the story he's telling is likely irrelevant to the GR divergences problem.
My earlier comment was about worldsheet conformal invariance, specifically the action of the modular group. Witten's argument for no UV problem, for the torus case, is that the analog of proper-time in loop integrals takes values in the fundamental domain in the upper half plane, and this is bounded away from zero, so no small-time problem. There are lots of potential technical problems to worry about (you need this argument to work for arbitrary genus, in super-moduli space, etc), but what I was wondering about was the following: the modular group acts on this domain, taking it in particular to another domain that isn't bounded away from zero. From another related angle, discussions of T-duality in string theory often claim that the right picture is that of some "minimum length", below which you should go to a T-dual picture (acting by the modular group). But, if there are potential IR problems, how do I know that those IR problems in the T-dual picture don't appear now as I go to the UV?
To be clear, I believe there is likely some answer to this, cleanly separating out what's UV and what's IR, but it's not there in the Physics Today piece as far as I can tell.

27. **Peter Orland**
November 6, 2015

Warren,

"I wasn't disagreeing, only that string theory is by far better than alternatives to its problems. "

I am not sure what you mean by this. It seems you are saying to say that string theory is on better theoretical footing than QFT. Such a position is simply not tenable. Calculations with QED and QCD aren't perfect, but there are many reasons to trust them, not least of which is comparison with experiments. We agree that there are problems in calculating with QFT, but these do not invalidate its successes.

And lattice measurements tell you more than vacuum properties (as I said earlier).

28. **Peter Orland**

I meant "trying to say", not "saying to say."

29. **Dave Miller in Sacramento**
November 6, 2015

Warren,

You said:
>Free string field theory is the same as string quantum mechanics, by the correspondence principle.

Doesn't string quantum mechanics suffer from the same sort of problem as "first-quantized" Klein-Gordon, i.e., no sensible meaning for probability? Can you suggest any place you can point me to where I can see how this works in detail?

A possibly related problem that bothers me is how you actually get a concrete number for the "probability" (really the probability density) in first-quantized string theory given the use of the Gupta-Bleuler constraints. In QED, you can always drop Gupta-Bleuler and just go to the Coulomb gauge: You then are stuck with an apparently instantaneous Coulomb interaction, but at least probabilities more or less make sense (positive-definite Hilbert space inner product, etc.).

Can you point me to any detailed discussion of how the analog of all this works in string theory? E.g., I am tempted to think there must be some analog of the instantaneous Coulomb interaction but have never seen this mentioned.

Thanks.

Dave

30. **Warren**
November 6, 2015

Woit:

There are technical difficulties with higher-loop amplitudes in string theory, still being investigated. (A paper out today seems to claim to solve them.) But there are good arguments for finiteness that hold up to as many loops as have been evaluated. (Maybe they are proofs; I'm not enough of an expert to tell.) In any case, the arguments seem better then those for the next best alternative, 4D N=8 supergravity. (& for loop quantum gravity arguments indicate the opposite.) But you're not going to get all the details into a Physics Today article.

Orland:

I meant to say that string theory is on more solid ground than any other quantum gravity theory, just as pQCD is for strongly interacting particles @ large transverse momenta. String theory clearly is not of as good standing as QCD, nor QCD as QED ("apples vs. oranges"). I am not aware of any calculations in lattice QCD that give the masses of radially excited hadrons as falling on linearly rising Regge trajectories, nor any that give low-energy scattering amplitudes of the sort described by nonlinear sigma models.

Dave:

@ the free level, strings are just a reducible, unitary representation of the Poincaré group. You can write the single-string Hilbert space as a direct sum of those for the "usual" particles. So if you understand free particles, you understand free strings. The free part of the string field theory action can be decomposed into the sum of field theory actions for particles of different spins. Nowadays quantization (for particles or strings) is better treated by BRST, which deals with unitarity in any gauge, particularly in the Feynman gauge, which is more practical than Coulomb gauge. Similar remarks apply to first-quantization: Stückelberg & Feynman solved the problem of the Klein paradox in that context by identifying "negative energy" particles as antiparticles. This interpretation can be applied either in classical mechanics, or in quantum mechanics in terms of the first-quantized path integral giving the Stückelberg-Feynman propagator.

31. **Warren**
November 6, 2015

Orland:

P.S. By "ground states" I meant in the quantum mechanical sense (like the hydrogen atom), i.e., masses (& some couplings) of the π,ϱ,N,Δ,…

32. **Peter Orland**
November 6, 2015

Warren,

I think you are overly pessimistic.

It's true that most of the work on Regge trajectories in the lattice literature is only on glueballs, but there is no fundamental obstacle to asking the same question for mesons and baryons (it is more difficult, of course).

There are attempts to work out scattering amplitudes. For example, the QCD corrections to light-by-light scattering are being studied on the lattice.

I don't work along these lines myself, but I don't see them as impossible lines of inquiry.

33. **chris**
November 6, 2015

Warren,

here is a recent review of excited lattice spectroscopy:
arXiv:1411.0405
And here is just one recent example of lattice calculations of scattering amplitudes:
arXiv:1504.01717

It is rather strange that you have singled out these two topics as unsolved by lattice, since there are major efforts going on in the US, Europe and Japan to address exactly these questions. There are of course things to be cleaned up (especially mapping out resonances in a finite box is a tricky thing) but there is no doubt whatsoever that the lattice will solve this in the coming years given enough computer power and algorithmic improvements.

By the way, for us lattice people it is funny to see claims that "QCD is nonperturbatively nonrenormalizable" and such. You know, because of asymptotic freedom the continuum limit of the lattice regularization scheme is well defined and that is QCD. In N-flavor QCD you define the physical point by N+1 experimental measurments, you go there and out pop all other observables. We don't care about perturbative approximations or models – if there are problems in them, they are not problems of QCD. QCD is perfectly well defined and consistent and we know how to do the path integral.

Oh, and one more thing. Your claim
"As far as solving UV problems, I'm pretty sure Witten means in quantum gravity. String theory seems to solve that. No alternative does (although some people have a conjecture for 4D N=8 supergravity)."
is a rather gross misstatement. There is plenty of evidence that gravity is asymptotically safe and no UV problem exists to begin with. For a recent review, see e.g. arXiv:1202.2274

34. **TS**
November 6, 2015

Can someone explain to me what renormalization in a non-perturbative context means? Obviously, the meaning must be different than what we mean when we apply renormalization in perturbative calculations, namely the task of relating measured quantities to the quantities that appear in the calculation. Since the measured quantities involve all orders of perturbation theory, it is not trivial to see how the measured quantities can be related to the ones used in the calculation. In a non-perturbative setting OTOH I would expect that the objects entering the calculation are the ones we observe in the lab without any further requirements on the theory: say, two pions in -> machinery -> two pions out, where all pions have a mass of 140 MeV, spin 0 and charge = ±1 (and, except for the choice of units, these would come out of a sufficiently well-developed theory).

A web search leaves me a bit puzzled: "non-perturbative renormalization" in this context appears to be not more than the setting of a numerical value for a mass (or several), which is more or less in line with what I would expect one needs for a non-perturbative computation, but why would one call this "renormalization" instead of "choice of units"?

35. **Peter Woit**
November 6, 2015

TS,
This is starting to get a bit far afield from the topic of the posting. But I think the simple answer to your question is that whatever your definition of qft is, it appears to need a cutoff, and the cutoff qft will be characterized by certain parameters ("bare parameters"). You hope to compute observable numbers in terms of such bare parameters (in perturbation theory, by Feynman diagrams, non-perturbatively by some other method such as a lattice Monte-Carlo). The hope is to remove the cutoff, varying bare parameters with the cutoff in such a way as to get a well-defined limit for physical observables. This is what I'd call "renormalization" in general, perturbative or non-perturbative.

A problem with Witten's argument is that it's purely about problems with renormalization in perturbation theory. If the short distance behavior of the theory is not governed by perturbation theory, such arguments will be irrelevant.

36. **Warren**
November 6, 2015

Chris:

Thanks for the references; I'll look them up. In fact, there is no proof that the continuum limit of QCD is universal, for the reasons I gave, & it's exactly because of asymptotic freedom. By "nonrenormalizable", I mean an infinite number of parameters must be introduced, because there are an infinite of renormalons, corresponding to an infinite number of color-singlet operators whose VEV's must be determined. "The lattice will solve this in the coming years given enough computer power and algorithmic improvements" is something I've been hearing for 40 years; given Moore's law you'd think it would've been done by now. So, yes, I have plenty of doubt. The only work I've seen on asymptotic safety in gravity is based on doing an ε epsilon from D=2, & I'm not satisfied by arguments that treat 2 as ≪ 1. In fact, any renormalization group arguments for finite changes in the coupling constant are dubious due to the arbitrariness of the β function past 2 loops.

Orland:

The only calculations I've seen on Regge trajectories in lattice gauge theories gives the result only near argument 0: the intercept & the slope @ 0. As to not seeing impossible lines of inquiry, I would say the same for string theory. Advances have been made in both in the last 40 years, both are hard problems, & both leave much to be desired.

37. **TS**
November 6, 2015

Thanks, Peter! The terminology makes a lot more sense to me now.

38. **Warren**
November 6, 2015

Chris:

Looked @ 1 of your papers: Uses HAL QCD approach, which calculates a 2-body potential from the lattice, then plugs that into a (continuum) Schrödinger equation to find the results. Not sure how much advantage that has to the old quark model stuff that began with linear (for confinement) plus Coulomb terms. But I'll keep reading…

But the asymptotic safety reference is the same old thing. Hard to calculate in an ∞ dimensional coupling space.

39. **Attila**
November 7, 2015

While it is true that universality of the continuum limit in QCD has not been
proven, if the continuum limit was not universal, I would not expect the
continuum extrapolations of different observables, taken with different discretizations, to agree so well. Even if the low lying hadron spectrum and the equation of state at mu_B=0 was the only thing the lattice could calculate, which I think is not true, that would already be quite impressive, since no other method can do even that. I have to add that I am a lattice practicioner, so if I did not believe in lattice results in general, that would be somewhat strange.
_
"The problems with QCD are IR problems, and I'm certainly willing to believe they can best be addressed by finding some form of string theory dual to QCD."
I think that is optimistic. As far as I know, one does have dual theories to
gauge theories closer to QCD than N=4 SYM, the problem is that the dual theory
gets crazier as you get closer to the real thing, and the whole approach loses the
computational advantage it had. An example of a computation in a theory closer
to the real thing (N=2* SYM) is: hep-th/1108.2053

40. **Warren**
November 9, 2015

Attila:

It's all about optimism, isn't it? People are optimistic about their own areas of research, & impressed with the results so far obtained, and dubious about claims in other areas. So lattice QCD can make good predictions for low energy (where renormalon contributions can be neglected, & plugging potentials into 1st-quantized calculations can be pretty good), with nothing but hopes for high energy, while the converse is true for string theory. Similar remarks apply to pQCD, which is good for large transverse momenta, where log corrections can be calculated, but power corrections (especially ones from higher twist) must be ignored.
